ON AN OPEN QUESTION IN RECOVERING STURM–LIOUVILLE-TYPE OPERATORS WITH DELAY

Nebojša Djurić1 and Sergey Buterin2

Abstract. In recent years, there appeared a considerable interest in the inverse spectral theory for functional-differential operators with constant delay. In particular, it is well known that specification of the spectra of two operators \( \ell_j, \ j = 0, 1 \), generated by one and the same functional-differential expression \(-y''(x) + q(x)y(x - a)\) under the boundary conditions \( y(0) = y^{(j)}(\pi) = 0 \) uniquely determines the complex-valued square-integrable potential \( q(x) \) vanishing on \((0, a)\) as soon as \( a \in [\pi/2, \pi)\). For many years, it has been a challenging open question whether this uniqueness result would remain true also when \( a \in (0, \pi/2)\). Recently, a positive answer was obtained for the case \( a \in [2\pi/5, \pi/2)\). In this paper, we give, however, a negative answer to this question for \( a \in [\pi/3, 2\pi/5)\) by constructing an infinite family of iso-bispectral potentials. Some discussion on a possibility of constructing a similar counterexample for other types of boundary conditions is provided, and new open questions are outlined.

Key words: functional-differential equation, deviating argument, constant delay, inverse spectral problem, iso-bispectral potential

2010 Mathematics Subject Classification: 34A55 34K29

1. Introduction

One of the first results in the inverse spectral theory says that the spectra of two boundary value problems for one and the same Sturm–Liouville equation with one common boundary condition:

\[-y''(x) + q(x)y(x) = \lambda y(x), \quad y(0) = y^{(j)}(\pi) = 0, \quad j = 0, 1, \tag{1}\]

uniquely determine the potential \( q(x) \), see [1], where also local solvability and, actually, stability of this inverse problem were established in the class of real-valued \( q(x) \in L_2(0, \pi) \). Later on, these results were refined and generalized to other classes of potentials and boundary conditions [2–7]. Moreover, there appeared methods, which gave global solution for the inverse Sturm–Liouville problem as well as for inverse problems for other classes of differential operators (see, e.g., monographs [7–10]).

In recent years, there was a considerable interest in inverse problems also for Sturm–Liouville-type operators with deviating argument (see, e.g., references therein), which are often more adequate for modelling various real world processes frequently possessing a nonlocal nature.

For \( j = 0, 1 \), denote by \( \{\lambda_{n,j}\} \) the spectrum of the boundary value problem \( L_j(a, q) \) of the form

\[-y''(x) + q(x)y(x - a) = \lambda y(x), \quad 0 < x < \pi, \quad y(0) = y^{(j)}(\pi) = 0, \tag{2}\]

where \( q(x) \) is a complex-valued function in \( L_2(0, \pi) \) and \( q(x) = 0 \) on \((0, a)\), while \( a \in (0, \pi)\). For functional-differential operators as well as for other classes of nonlocal ones, classical method of the inverse spectral theory for differential operators do not work. Consider the following inverse problem.

Inverse Problem 1. Given the spectra \( \{\lambda_{n,0}\} \) and \( \{\lambda_{n,1}\} \), find the potential \( q(x) \).

Instead of (2), one could alternatively impose the boundary conditions

\[y'(0) - hy(0) = y^{(j)}(\pi) = 0 \tag{4}\]

with a complex parameter \( h \), which can be found given the input data of Inverse Problem 1. Various aspects of Inverse Problem 1 were studied in [11–12, 14–22, 24–26, 27] and other works.

The values $\pi/2$ and $2\pi/5$ of the delay parameter $a$ are critical for the solution of this inverse problem. Specifically, in the case $a \geq \pi/2$, the dependence of the characteristic function of each problem $L_j(a,q)$ on the potential $q(x)$ is linear, while for $a < \pi/2$ it is nonlinear. In the linear case, the uniqueness of solution of Inverse Problem 1 is well known. Moreover, this problem is then overdetermined. Thus, in $[15]$, the conditions on an arbitrary increasing sequence of natural numbers \( \{n_k\}_{k \geq 1} \) were obtained that are necessary and sufficient for the unique determination of the potential $q(x)$ by specifying the corresponding subspectra \( \{\lambda_{n_k} \} \) and \( \{\lambda_{n_k,1} \} \). The nonlinear case $a < \pi/2$ is much more difficult. However, in $[12,16,17]$ for various types of boundary conditions and for any fixed $a \in (0,\pi)$, it was established that if the given spectra coincide with the spectra of the corresponding problems with the zero potential, then $q(x)$ is zero too.

