FOCUSING $\Phi^4_3$-MODEL WITH A HARTREE-TYPE NONLINEARITY

TADAHIRO OH, MAMORU OKAMOTO, AND LEONARDO TOLOMEO

Abstract. We study a focusing $\Phi^4_3$-model with a Hartree-type nonlinearity, where the potential for the Hartree nonlinearity is given by the Bessel potential of order $\beta$. We first apply the variational argument introduced by Barashkov and Gubinelli (2018) and construct the focusing Hartree $\Phi^4_3$-measure for $\beta > 2$. We also show that the threshold $\beta = 2$ is sharp in the sense that the associated Gibbs measure is not normalizable for $\beta < 2$. Furthermore, we show that the following dichotomy holds at the critical value $\beta = 2$: normalizability in the weakly nonlinear regime and non-normalizability in the strongly nonlinear regime. We then establish a sharp almost sure global well-posedness result for the canonical stochastic quantization of the focusing Hartree $\Phi^4_3$-measure. Namely, we study the three-dimensional stochastic damped nonlinear wave equation (SdNLW) with a cubic nonlinearity of Hartree-type, forced by an additive space-time white noise. Using ideas from paracontrolled calculus, in particular from the recent work by Gubinelli, Koch, and the first author (2018), we prove local well-posedness of the focusing Hartree SdNLW for $\beta > 2$ (and $\beta = 2$ in the weakly nonlinear regime). In order to handle the resonant interaction, we rewrite the equation into a system of three unknowns. We then establish almost sure global well-posedness and invariance of the focusing Hartree $\Phi^4_3$-measure via Bourgain’s invariant measure argument (1994, 1996). In view of the non-normalizability result, our almost sure global well-posedness result is sharp. In Appendix, we also consider the (parabolic) stochastic quantization for the focusing Hartree $\Phi^4_3$-measure and construct global-in-time invariant dynamics for $\beta > 2$ (and $\beta = 2$ in the weakly nonlinear regime). We also consider the Hartree $\Phi^4_3$-measure in the defocusing case. By adapting our argument from the focusing case, we first construct the defocusing Hartree $\Phi^4_3$-measure and the associated invariant dynamics for the defocusing Hartree SdNLW for $\beta > 1$. By introducing further renormalizations at $\beta = 1$ and $\beta = \frac{1}{2}$, we extend the construction of the defocusing Hartree $\Phi^4_3$-measure for $\beta > 0$, where the resulting measure is shown to be singular with respect to the reference Gaussian free field for $0 < \beta \leq \frac{1}{2}$.

1. Introduction

1.1. Focusing Hartree $\Phi^4_3$-measure and its canonical stochastic quantization. In this paper, we study the Gibbs measure $\rho$ with a Hartree-type nonlinearity on the three-dimensional torus on $\mathbb{T}^3 = (\mathbb{R}/2\pi\mathbb{Z})^3$, formally written as

$$
d\rho(u) = Z^{-1} \exp \left( \frac{\sigma}{4} \int_{\mathbb{T}^3} (V * u^2) u^2 dx \right) d\mu(u), \quad (1.1)
$$

and its associated stochastic quantization. Here, $\mu$ is the massive Gaussian free field on $\mathbb{T}^3$ and $\sigma \in \mathbb{R} \setminus \{0\}$. The associated energy functional for the Gibbs measure $\rho$ in (1.1) is given by

$$
E(u) = \frac{1}{2} \int_{\mathbb{T}^3} |(\nabla)u|^2 dx - \frac{\sigma}{4} \int_{\mathbb{T}^3} (V * u^2) u^2 dx. \quad (1.2)
$$

Hartree Gibbs measures of the form (1.1) with various potentials appear in different contexts, in particular as limits of the corresponding many-body quantum Gibbs states [49, 52, 50, 51, 52, 53, 79, 33]. See also [13, 14]. In this paper, we take $V$ to be the kernel for the Bessel potential of order $\beta^2$

$$
V * f = (\nabla)^{-\beta} f = (1 - \Delta)^{-\frac{\beta}{2}} f. \quad (1.3)
$$

1In this introduction, we keep our discussion at a formal level and do not worry about various renormalizations required to give a proper meaning to various objects.

2In the following, we simply refer to $V$ in (1.3) as the Bessel potential of order $\beta$. 
In the defocusing case ($\sigma < 0$), the Gibbs measure $\rho$ in (1.1) corresponds to the well-studied $\Phi^4_3$-measure when $\beta = 0$. The construction of the $\Phi^4_3$-measure is one of the early achievements in constructive Euclidean quantum field theory; see [35, 36, 29, 72, 18, 1, 4, 41]. For an overview of the constructive program with respect to the $\Phi^4_3$-model, see the introductions in [1, 41].

Our main goal in this paper is to study the Gibbs measure $\rho$ and its associated dynamics in the focusing case ($\sigma > 0$), following the program initiated by Lebowitz-Rose-Speer [48] in the one-dimensional setting. Previously, Bourgain [13] studied the focusing Hartree Gibbs measure on $\mathbb{T}^3$. With a proper renormalization and a Wick-ordered $L^2$-cutoff, he constructed the focusing Hartree Gibbs measure $\rho$ in (1.1) for $\beta > 2$ (in the complex-valued setting); see (1.44) below. Furthermore, he studied the associated Hartree nonlinear Schrödinger equation (NLS) on $\mathbb{T}^3$:

$$i\partial_t u + (1 - \Delta)u - \sigma(V * |u|^2)u = 0,$$

and constructed invariant Gibbs dynamics for (1.4) for $\beta > 2$. We point out that such a Gibbs measure with a (Wick-ordered) $L^2$-cutoff is not suitable for stochastic quantization in the heat and wave settings due to the lack of the $L^2$-conservation. In order to overcome this issue, we consider the focusing Hartree Gibbs measure with a taming by the Wick-ordered $L^2$-norm:

$$d\rho(u) = Z^{-1}\exp\left(\frac{\sigma}{4}\int_{\mathbb{T}^3}(V*|u|^2):u^2:dx - A\int_{\mathbb{T}^3}|u|^2dx\right)d\mu(u)$$

for suitable $A, \gamma > 0$. See [11] for the $\Phi^2_3$-measure on $\mathbb{T}^2$ with a taming by the Wick-ordered $L^2$-norm.

We now state our first main result in a somewhat formal manner. In the defocusing case ($\sigma < 0$), we study the Hartree Gibbs measure $\rho$ in (1.1) for $\beta > 0$ (without a cutoff or taming by the Wick-ordered $L^2$-norm).

**Theorem 1.1.** Given $\beta > 0$, let $V$ be the Bessel potential of order $\beta$.

(i) (focusing case). Let $\sigma > 0$. Then, the following statements hold:

- Let $\beta > 2$ and $\max\left(\frac{\beta+1}{2}, 2\right) \leq \gamma < 3$ with $\gamma > 2$ when $\beta = 3$. Then, the focusing Hartree Gibbs measure $\rho$ in (1.5) exists as a limit of the truncated Gibbs measures, provided that $A > 0$ is sufficiently large.

- Let $1 < \beta < 2$. Then, the focusing Hartree Gibbs measure $\rho$ in (1.5) is not normalizable (i.e. $Z = \infty$) for any $A, \gamma > 0$.

- (critical case). Let $\beta = 2$ and $A > 0$. Then, by choosing $\gamma = 3$, the focusing Hartree Gibbs measure $\rho$ in (1.5) exists in the weakly nonlinear regime, i.e. for sufficiently small $\sigma = \sigma(A) > 0$, while it is not normalizable for any $\gamma > 0$ (and any $A > 0$) in the strongly nonlinear regime (i.e. $\sigma \gg 1$).

Furthermore, when the focusing Hartree Gibbs measure $\rho$ exists, it is equivalent to the base massive Gaussian free field $\mu$. 

(ii) (defocusing case) Let $\sigma < 0$. Given any $\beta > 1$, the defocusing Hartree Gibbs measure $\rho$ in (1.5) with $A = 0$ exists as a limit of the truncated Gibbs measures. By introducing further renormalizations at $\beta = 1$ and $\beta = \frac{1}{2}$, the defocusing Hartree Gibbs measure can be constructed as a limit of the truncated Gibbs measures for $\beta > 0$.

