On estimation of quadratic variation for multivariate pure jump semimartingales *

Johannes Heiny †  Mark Podolskij‡

September 8, 2020

Abstract

In this paper we present the asymptotic analysis of the realised quadratic variation for multivariate symmetric $\beta$-stable Lévy processes, $\beta \in (0, 2)$, and certain pure jump semimartingales. The main focus is on derivation of functional limit theorems for the realised quadratic variation and its spectrum. We will show that the limiting process is a matrix-valued $\beta$-stable Lévy process when the original process is symmetric $\beta$-stable, while the limit is conditionally $\beta$-stable in case of integrals with respect to symmetric $\beta$-stable motions. These asymptotic results are mostly related to the work 5, which investigates the univariate version of the problem. Furthermore, we will show the implications for estimation of eigenvalues and eigenvectors of the quadratic variation matrix, which is a useful result for the principle component analysis. Finally, we propose a consistent subsampling procedure in the Lévy setting to obtain confidence regions.

Key words: high frequency data, Lévy processes, limit theorems, quadratic variation, semimartingales.

AMS 2010 subject classifications: 60F05, 60F17, 62M15, 62H25.

1 Introduction

During the past two decades statistics and limit theorems for Itô semimartingales have received a great deal of attention in the literature. This has been mainly motivated by numerous applications in finance among other fields of science. A tremendous progress

has been achieved in the statistical and probabilistic analysis of fine structure of Itô semi-
martingales in the infill asymptotic regime. A detailed account of the asymptotic theory
for high frequency observations of semimartingales can be found in the monograph [7].

Statistical estimation of quadratic variation of Itô semimartingales is probably one
of the most important statistical problems in financial applications. Indeed, quadratic
variation determines the variability of price processes in finance and it plays a crucial role
in option pricing, predictions and other applications. During the past twenty years there
has been a number of studies devoted to statistical inference for quadratic variation in
various settings. Some accounts on this topic can be found in [3, 4, 6, 9] among many
other contributions. For a $d$-dimensional Itô semimartingale $(Y_t)_{t\geq 0}$ defined on a filtered
probability space $(\Omega, \mathcal{F}, (\mathcal{F}_t)_{t\geq 0}, \mathbb{P})$ and observed at time points $i\Delta_n, i = 0, \ldots, \lfloor t/\Delta_n \rfloor$, the classical estimator of the quadratic variation $[Y]_t$ is given by the “sum of squares”

$$ [Y]_t^n := \sum_{i=1}^{\lfloor t/\Delta_n \rfloor} (Y_{i\Delta_n} - Y_{(i-1)\Delta_n}) (Y_{i\Delta_n} - Y_{(i-1)\Delta_n})^\top \xrightarrow{\mathbb{P}} [Y]_t, $$

which we call the *realised quadratic variation*. In the continuous Itô semimartingale framework, where $(Y_t)_{t\geq 0}$ has the form

$$ Y_t = Y_0 + \int_0^t a_s ds + \int_0^t \sigma_s dW_s $$

with $a$ being a $d$-dimensional drift, $\sigma$ a $\mathbb{R}^{d\times d}$-valued volatility process and $W$ a $d$-dimensional Brownian motion, estimation of quadratic variation has been investigated in e.g. [3, 4]. In particular, under minimal assumptions on $a$ and $\sigma$, they proved the following functional stable weak limit theorem. We refer to the next section for the formal definition of stable convergence.

**Theorem 1.1.** ([7, Theorem 5.4.2]) Let $a$ be a predictable locally bounded drift and $\sigma$ a càdlàg volatility process. Then we obtain the functional stable convergence

$$ \Delta_n^{-1/2} ([Y]_t^n - [Y]_t) \xrightarrow{\mathbb{L}, \mathbb{P}} M_t, $$

where, conditionally on $\mathcal{F}$, $(M_t)_{t\geq 0}$ is a Gaussian martingale with mean zero and conditional covariance function

$$ \mathbb{E}[M_t^{jk} M_t^{j'k'} | \mathcal{F}] = c_t^{jj'} c_t^{kk'} + c_t^{jk} c_t^{kj'}, \quad c_t := \sigma_t \sigma_t^\top. $$

The first result on this problem for general Itô semimartingales with non-vanishing continuous martingale part appeared in [3]. The author investigated processes of the type

$$ Y_t = Y_0 + \int_0^t a_s ds + \int_0^t \sigma_s dW_s + J_t, $$

where $J$ denotes the jump part of $Y$. He proved the following result.
Theorem 1.2. (Theorem 5.4.2) Assume that $a$ is predictable and locally bounded drift, $\sigma$ is càdlàg and $J$ is a pure jump Itô semimartingale with a locally bounded characteristic. Then we obtain the functional stable convergence

$$
\Delta_n^{-1/2} \left( [Y]_t^{\Delta_n} - [Y]_{\Delta_n(t/\Delta_n)} \right) \overset{L}{\longrightarrow} M_t + \sum_{m: T_m \leq t} \left( \Delta Y_{T_m} R_m^- + R_m \Delta Y_{T_m}^\top \right),
$$

where $(M_t)_{t \geq 0}$ has been introduced in Theorem 1.1, $(T_m)_{m \geq 1}$ (resp. $\Delta Y_{T_m}$) denote the jump times (resp. jump sizes) of $Y$, $R_m = \sqrt{\kappa_m \sigma_{T_m} - \Psi_+^m + \sqrt{1 - \kappa_m \sigma_{T_m}}} \Psi_-^m$ and

$$(\kappa_m)_{m \geq 1} \text{i.i.d. } \sim \mathcal{U}(0,1), \quad (\Psi^+_m)_{m \geq 1}, (\Psi^-_m)_{m \geq 1} \text{i.i.d. } \sim \mathcal{N}_d(0, I_d).$$

Furthermore, conditionally on $\mathcal{F}$, the processes $(M_t)_{t \geq 0}, (\kappa_m)_{m \geq 1}, (\Psi^+_m)_{m \geq 1}$ and $(\Psi^-_m)_{m \geq 1}$ are mutually independent.

Quite surprisingly, central limit theorems for quadratic variation only require very weak assumptions on the model in both settings. Things are different in the pure jump setting, which has been recently studied in [5]. In the latter framework the authors consider univariate stochastic integral processes, where the driving motion is locally $\beta$-stable with $\beta \in (0,2)$. They show a stable weak limit theorem for the realised quadratic variation with a $\beta$-stable limit in most interesting cases.

The aim of this paper is to provide a weak limit theory for the realised quadratic variation in the setting of multivariate symmetric $\beta$-stable Lévy processes and related stochastic integral models. We will show that the limiting process is a matrix-valued $\beta$-stable Lévy motion in the pure Lévy case and we will determine its directional measure. In the setting of integral models driven by a multivariate symmetric $\beta$-stable Lévy process we will prove that the limit is conditionally $\beta$-stable. Another important contribution of our paper is the asymptotic analysis of the associated eigenvalues and eigenvectors, which is of major importance for the principal component analysis. This part provides an extension of the classical work [2], which gave a complete theory for the principal component analysis in the Gaussian i.i.d. setting.

The paper is organised as follows. Section 2 presents the models, notations and the main theoretical results. Section 3 is devoted to construction of asymptotic confidence regions via a subsampling approach in the Lévy setting. Finally, the proofs of the main results are collected in Section 4.

2 The model, notation and main results

2.1 Notation

In this subsection we briefly introduce the main notations used throughout the paper. For $a \in \mathbb{C}$ we write $|a|$ to denote the norm of $a$. For a vector or a matrix $x$ the transpose of $x$ is denoted by $x^\top$. The notation $\|x\|$ (resp. $\langle x, y \rangle$) stands for the Euclidean norm of $x \in \mathbb{R}^d$ (resp. the scalar product of $x, y \in \mathbb{R}^d$). We associate to the Frobenius norm $\| \cdot \|_{\text{tr}}$.
the scalar product
\[ \langle A_1, A_2 \rangle_{\text{tr}} := \text{tr}(A_1^T A_2), \quad A_1, A_2 \in \mathbb{R}^{d_1 \times d_2}, \]
where \( \text{tr} \) denotes the trace. We denote by \( \|A\|_{\text{op}} \) the operator norm of \( A \in \mathbb{R}^{d_1 \times d_2} \). For a symmetric matrix \( A \in \mathbb{R}^{d \times d} \) we write \( \lambda_{\text{max}}(A), \lambda_{\text{min}}(A) \) for the largest and the smallest eigenvalue of \( A \), respectively. Furthermore, \( A_1 \otimes A_2 \) stands for the Kronecker product of \( A_1 \) and \( A_2 \), and \( A \otimes^2 := A \otimes A \). In particular, for column vectors \( x, y \in \mathbb{R}^d \) we have \( x \otimes y = x y^T \). We also introduce the symmetric tensor
\[ x \odot y = x y^T + y x^T. \]
The set \( S_d \) denotes the Euclidean unit sphere in \( \mathbb{R}^d \). For a càdlàg stochastic process \((Y_t)_{t \geq 0}\) we denote by \( Y_{t-} \) the left limit of \( Y \) at point \( t \) and by \( \Delta Y_t = Y_t - Y_{t-} \) the jump at \( t \). Throughout this paper \( \Delta_n \) is a sequence of positive numbers satisfying \( \Delta_n \to 0 \) and we write
\[ \Delta_n Y := Y_{\Delta_n} - Y_{(i-1)\Delta_n}. \]
If not stated otherwise, the asymptotic relations are with respect to \( n \to \infty \) throughout this paper. For stochastic processes \( Y^n \) and \( Y \) we denote by \( Y^n \xrightarrow{u,c,p} Y \) the uniform convergence in probability, that is
\[ \sup_{t \in [0,T]} |Y^n_t - Y_t| \xrightarrow{\mathbb{P}} 0 \quad \text{for any } T > 0. \]
In the following we will often use the notion of *stable convergence*. We recall that a sequence of random variables \((Y_n)_{n \in \mathbb{N}}\) defined on \((\Omega, \mathcal{F}, \mathbb{P})\) is said to converge stably with limit \( Y \) \( \xrightarrow{L} Y \) defined on an extension \((\Omega', \mathcal{F}', \mathbb{P}')\) of the original probability space \((\Omega, \mathcal{F}, \mathbb{P})\), iff for any bounded, continuous function \( g \) and any bounded \( \mathcal{F}\)-measurable random variable \( Z \) it holds that
\[ \mathbb{E}[g(Y_n)Z] \to \mathbb{E}[g(Y)Z], \quad n \to \infty. \]
If not mentioned otherwise, the stable convergence is understood in the sense of Skorokhod \( J_1 \)-topology for stochastic processes defined on the interval \([0,T]\). We refer to [1, 10] for a detailed exposition of stable convergence.