Under the general settings, i.e. for arbitrary nonzero potentials, it was a long term challenging open question whether the uniqueness of solution of Inverse Problem 1 takes place for $a < \pi/2$. Recently, a positive answer to this question was given independently in $[18]$ (for the conditions (3)) and in $[20]$ (for (4)) as soon as $a \in [2\pi/5,\pi/2]$.

In the present paper, we give a negative answer to the open question formulated above in the case when $a \in [\pi/3,2\pi/5]$. Namely, for each such $a$, we construct an infinite family of different iso-bispectral potentials $q(x)$, i.e. of those for which the problems $L_0(a,q)$ and $L_1(a,q)$ have one and the same pair of spectra. This looks quite unusual in light of the classical results for the case of $a = 0$. Our counterexample appears even more unexpected under consideration that the recent paper $[27]$ announces that specification of the spectra of both boundary value problems consisting of (2) and (4) uniquely determines the potential $q(x)$ also for $a \in [\pi/3,2\pi/5]$. Although in $[27]$ Robin boundary conditions were imposed also in the point $\pi$, they can be easily reduced to (4). In Section 3, we discuss why our result does not refute the uniqueness theorem in $[27]$ for $a \in [\pi/3,2\pi/5]$ (see Remark 2).

In the next section, we formulate the main result of the paper (Theorem 1) and outline some new prospects in studying Inverse Problem 1 (Remark 1). The proof of Theorem 1 is provided in Section 3.

2. The main result

Fix $a \in [\pi/3,2\pi/5]$. For a nonzero real-valued function $h(x) \in L_2(5a/2,\pi)$, we consider the integral operator

$$M_h f(x) = \int_{\frac{3a}{2}}^{x} K_k(x + t - \frac{a}{2}) f(t) \, dt, \quad \frac{3a}{2} < x < \pi - a, \quad \text{where} \quad K_k(x) = \int_{x}^{\pi} h(\tau) \, d\tau. \quad (5)$$

Thus, $M_h$ is a nonzero compact Hermitian operator acting in the space $L_2(3a/2,\pi - a)$. Hence, it has at least one nonzero real eigenvalue $\eta$. We assume that $\eta = 1$, which can always be achieved by choosing $h(x)/\eta$ instead of $h(x)$. Let $e(x)$ be the corresponding eigenfunction, i.e.

$$M_h e(x) = e(x), \quad \frac{3a}{2} < x < \pi - a. \quad (6)$$

Consider the one-parametric family of potentials $B := \{q_\alpha(x)\}_{\alpha \in \mathbb{C}}$ determined by the formula

$$q_\alpha(x) = \begin{cases} 0, & x \in \left(0, \frac{3a}{2}\right) \cup \left(\pi - a, 2a\right) \cup \left(\pi - \frac{a}{2}, \frac{5a}{2}\right), \\ \alpha e(x), & x \in \left(\frac{3a}{2}, \pi - a\right), \\ -\alpha K_h \left(x + \frac{a}{2}\right) \int_{\frac{3a}{2}}^{x} e(t) \, dt, & x \in \left(2a, \pi - \frac{a}{2}\right), \\ h(x), & x \in \left(\frac{5a}{2}, \pi\right). \end{cases} \quad (7)$$

The main result of the present paper is the following theorem.
Theorem 1. For \( j = 0, 1 \), the spectrum \( \{\lambda_{n,j}\} \) of the boundary value problem \( L_j(a, q_\alpha) \) does not depend on \( \alpha \).

Theorem 1 means that the problems \( L_0(a, q_\alpha) \) and \( L_1(a, q_\alpha) \) have one and the same pair of spectra \( \{\lambda_{n,0}\} \) and \( \{\lambda_{n,1}\} \) for all values of the parameter \( \alpha \in \mathbb{C} \), i.e. the solution of Inverse Problem 1 is not unique. We note that, since the zero potential does not belong to \( B \), Theorem 1 does not contradict the uniqueness result in [12]. The proof of Theorem 1 is given in the next section.