For $\beta > \frac{1}{2}$, the defocusing Hartree Gibbs measure $\rho$ is equivalent to the base massive Gaussian free field $\mu$, while they are mutually singular for $0 < \beta \leq \frac{1}{2}$.

See Theorems 1.10 and 1.14 in Subsection 1.2 for the precise statements. We point out that the Gibbs measure is constructed as a strong limit in the theorem above except for the defocusing case with $0 < \beta \leq \frac{1}{2}$, where the limiting Gibbs measure is constructed only as a weak limit of the truncated Gibbs measures.

Theorem 1.1 provides a complete picture on the construction of the Hartree Gibbs measures on $\mathbb{T}^3$, which is of particular interest in the focusing case due to its critical nature at $\beta = 2$. Note that when $\beta = 2$, the potential $V$ essentially corresponds to the Coulomb potential $V(x) = |x|^{-1}$; see (1.12). A precise value of $\sigma$ does not play any role unless $\beta = 2$ in the focusing case and thus we simply set $\sigma = \pm 1$ except for this endpoint focusing case ($\beta = 2$). The results in Theorem 1.1 extend to the Hartree Gibbs measure with a Wick-ordered $L^2$-cutoff studied by Bourgain [13], proving essential sharpness of his result for $\beta > 2$. In the defocusing case, Theorem 1.1 also improves Bourgain’s Gibbs measure construction for $\beta > \frac{3}{2}$ [13] to $\beta > 0$.

Next, we discuss stochastic dynamics associated with the Gibbs measures constructed in Theorem 1.1. This process is known as stochastic quantization [73]. While we may consider the usual parabolic stochastic quantization where the linear part is given by the heat operator, we consider the following stochastic damped nonlinear wave equation (SdNLW) with a cubic nonlinearity of Hartree-type, posed on $\mathbb{T}^3$:

$$
\partial_t^2 u + \partial_t u + (1 - \Delta) u - \sigma (V * u^2) u = \sqrt{2} \xi, \quad (x, t) \in \mathbb{T}^3 \times \mathbb{R}_+ ,
$$

$$
(1.6)
$$

3After the completion of this paper, we learned that Bringmann [16] independently studied the construction of the Hartree Gibbs measures in the defocusing case and obtained analogous results for $\beta > 0$. We point out some differences between [16] and our work in the defocusing case. Bringmann proves tightness of the truncated defocusing Hartree Gibbs measures, using the Laplace transform as in a recent work [4] by Barashkov and Gubinelli. This yields convergence of the truncated Gibbs measures up to a subsequence. However, uniqueness of the limiting Gibbs measure is not studied in [16]. In this paper, we establish tightness by a more direct argument and also prove uniqueness of the limiting Gibbs measure (which implies convergence of the entire sequence); see Section 6 for the most intricate case $0 < \beta \leq \frac{1}{2}$. In [16], Bringmann also proves singularity of the defocusing Hartree Gibbs measure with respect to the massive Gaussian free field $\mu$ in the range $0 < \beta < \frac{1}{2}$. This is done by first establishing singularity of the reference shifted measure with respect to $\mu$ as in [5]. In Subsection 1.4, we present a direct proof of singularity of the Gibbs measure without referring to the shifted measure for $0 < \beta \leq \frac{1}{2}$, including the endpoint $\beta = \frac{1}{2}$ which is not covered in [16]. See Remark 1.13 and Appendix C on absolute continuity of the Gibbs measure with respect to the shifted measure. We point out that the focusing case is not studied in [16].

As for the dynamical problem, our results are complementary. Our main focus in this paper is to study the focusing case. In Theorem 1.2, we establish a sharp result on almost sure global well-posedness of the focusing Hartree SdNLW (1.6) and invariance of the focusing Hartree Gibbs measure. In the defocusing case, we only handle the range $\beta > 1$, where we need the same renormalization as in the focusing case.

In the second preprint [17], Bringmann studies the dynamical problem in the defocusing case, more precisely, the defocusing Hartree NLW (1.8) with $\sigma < 0$ and his analysis goes much further than that presented in our paper. In this remarkable preprint, Bringmann proves its almost sure global well-posedness and invariance of the defocusing Hartree Gibbs measures for the entire range $\beta > 0$.

4The non-normalizability in Theorem 1.1(i) for $1 < \beta < 2$ may be extended for lower values of $\beta$ by introducing further renormalizations as in the defocusing case. We, however, do not pursue this issue.

5See Remark 1.5 and Appendix A for the parabolic stochastic quantization of the Hartree Gibbs measure.
where \( \sigma \in \mathbb{R} \setminus \{0\} \), \( u \) is an unknown function, and \( \xi \) denotes a (Gaussian) space-time white noise on \( T^3 \times \mathbb{R}_+ \) with the space-time covariance given by
\[
\mathbb{E} [\xi(x_1,t_1)\xi(x_2,t_2)] = \delta(x_1 - x_2)\delta(t_1 - t_2).
\]

With \( \vec{u} = (u, \partial_t u) \), define the energy \( E(\vec{u}) \) by
\[
E(\vec{u}) = E(u) + \frac{1}{2} \int_{T^3} (\partial_t u)^2 dx + \frac{1}{2} \int_{T^3} (\partial_t u)^2 dx - \frac{\sigma}{4} \int_{T^3} (V \ast u^2) u^2 dx,
\]
where \( E(u) \) is as in (1.2). This is precisely the energy (= Hamiltonian) of the (deterministic) nonlinear wave equation (NLW) on \( T^3 \) with a cubic Hartree-type nonlinearity:
\[
\partial_t^2 u + (1 - \Delta) u - \sigma (V \ast u^2) u = 0.
\]
(1.8)

Then, by letting \( v = \partial_t u \), we can write (1.6) as
\[
\partial_t \begin{pmatrix} u \\ v \end{pmatrix} = \begin{pmatrix} \frac{\partial E}{\partial v} \\ -\frac{\partial E}{\partial u} \end{pmatrix} + \begin{pmatrix} 0 \\ \sqrt{2\xi} \end{pmatrix}.
\]
(1.9)

Thus, it is easy to see that the Gibbs measure \( \vec{\rho} \), formally given by
\[
\text{"d}\vec{\rho}(\vec{u}) = Z^{-1} e^{-E(\vec{u})} d\vec{u} = d\rho \otimes d\mu_0(\vec{u})
\]
remains invariant under the dynamics of Hartree SdNLW (1.6). Here, \( \rho \) is the Hartree Gibbs measure in (1.1) and \( \mu_0 \) denotes the white noise measure; see (1.17). Namely, Hartree SdNLW (1.6) is the so-called canonical stochastic quantization equation\( ^{6} \) for the Gibbs measure \( \vec{\rho} \). See [76].

Stochastic nonlinear wave equations (SNLW) have been studied extensively in various settings; see [25, Chapter 13] and [59] for the references therein. In recent years, we have seen a rapid progress in the well-posedness theory of SNLW with space-time white noise forcing:\( ^{7} \)
\[
\partial_t^2 u + \partial_t u + (1 - \Delta) u + \mathcal{N}(u) = \xi
\]
(1.11)
for a power-type nonlinearity [42, 43, 44, 66, 60, 59, 82] and for trigonometric and exponential nonlinearities [64, 67, 65]. We also mention the works [71, 63, 62] on nonlinear wave equations with rough random initial data and [27, 28] on SNLW with more singular (both in space and time) noises. In [43], Gubinelli, Koch, and the first author studied the hyperbolic \( \Phi^3 \)-model (i.e. \( \Phi^3 \) on \( T^3 \) with \( \mathcal{N}(u) = u^2 \)) by combining the paracontrolled calculus [39, 21, 56], originally introduced in the parabolic setting, with the multilinear harmonic analytic approach, more traditional in studying dispersive equations. In particular, one of the new ingredients in [43] was the introduction of \textit{paracontrolled operators} (namely, random operators with an embedded paracontrolled structure) as a part of the predefined enhanced data set. These paracontrolled operators introduced in [43] play an important role in studying well-posedness of Hartree SdNLW (1.6). See Subsection 2.2.