Finally, we will deal with \( \mathbb{R}^d \)-valued (or \( \mathbb{R}^{d \times d} \)-valued) Lévy processes \((Y_t)_{t \geq 0}\) without a Gaussian part. They are characterised by the Lévy triplet \((\gamma, 0, \nu)\), i.e.
\[ \mathbb{E}[\exp(i \langle u, Y_t \rangle)] = \exp \left( i \langle \gamma, u \rangle + \int_{\mathbb{R}^d} \left\{ \exp(i \langle x, u \rangle) - 1 - i \langle x, u \rangle \mathbb{1}_{\{||x|| \leq 1\}} \right\} \nu(dx) \right) \]
for \( u, \gamma \in \mathbb{R}^d \) and a measure \( \nu \) satisfying \( \nu(\{0\}) = 0, \int_{\mathbb{R}^d} (1 + ||x||^2) \nu(dx) < \infty \). When we consider \( \mathbb{R}^{d \times d} \)-valued Lévy processes we use the scalar product \( \langle \cdot, \cdot \rangle_{\text{tr}} \) instead.

### 2.2 The setting

We consider a filtered probability space \((\Omega, \mathcal{F}, (\mathcal{F}_t)_{t \geq 0}, \mathbb{P})\), satisfying the usual conditions, on which we define a \( d \)-dimensional symmetric \( \beta \)-stable Lévy process \((L_t)_{t \geq 0}\) with Lévy
triplet $(0, 0, G)$. Here $G$ denotes the Lévy measure of $L$, which admits the representation
\[ G(dx) = \frac{1}{\rho^1 + \rho^2} d\rho H(d\theta), \tag{2.1} \]
where $x = (\rho, \theta) \in \mathbb{R}_+ \times S_d$ and $H$ denotes a symmetric finite measure on $S_d$ (called the direction measure). We will also consider integrals $(X_t)_{t \geq 0}$ of the type
\[ X_t = \int_0^t \sigma_s \, dL_s, \tag{2.2} \]
where $\sigma$ is a càdlàg $\mathbb{R}^{d \times d}$-valued volatility process. Our main focus is on the classical realised quadratic variation, which is defined as
\[ [Y]_t^n := \left\{ \sum_{i=1}^{\lfloor t/\Delta_n \rfloor} (\Delta Y_s)^{\otimes 2} : s \in [0, t] \right\} \]
for any semimartingale $(Y_t)_{t \geq 0}$. When $Y$ is a pure jump semimartingale, which in particular applies to $Y = L$ and $Y = X$, it holds that
\[ [Y]_t^n \xrightarrow{\mathbb{P}} [Y]_t := \sum_{s \in [0, t]} (\Delta Y_s)^{\otimes 2} \quad \text{as } \Delta_n \to 0. \]

The main aim of this paper is to study the weak limit theory associated to the above convergence and its consequences for estimation of the spectrum of $[Y]_t$. We start with the following proposition.

**Proposition 2.1.** Assume that $\operatorname{span}(\text{supp}(H)) = \mathbb{R}^d$. Then the eigenvalues $\lambda_1, \ldots, \lambda_d$ of $[L]_t$ are all distinct and strictly positive $\mathbb{P}$-almost surely.

**Proof.** The assumption $\operatorname{span}(\text{supp}(H)) = \mathbb{R}^d$ obviously implies that $\text{supp}(H)$ contains linearly independent vectors $x_1, \ldots, x_d \in \mathbb{R}^d$. After a change of basis we can assume without loss of generality that $x_j = e_j$, $j = 1, \ldots, d$, where $(e_j)_{1 \leq j \leq d}$ denotes the standard basis of $\mathbb{R}^d$.

We recall that for two probability measures $\nu_1, \nu_2$ it holds that $\text{supp}(\nu_1 * \nu_2) = \text{supp}(\nu_1) + \text{supp}(\nu_2)$, where $\nu_1 * \nu_2$ denotes the convolution of $\nu_1$ and $\nu_2$. From this observation we deduce that there exist further vectors $x_{d+1}, \ldots, x_q \in \mathbb{R}^d$ such that the law $\nu^f$ of $[L]_t$ satisfies
\[ \text{supp} (\nu^f) = \left\{ \sum_{j=1}^q a_j x_j^{\otimes 2} : a_j \geq 0 \right\}. \]

Here $q$ is a number satisfying $d \leq q \leq d(d + 1)/2$ and symmetric matrices $(x_j^{\otimes 2})_{1 \leq j \leq q}$ are linearly independent. In other words, $\text{supp}(\nu^f)$ is a convex cone of dimension $q$. According to e.g. [11, Theorem 27.10], $\nu^f$ has a Lebesgue density on $\text{supp}(\nu^f)$. For a symmetric
matrix $A \in \mathbb{R}^{d \times d}$ let us denote by $\lambda_1(A), \ldots, \lambda_d(A)$ the real eigenvalues of $A$. We observe that the sets

$$S_1 = \left\{ A = \sum_{j=1}^{q} a_j x_j^2 : a_j \geq 0, \det(A) = 0 \right\},$$

$$S_2 = \left\{ A = \sum_{j=1}^{q} a_j x_j^2 : a_j \geq 0, \lambda_j(A) = \lambda_{j_2}(A) \text{ for some } j_1 \neq j_2 \right\}$$

are closed with an empty interior in $\text{supp}(\nu^t)$. Indeed, consider the set $S_1$ and define $f(a_1, \ldots, a_q) := \sum_{j=1}^{q} a_j x_j^2$. Recalling that $x_j = e_j$, $j = 1, \ldots, d$, and assuming that $\det(f(a_1, \ldots, a_q)) = 0$ for some $a_j \geq 0$, we deduce

$$\det(f(a_1 + \varepsilon, \ldots, a_d + \varepsilon, a_{d+1}, \ldots, a_q)) = \det(f(a_1, \ldots, a_q) + \varepsilon I_d) \neq 0$$

for some small enough $\varepsilon > 0$. Hence, the set $S_1$ has an empty interior and the proof works similarly for the set $S_2$. Consequently, both sets have Lebesgue measure 0 on $\text{supp}(\nu^t)$, which implies the statement of the proposition.

This result will play an important role if we want to transfer the limit theory for $[Y]_t$ to the spectrum of $[Y]_t$. In the next step we introduce the sequence

$$\delta_n = (\Delta_n \log(1/\Delta_n))^{-1/\beta}, \quad n \geq 1,$$

which will turn out to be the rate of convergence for the estimator $[L]^p_t$. We deduce the following result.

**Theorem 2.2.** For any $\beta \in (0, 2)$ we obtain the functional stable convergence

$$U^n_t := \delta_n \left( [L]^p_t - [L]_{\Delta_n[t/\Delta_n]} \right) \xrightarrow{L^q} U_t,$$

where $(U_t)_{t \geq 0}$ is an $\mathbb{R}^{d \times d}$-valued Lévy process with characteristic triplet $(0, 0, \nu_U)$ and the Lévy measure $\nu_U$ is given by

$$\nu_U(B) = \frac{1}{2\beta} \int_{\mathbb{S}_{d \times d}} \mu(dz) \int_{\mathbb{R}_+} 1_B(\rho z) \rho^{-1-\beta} d\rho, \quad B \in \mathcal{B}(\mathbb{R}^d \oplus \mathbb{R}^d),$$

and

$$\mu(z) = \int_{\mathbb{S}_{d \times d}} 1_z \left( \frac{\theta_1 \odot \theta_2}{\| \theta_1 \odot \theta_2 \|_{\text{tr}}} \right) (2(1 + \langle \theta_1, \theta_2 \rangle^2))^{\beta/2} H(d\theta_1)H(d\theta_2), \quad z \in \mathcal{B}(\mathbb{S}_{d \times d}),$$

where $\mathbb{S}_{d \times d}$ denotes the unit sphere with respect to the Frobenius norm $\| \cdot \|_{\text{tr}}$ and $B$ is bounded away from $0 \in \mathbb{R}^{d \times d}$. Moreover, the process $U$ is defined on an extension $(\Omega, \mathcal{F}, (\mathcal{F}_t)_{t \geq 0}, \mathbb{P})$ of the original space $(\Omega, \mathcal{F}, (\mathcal{F}_t)_{t \geq 0}, \mathbb{P})$ and is independent of the $\sigma$-algebra $\mathcal{F}$.
Let us give some remarks about the Lévy measure $\nu_U$ of the limiting process $(U_t)_{t \geq 0}$. Since $\nu_U$ admits the representation (2.5), where $\mu$ is a finite measure on the unit sphere $\mathbb{S}_{d \times d}$, the process $(U_t)_{t \geq 0}$ is an $\mathbb{R}^{d \times d}$-valued $\beta$-stable Lévy process. Furthermore, the support of the directional measure $\mu$ is given as

$$\text{supp}(\mu) = \left\{ \frac{\theta_1 \circ \theta_2}{\|\theta_1 \circ \theta_2\|_1} \in \mathbb{S}_{d \times d} : \theta_1, \theta_2 \in \text{supp}(H) \right\},$$

which in particular shows that the jumps of $U$ have at most rank 2. The latter fact is not surprising since the jumps of $[L]_t^r$ and $[L]_{\Delta_n(t/\Delta_n)}$ have rank 1. Finally, we remark that the specific centring via $[L]_{\Delta_n(t/\Delta_n)}$ is needed to prove the functional stable convergence as it guarantees that both processes jump at the same time. If one is interested in pointwise stable convergence it suffices to use the more natural centring $[L]_t$.