Remark 1. This reminds the situation of the following operator with frozen argument:

\[
\ell y = -y''(x) + q(x) y(b), \quad y^{(a)}(0) = y^{(b)}(1) = 0, \quad a, b \in \{0, 1\}, \quad b \in [0, 1].
\]

It is known that the unique recoverability of \( q(x) \) from the spectrum of \( \ell \) depends on the triple of parameters \( (a, b, q) \). In [28], one can find a complete description of all degenerate and non-degenerate cases for rational values of \( b \), while for irrational ones the uniqueness always takes place, see [29].

Theorem 1 opens the analogous type of questions for Inverse Problem 1, which consist in giving description of ranges of the delay parameter \( a \) along with the types of boundary conditions, for which the uniqueness of solution of Inverse Problem 1 takes place. In the opposite degenerate cases, it would be interesting to describe classes of iso-bispectral potentials. It is especially important to investigate the case of arbitrarily small values of \( a \) making the problem "close" to the classical case [11].

3. Proof of Theorem 1

Let \( S(x, \lambda) \) be a solution of equation (21) under the initial conditions \( S(0, \lambda) = 0 \) and \( S'(0, \lambda) = 1 \). For \( j = 0, 1 \), eigenvalues of the problem \( L_j(a, q) \) coincide with zeros of its characteristic function \( \Delta_j(\lambda) = S^{(j)}(\pi, \lambda) \). Thus, the spectrum of any problem \( L_j(a, q) \) does not depend on \( q(x) \in B \) for some subset \( B \subset L_2(0, \pi) \) as soon as neither does the corresponding characteristic function \( \Delta_j(\lambda) \). Put \( \rho^2 = \lambda \) and denote

\[
\omega := \int_0^\pi q(x) \, dx.
\]  
(8)

The following representations hold (see, e.g., [26]):

\[
\begin{align*}
\Delta_0(\lambda) &= \frac{\sin \rho \pi}{\rho} - \omega \frac{\cos \rho (\pi - a)}{2 \rho^2} + \frac{1}{2 \rho^2} \int_0^\pi w_0(x) \cos \rho (\pi - 2x + a) \, dx, \\
\Delta_1(\lambda) &= \cos \rho \pi + \omega \frac{\sin \rho (\pi - a)}{2 \rho} - \frac{1}{2 \rho} \int_0^\pi w_0(x) \sin \rho (\pi - 2x + a) \, dx,
\end{align*}
\]
(9)  
(10)

where the function \( w_0(x) \) is determined by the following formula for \( k = 0 \):

\[
w_k(x) = \begin{cases} 
q(x), & x \in (a, \frac{3a}{2}) \cup (\pi - \frac{a}{2}, \pi), \\
q(x) + Q_k(x), & x \in (\frac{3a}{2}, \pi - \frac{a}{2}),
\end{cases}
\]
(11)

while

\[
Q_k(x) = \int_{x - \frac{a}{2}}^{x - a} (q(t + a) - q(t)) \, dt - \int_{x - a}^x q(t) \, dt + \frac{1}{2} \int_{x - a}^x q(t - a) \, dt + \frac{1}{2} \int_x^\pi q(t) \, dt - \frac{1}{2} \int_x^{x + a} q(t) \, dt.
\]
(12)

Note that, since the function \( \Delta_0(\lambda) \) is entire in \( \lambda \), representation (9) implies

\[
\omega = \int_0^\pi w_0(x) \, dx,
\]
(13)