Before stating our well-posedness result, let us study (1.6) from the scaling point of view. Recall that the Bessel potential of order \( \beta \) on \( T^3 \) can be written (for some \( c > 0 \)) as
\[
V(x) = c |x|^{\beta - 3} + K(x)
\]
(1.12)
\[ ^{6}\text{Namely, the Langevin equation with the momentum } v = \partial_t u.
\[ ^{7}\text{Some of the works mentioned below are on SNLW without damping.} \]
for $0 < \beta < 3$ and $x \in \mathbb{T}^3 \setminus \{0\}$, where $K$ is a smooth function on $\mathbb{T}^3$. See Lemma 2.2 in [64].

In order to study the scaling property of Hartree SdNLW (1.6), let us consider the following nonlinear wave equation (NLW) on $\mathbb{R}^3$ (without damping):

$$\partial_t^2 u - \Delta u \pm (|x|^{\beta - 3} \ast u^2) u = 0. \quad (1.13)$$

A simple calculation shows that (1.13) is invariant under the following scaling:

$$u(x, t) \mapsto u(\lambda x, \lambda t) = \lambda^{1+\frac{\beta}{2}} u(\lambda x, \lambda t)$$

for $\lambda > 0$. Namely, the equation (1.13) with a cubic Hartree nonlinearity scales like the following NLW with a power nonlinearity:

$$\partial_t^2 u - \Delta u \pm |u|^{4+\beta} u = 0.$$  

From this scaling point of view, the quadratic SNLW studied in [43] corresponds to Hartree SdNLW (1.6) with $\beta = 2$.

**Theorem 1.2.** Let $V$ be the Bessel potential of order $\beta$ with

(i) $\beta \geq 2$ in the focusing case and (ii) $\beta > 1$ in the defocusing case.

In the focusing case with $\beta = 2$, we also assume that $\sigma > 0$ is sufficiently small. Then, the cubic Hartree SdNLW (1.6) on the three-dimensional torus $\mathbb{T}^3$ (with a proper renormalization) is almost surely globally well-posed with respect to the random initial data distributed by the (renormalized) Gibbs measure $\vec{\rho}$ in (1.10). Furthermore, the Gibbs measure $\vec{\rho}$ is invariant under the resulting dynamics.

See Theorem 2.1 for the precise statement. Theorem 1.2 is a wave-analogue of Bourgain’s result in [13] on the Hartree NLS (1.4) for $\beta > 2$ mentioned above. In the focusing case, we extend the result to the endpoint case $\beta = 2$ in the weakly nonlinear regime. In view of the non-normalizability of the focusing Hartree Gibbs measure (Theorem 1.1), Theorem 1.2 is sharp in the focusing case. In terms of the scaling, Theorem 1.2 for $\beta > 1$ in the defocusing case may be viewed as a (slight) improvement from [43] on the quadratic nonlinearity (corresponding to $\beta = 2$).

Given the construction of the Gibbs measure in Theorem 1.1, the main task in proving Theorem 1.2 is the construction of local-in-time dynamics almost surely with respect to the Gibbs measure. We go over the well-posedness aspects in Section 2. In particular, in Subsection 2.2 by using the ideas from the paracontrolled calculus, we rewrite (the renormalized version of) Hartree SdNLW (1.6) into a system of three unknowns, for which we prove local well-posedness.

**Remark 1.3.** In view of (1.12), (the kernel of) the Bessel potential $V(x)$ is not non-negative on $\mathbb{T}^3$. Nonetheless, the potential part of the energy in (1.7) (for a smooth function $u$) is non-negative. Indeed, Parseval’s identity yields

$$\int_{\mathbb{T}^3} (V \ast u^2) u^2 dx = \sum_{n \in \mathbb{Z}^3} \tilde{V}(n)|\tilde{u}^2(n)|^2 \geq 0.$$ 

This justifies the use of the terminology ‘defocusing / focusing’.

---

8 Namely, $\sigma > 0$ in (1.6).
9 Note that, in view of (1.12), the potential $V$ is uniformly bounded from below by a (possibly negative) constant.
Remark 1.4. We point out that a slight modification of our proof of Theorem 1.2 yields the corresponding results (namely, almost sure global well-posedness and invariance of the associated Gibbs measure) for the (deterministic) cubic Hartree NLW (1.8) on $\mathbb{T}^3$ for (i) $\beta > 2$ (and $\beta = 2$ in the weakly nonlinear regime) in the focusing case and (ii) $\beta > 1$ in the defocusing case. As pointed above, this result is sharp in the focusing case.

Remark 1.5. In Appendix A, we consider the parabolic stochastic quantization of the focusing Hartree Gibbs measure $\rho$ constructed in Theorem 1.1. Namely, we study the following stochastic nonlinear heat equation on $\mathbb{T}^3$ with a focusing Hartree nonlinearity ($\sigma > 0$):

$$\partial_t u + (1 - \Delta)u - \sigma(V * u^2)u = \sqrt{2} \xi. \quad (1.14)$$

When $\beta > 2$, (and $\beta = 2$ in the weakly nonlinear regime, $0 < \sigma \ll 1$), we prove almost sure global well-posedness of (1.14) and invariance of the focusing Hartree Gibbs measure. In view of the non-normalizability result in Theorem 1.1, this result is also sharp.

Remark 1.6. In terms of scaling, the critical case ($\beta = 2$) corresponds to the $\Phi^3_3$-model. In [61], we study the Gibbs measure construction and its canonical stochastic quantization for the $\Phi^3_3$-model, where we exhibit a dichotomy in the strongly and weakly nonlinear regimes as in Theorem 1.1(i) with $\beta = 2$. In the weakly nonlinear regime, this work extends the local-in-time solutions constructed in [43] globally in time.

Remark 1.7. In [81], the third author introduced a new approach to establish unique ergodicity of Gibbs measures for stochastic dispersive/hyperbolic equations. In particular, ergodicity of the Gibbs measures was shown in [81] for the cubic SdNLW on $\mathbb{T}$ and the cubic stochastic damped nonlinear beam equation on $\mathbb{T}^3$. See also [30] on the asymptotic Feller property of the invariant Gibbs dynamics for these models. In [83], the third author further developed the methodology and managed to prove ergodicity of the hyperbolic $\Phi^4_3$-model, i.e. (1.11) on $\mathbb{T}^2$ with $N(u) = u^3$.

Remark 1.8. In the defocusing case, the threshold value $\beta = 1$ in Theorem 1.2 is by no means sharp but a further renormalization is required in order to treat the problem for $\beta \leq 1$ (as mentioned in Theorem 1.1) [17]. When $\beta = 0$, Hartree SdNLW (1.6) with $\sigma = -1$ reduces to the following hyperbolic $\Phi^4_3$-model on $\mathbb{T}^3$:

$$\partial^2_t u + \partial_t u + (1 - \Delta)u + u^3 = \sqrt{2} \xi. \quad (1.15)$$

In the parabolic setting, we have seen a tremendous progress in the study of singular stochastic PDEs over the last ten years and, in particular, the well-posedness theory of the parabolic $\Phi^4_3$-model:

$$\partial_t u + (1 - \Delta)u + u^3 = \sqrt{2} \xi, \quad (1.16)$$

has been studied by many authors. See [46, 39, 21, 17, 50, 57, 1, 40] and references therein. Up to date, the well-posedness issue of the hyperbolic $\Phi^4_3$-model (1.15) remains as an important open problem.

We also note that the well-posedness issue of NLS (1.4) with the Gibbs measure for $\beta = 0$, corresponding to the dispersive $\Phi^4_3$-model, is a challenging open problem, expected to be much

---

10As mentioned in Footnote 3, Bringmann [17] studied the defocusing Hartree NLW (1.8) with $\sigma < 0$ and proved its almost sure global well-posedness and invariance of the defocusing Hartree Gibbs measures for the entire range $\beta > 0$. We expect that his analysis also applies to the defocusing Hartree SdNLW (1.6) and yields the corresponding well-posedness result for $\beta > 0$. 

harder than the hyperbolic $\Phi^4_3$-model mentioned above. We mention a recent breakthrough \cite{26} by Deng, Nahmod, and Yue, making an important step in this direction.