**Remark 2.3.** (a) The symmetry of the directional measure $H$, and hence of the Lévy process $L$, is assumed for simplicity of the representation of the limiting process $U$. As it has been demonstrated in [3] in the univariate setting, $U$ may contain an additional drift term when $H$ is not symmetric. Furthermore, according to the theory of [3] one can relax the assumptions on $L$ to allow for certain locally $\beta$-stable Lévy processes.

(b) There exists an alternative representation of the Lévy measure $\nu_U$ with respect to a different “directional” measure. Indeed, we may write

$$\nu_U(B) = \frac{1}{2\beta} \int_{\mathbb{S}_d \otimes \mathbb{S}_d} \mu'(dz) \int_{\mathbb{R}^+} 1_B(\rho z) \rho^{1-\beta} d\rho, \quad B \in \mathcal{B}(\mathbb{R}^d \otimes \mathbb{R}^d),$$

$$\mu'(z) = \int_{\mathbb{S}_d^2} 1_z(\theta_1 \circ \theta_2) H(d\theta_1) H(d\theta_2), \quad z \in \mathcal{B}(\mathbb{S}_d \otimes \mathbb{S}_d).$$

In some sense it is a more natural representation of $\nu_U$. 

Now, we would like to determine the asymptotic theory for the eigenvalues and eigenvectors of the estimator $[L]^r_t$. Let us recall a standard result on differentiability of eigenvalues/eigenvectors considered as functions of the underlying matrix. Consider a symmetric matrix $A_0$ with distinct eigenvalues $\lambda_1, \ldots, \lambda_d > 0$ and let $v_1, \ldots, v_d \in \mathbb{R}^d$ be the corresponding eigenvectors with unit length. Then, using differential notation, we obtain the identities

$$d\lambda_i = v_i^\top (dA)v_i, \quad dv_i = (\lambda_i I_d - A_0)^+ (dA)v_i,$$

where $(\lambda_i I_d - A_0)^+$ denotes the Moore-Penrose pseudoinverse of the matrix $\lambda_i I_d - A_0$. We recall that a Moore-Penrose pseudoinverse $A^+$ of a matrix $A \in \mathbb{R}^{d \times d}$ is defined via four properties: (i) $AA^+A = A$, (ii) $A^+AA^+ = A^+$, (iii) $AA^+$ is Hermitian and (iv) $A^+A$ is Hermitian. As a consequence of these identities we deduce the following statement.

**Corollary 2.4.** Assume that $\text{span}(\text{supp}(H)) = \mathbb{R}^d$. Denote by $\lambda(t) = (\lambda_1(t), \ldots, \lambda_d(t))^\top$ (resp. $\lambda^\ast(t) = (\lambda_1(t), \ldots, \lambda_d(t))^\top$) and $v(t) = (v_1(t), \ldots, v_d(t))$ (resp. $v^\ast(t) = (v_1(t), \ldots, v_d(t))$) the eigenvalues/eigenvectors of $[L]^r_t$ (resp. of $[L]^r_t$). Then, for a fixed $t > 0$, we obtain the stable convergence

$$\delta_n (\lambda^n(t) - \lambda(t), v^n(t) - v(t)) \xrightarrow{\mathcal{L}} \left( (v_i(t) \top U_t v_i(t))_{1 \leq i \leq d}, \left((\lambda_i(t) I_d - [L]_t)^+ U_t v_i(t)\right)_{1 \leq i \leq d} \right),$$

where the process $(U_t)_{t \geq 0}$ has been defined in Theorem 2.2.
Proof. According to Proposition 2.1 the random eigenvalues \((\lambda_i)_{1 \leq i \leq d}\) are distinct and strictly positive \(P\)-almost surely. Hence, the mappings \(\lambda(t)\) and \(v(t)\) seen as functions in \([L]_t\) are infinitely often differentiable and the first derivatives are given by (2.6). Thus, the result follows from the \(\delta\)-method for stable convergence and Theorem 2.2. \(\Box\)

Remark 2.5. In this remark we discuss two standard examples of Lévy processes \(L\).

(a) (i.i.d. case): We consider a symmetric \(\beta\)-stable Lévy process \(L = (L^1, \ldots, L^d)\) with i.i.d. components. In this setting the directional measure \(H\) of \(G\) is proportional to the uniform measure on the set \((\pm e_i)_{1 \leq i \leq d}\), where \((e_i)_{1 \leq i \leq d}\) is the standard orthonormal basis of \(\mathbb{R}^d\), i.e.

\[
H(\{\pm e_i\}) = a > 0, \quad \forall 1 \leq i \leq d.
\]

Since the components of \(L\) have no common jumps we have \([L]_t = \text{diag}([L^1]_t, \ldots, [L^d]_t)\). According to Remark 2.3 the support of \(\mu'\) is given by the set \((\pm e_i \circ e_j)_{1 \leq i \leq j \leq d}\) and it holds that

\[
\mu'((\pm e_i \circ e_j)) = a^2, \quad 1 \leq i \leq j \leq d.
\]

In other words, the elements \((U^i_j)_{1 \leq i \leq j \leq d}\) are independent one-dimensional symmetric \(\beta\)-stable Lévy processes. Finally, by Corollary 2.4, the limit of \(\delta_n (\lambda^n(t) - \lambda(t))\) is an \(\mathbb{R}^d\)-valued symmetric \(\beta\)-stable process with i.i.d. components.

(b) (uniform case): Here we consider a symmetric \(\beta\)-stable Lévy process \(L\) with directional measure

\[
H(d\theta) = a \mathbb{1}_{S_d}(\theta) d\theta, \quad a > 0.
\]

In this setting \([L]_t\) is a matrix-valued \(\beta/2\)-stable Lévy motion with directional measure

\[
\tilde{H}(A) = a \int_{S_d} \mathbb{1}_A(\theta^{\otimes 2}) d\theta, \quad A \in \mathcal{B}(S_d \times d).
\]

The measure \(\mu'\) associated with the limiting process \(U\) is given by

\[
\mu'(z) = a^2 \int_{S_d^2} \mathbb{1}_z(\theta_1 \circ \theta_2) d\theta_1 d\theta_2.
\]

In this case it seems hard to compute the exact asymptotic distribution of the eigenvalues \(\delta_n (\lambda^n(t) - \lambda(t))\), but according to Corollary 2.4 it is necessarily \(\beta\)-stable conditionally on \(\mathcal{F}\) with dependent components. \(\Box\)

The main result of Theorem 2.2 extends to the more general setting of processes \((X_t)_{t \geq 0}\) that have been introduced in (2.2).

Proposition 2.6. Assume that \((\sigma_t)_{t \geq 0}\) is an Itô semimartingale with local random characteristics \((\gamma_t^a, c_t^a, \nu_t^a)\) such that the processes \((\gamma_t^a)_{t \geq 0}, (c_t^a)_{t \geq 0}\) and \(\int (\|x\|_t^2 \wedge 1) \nu_t^a(dx)\) are locally bounded. Then it holds that

\[
\delta_n ([X]_t^n - [X]_{\Delta_n[t/\Delta_n]}) \xrightarrow{\mathcal{L}-\mathbb{P}} \int_0^t \sigma_{s-} dU_s \sigma_{s-}^\top,
\]

where the \(\mathbb{R}^{d \times d}\)-valued Lévy process \((U_t)_{t \geq 0}\) has been defined in Theorem 2.2. In particular, the limiting process in (2.7) is \(\beta\)-stable conditionally on \(\mathcal{F}\).
Proof. The proof of Proposition 2.6 is obtained by a local approximation of the process $(\sigma_t)_{t \geq 0}$ and application of Theorem 2.2. Using Itô formula we can write

$$\delta_n \left( [X]^n_t - [X]_{\Delta_n} [t/\Delta_n] \right) = \delta_n \sum_{i=1}^{\lfloor t/\Delta_n \rfloor} \int_{(i-1)\Delta_n}^{i\Delta_n} (X_s - X_{(i-1)\Delta_n}) \odot dX_s.$$ 

Applying the latter we obtain the decomposition

$$\delta_n \left( [X]^n_t - [X]_{\Delta_n} [t/\Delta_n] \right) = \sum_{i=1}^{\lfloor t/\Delta_n \rfloor} (\zeta^n_i + \zeta'^n_i)$$

with

$$\zeta^n_i = \delta_n \sigma_{(i-1)\Delta_n} \int_{(i-1)\Delta_n}^{i\Delta_n} (L_s - L_{(i-1)\Delta_n}) \odot dL_s \sigma^T_{(i-1)\Delta_n},$$

$$\zeta'^n_i = \delta_n \left( \int_{(i-1)\Delta_n}^{i\Delta_n} (X_s - X_{(i-1)\Delta_n}) \odot dX_s - \sigma_{(i-1)\Delta_n} \int_{(i-1)\Delta_n}^{i\Delta_n} (L_s - L_{(i-1)\Delta_n}) \odot dL_s \sigma^T_{(i-1)\Delta_n} \right).$$

According to [5, Lemma 6.9] and Theorem 2.2 we have the functional stable convergence

$$\sum_{i=1}^{\lfloor t/\Delta_n \rfloor} \zeta^n_i \overset{D}{\longrightarrow} \int_0^t \sigma_{s-} \sigma^T_s.$$ 

Thus, it suffices to show that \(\sum_{i=1}^{\lfloor t/\Delta_n \rfloor} \zeta'^n_i \overset{u.c.p.}{\longrightarrow} 0\). Since the latter can be proved componentwise, we may use the univariate argument of [5, Proposition 7.2] to complete the proof of Proposition 2.6.

When the spectrum of the quadratic variation \([X]_t\) is non-degenerate in the sense of Proposition 2.1, a direct analogue of Corollary 2.4 gives the asymptotic theory for estimation of eigenvalues/eigenvectors of \([X]_t\).