which can also be checked independently by direct calculation using (11) and (12) for \( k = 0 \). Thus, the spectrum of \( L_j(a, q), j = 0, 1 \), is independent of \( q(x) \in B \) if so is the function \( w_0(x) \).
By changing the order of integration in \((12)\), it is easy to obtain the representation
\[
Q_k(x) = \int_a^{x-\frac{a}{2}} q(t) dt \int_{\pi}^{\frac{\pi}{2}} q(\tau) d\tau - (-1)^k \int_a^{\pi-x+\frac{a}{2}} q(t) dt \int_{\pi}^{\pi-x} q(\tau) d\tau,
\]
where \(x \in (3a/2, \pi-a/2)\). Let \(q(x) = 0\) on \((a, 3a/2)\). Then \((13)\) takes the form
\[
Q_k(x) = \begin{cases} 
-(-1)^k M_{q_2} q_1(x), & x \in \left(\frac{3a}{2}, \pi-a\right), \\
0, & x \in (\pi-a, 2a), \\
K_{q_2} \left(x + \frac{a}{2}\right) \int_{\frac{3a}{2}}^{x-\frac{a}{2}} q_1(t) dt, & x \in \left(2a, \pi-a \frac{a}{2}\right),
\end{cases}
\]
where
\[
q_1(x) = q(x), \quad q_2(x) = q(x), \quad x \in \left(\frac{5a}{2}, \pi\right),
\]
while \(M_h\) and \(K_h(x)\) are determined by \((5)\). Thus formulae \((11)\) and \((15)\) give
\[
w_k(x) = \begin{cases} 
0, & x \in \left(a, \frac{3a}{2}\right), \\
q(x), & x \in (\pi-a, 2a), \\
q(x) + K_{q_2} \left(x + \frac{a}{2}\right) \int_{\frac{3a}{2}}^{x-\frac{a}{2}} q_1(t) dt, & x \in \left(2a, \pi-a \frac{a}{2}\right),
\end{cases}
\]
Substituting \(q(x) = q_\alpha(x)\) into \((16)\) for \(k = 0\), where \(q_\alpha(x)\) is determined by \((7)\), and taking \((6)\) into account, we arrive at
\[
w_0(x) = \begin{cases} 
0, & x \in \left(a, \frac{5a}{2}\right), \\
h(x), & x \in \left(\frac{5a}{2}, \pi\right).
\end{cases}
\]
Thus, according to \((9)\), \((10)\) and \((13)\), the characteristic function \(\Delta_j(\lambda)\) of the problem \(L_j(a, q_\alpha)\) for each \(j = 0, 1\) is independent of \(\alpha\), which finishes the proof of Theorem 1.

**Remark 2.** Thus, we have constructed a class \(B\) of potentials on those the function \(w_0(x)\) appearing in representations \((9)\) and \((10)\) does not depend. By virtue of relation \((13)\), this independence is inherited by both characteristic functions \(\Delta_0(\lambda)\) and \(\Delta_1(\lambda)\), which gives Theorem 1.

Let us show why this strategy fails (at least, in the present form) in the case of boundary conditions \((4)\). For \(j = 0, 1\), denote by \(M_j(a, h, q)\) the boundary value problem for equation \((2)\) with boundary conditions \((4)\). Then eigenvalues of the problem \(M_j(a, 0, q)\) coincide with zeros of its characteristic function \(\Theta_j(\lambda) := C^j(\pi, \lambda)\), where \(C(x, \lambda)\) is the solution of \((2)\) under the initial conditions \(C(0, \lambda) = 1\) and \(C'(0, \lambda) = 0\). Analogously to \((9)\) and \((10)\), one can obtain the representations (see, e.g., \((24)\)):
\[
\Theta_0(\lambda) = \cos \rho \pi + \frac{\sin \rho (\pi-a)}{2\rho} + \frac{1}{2\rho} \int_a^{\pi} w_1(x) \sin \rho (\pi-2x+a) dx,
\]
\[
\Theta_1(\lambda) = -\rho \sin \rho \pi + \frac{\omega}{2} \cos \rho (\pi-a) + \frac{1}{2} \int_a^{\pi} w_1(x) \cos \rho (\pi-2x+a) dx,
\]
\[
\Theta_2(\lambda) = \frac{\cos \rho \pi}{2\rho} + \frac{1}{2\rho} \int_a^{\pi} w_1(x) \sin \rho (\pi-2x+a) dx,
\]
where \( \omega \) is determined by formula (8), while the function \( w_1(x) \) has the form (11) for \( k = 1 \). Analogously to \( B \), one can construct a family \( B_1 \) of potentials \( p_\alpha(x) \) on those the function \( w_1(x) \) does not depend. Indeed, for this purpose, the same scheme can be used but involving the operator \( -M_h \) instead of \( M_h \). However, the main difference from the case of boundary conditions (3) is that, in the case of (4), there is no relation analogous to (13). In other words, the constant \( \omega \) is not determined by the function \( w_1(x) \). Thus, each characteristic function (17) and (18) could depend on \( \alpha \) even if \( w_1(x) \) did not. So the presented scheme does not refute the uniqueness theorem in [27].