1.2. Hartree Gibbs measures. In this subsection, we describe a renormalization procedure (and also a taming by the Wick-ordered $L^2$-norm in the focusing case) required to construct the Gibbs measure $\hat{\rho}$ in (1.10) and make precise statements on the Gibbs measure construction (Theorems 1.10 and 1.14). For this purpose, we first fix some notations. Given $s \in \mathbb{R}$, let $\mu_s$ denote a Gaussian measure, formally defined by

$$d\mu_s = Z_s^{-1} e^{-\frac{1}{2} \|u\|_{\mathbb{H}^s}^2} du = Z_s^{-1} \prod_{n \in \mathbb{Z}^3} e^{-\frac{1}{2} (n, \hat{u}(n))^2} d\hat{u}(n), \quad (1.17)$$

where $\langle \cdot \rangle = (1 + |\cdot|^2)^{\frac{1}{2}}$ and $\hat{u}(n)$ denotes the Fourier transforms of $u$. Note that $\mu_s$ corresponds to the massive Gaussian free field $\mu_1$ when $s = 1$ and to the white noise measure $\mu_0$ when $s = 0$. On $\mathbb{T}^3$, it is well known that $\mu_s$ is a Gaussian probability measure supported on $W^{s-\frac{1}{2} - \varepsilon, p}(\mathbb{T}^3)$ for any $\varepsilon > 0$ and $1 \leq p \leq \infty$. For simplicity, we set $\mu = \mu_1$ and

$$\bar{\mu} = \mu_1 \otimes \mu_0. \quad (1.18)$$

Note that $\mu$ and $\bar{\mu}$ serve as the reference Gaussian measures for the Gibbs measures $\rho$ in (1.1) and $\bar{\rho}$ in (1.10), respectively.

We now go over the Fourier representation of functions distributed by $\mu$ and $\bar{\mu}$. Define the index set $\Lambda$ and $\Lambda_0$ by

$$\Lambda = \bigcup_{j=0}^{2} \mathbb{Z}^j \times \mathbb{N} \times \{0\}^{2-j} \quad \text{and} \quad \Lambda_0 = \Lambda \cup \{(0,0,0)\} \quad (1.19)$$

such that $\mathbb{Z}^3 = \Lambda \cap (-\Lambda) \cap \{(0,0,0)\}$. Then, let $\{g_n\}_{n \in \Lambda_0}$ and $\{h_n\}_{n \in \Lambda_0}$ be sequences of mutually independent standard complex-valued\footnote{This means that $g_n, h_n \sim \mathcal{N}(0,1)$ and $\text{Re} g_n, \text{Im} g_n, \text{Re} h_n, \text{Im} h_n \sim \mathcal{N}(0, \frac{1}{2})$ for $n \neq 0$.} Gaussian random variables on a probability space $(\Omega, \mathcal{F}, \mathbb{P})$ and set $g_{-n} := \overline{g_n}$ and $h_{-n} := \overline{h_n}$ for $n \in \Lambda_0$. Moreover, we assume that $\{g_n\}_{n \in \Lambda_0}$ and $\{h_n\}_{n \in \Lambda_0}$ are independent from the space-time white noise $\xi$ in (1.6). We now define random distributions $u = u^\omega$ and $v = v^\omega$ by the following Gaussian Fourier series\footnote{By convention, we endow $\mathbb{T}^3$ with the normalized Lebesgue measure $dx_{\mathbb{T}^3} = (2\pi)^{-3} dx$.}

$$u^\omega = \sum_{n \in \mathbb{Z}^3} g_n(\omega) e_n \quad \text{and} \quad v^\omega = \sum_{n \in \mathbb{Z}^3} h_n(\omega) e_n, \quad (1.20)$$

where $e_n = e^{in \cdot x}$. Denoting the law of a random variable $X$ by $\text{Law}(X)$, we then have

$$\text{Law}((u,v)) = \bar{\mu}_1 = \mu \otimes \mu_0$$

for $(u,v)$ in (1.20). Note that that $\text{Law}((u,v)) = \bar{\mu}$ is supported on

$$\mathcal{H}^s(\mathbb{T}^3) := H^s(\mathbb{T}^3) \times H^{s-1}(\mathbb{T}^3)$$

for $s < -\frac{1}{2}$ but not for $s \geq -\frac{1}{2}$.

Remark 1.9. In the following, we only discuss the construction and non-normalizability of the (renormalized) Gibbs measure $\rho$ on $u$, formally written in (1.1). The Gibbs measure $\bar{\rho}$ on a vector $\bar{u} = (u, \partial_t u)$ for SdNLW (1.6) and NLW (1.8), formally defined in (1.10), decouples as the Gibbs
measure \( \rho \) on the first component \( u \) and the white noise measure \( \mu_0 \) on the second component \( \partial_t u \). Thus, once we prove Theorem 1.1 for the Gibbs measure \( \rho \) on \( u \), by setting
\[
d\tilde{\rho}(\tilde{u}) = d\rho \otimes d\mu_0(\tilde{u}),
\]
we see that the corresponding results extend to the Gibbs measure \( \tilde{\rho} \). See also Remarks 1.11 and 1.16.

- **Defocusing case:** Let us first consider the defocusing case. A precise value of \( \sigma < 0 \) in (1.1) does not play any role and thus we simply set \( \sigma = -1 \). In view of (1.2), we can write the formal expression (1.1) for the Gibbs measure \( \rho \) as
\[
d\rho(u) = Z^{-1} e^{-E(u)} du = Z^{-1} \exp \left( -\frac{1}{4} \int_{\mathbb{T}^3} (V \ast u^2) u^2 dx \right) d\mu(u).
\]
(1.21)

Since \( u \) in the support of \( \mu \) is not a function, the quartic potential energy is not well defined and thus a proper renormalization is required to give a meaning to (1.21). In order to explain the renormalization process, we first study the regularized model. Given \( N \in \mathbb{N} \), we define the (spatial) frequency projector \( \pi_N \) by
\[
\pi_N f = \sum_{|n| \leq N} \hat{f}(n) e_n.
\]
(1.22)

Let \( u \) be as in (1.20) and set \( u_N = \pi_N u \). Note that, for each fixed \( x \in \mathbb{T}^3 \), \( u_N(x) \) is a mean-zero real-valued Gaussian random variable with variance
\[
\sigma_N = \mathbb{E}[u_N^2(x)] = \sum_{|n| \leq N} \frac{1}{\langle n \rangle^2} \sim N \to \infty,
\]
(1.23)
as \( N \to \infty \). See also (2.12) below. We then define the Wick power \( :u_N^2 : \) by
\[
:u_N^2 : = u_N^2 - \sigma_N.
\]
(1.24)

Let us consider the renormalized potential energy. By Parseval’s identity, we have
\[
\int_{\mathbb{T}^3} (V \ast :u_N^2 :) :u_N^2 : = \sum_{n \in \mathbb{Z}^3} \hat{V}(n) \langle :u_N^2 : (n) \rangle^2
\]
\[
= \sum_{n \in \mathbb{Z}^3} \hat{V}(n) \left( \sum_{n_1, n_2 \in \mathbb{Z}^3 \atop |n_1|, |n_2| \leq N \atop n_1 + n_2 = n} \hat{u}(n_1)\hat{u}(n_2) - 1_{n=0} \cdot \sigma_N \right)
\]
\[
\times \left( \sum_{n_1', n_2' \in \mathbb{Z}^3 \atop |n_1'|, |n_2'| \leq N \atop n_1' + n_2' = n} \hat{u}(n_1')\hat{u}(n_2') - 1_{n=0} \cdot \sigma_N \right).
\]
(1.25)

While the Wick renormalization (1.24) removes certain singularities, we still need to subtract a divergent contribution from the renormalized potential energy in (1.25). By setting
\[
\alpha_N := \sum_{n_1, n_2 \in \mathbb{Z}^3 \atop |n_1|, |n_2| \leq N \atop n_1 + n_2 \neq 0} \frac{\hat{V}(n_1 + n_2)}{\langle n_1 \rangle^2 \langle n_2 \rangle^2},
\]
(1.26)

\( ^{13} \)Hereafter, we simply use \( Z, Z_N \), etc. to denote various normalization constants.
we define the full renormalized potential energy $R_N(u)$ by
\[ R_N(u) = \frac{1}{4} \int_{\mathbb{T}^3} (V \ast : u_N^2 : ) : u_N^2 : dx - \frac{1}{2} \alpha_N. \tag{1.27} \]

With (1.3) and Lemma 3.4 below, we see that $\alpha_N$ is uniformly bounded in $N \in \mathbb{N}$ when $\beta > 2$ and thus the subtraction of $\frac{1}{2} \alpha_N$ in (1.27) is not necessary in this case. Thanks to the presence of $\alpha_N$ in (1.27), we can show that $R_N$ converges to some $R$ in $L^p(\mu)$ when $\beta > 1$. See Lemma 5.1 below.