3 A subsampling procedure

We remark that the theoretical result of (2.4) in Theorem 2.2 is hard to use for statistical applications since the directional measure \(H\) on \(S_d\) is unknown in general. The estimation of this infinite dimensional object is far from obvious and even if \(H\) were known there exist no reliable numerical methods to generate the limiting process \((U_t)_{t \geq 0}\). Instead our aim is to propose a subsampling method, which automatically adapts to the unknown limiting distribution.

The main idea is to construct \(M\) independent copies \(\zeta_{n,m}, m = 1, \ldots, M\), such that

\[ \mathbb{P}(\zeta_{n,m} \in A) \to \overline{\mathbb{P}} (U_1 \in A) \quad \text{as } n \to \infty, \]
for any open cylindrical set $A \in \mathbb{R}^{d \times d}$ (recall that $\mathbb{P}$ denotes the probability measure on the extended space). Then, as $M \to \infty$, we deduce that
\[
\frac{1}{M} \sum_{m=1}^{M} \mathbb{1}_{\{\zeta_{n,m} \in A\}} \xrightarrow{\mathcal{L}} \mathbb{P}(U_{1} \in A).
\]

Hence, the left hand side gives a consistent estimator of the unknown distribution of $U_{1}$. Unfortunately, it seems impossible to achieve the goal with just one additional scale $M$, and we will use an additional parameter $k \to \infty$. We first divide the interval $(0, 1]$ into $M$ equidistant blocks $I_{m} := ((m - 1)/M, m/M]$ for $m = 1, \ldots, M$. Then we introduce the empirical quadratic variation over the block $I_{m}$ computed at frequency $\Delta_{n}$:
\[
z(\Delta_{n})_{m}^{n} := \sum_{i: (i-1)\Delta_{n}, i\Delta_{n} \in I_{m}} (\Delta_{i}^{n} L)^{\otimes 2}.
\]

Since the convergence rate $\delta_{n} =: \delta(\Delta_{n})$ introduced in (2.3) depends on the unknown parameter $\beta \in (0, 2)$, we need to construct its estimator. For $p \in (-1/2, 0)$ we define the statistic
\[
r_{n} := \frac{\sum_{i=2}^{\lfloor 1/\Delta_{n} \rfloor} \|L_{i\Delta_{n}} - L_{i-\Delta_{n}}\|^{p}}{\sum_{i=1}^{\lfloor 1/\Delta_{n} \rfloor} \|\Delta_{i}^{n} L\|^{p}} \xrightarrow{\mathbb{P}} 2^{p/\beta},
\]
where the convergence follows by self-similarity and the law of large numbers. Hence, $\hat{\beta}_{n} := p \log(2)/\log(r_{n})$ is a $\Delta_{n}^{-1/2}$-consistent estimator of $\beta$ by the central limit theorem since $\mathbb{E}[\|\Delta_{i}^{n} L\|^{2p}] < \infty$ for any $p \in (-1/2, 0)$. Similarly, we can define an estimator $\hat{\beta}_{n,m}$, which is built upon observations on the interval $I_{m}$. By analogous reasoning this estimator satisfies $\hat{\beta}_{n,m} - \beta = O_{\mathbb{P}}((\Delta_{n} M)^{-1/2})$. We now set
\[
\hat{\delta}_{m}(\Delta_{n}) := (\Delta_{n} \log(1/\Delta_{n}))^{-1/2} \hat{\beta}_{n,m} \quad \text{and} \quad \zeta_{n,m,k} := \hat{\delta}_{m}(k\Delta_{n}) M^{1/\hat{\beta}_{n,m}} (z(k\Delta_{n})_{m}^{n} - z(\Delta_{n})_{m}^{n}).
\]

Finally, we introduce the statistic
\[
S_{n}^{M,k}(A) := \frac{1}{M} \sum_{m=1}^{M} \mathbb{1}_{\{\zeta_{n,m,k} \in A\}}.
\]

Let us briefly describe the intuition behind this statistic. First of all, we note that the terms $z(k\Delta_{n})_{m}^{n}, z(\Delta_{n})_{m}^{n}, m = 1, \ldots, M$, are independent and identically distributed. In the next step we observe that, according to Theorem 2.2, the quantity $\delta_{n}(z(\Delta_{n})_{m}^{n} - ([L]_{m/M} - [L]_{(m-1)/M}))$ is close in distribution to $U_{m/M} - U_{(m-1)/M}$, which due to self-similarity has the same distribution as $M^{-1/\beta}U_{1}$. However, since the quadratic variation over $I_{m}$ is an unknown quantity, it needs to be replaced by an empirical quantity without affecting the asymptotic theory. To do so we replace the statistic $z(\Delta_{n})_{m}^{n}$ by $z(k\Delta_{n})_{m}^{n}$ for some $k \to \infty$ while using $z(\Delta_{n})_{m}^{n}$ as a proxy for the quadratic variation over $I_{m}$. Finally, adjusting and estimating the convergence rate, we obtain the quantity $\zeta_{n,m,k}$. The formal convergence result is as follows.

**Proposition 3.1.** Assume that $M, k \to \infty$ such that $kM\Delta_{n} \to 0$. For any open cylindrical set $A \in \mathbb{R}^{d \times d}$ it holds that
\[
S_{n}^{M,k}(A) \xrightarrow{\mathcal{L}} \mathbb{P}(U_{1} \in A).
\]
Proof. Since $M \to \infty$ and the random variables $(\zeta_{n,m,k})_{1 \leq m \leq M}$ are i.i.d, we just need to prove that
\[
\zeta_{n,m,k} \xrightarrow{d} U_1 \quad \text{as } M, k \to \infty, \; kM\Delta_n \to 0,
\]
for a fixed $m$. We analyse the various errors associated with $\zeta_{n,m,k}$. We first prove the convergence
\[
\delta(\Delta_n)M^{1/\beta} \left( z(\Delta_n)^n_m - \left( [L]_{m}^n - [L]_{m-1}^n \right) \right) \xrightarrow{d} U_1 \quad \text{as } M \to \infty, \; M\Delta_n \to 0. \tag{3.1}
\]
We set $RV(\Delta_n) = \sum_{i=1}^{[1/\Delta_n]} (\Delta_i^n L)^\otimes 2$. Due to self-similarity of the Lévy process $L$ and its quadratic variation $[L]$, we obtain the identity in distribution
\[
\delta(\Delta_n)M^{1/\beta} \left( z(\Delta_n)^n_m - \left( [L]_{m}^n - [L]_{m-1}^n \right) \right) \overset{d}{=} \delta(\Delta_n)M^{-1/\beta} (RV(M\Delta_n) - [L]_1 + o_P(1)).
\]
We conclude from Theorem 2.2 that $\delta(M\Delta_n) (RV(M\Delta_n) - [L]_1) \xrightarrow{d} U_1$. On the other hand, we have that $\delta(\Delta_n)M^{-1/\beta} / \delta(M\Delta_n) \to 1$. Hence, the convergence in (3.1) holds. Applying this convergence to $k\Delta_n$ instead of $\Delta_n$ we also deduce the convergence
\[
\delta(k\Delta_n)M^{1/\beta} \left( z(k\Delta_n)^n_m - \left( [L]_{m}^n - [L]_{m-1}^n \right) \right) \xrightarrow{d} U_1.
\]
Combining the latter with the original statement (3.1), we obtain that
\[
\delta(k\Delta_n)M^{1/\beta} (z(k\Delta_n)^n_m - z(\Delta_n)^n_m) \xrightarrow{d} U_1,
\]
because $k \to \infty$. Finally, recalling that $\beta_{n,m} - \beta = O_P((\Delta_n M)^{-1/2})$, it holds that
\[
\delta_m(k\Delta_n)^{1/\beta_{n,m}} - \delta(k\Delta_n)^{1/\beta} = O_P \left( \delta(k\Delta_n)\Delta_n^{1/2}M^{-1/2} \log(1/\Delta_n) \right).
\]
Consequently, we obtain the statement of Proposition 3.1. $\square$

Suppose that we are aiming to estimate a quantity $f([L]_1)$ for a function $f : \mathbb{R}^{d \times d} \to \mathbb{R}$, which is continuously differentiable in a neighbourhood of $[L]_1$. One important example is the function $f(A) = \lambda_{\max}(A)$, which satisfies the differentiability condition under assumptions of Proposition 2.1. Applying the $\delta$-method to Theorem 2.2 we deduce the stable convergence
\[
\delta_n (f([L]_1^n) - f([L]_1)) \xrightarrow{L^2} \langle \nabla f([L]_1), U_1 \rangle_{tr}.
\]
In this case we can apply a similar subsampling procedure to obtain confidence regions for the unknown parameter. Indeed, defining the quantity
\[
\zeta_{n,m,k}(f) := \delta_m(k\Delta_n)^{1/\beta_{n,m}} (f(z(k\Delta_n)^n_m) - f(z(\Delta_n)^n_m)),
\]
we deduce the convergence
\[
S_n^{M,k}(f, w) := \frac{1}{M} \sum_{m=1}^{M} 1_{\{\zeta_{n,m,k}(f) \leq w\}} \xrightarrow{L^2} \mathbb{P} \left( \langle \nabla f([L]_1), U_1 \rangle_{tr} \leq w \right)
\]
for any \( w \in \mathbb{R} \).

In the framework of integral processes \( X \), things seem to be more complicated. We can propose a modified subsampling method, but, due to the stochastic nature of \( \sigma \), it will only assess the conditional distribution of the limit in (2.7) given the path \( (\sigma_s(\omega))_{s \geq 0} \) for a fixed \( \omega \in \Omega \). However, this does not seem to suffice to construct confidence regions for the quadratic variation \( [X]_t \).

4 Proof of Theorem 2.2

All positive constants appearing in the proofs are denoted by \( C \) although they may change from line to line.