Define the truncated renormalized Gibbs measure $\rho_N$ by
\[ d\rho_N(u) = Z_N^{-1} e^{-R_N(u)} d\mu(u). \tag{1.28} \]

Then, we have the following uniform exponential integrability of the density, which allows us to construct the limiting Gibbs measure $\rho$.

**Theorem 1.10** (defocusing case). Let $V$ be the Bessel potential of order $\beta > 0$.

(i) Let $\beta > 1$. Then, given any finite $p \geq 1$, there exists $C_p > 0$ such that
\[ \sup_{N \in \mathbb{N}} \left\| e^{-R_N(u)} \right\|_{L^p(\mu)} \leq C_p < \infty. \tag{1.29} \]

Moreover, we have
\[ \lim_{N \to \infty} e^{-R_N(u)} = e^{-R(u)} \quad \text{in} \ L^p(\mu). \tag{1.30} \]

As a consequence, the truncated renormalized Gibbs measure $\rho_N$ in (1.28) converges, in the sense of (1.30), to the defocusing Hartree Gibbs measure $\rho$ given by
\[ d\rho(u) = Z^{-1} e^{-R(u)} d\mu(u). \tag{1.31} \]

The resulting Gibbs measure $\rho$ is equivalent to the base massive Gaussian free field $\mu = \mu_1$.

(ii) By introducing further renormalizations at $\beta = 1$ and $\beta = \frac{1}{2}$, we replace the potential energy $R_N(u)$ in (1.27) by the new renormalized potential energies:
\[ R^\circ_N(u) \quad \text{for} \ \frac{1}{2} < \beta \leq 1 \quad \text{and} \quad R_N^\circ(u) \quad \text{for} \ 0 < \beta \leq \frac{1}{2}. \]

Then, the uniform exponential integrability (1.29) holds for (a) any finite $p \geq 1$ when $\frac{1}{2} < \beta \leq 1$ and (b) $p = 1$ when $0 < \beta \leq \frac{1}{2}$.

(ii.a) Let $\frac{1}{2} < \beta \leq 1$. Then, $R^\circ_N$ converges to some limit $R^\circ$ in $L^p(\mu)$ and we have
\[ \lim_{N \to \infty} e^{-R^\circ_N(u)} = e^{-R^\circ(u)} \quad \text{in} \ L^p(\mu). \tag{1.32} \]

As a consequence, the truncated renormalized Gibbs measure $\rho_N$ in (1.28) (with $R_N$ replaced by $R^\circ_N$) converges, in the sense of (1.30), to the defocusing Hartree Gibbs measure $\rho$ in (1.31) (with $R$ replaced by $R^\circ$). The resulting Gibbs measure $\rho$ is equivalent to the base massive Gaussian free field $\mu$.

(ii.b) Let $0 < \beta \leq \frac{1}{2}$. The truncated renormalized Gibbs measure $\rho_N$ in (1.28) (with $R_N$ replaced by $R_N^\circ$) converges weakly to a unique limit $\rho$. In this case, the resulting Gibbs measure $\rho$ and the base massive Gaussian free field $\mu$ are mutually singular.

See (1.38) and (6.23) for the definitions of $R_N^\circ$ and $R_N^\circ$. Theorem 1.10 is an improvement of the defocusing Hartree Gibbs measure construction by Bourgain [13], where he essentially proved an analogue of Theorem 1.10 for $\beta > \frac{3}{2}$. See [13] for a precise statement.
The main task in proving Theorem 1.10 is to show the uniform exponential bound (1.29). We establish the bound (1.29) by applying the variational approach introduced by Barashkov and Gubinelli \[4\] in the construction of the $\Phi^4_3$-measure. See also \[45, 65\]. We point out that further renormalizations are required in order to go below the thresholds $\beta = 1$ and $\beta = \frac{1}{2}$ and that the renormalization introduced for $0 < \beta \leq \frac{1}{2}$ (see (6.23)) only appears at the level of the Gibbs measure but not in the associated equation. See Remarks 1.12 and 5.2 and Subsection 6.2 below.

When $\beta = 0$, the Gibbs measure corresponds to the $\Phi^4_3$-measure whose construction requires a further renormalization to remove a logarithmic divergence; see \[35, 36, 29, 72, 18, 1, 4, 41\]. If we consider a $\Phi^4_3$-measure but with a smoother base Gaussian measure $\mu_s$, $s > 1$, such a logarithmic divergence does not appear and thus the second renormalization is not needed. Thus, it is interesting to see that the defocusing Hartree Gibbs measure $\rho$ requires renormalizations at $\beta = 1$ and $\frac{1}{2}$.

Once the uniform bound (1.29) is established, the $L^p$-convergence (1.30) of the densities follows from (softer) convergence in measure of the densities. See Remark 3.8 in \[85\]. For $0 < \beta \leq \frac{1}{2}$, such convergence in measure of the densities no longer holds, which is essentially the source of the singularity of the Gibbs measure in this range. See Remark 5.2. For this range of $\beta$, we use the more refined Boué-Dupuis variational formula (Lemma 5.11) to prove uniqueness of the limiting Gibbs measures and its singularity with respect to the base Gaussian free field. Our proof of the singularity is strongly inspired by a recent work \[5\] by Barashkov and Gubinelli, where they proved the “folklore” singularity of the $\Phi^4_3$-measure with respect to the base Gaussian free field. While the proof of the singularity in \[5\] goes through the shifted measure, we present a direct argument without referring to shifted measures. See Remark 1.13.

We present the proof of Theorem 1.10 (i) for $\beta > 1$ in Section 5, while the proof of Theorem 1.10 (ii) for $0 < \beta \leq 1$ is discussed in detail in Section 6.

Remark 1.11. Let $\beta > 1$. Define the renormalized energy:

$$E^\flat(u) = \frac{1}{2} \int_{T^3} |\langle \nabla \rangle u|^2 dx + R(u). \quad (1.33)$$

In view of the definition of $\mu = \mu_1$, (1.31), and (1.33), we can also write the defocusing Hartree Gibbs measure $\rho$ formally as

$$d\rho = Z^{-1} e^{-E^\flat(u)} du.$$ 

Similarly, by defining the renormalized energy for SdNLW (1.16) and NLW (1.8) by

$$\mathcal{E}^\flat(\vec{u}) = \frac{1}{2} \int_{T^3} |\langle \nabla \rangle \vec{u}|^2 dx + \frac{1}{2} \int_{T^3} (\partial_t \vec{u})^2 dx + R(\vec{u}), \quad (1.34)$$

we can write the defocusing Hartree Gibbs measure $\vec{\rho} = \rho \otimes \mu_0$ on a vector $\vec{u} = (u, \partial_t u)$ as

$$d\vec{\rho} = Z^{-1} e^{-\mathcal{E}^\flat(\vec{u})} d\vec{u}. \quad (1.35)$$

In the following subsections, we discuss well-posedness of the SdNLW dynamics, emanating from the renormalized energy $\mathcal{E}^\flat(\vec{u})$ in (1.34).

Remark 1.12. We briefly discuss the renormalization required for $\beta \leq 1$. See Subsection 6.2 for a further renormalization required for $\beta \leq \frac{1}{2}$. Define $\kappa_N(n)$ by

$$\kappa_N(n) = \sum_{\substack{n_1 \in \mathbb{Z}^3 \ni n_1 \neq -n_1 \quad |n_1| \leq N}} \tilde{V}(n + n_1) \langle n_1 \rangle^{-2}. \quad (1.36)$$
Note that the limit \( \kappa(n) = \lim_{N \to \infty} \kappa_N(n) \) exists if and only if \( \beta > 1 \). This term exactly cancels the divergence part of \( R_N(u) \) which emerges at \( \beta = 1 \). See Remark \( 5.2 \).

With a slight abuse of notation, define \( K_N \) and \( K_{N}^{1/2} \) by

\[
K_N(x) = \sum_{n \in \mathbb{Z}^3} \kappa_n(x)e_n(x) \quad \text{and} \quad K_{N}^{1/2}(x) = \sum_{n \in \mathbb{Z}^3} \kappa_n^{1/2}(x)e_n(x).
\]

Then, for \( \frac{1}{2} < \beta \leq 1 \), we can introduce a further renormalization to \( R_N(u) \) in (1.27) by setting

\[
R_N^\beta(u) = R_N(u) - \int_{\mathbb{T}^3} (K_{N}^{1/2} * u_N)^2 \, dx.
\]

The truncated renormalized Gibbs measure \( \rho_N \) is then given by

\[
d\rho_N(u) = Z_N^{-1} e^{-R_N^\beta(u)} d\mu(u),
\]

for which we prove the following uniform exponential integrability:

\[
\sup_{N \in \mathbb{N}} \left\| e^{-R_N^\beta(u)} \right\|_{L^p(\mu)} \leq C_p < \infty
\]

for any finite \( p \geq 1 \) and the convergence claimed in Theorem 1.10 (ii.a). This allows us to construct the Gibbs measure \( \rho \) given by

\[
d\rho(u) = Z^{-1} e^{-R^\beta(u)} d\mu(u)
\]

as a limit of the truncated renormalized Gibbs measures \( \rho_N \) in (1.39), provided that \( \beta > \frac{1}{2} \).

For \( 0 < \beta \leq \frac{1}{2} \), we introduce another renormalization, based on a change of variables (6.20) as in [4], and prove the uniform exponential integrability for a new renormalized potential energy \( R_N^{\infty}(u) \):

\[
\sup_{N \in \mathbb{N}} \mathbb{E}_\mu\left[ e^{-R_N^{\infty}(u)} \right] < \infty.
\]

We can prove the uniform exponential integrability only for \( p = 1 \) due to the renormalization introduced at \( \beta = \frac{1}{2} \) (which is aimed to cancel a second order interaction). Unfortunately, the convergence of \( R_N^{\infty}(u) \) or the density no longer holds in this case. We establish uniqueness of the limiting Gibbs measure in a direct manner. See Subsection 6.3.

**Remark 1.13.** As mentioned above, our proof of the singularity of the Gibbs measure does not make use of the shifted measure. In Appendix C, we show that the Gibbs measure \( \rho \) is absolutely continuous with respect to the shifted measure, more precisely, to the law of \( Y(1) - 3(1) + W(1) \), where \( Y(1) \) is as in (5.12) with \( \text{Law}(Y(1)) = \mu, 3 = 3(Y) \) is the limit of \( 3^N \) defined in (6.19), and the auxiliary process \( W = W(Y) \) is defined in (C.1).

**Focusing case:** Let us first go over the Gibbs measure construction in the two-dimensional setting. In the defocusing case, the standard Wick renormalization and Nelson’s argument [58] allow us to construct the (defocusing) \( \Phi^{1}_{2} \)-measure on \( \mathbb{T}^2 \):

\[
d\rho(u) = Z^{-1} e^{-\frac{1}{2} \int_{\mathbb{T}^2} u^2 : d\mu(u)}.
\]

See [78, 37, 24, 70]. On the other hand, in the focusing case, Brydges and Slade [19] proved non-normalizability of \( \Phi^{1}_{2} \)-measure, even with a (Wick-ordered) \( L^2 \)-cutoff. In [11], Bourgain reported Jaffe’s construction of a \( \Phi^{1}_{2} \)-measure endowed with a Wick-ordered \( L^2 \)-cutoff:

\[
d\rho = Z^{-1} 1_{\{f_{\mathbb{T}^2} : u^2 : d\mu(u) \leq K\}} e^{f_{\mathbb{T}^2} u^2 : d\mu(u)}.
\]
Unfortunately, this measure is not suitable for studying the associated heat and wave dynamics due to the lack of the $L^2$-conservation in the deterministic setting. In [1], Bourgain instead proposed to consider the Gibbs measure of the form:

$$d\bar{\mu}(\bar{u}) = Z^{-1} e^{\int_{T^2} |\bar{u}|^2 : dx - A \left( \int_{T^2} |\bar{u}|^2 : dx \right)^{2}} d\bar{\mu}(\bar{u})$$

(1.43)

(for sufficiently large $A > 0$) in studying NLW dynamics on $T^2$. See [7] for the construction of the associated NLW dynamics.

Let us now discuss the focusing Hartree Gibbs measure in the three-dimensional setting. In [13], Bourgain studied the construction of the Gibbs measure for the Hartree NLS (1.4) on $T^3$. In the focusing case, he constructed the Gibbs measure with a Wick-ordered $L^2$-cutoff (for complex-valued $u$):

$$d\rho(u) = Z^{-1} e^{\frac{1}{4} \int_{T^3} (V * |u|^2) : |u|^2 : dx} d\mu(u)$$

(1.44)

for $\beta > 2$. As in the two-dimensional case, such a measure is not suitable for studying the NLW or heat dynamics due to the non-conservation of the $L^2$-norm. Following Bourgain’s proposition (1.43) in the two-dimensional case [11], we consider the following Hartree Gibbs measure on $T^3$ in the focusing case ($\sigma > 0$):

$$d\rho(u) = Z^{-1} e^{\frac{1}{4} \int_{T^3} (V * |u|^2) : |u|^2 : dx - A \left( \int_{T^3} |u|^2 : dx \right)^{2}} d\mu(u)$$

(1.45)

for some suitable $A, \gamma > 0$. Thus, we replace $R_N$ in (1.27) by

$$R_N(u) = \frac{\sigma}{4} \int_{T^3} (V * u_N^2) : u_N^2 : dx - A \left( \int_{T^3} u_N^2 : dx \right)^{2} - \frac{\sigma}{2} \alpha_N$$

(1.46)

and define the truncated renormalized Gibbs measure $\rho_N$ by

$$d\rho_N(u) = Z_N^{-1} e^{R_N(u)} d\mu(u).$$

(1.47)

Then, we have the following result in the focusing case.

**Theorem 1.14** (focusing case). Let $\sigma > 0$ and $V$ be the Bessel potential of order $\beta > 0$.

(i) Given $\beta > 2$, let $\frac{\beta^2 - 1}{\beta^2 - 2} \leq \gamma < 3$, with $\gamma > 2$ when $\beta = 3$, and $A > 0$ be sufficiently large. Then, given any finite $p \geq 1$, $R_N$ defined in (1.46) converges to some limit $R$ in $L^p(\mu)$. Moreover, there exists $C_p > 0$ such that

$$\sup_{N \in \mathbb{N}} \left\| e^{R_N(u)} \right\|_{L^p(\mu)} \leq C_p < \infty.$$  

(1.48)

In particular, we have

$$\lim_{N \to \infty} e^{R_N(u)} = e^{R(u)} \text{ in } L^p(\mu).$$

(1.49)

As a consequence, the truncated renormalized Gibbs measure $\rho_N$ in (1.47) converges, in the sense of (1.49), to the focusing Hartree Gibbs measure $\rho$ given by

$$d\rho(u) = Z^{-1} e^{R(u)} d\mu(u).$$

(1.50)

Furthermore, the resulting Gibbs measure $\rho$ is equivalent to the base massive Gaussian free field $\mu$.