The basic idea behind the proof of Theorem 2.2 is to show the functional weak convergence (with respect to the Skorokhod \( J_1 \)-topology)

\[
(L_{\Delta_n[t/\Delta_n]}, U^n_t) \xrightarrow{d} (L_t, U_t),
\]

which implies the functional stable convergence \( U^n \xrightarrow{\mathcal{L}} U \) according to e.g. [5, Lemma 6.9]. Following the arguments of [5] (cf. the proof of Proposition 7.3 therein) the laws of \( L_{\Delta_n[t/\Delta_n]} \) and \( U^n \) factorise asymptotically, which guarantees the independence of the limits \( L \) and \( U \). Hence, the crucial step is the proof of the functional weak convergence

\[
U^n \xrightarrow{d} U,
\]

which we will show in the following.

4.1 Main decompositions

We are mainly following the decompositions proposed in [5] adapted to the multivariate setting. First of all, instead of dealing with the original Lévy measure defined at (2.1), we may truncate it and work with \( G \) restricted to the unit ball \( \|x\| \leq 1 \) (see the argument behind [5, Assumption S2]). So, from now on we assume that

\[
G(dx) = \frac{\mathbb{1}_{(0,1]}(\rho)}{\rho^{1+\beta}} d\rho H(d\theta), \quad x = (\rho, \theta) \in \mathbb{R}_+ \times S_d.
\]

An important decomposition is given by

\[
L = M(v) + A(v), \quad v \in (0,1),
\]

where \( A(v)_t = \sum_{s \leq t} \Delta L_s \mathbb{1}_{\{\|\Delta L_s\| > v\}} \), which corresponds to the classical Lévy-Itô decomposition (recall that the directional measure \( H \), and hence \( G \), is symmetric). When \( \beta > 1 \), \( M(v) \) is a martingale. Now, we set

\[
v_n = \begin{cases} 
\Delta_n^{1/(2\beta)} \log(1/\Delta_n), & \text{if } \beta > 1 \\
(\Delta_n \log(1/\Delta_n))^{1/\beta}, & \text{if } \beta \leq 1
\end{cases}
\]
and define \( M^n = M(v_n), A^n = A(v_n) \). We note that the process \( M^n \) has the Lévy triplet \((0, 0, G(dx)\mathbb{1}_{\{||x|| \leq v_n\}})\) and \( A^n \) is a compound Poisson process with intensity \( G(dx)\mathbb{1}_{\{v_n < ||x|| \leq 1\}}/G(v_n) \), and \( M^n \) and \( A^n \) are independent.

Finally, we denote by \( \tau(n, i) \) (resp. \( T(n, i)_j \)) the number of jumps (resp. the time of the \( j \)th jump) with norm larger than \( v_n \) in the interval \(((i-1)\Delta_n, i\Delta_n]\). Due to Itô formula we have that

\[
U^n_t = \delta_n ([L^n_t - [L^n_{t/\Delta_n}]) = \sum_{i=1}^{\lfloor t/\Delta_n \rfloor} \xi^n_i,
\]

\[
\xi^n_i = \delta_n \int_{(i-1)\Delta_n}^{i\Delta_n} (L_{s-} - L_{(i-1)\Delta_n}) \circ dL_s.
\]

Now, we further decompose the quantity \( \xi^n_i \) in terms of \( M^n \) and \( A^n \), and according to the number of jumps of \( A^n \) within the interval \(((i-1)\Delta_n, i\Delta_n]\). More specifically, we have that 

\[
\xi^n_i = \sum_{j=1}^{5} \xi^n_i(j) \text{ with } \\
\xi^n_i(1) = \delta_n \Delta^n_i M^n \circ \Delta L_{T(n,i)} \mathbb{1}_{\{\tau(n,i) = 1\}} \\
\xi^n_i(2) = \delta_n \Delta L_{T(n,i)} \circ \Delta L_{T(n,i)} \mathbb{1}_{\{\tau(n,i) = 2\}} \\
\xi^n_i(3) = \delta_n \Delta^n_i A^n \mathbb{1}_{\{\tau(n,i) \geq 2\}} \\
\xi^n_i(4) = \delta_n \int_{(i-1)\Delta_n}^{i\Delta_n} (M^n_{s-} - M^n_{(i-1)\Delta_n}) \circ dM^n_s \\
\xi^n_i(5) = \delta_n \int_{(i-1)\Delta_n}^{i\Delta_n} (A^n_{s-} - A^n_{(i-1)\Delta_n}) \circ dA^n_s \mathbb{1}_{\{\tau(n,i) \geq 3\}}
\]

We will see that \( \xi^n_i(1) \) represents the dominating part when \( \beta > 1 \), while \( \xi^n_i(2) \) is dominating when \( \beta \leq 1 \).

### 4.2 Preliminary results

In this subsection we demonstrate some technical results, which are necessary to prove Theorem 2.2. We start with a number of conditions that ensure negligibility of certain partial sums. The result below is a direct multivariate extension of [5, Lemma 6.6].

**Lemma 4.1.** Let \( n^i_t \) be \( \mathbb{R}^{d \times d} \)-valued \( \mathcal{F}_{i\Delta_n} \)-measurable random variables. Then each of the following conditions implies the uniform convergence \( \sum_{i=1}^{\lfloor t/\Delta_n \rfloor} n^i_t \overset{u.c.p.}{\longrightarrow} 0 \):

\[
\sum_{i=1}^{[t/\Delta_n]} \mathbb{E}[\|\eta^n_i\|_{\text{op}} \wedge 1] \to 0, \tag{4.2}
\]
\[
\sum_{i=1}^{[t/\Delta_n]} \mathbb{E}[\eta_i^n F_{(i-1)\Delta_n}] \xrightarrow{u.c.p.} 0 \quad \text{and} \quad \sum_{i=1}^{[t/\Delta_n]} \mathbb{E}[\|\eta^n_i\|^2_{\text{op}} F_{(i-1)\Delta_n}] \xrightarrow{\mathbb{P}} 0, \tag{4.3}
\]
\[
\sum_{i=1}^{[t/\Delta_n]} \mathbb{E}[\eta_i^n 1\{\|\eta^n_i\|_{\text{op}} \leq 1\} F_{(i-1)\Delta_n}] \xrightarrow{u.c.p.} 0, \quad \sum_{i=1}^{[t/\Delta_n]} \mathbb{P}(\|\eta^n_i\|_{\text{op}} > 1) \to 0,
\]
\[
\sum_{i=1}^{[t/\Delta_n]} \mathbb{E}[\|\eta^n_i\|^2_{\text{op}} 1\{\|\eta^n_i\|_{\text{op}} \leq 1\}] \to 0. \tag{4.4}
\]

The operator norm can be replaced by any other norm on \(\mathbb{R}^{d \times d}\).

In the next lemma we demonstrate some inequalities for the moments of \(M^n\) and related processes. They both follow from [7, Proposition 2.1.10].

**Lemma 4.2.** Let \(W\) be a predictable \(\mathbb{R}^d\)-valued process and \(u > 0\) fixed. Then it holds that

\[
\mathbb{E} \left[ \sup_{s \leq t} \left\| \int_u^{u+s} W_s \circ dM^n_s \right\|^p \right] \leq C v_n^{-\beta} \mathbb{E} \left[ \int_u^t \|W_s\|^p ds \right], \tag{4.5}
\]
\[
\mathbb{E} \left[ \sup_{s \leq t} \left\| M^n_{u+s} - M^n_u \right\|^p \right] \leq C t v_n^{-\beta}, \tag{4.6}
\]

for \(1 \leq p \leq 2\) when \(\beta \geq 1\) and \(\beta < p \leq 1\) if \(\beta < 1\).

Below we state a number of inequalities related to the compound Poisson part of the Lévy process \(L\). They directly follow from the univariate inequalities of [5, Lemma 6.2 and 6.3], since the objects \(\tau(n, i)\) and \(\|\Delta L_{T(n, i)k}\|\) are one-dimensional.

**Lemma 4.3.** Recall the definition of random variables \(\tau(n, i)\) and \(T(n, i)\) from the previous subsection and let \(w > 0\), \(b := H(\mathbb{S}_d)/\beta\).

(i) For any \(1 \leq j \leq m\), it holds on the set \(\{\tau(n, i) \geq j - 1\}\) that

\[
\mathbb{P}(\tau(n, i) \geq m) \leq C \left( \Delta_n/v_n^\beta \right)^{m-j+1}. \tag{4.7}
\]

(ii) For any \(1 \leq j \leq m\), it holds on the set \(\{\tau(n, i) \geq j - 1\}\) that

\[
\mathbb{E} \left[ (\|\Delta L_{T(n, i)k}\| \wedge w)^p 1\{\tau(n, i) \geq m\} \right] \leq C \begin{cases} 
\Delta_n \left( \frac{b \Delta_n}{v_n^\beta} \right)^{m-j} w^{p-\beta} & \text{for } p > \beta \\
\Delta_n \left( \frac{b \Delta_n}{v_n^\beta} \right)^{m-j} \log(1/\Delta_n) & \text{for } p = \beta \\
\Delta_n \left( \frac{b \Delta_n}{v_n^\beta} \right)^{m-j} v_n^{-p-\beta} & \text{for } p < \beta.
\end{cases} \tag{4.8}
\]
(iii) For any $1 \leq j < k < r \leq m$, it holds on the set $\{\tau(n,i) \geq j - 1\}$ that

$$
E \left[ \left( \| \Delta L_{T(n,i)} \| \| \Delta L_{T(n,i)} \| \land w \right)^p \mathbb{1}_{\{\tau(n,i) \geq j - 1\}} \right] \quad (4.9)
$$

\[
\leq C \left\{ \begin{array}{ll}
\Delta_n^2 \log(1/\Delta_n) \left( \frac{b \Delta_n}{v_n} \right)^{m-j-1} w^{p-\beta} & \text{for } p > \beta \\
\Delta_n^2 (\log(1/\Delta_n))^2 \left( \frac{b \Delta_n}{v_n} \right)^{m-j-1} & \text{for } p = \beta.
\end{array} \right.
\]

4.3 Proof of Theorem 2.2 in the case $\beta \in (1, 2)$

4.3.1 Negligible terms

We have $E[\xi_t^n(4)|F_{(i-1)\Delta_n}] = 0$. Using (4.5) and (4.6) for $p = 2$ we get

$$
E[\|\xi_t^n(4)\|_{tr}^2 \leq C \Delta_n^2 \delta_n^2 v_n^{4-2\beta} = C \Delta_n (\log(1/\Delta_n))^{4-2(\beta+1/\beta)}.
$$

Since $\beta + 1/\beta > 2$ for $\beta > 1$, we deduce for $t > 0$ that

$$
\sum_{i=1}^{[t/\Delta_n]} E[\|\xi_t^n(4)\|_{tr}^2 | F_{(i-1)\Delta_n}] \xrightarrow{\mathbb{P}} 0.
$$

Thus, by condition (4.3) we obtain that

$$
\sum_{i=1}^{[t/\Delta_n]} \xi_t^n(4) \xrightarrow{u.c.p.} 0.
$$

For $j = 2, 3, 5$ we have

$$
E[\|\xi_t^n(j)\|_{op} \land 1] \leq \mathbb{P}(\tau(n,i) \geq 2) \leq C \left( \Delta_n/v_n^\beta \right)^2 = C \Delta_n (\log(1/\Delta_n))^{-2\beta}
$$

by (4.7) applied to $m = 2$. Hence, we conclude that $\sum_{i=1}^{[t/\Delta_n]} E[\|\xi_t^n(j)\|_{op} \land 1] \to 0$ and we deduce by (4.2) that

$$
\sum_{i=1}^{[t/\Delta_n]} \xi_t^n(j) \xrightarrow{u.c.p.} 0 \quad \text{for } j = 2, 3, 5.
$$

Putting things together we have shown that $\sum_{i=1}^{[t/\Delta_n]} \xi_t^n(j) \xrightarrow{u.c.p.} 0$ for $j = 2, 3, 4, 5$.

4.3.2 The dominating term

In this subsection we treat the term $\xi_t^n(1)$, which constitutes the dominating part in the case $\beta > 1$. We will show the functional weak convergence $\sum_{i=1}^{[t/\Delta_n]} \xi_t^n(1) \xrightarrow{d} U_t$, and hence (4.11), by analysing the characteristic function. Set $i = \sqrt{-1}$. Defining

$$
\varphi_t^n(u) = E \left[ \exp \left( i \left< u, \sum_{i=1}^{[t/\Delta_n]} \xi_t^n(1) \right>_{tr} \right) \right] \quad \text{and} \quad \varphi_t(u) = E \left[ \exp \left( i \left< u, U_t \right>_{tr} \right) \right],
$$
it suffices to prove that $\varphi^n(u) \xrightarrow{u.c.p.} \varphi(u)$ for any $u \in \mathbb{R}^{d \times d}$ (see [3], Corollary VII.4.43; here there is no randomness involved and $\xrightarrow{u.c.p.}$ just stands for uniform convergence in time on compact intervals). We note that $(\xi^n_1(1))_{1 \leq t \leq \lfloor t/\Delta_n \rfloor}$ is a sequence of i.i.d. random variables and introduce the normalised characteristic function of $\xi^n_1(1)$:

$$R^n(u) = \mathbb{E} \left[ \exp(i\langle u, \xi^n_1(1) \rangle_{tr}) \right] - 1, \quad u \in \mathbb{R}^{d \times d}.$$ 

We will use the following well known statement from analysis (see for example [5, Lemma 6.7]). Let $a^n_i$ be complex numbers. Then it holds

$$\sum_{i=1}^{\lfloor t/\Delta_n \rfloor} a^n_i \xrightarrow{u.c.p.} g(t) \quad \text{and} \quad g \text{ is continuous} \implies \prod_{i=1}^{\lfloor t/\Delta_n \rfloor} (1 + a^n_i) \xrightarrow{u.c.p.} \exp(g(t)). \tag{4.10}$$

Applying the result of (4.10) to the setting $a^n_i = R^n(u)$, it suffices to show that

$$\Delta_n^{-1} R^n(u) \to \log \mathbb{E} \left[ \exp(i\langle u, U_1 \rangle_{tr}) \right] \quad \text{as} \ \Delta_n \to 0$$

to conclude $\varphi^n(u) \xrightarrow{u.c.p.} \varphi(u)$ for each $u \in \mathbb{R}^{d \times d}$ and hence the convergence (4.1). To compute the quantity $R^n(u)$ we recall that $M^n$ has the Lévy triplet $(0, 0, G(dx)1_{\{\|x\| \leq v_n\}})$ and $A^n$ is a compound Poisson process with intensity $\overline{G}(v_n) := G(\{x \in \mathbb{R}^d : v_n < \|x\| \leq 1\})$ and jump distribution $G(dx)1_{\{v_n < \|x\| \leq 1\}}/\overline{G}(v_n)$, and $M^n$ and $A^n$ are independent. We also observe the identity $\langle u, xy \rangle_{tr} = \langle x, uy \rangle = \langle y, u^\top x \rangle$ for any $x, y \in \mathbb{R}^d$ and $u \in \mathbb{R}^{d \times d}$. Hence, recalling the definition of $\xi^n_1(1)$ we obtain the formula

$$\mathbb{E} \left[ \exp(i\langle u, \xi^n_1(1) \rangle_{tr}) \right] = \mathbb{E} \left[ \exp(i\Delta_n^1 M^n, \delta_n(u + u^\top) \Delta L_{(n,1)}(1))_{\tau(n,1)=1} \right].$$

By conditioning we thus deduce that

$$R^n(u) = \alpha_n \Delta_n \int_{v_n < \|y\| \leq 1} \{\exp(z_n(u, y)) - 1\} G(dy),$$

$$z_n(u, y) = \Delta_n \int_{\|x\| \leq v_n} \{\exp(i\langle x, \delta_n(u + u^\top)y \rangle) - 1 - i\langle x, \delta_n(u + u^\top)y \rangle\} G(dx),$$

with $\alpha_n := \exp(-\Delta_n^1 \overline{G}(v_n)) \to 1$ since $\overline{G}(v_n) \leq C\Delta_n^{-1/2}(\log(1/\Delta_n))^{-\beta}$. We now decompose $R^n(u) = \rho_n(u) + \rho_n'(u)$ with

$$\rho_n(u) = \alpha_n \Delta_n \int_{v_n < \|y\| \leq 1} \left( \int_{\|x\| \leq v_n} \{\exp(i\langle u, \delta_n x \otimes y \rangle_{tr}) - 1 - i\langle u, \delta_n x \otimes y \rangle_{tr} G(dx)\} G(dy),$$

$$\rho_n'(u) = \alpha_n \Delta_n \int_{v_n < \|y\| \leq 1} \{\exp(z_n(u, y)) - 1 - z_n(u, y)\} G(dy).$$

We observe that for any $w > 0$ it holds that

$$\int (w\|x\|) \wedge (w\|x\|)^2 G(dx) = C \left( w \int_{w^{-1}} r^{-\beta} dr + w^2 \int_{w^{-1}} r^{1-\beta} dr \right) \leq Cw^{\beta}.$$
In conjunction with the inequality $|\exp(iw) - 1 - iw| \leq C(|w| \wedge w^2)$, we deduce, for a fixed $u \in \mathbb{R}^{d \times d}$, that

$$|z_n(u, y)| \leq C \Delta_n \int (\delta_n ||y|| ||x||) \wedge (\delta_n ||y|| ||x||)^2 G(dx) \leq C \Delta_n \delta_n^3 ||y||^3 = C ||y||^3 / \log(1/\Delta_n).$$

Consequently, we obtain for a fixed $u \in \mathbb{R}^{d \times d}$

$$|\rho_n'(u)| \leq C \alpha_n \Delta_n \int_{v_n < ||y|| \leq 1} |z_n(u, y)|^2 G(dy) \leq C \alpha_n \Delta_n (\log(1/\Delta_n))^{-1} = o(\Delta_n).$$

This proves the approximation

$$\Delta_n^{-1} R_n(u) = \Delta_n^{-1} \rho_n(u) + o(1) = \alpha_n \int \{\exp(i\langle u, z \rangle_{tr}) - 1 - i\langle u, z \rangle_{tr}\} \nu_n(dz) + o(1),$$

where $\nu_n$ is a Lévy measure on $\mathbb{R}^{d \times d}$ defined by

$$\nu_n(A) = \Delta_n \int_{v_n < ||y|| \leq 1} \left( \int_{||x|| \leq v_n} 1_A(\delta_n x \odot y)G(dx) \right) G(dy).$$

Note that $\nu_n$ is a Lévy measure that satisfies $\int (||x||_{tr} \wedge ||x||^2_{tr}) \nu_n(dx) < \infty$. To analyse the convergence of the measure $\nu_n$, we observe the following identities: For $x, y \in \mathbb{R}^d$ it holds that $\text{tr}(x \odot y) = 2\langle x, y \rangle$ and $||x \odot y||^2_{tr} = 2(||x||^2 ||y||^2 + \langle x, y \rangle^2)$.