(ii) (non-normalizability). Let $1 < \beta < 2$. Then, for any $A > 0$ and $\gamma > 0$, we have

$$\sup_{N \in \mathbb{N}} E_{\mu} \left[ e^{R_N(u)} \right] = \infty.$$  

(1.51)

---

14. This measure does not make sense in the complex-valued setting and hence is not suitable also for the Schrödinger dynamics.
In particular, the focusing Hartree Gibbs measure $\rho$ in (1.50) can not be defined as a probability measure for $1 < \beta < 2$.

(iii) (critical case). Let $\beta = 2$. Then, there exist $\sigma_1 \geq \sigma_0 > 0$ such that

(iii.a) (strongly nonlinear regime). For $\sigma > \sigma_1$, the focusing Hartree Gibbs measure $\rho$ in (1.50) is not normalizable in the sense of (1.51) for any $A > 0$ and $\gamma > 0$.

(iii.b) (weakly nonlinear regime). For $0 < \sigma < \sigma_0$, then by choosing $\gamma = 3$ and $A > 0$ sufficiently large, we can construct the focusing Hartree Gibbs measure $\rho$ in (1.50) as in Part (i). In particular, (1.48) and (1.49) hold with a restricted range $1 \leq p < p(\sigma)$ in this case.

As in the defocusing case, we prove Theorem 1.14 using the variational approach by Barashkov and Gubinelli in [4]. In the focusing case, the potential energy for the drift $\Theta$ appears with the $-$ sign and we need the lower bound $\gamma \geq \frac{\beta + 1}{\beta - 1}$ to control this part. See (5.40) below. Furthermore, in the non-endpoint case $\beta > 2$, the upper bound $\gamma < 3$ essentially ensures that $\int_{\mathbb{T}^3} \Theta^2 dx \gamma$ is the leading part of the second term on the right-hand side of (1.46). See Lemma 5.8 below. In the critical case $\beta = 2$ under the weakly nonlinear assumption $0 < \sigma < \sigma_0$, the Gibbs measure construction requires a more refined argument. See Subsection 5.6.

Theorem 1.14 shows that our Gibbs measure construction in the focusing case is sharp. Our argument also shows that Bourgain’s construction [13] of the focusing Hartree Gibbs measure (1.44) for $\beta > 2$ is also sharp modulo the endpoint case $\beta = 2$, where an analogous dichotomy follows as a corollary to Theorem 1.14 (iii). See Remark 5.10. We also mention related works [48, 19, 75, 15, 69, 61, 68] on the non-normalizability (and other issues) for focusing Gibbs measures.

Our proof of the non-normalizability in Theorem 1.14 is inspired by a recent work by Weber and the third author [84] on the non-construction of the Gibbs measure for the focusing cubic NLS on the real line, giving an alternative proof of Rider’s result [75], and is also based on the variational formulation due to Barashkov and Gubinelli [4]. For this approach, we need to construct a drift $\Theta$ which achieves the desired divergence. The lower threshold $\beta = 1$ in Theorem 1.14 (ii) naturally appears due to the necessity of a further renormalization for $\beta \leq 1$ (required even in the defocusing case). See Remark 1.12. We expect that once we endow with a proper renormalization, the non-normalizability result may be extended for lower values of $\beta \leq 1$.

We present the proof of Theorem 1.14 in Section 5.

Remark 1.15. (i) While we stated Theorem 1.14 for the Bessel potential, the Gibbs measure construction holds for any Hartree potential $V$, satisfying

$$|\hat{V}(n)| \lesssim \langle n \rangle^{-\beta}$$

(1.52)

for $n \in \mathbb{Z}^3$ and the non-normalizability holds for any Hartree potential $V$, satisfying $|\hat{V}(n)| \gtrsim \langle n \rangle^{-\beta}$ for $n \in \mathbb{Z}^3$.

(ii) In the two-dimensional case, the focusing Hartree Gibbs measure $\rho$ in (1.45) (also $\rho$ in (1.44) with a Wick-ordered $L^2$ cutoff) can be easily constructed for $\beta > 0$ (and suitable $\gamma > 2$) via the variational argument. When $\beta = 0$, it is not normalizable in view of the result [19] by Brydges and Slade.

Remark 1.16. Let $\beta \geq 2$. Define the renormalized energy:

$$E^2(u) = \frac{1}{2} \int_{\mathbb{T}^3} |\langle \nabla \rangle u|^2 dx - R(u),$$

(1.53)
where $\mathcal{R}(u)$ is the limit of $\mathcal{R}_N(u)$. Then, as in Remark 1.11, we can also write $\rho$ in (1.45) formally as

$$d\rho = Z^{-1}e^{-\mathcal{E}^\sharp(\bar{u})}du.$$  

Similarly, by defining the renormalized energy for SdNLW (1.6) and NLW (1.8) by

$$\mathcal{E}^\sharp(\bar{u}) = \frac{1}{2} \int_{\mathbb{T}^3} |(\nabla) u|^2 dx + \frac{1}{2} \int_{\mathbb{T}^3} (\partial_t u)^2 dx - \mathcal{R}(u),$$  

we can write the focusing Hartree Gibbs measure $\bar{\rho} = \rho \otimes \mu_0$ on a vector $\bar{u} = (u, \partial_t u)$ as

$$d\bar{\rho} = Z^{-1}e^{-\mathcal{E}^\sharp(\bar{u})}d\bar{u}.$$  

In the focusing case, the second term in (1.46) introduces an extra term for the resulting equations. See (2.1) and (A.1).

### 2. Invariant dynamics for Hartree SdNLW

In this section, we consider the canonical stochastic quantization for the Hartree Gibbs measure constructed in Theorems 1.10 and 1.14 and describe our strategy for constructing global-in-time invariant Gibbs dynamics.

#### 2.1. Main results.

Let $\bar{\rho}$ be the focusing Hartree Gibbs measure ($\sigma > 0$) constructed in Theorem 1.14. As pointed out in Remark 1.16, the energy for $\bar{\rho}$ is given by $\mathcal{E}^\sharp(\bar{u})$ in (1.54). By considering the Langevin equation, i.e. (1.9) with $\mathcal{E}$ replaced by $\mathcal{E}^\sharp$, we obtain the following focusing Hartree SdNLW:

$$\partial_t^2 u + \partial_t u + (1 - \Delta)u - \sigma(V* : u^2:)u + M_\gamma(:u^2:)u = \sqrt{2}\xi,$$  

where $M_\gamma$ is defined by

$$M_\gamma(u) := 2A\gamma \left| \int_{\mathbb{T}^3} u dx \right|^2 \int_{\mathbb{T}^3} u dx$$  

and $:u^2:$ denotes the Wick renormalization of $u^2$. The last term $M_\gamma(:u^2:)u$ on the left-hand side of (2.1) appears due to the taming via a power of the Wick-ordered $L^2$-norm in (1.45) and (1.46). Given $N \in \mathbb{N}$, we also consider the truncated focusing Hartree SdNLW:

$$\partial_t^2 u_N + \partial_t u_N + (1 - \Delta)u_N - \sigma\pi_N ((V* : (\pi_N u_N)^2:)\pi_N u_N) + M_\gamma(:\pi_N u_N^2:)\pi_N u_N = \sqrt{2}\xi,$$  

where $:(\pi_N u_N)^2:) = (\pi_N u_N)^2 - \sigma_N$. Our main goal here is to construct invariant Gibbs dynamics for the focusing Hartree SdNLW (2.1) as a limit of the truncated dynamics (2.3).

In the defocusing case ($\sigma < 0$), the energy for the Gibbs measure (for $\beta > 1$) is given by $\mathcal{E}^\flat(u)$ in (1.34), giving rise to the following defocusing Hartree SdNLW:

$$\partial_t^2 u + \partial_t u + (1 - \Delta)u - \sigma(V* : u^2:)u = \sqrt{2}\xi$$  

and its truncated version:

$$\partial_t^2 u_N + \partial_t u_N + (1 - \Delta)u_N - \sigma\pi_N ((V* : (\pi_N u_N)^2:)\pi_N u_N) = \sqrt{2}\xi$$  

for $N \in \mathbb{N}$.