In the final step we will show that the Lévy measure $\nu_n$ converges, which requires to prove the conditions of [11, Theorem 8.7]. Recall that $S_{d \times d}$ denotes the unit sphere on $\mathbb{R}^{d \times d}$ equipped with the Frobenius norm $|| \cdot ||_{tr}$. Since $\int_{||z||_{tr} \geq 1}(u, z)_{tr} \nu_n(dz) = 0$ due to the symmetry of the measure $G$, it suffices to show the following conditions:

$$\lim_{n \to \infty} \nu_n(B \times (w, \infty)) = \nu_U(B \times (w, \infty)) \quad \text{for } B \in \mathcal{B}(S_{d \times d}), w > 0, \quad (4.11)$$

$$\lim_{\varepsilon \to 0} \limsup_{n \to \infty} \int_z \|z\|^2_{tr} \nu_n(dz) = 0. \quad (4.12)$$

First of all, we observe that the support of $\nu_U$ must be contained in $\mathbb{R}^d \odot \mathbb{R}^d$. We start by showing the condition (4.11). Recalling the definition of the Lévy measure $G$, we obtain the identity

$$\nu_n(B \times (w, \infty)) = \Delta_n \int_{S_{d \times d}} \int_{(0, v_n) \times (v_n, 1)} 1_B \left( \frac{\theta_1 \odot \theta_2}{||\theta_1 \odot \theta_2||_{tr}} \right) \mathbb{1}_{(w, \infty)} \left( \delta_n \rho_1 \rho_2 \sqrt{2(1 + \langle \theta_1, \theta_2 \rangle^2)} \right)$$

$$\times (\rho_1 \rho_2)^{-1-\beta} d\rho_1 d\rho_2 H(d\theta_1)H(d\theta_2).$$

We compute the integral with respect to $d\rho_1 d\rho_2$. Observe that $\delta_n v_n^2 \to \infty$ and hence, for
any $r > 0$, it holds that

$$\Delta_n \int_{(0,v_n) \times (v_n,1)} 1_{(w,\infty)} (\delta_n \rho_1 \rho_2 r) (\rho_1 \rho_2)^{-1-\beta} d\rho_1 d\rho_2 \quad (4.13)$$

$$= \Delta_n \int_{(v_n,1)} \left( \int_{w/(\delta_n \rho_2 r)}^v \rho_1^{-1-\beta} d\rho_1 \right) \rho_2^{-1-\beta} d\rho_2$$

$$= \frac{\Delta_n \delta_n r^\beta}{\beta^\beta} \int_{(v_n,1)} \rho_2^{-1} d\rho_2 + o(1) = \frac{r^\beta}{2^{3\beta} \omega_3} + o(1),$$

where we used that $2\beta \log(1/v_n) / \log(1/\Delta_n) \to 1$. Hence, we conclude the convergence in $(4.11)$ with

$$\nu_U(A) = \frac{1}{2\beta} \int_{S_{d \times d}} \mu(dz) \int_0^\infty 1_A(\rho z) \rho^{-1-\beta} d\rho, \quad A \in \mathcal{B}(\mathbb{R}^d \circ \mathbb{R}^d),$$

and

$$\mu(z) = \int_{S^2} 1_z \left( \frac{\theta_1 \circ \theta_2}{\|\theta_1 \circ \theta_2\|_\text{tr}} \right) \left( 2(1 + \langle \theta_1, \theta_2 \rangle^2)^{\beta/2} \right) \left( \frac{\delta_n \rho_1 \rho_2 \sqrt{2(1 + \langle \theta_1, \theta_2 \rangle^2)}}{\rho_1^{-1-\beta} d\rho_1 d\rho_2} \right) H(d\theta_1) H(d\theta_2), \quad z \in \mathcal{B}(S_{d \times d}).$$

Now, we turn our attention to condition (4.12). For $\varepsilon > 0$ we have that

$$\int_{z: \|z\|_{\text{tr}} \leq \varepsilon} \|z\|^2_{\text{tr}} \nu_n(dz) = \Delta_n \int_{S^2} \int_{(0,v_n) \times (v_n,1)} 1_{S_{d \times d}} \left( \frac{\theta_1 \circ \theta_2}{\|\theta_1 \circ \theta_2\|_\text{tr}} \right) 1_{(0,\varepsilon)} \left( \delta_n \rho_1 \rho_2 \sqrt{2(1 + \langle \theta_1, \theta_2 \rangle^2)} \right)$$

$$\times (\rho_1 \rho_2)^{-1-\beta} \left( \delta_n \rho_1 \rho_2 \sqrt{2(1 + \langle \theta_1, \theta_2 \rangle^2)} \right)^2 d\rho_1 d\rho_2 H(d\theta_1) H(d\theta_2).$$

A similar computation as in $(4.13)$ gives for any $r > 0$:

$$\Delta_n \delta_n r^2 \int_{(0,v_n) \times (v_n,1)} 1_{(0,\varepsilon)} \left( \delta_n \rho_1 \rho_2 r \right) (\rho_1 \rho_2)^{-1-\beta} d\rho_1 d\rho_2$$

$$= \Delta_n \delta_n r^2 \int_{(v_n,1)} \left( \int_0^{\varepsilon/(\delta_n \rho_2 r)} \rho_1^{-1-\beta} d\rho_1 \right) \rho_2^{-1-\beta} d\rho_2$$

$$\to \frac{r^\beta \varepsilon^{2-\beta}}{2\beta(2-\beta)} \text{ as } n \to \infty.$$
4.4 Proof of Theorem 2.2 in the case $\beta \in (0, 1)$

4.4.1 Negligible terms

Recall that $v_n = (\Delta_n \log(1/\Delta_n))^{1/\beta} = \delta_n^{-1}$ when $\beta \leq 1$. In this subsection we show that the terms $\sum_{i=1}^{[t/\Delta_n]} \xi^n_i(j)$ are negligible for $j = 1, 3, 4, 5$. We start with $j = 4$. If $\beta = 1$, we observe that $\mathbb{E}[\xi^n_i(4) | F_{(i-1)\Delta_n}] = 0$ and

$$\mathbb{E}[\|\xi^n_i(4)\|_{\text{op}}^2] \leq C \Delta_n^2 \delta_n v_n^2 = C \Delta_n^2,$$

where the above inequality follows from (4.5) and (4.6). Hence, $\sum_{i=1}^{[t/\Delta_n]} \xi^n_i(4) \overset{u.c.p.}{\to} 0$ by (4.3) when $\beta = 1$. For $\beta < 1$ we use the inequalities (4.5) and (4.6) with $p = 1$ to obtain that

$$\mathbb{E}[\|\xi^n_i(4)\|_{\text{op}}] \leq C \Delta_n^2 \delta_n v_n^{2(1-\beta)} = o(\Delta_n).$$

Thus, we conclude that $\sum_{i=1}^{[t/\Delta_n]} \xi^n_i(4) \overset{u.c.p.}{\to} 0$ by (4.2) when $\beta < 1$.

Now, we consider the case $j = 3$. Notice that $\|x \odot y\|_{\text{op}} \leq 2\|x\|\|y\|$ for all $x, y \in \mathbb{R}^d$. Hence, we obtain that

$$\|\xi^n_i(3)\|_{\text{op}} \leq C \delta_n \|\Delta_i^n M^n\| \sum_{j \geq 1} \|\Delta L_{T(n,i)}\| \mathbb{I}_{\{r(n,i) \geq 2v_j\}}.$$

Observe that $M^n$ and $A^n$ are independent, and applying (4.8) for $w = 1$ along with (4.6) (either for $p = 1$ when $\beta < 1$ or for $p = 2$ when $\beta = 1$), we deduce the inequality

$$\mathbb{E}[\|\xi^n_i(3)\|_{\text{op}}] \leq C \left\{ \begin{array}{ll}
\delta_n \Delta_n^{5/2} v_n^{-1/2} \log(1/\Delta_n) & \text{if } \beta = 1 \\
\delta_n \Delta_n^{3} v_n^{-2\beta} & \text{if } \beta < 1.
\end{array} \right.$$  

In both cases we have that $\sum_{i=1}^{[t/\Delta_n]} \mathbb{E}[\|\xi^n_i(3)\|_{\text{op}}] \to 0$ and hence $\sum_{i=1}^{[t/\Delta_n]} \xi^n_i(3) \overset{u.c.p.}{\to} 0$.

Next, we consider the case $j = 1$. We start with $\beta < 1$. As in the previous case we get

$$\|\xi^n_i(1)\|_{\text{op}} \leq C \delta_n \|\Delta_i^n M^n\| \|\Delta L_{T(n,i)}\| \mathbb{I}_{\{r(n,i) = 1\}}.$$

By inequalities (4.6) and (4.8) applied for $w = 1$ and $m = j = 1$, we then deduce that

$$\mathbb{E}[\|\xi^n_i(1)\|_{\text{op}}] \leq C \delta_n \Delta_n^{2} v_n^{1-\beta} = \Delta_n (\log(1/\Delta_n))^{-1}.$$

This immediately implies that $\sum_{i=1}^{[t/\Delta_n]} \xi^n_i(1) \overset{u.c.p.}{\to} 0$. When $\beta = 1$ we first observe that $\mathbb{E}[\xi^n_i(1) | F_{(i-1)\Delta_n}] = 0$ due to independence of $A_n$ and $M_n$. On the other hand, using again (4.6) and (4.8), we obtain that

$$\mathbb{E}[\|\xi^n_i(1)\|_{\text{op}} | F_{(i-1)\Delta_n}] \leq C \delta_n^2 \mathbb{E}[\|\Delta_i^n M^n\|^2 \|\Delta L_{T(n,i)}\|^2 \mathbb{I}_{\{r(n,i) = 1\}}] \leq C \delta_n^2 \Delta_n^2 v_n.$$

Hence, by (4.3) we conclude that $\sum_{i=1}^{[t/\Delta_n]} \xi^n_i(1) \overset{u.c.p.}{\to} 0$. 
Finally, let us treat the case $j = 5$. We use the decomposition $\xi^n_i(1) = \eta^n_i(1, 2) + \eta^n_i(1, 3) + \eta^n_i(2, 3) + \eta^n_i$ with

$$
\eta^n_i(j, k) = \delta_n \Delta L_{T(n,i), j} \bigcirc \Delta L_{T(n,i), k} \mathbb{1}_{\{r(n,i) = 3\}},
$$

$$
\eta^n_i = \delta_n \sum_{r=2}^{\infty} \sum_{k=1}^{R} \Delta L_{T(n,i), r} \bigcirc \Delta L_{T(n,i), k} \mathbb{1}_{\{r(n,i) \geq r\forall 4\}}.
$$

Recalling the inequality $(\sum_j a_j)^{\beta} \leq \sum_j a_j^{\beta}$ for positive real numbers $a_j$ and $\beta \leq 1$, and applying (4.9) for $w = 1$ we deduce that

$$
\mathbb{E}[\|\eta^n_i\|_{\text{op}} \wedge 1] \leq \mathbb{E}[\|\eta^n_i\|_{\text{op}}^{\beta}] \leq C\delta_n^{\beta} \sum_{r=2}^{\infty} \sum_{k=1}^{R} \mathbb{E} \left[ \|\Delta L_{T(n,i), j}\|^{\beta} \|\Delta L_{T(n,i), k}\|^{\beta} \mathbb{1}_{\{r(n,i) \geq r\forall 4\}} \right].
$$

$$
\leq C\delta_n^{\beta} \Delta_n^{\beta} (\log(1/\Delta_n))^{2} \sum_{r=2}^{\infty} \sum_{k=1}^{R} \left( \frac{b\Delta_n}{v_n^2} \right)^{r\forall 4-2} \leq C\delta_n^{\beta} \Delta_n^{\beta} (\log(1/\Delta_n))^{2} / v_n^{2\beta}
$$

$$
= C\Delta_n / \log(1/\Delta_n).
$$

Hence, via (4.2) we conclude that $\sum_{i=1}^{\lfloor t/\Delta_n \rfloor} \eta^n_i \overset{u.c.p.}{\longrightarrow} 0$. When $\beta < 1$ we deduce from (4.9) applied to $w = 1/\delta_n$ that

$$
\mathbb{E}[\|\eta^n_i(j, k)\|_{\text{op}} \wedge 1] \leq C\delta_n^{\beta} \Delta_n^{3} \log(1/\Delta_n) / v_n^{\beta} = C\Delta_n / \log(1/\Delta_n), \quad 1 \leq j < k \leq 3,
$$

and thus we again conclude that $\sum_{i=1}^{\lfloor t/\Delta_n \rfloor} \eta^n_i(j, k) \overset{u.c.p.}{\longrightarrow} 0$. In the setting $\beta = 1$ we will show that condition (4.4) is satisfied. First, we observe that random variables $\eta^n_i(n, j)$ have symmetric distribution since $G$ is symmetric. Consequently, we deduce the identity

$$
\mathbb{E} \left[ \eta^n_i(j, k) \mathbb{1}_{\{\|\eta^n_i(j, k)\|_{\text{op}} \leq 1\}} \right] = 0.
$$

On the other hand, using again (4.9) for $w = 1/\delta_n$ and $p = 2$ we obtain that

$$
\mathbb{E} \left[ (\|\eta^n_i(j, k)\|_{\text{op}} \wedge 1)^2 \right] \leq C\delta_n \Delta_n^{3} \log(1/\Delta_n) / v_n = C\Delta_n / \log(1/\Delta_n).
$$

Thus, all conditions of (4.4) are satisfied and we conclude that $\sum_{i=1}^{\lfloor t/\Delta_n \rfloor} \eta^n_i(j, k) \overset{u.c.p.}{\longrightarrow} 0$ for $1 \leq j < k \leq 3$ and $\beta = 1$.

**4.4.2 The dominating term**

In this subsection we prove that $\sum_{i=1}^{\lfloor t/\Delta_n \rfloor} \xi^n_i(2) \overset{d}{\longrightarrow} U_t$. We will apply [8, Theorem VII.3.4], which holds for partial sums of independent random variables. The following conditions
are sufficient to guarantee the functional weak convergence \( \sum_{i=1}^{[t/\Delta_n]} \xi^n(2) \xrightarrow{d} U_t \):

\[
\sum_{i=1}^{[t/\Delta_n]} \mathbb{E} \left[ \xi^n(2) \mathbb{I}_{\{\|\xi^n(2)\|_{tr} \leq 1\}} \right] \xrightarrow{u.c.} 0, \\
\lim_{\varepsilon \to 0} \lim_{n \to \infty} \sup_{t \geq 0} \sum_{i=1}^{[t/\Delta_n]} \mathbb{E} \left[ \|\xi^n(2)\|_{tr}^2 \mathbb{I}_{\{\|\xi^n(2)\|_{tr} \leq \varepsilon\}} \right] = 0 \quad \text{for any } t > 0, \\
\lim_{n \to \infty} \sum_{i=1}^{[t/\Delta_n]} \mathbb{P}(\xi^n(2) \in A) = tvU_t(A),
\]

where the last condition holds for all sets of the form \( A = \{\rho B : B \in \mathcal{B}(\mathbb{S}_d \odot \mathbb{S}_d), \rho \in (w, \infty)\} \) with \( w > 0 \). In our setting conditions (4.14)-(4.16) simplify even further, because \( \xi^n(2) \) are identically distributed.

Since the Lévy measure \( G \) is symmetric, we immediately deduce that the expectation \( \mathbb{E}[\xi^n(2) \mathbb{I}_{\{\|\xi^n(2)\|_{tr} \leq 1\}}] = 0 \) and hence (4.14) holds. We proceed with the proof of condition (4.15). For \( x, y \in \mathbb{R}^d \) it holds \( \|x \odot y\|_{tr}^2 = 2(\|x\|^2\|y\|^2 + \langle x, y \rangle^2) \) from which we deduce that

\[
\sqrt{2}\|x\|\|y\| \leq \|x \odot y\|_{tr} \leq 2\|x\|\|y\|. 
\]

Recalling the definition of the term \( \xi^n(2) \) and using (4.17), we get the inequality

\[
\mathbb{E} \left[ \|\xi^n(2)\|_{tr}^2 \mathbb{I}_{\{\|\xi^n(2)\|_{tr} \leq \varepsilon\}} \right] \leq C\delta_n^2 \mathbb{E} \left[ \|\Delta L_{T(n,1)}\|_{tr}^2 \|\Delta L_{T(n,2)}\|_{tr}^2 \mathbb{I}_{\{\tau(n,1) = 2, \delta_n\|\Delta L_{T(n,1)}\|_{tr} \leq \varepsilon/\sqrt{2}\}} \right] =: r^n_t.
\]

Noting that \( \delta_n v_n = 1 \), we conclude that

\[
\begin{align*}
\frac{r^n_t}{\Delta_n^2} &\leq C\Delta_n^2 \delta_n^2 \int_{(v_n,1)^2} (\rho_1\rho_2)^{1-\beta} \mathbb{I}_{\{\delta_n\rho_1\rho_2 \leq \varepsilon/\sqrt{2}\}} d\rho_1 d\rho_2 \\
&= C\Delta_n^2 \delta_n^2 \int_{v_n} \rho_1^{1-\beta} \left( \int_{v_n} \rho_2^{1-\beta} d\rho_2 \right) d\rho_1 \\
&\leq \Delta_n^2 \delta_n^2 \left( C\frac{\varepsilon^{2-\beta}\delta_n^2}{\log \delta_n} + C\varepsilon^{2-\beta} \right) \leq C\Delta_n^2 \delta_n^2 \left( \frac{\varepsilon^{2-\beta}}{\log \delta_n} + 1 \right).
\end{align*}
\]

The latter implies \( \lim_{n \to \infty} \Delta_n^{-1} r^n_t = 0 \), and consequently condition (4.15) holds.

Now, we show the condition (4.16) for the announced sets \( A \). First of all, we deduce that

\[
\Delta_n^{-1} \mathbb{P}(\xi^n(2) \in A) = \frac{\Delta_n K}{2} \int_{(v_n,1)^2} (\rho_1\rho_2)^{-1-\beta} \mathbb{I}_{(w,\infty)}(\delta_n\rho_1\rho_2) d\rho_1 d\rho_2 + o(1),
\]

where \( K = \int_{\mathbb{S}_d} \mathbb{I}_B(x \odot y) H(dx)H(dy) \). Assume for the moment that \( w \in (0,1) \). In this
case we have that \( w/(\delta_n \rho_1) < 1 \) for any \( \rho_1 \geq v_n \). Hence, we get that
\[
\frac{\Delta_n K}{2} \int_{(v_n,1]^2} (\rho_1 \rho_2)^{-1-\beta} \mathbf{1}_{(\delta_n \rho_1 \rho_2)} d\rho_1 d\rho_2
\]
\[
= \frac{\Delta_n K}{2} \left( \int_{v_n}^{w} \rho_1^{-1-\beta} \left( \int_{\delta_n \rho_1}^{1} \rho_1^{-1-\beta} d\rho_2 \right) d\rho_1 + \frac{\delta_n^\beta}{\beta} \int_{w/(\delta_n \rho_1)}^{1} \rho_1^{-1-\beta} d\rho_1 \right)
\]
\[
= K \Delta_n \delta_n^\beta \log(\delta_n) \frac{\log(\delta_n)}{2 \beta w^\beta} + o(1) = \frac{K}{2 \beta^2 w^\beta} + o(1).
\]

Consequently, we obtain the convergence in (4.16) for \( w \in (0,1) \). For \( w \geq 1 \) we have that \( w/(\delta_n \rho_1) \leq 1 \) for any \( \rho_1 \geq v_n \). Thus, we deduce that
\[
\frac{\Delta_n K}{2} \int_{(v_n,1]^2} (\rho_1 \rho_2)^{-1-\beta} \mathbf{1}_{(\delta_n \rho_1 \rho_2)} d\rho_1 d\rho_2
\]
\[
= \frac{\Delta_n K}{2} \int_{wv_n}^{w} \rho_1^{-1-\beta} \left( \int_{w/(\delta_n \rho_1)}^{1} \rho_1^{-1-\beta} d\rho_2 \right) d\rho_1
\]
\[
= \frac{\Delta_n K}{2 \beta} \int_{wv_n}^{w} \rho_1^{-1-\beta} \left( \frac{w}{(\delta_n \rho_1)}^{-\beta} - 1 \right) d\rho_1
\]
\[
= K \Delta_n \delta_n^\beta \log(\delta_n) \frac{\log(\delta_n)}{2 \beta w^\beta} + o(1) = \frac{K}{2 \beta^2 w^\beta} + o(1).
\]

This implies that the convergence in (4.16) also holds for \( w \geq 1 \), which completes the proof.