---

15In order to give a proper meaning to $:u^2:$, we need to assume a structure on $u$ (see (2.14)). We postpone this discussion to the next subsection.
Theorem 2.1. Let \( V \) be the Bessel potential of order \( \beta \) with

(i) \( \beta \geq 2 \) in the focusing case and (ii) \( \beta > 1 \) in the defocusing case.

In the focusing case with \( \beta \geq 2 \), we also assume that \( \sigma > 0 \) is sufficiently small.

(i) (focusing case) Let \( A > 0 \) be sufficiently large and \( \gamma > 0 \) satisfy

\[
\max(\frac{\beta+1}{2}, 2) \leq \gamma < 3
\]

with \( \gamma > 2 \) when \( \beta = 3 \). Then, the focusing Hartree SdNLW (2.1) is almost surely globally well-posed with respect to the random initial data distributed by the Gibbs measure \( \tilde{\rho} = \rho \otimes \mu_0 \) in (1.55). Furthermore, \( \tilde{\rho} \) is invariant under the resulting dynamics.

More precisely, there exists a non-trivial stochastic process \((u, \partial_t u) \in C(\mathbb{R}_+; \mathcal{H}^{-\frac{1}{2}-\varepsilon}(\mathbb{T}^3))\) for any \( \varepsilon > 0 \) such that, given any \( T > 0 \), the solution \((u_N, \partial_t u_N)\) to the truncated Hartree SdNLW (2.3) with the random initial data distributed by the truncated Gibbs measure \( \tilde{\rho}_N = \rho_N \otimes \mu_0 \), where \( \rho_N \) is as in (1.47), converges to \((u, \partial_t u)\) in \( C([0,T]; \mathcal{H}^{-\frac{1}{2}-\varepsilon}(\mathbb{T}^3))\). Furthermore, we have Law \(((u(t), \partial_t u(t))) = \tilde{\rho} \) for any \( t \in \mathbb{R}_+ \).

(ii) (defocusing case) Let \( \beta > 1 \). Then, the corresponding results from Part (i) hold for the defocusing Hartree SdNLW (2.4), its truncated version (2.5), and the Gibbs measure \( \rho \) in (1.35).

In view of Theorem 1.14, Theorem 2.1 (i) on the focusing case is sharp. On the other hand, the threshold \( \beta = 1 \) in Theorem 2.1 (ii) is by no means sharp. As we saw in Theorem 1.10 on the Gibbs measure construction, we need to introduce another renormalization to go below \( \beta = 1 \). Since our main goal in this paper is to obtain a sharp result in the focusing case, we limit ourselves only to the range \( \beta > 1 \) in the defocusing case, where the same renormalization as in the focusing case suffices.

The main task in proving Theorem 2.1 is the construction of local-in-time solutions. Indeed, once this is achieved, by adapting Bourgain’s invariant measure argument \([10, 12]\) to the stochastic PDE setting (as in \([44]\)), we obtain the desired almost sure global well-posedness and invariance of the Gibbs measure. Since this argument is standard by now, we only give a sketch in Section 9.

Our main strategy for constructing local-in-time dynamics is to adapt the paracontrolled approach in the hyperbolic / dispersive setting as in \([43]\), where the quadratic SNLW on \( \mathbb{T}^3 \) was studied. By viewing the cubic Hartree nonlinearity \( (V \ast u^2)u \), written without a renormalization as iterated bilinear interactions\(10\) the exact paracontrolled operators used in \([43]\) appear in the study of the cubic Hartree SdNLW (2.1) and (2.4). In the next subsection, we describe the basic setup of our paracontrolled approach.

Remark 2.2. Here, we used the sharp frequency cutoff \( \pi_N \). It is, however, possible to use regularization via a mollification and show that the limiting process is independent of mollification kernels. See \([43]\) for a further discussion. We also point out that there are certain approximations which lead to a wrong (and even divergent) limit. See \([62]\) for such an example in the context of the deterministic NLW with random initial data.

2.2. Paracontrolled approach: defocusing case. In this subsection, we go over a paracontrolled approach in the simpler defocusing case \( (\sigma < 0) \). Since a precise value of \( \sigma < 0 \) does not play any role, we set \( \sigma = -1 \). Proceeding in the spirit of \([21, 56, 43]\), we transform the defocusing Hartree SdNLW (2.4) to a system of PDEs. Unlike the previous works \([21, 56, 43]\), the resulting system (see (2.31) below) consists of three equations. We then state our local well-posedness result of the resulting system. The focusing case is treated in the next subsection.

\(10\)In \([13]\), Bourgain used this viewpoint in studying the cubic Hartree NLS \([14]\).
The main difficulty in studying Hartree SdNLW (2.4) comes from the roughness of the space-time white noise. This is already manifested at the level of the linear equation. Let \( \Psi \) be the solution to the following linear stochastic damped wave equation:

\[
\begin{cases}
\partial_t^2 \Psi + \partial_t \Psi + (1 - \Delta) \Psi = \sqrt{2} \xi \\
(\Psi, \partial_t \Psi)|_{t=0} = (\phi_0, \phi_1),
\end{cases}
\]

where \((\phi_0, \phi_1) = (\phi_0^\omega, \phi_1^\omega)\) is a pair of the Gaussian random distributions with \(\text{Law}((\phi_0^\omega, \phi_1^\omega)) = \hat{\mu} = \mu_1 \otimes \mu_0\). Define the linear damped wave propagator \(D(t)\) by

\[
D(t) = e^{-\frac{1}{2} \frac{t}{\sqrt{\frac{3}{4} - \Delta}}} \sqrt{\frac{3}{4} - \Delta} ,
\]

viewed as a Fourier multiplier operator. By setting

\[
[n] = \sqrt{\frac{3}{4} + |n|^2} ,
\]

we have

\[
D(t)f = e^{-\frac{1}{2} \sum_{n \in \mathbb{Z}^3} \frac{\sin(t[n])}{[n]} f(n)e_n} .
\]

Then, the stochastic convolution \(\Psi\) can be expressed as

\[
\Psi(t) = \partial_t D(t) \phi_0 + D(t)(\phi_0 + \phi_1) + \sqrt{2} \int_0^t D(t - t') dW(t'),
\]

where \(W\) denotes a cylindrical Wiener process on \(L^2(\mathbb{T}^3)\):

\[
W(t) = \sum_{n \in \mathbb{Z}^3} B_n(t)e_n
\]

and \(\{B_n\}_{n \in \mathbb{Z}^3}\) is defined by \(B_n(t) = \langle \xi, 1_{[0, t]} \cdot e_n \rangle_{x,t}\). Here, \(\langle \cdot, \cdot \rangle_{x,t}\) denotes the duality pairing on \(\mathbb{T}^3 \times \mathbb{R}\). As a result, we see that \(\{B_n\}_{n \in A_0}\) is a family of mutually independent complex-valued Brownian motions conditioned so that \(B_{-n} = \overline{B_n}\), \(n \in \mathbb{Z}^3\). By convention, we normalized \(B_n\) such that \(\text{Var}(B_n(t)) = t\). It is easy to see that \(\Psi\) almost surely lies in \(C(\mathbb{R}_+; W^{-\frac{1}{2}-\varepsilon, \infty}(\mathbb{T}^3))\) for any \(\varepsilon > 0\). See Lemma 4.1 below.

Given \(N \in \mathbb{N}\), we define the truncated stochastic convolution \(\Psi_N\) by

\[
\Psi_N = \pi_N \Psi ,
\]

where \(\pi_N\) is the (spatial) frequency projection defined in (1.22). Then, for each fixed \((x, t) \in \mathbb{T}^3 \times \mathbb{R}_+\), a direct computation with (2.8) and (2.9) shows that the random variable \(\Psi_N(x, t)\) is a mean-zero real-valued Gaussian random variable with variance

\[
\sigma_N = \mathbb{E}[\Psi_N(x, t)^2] = \sum_{|n| \leq N} \frac{1}{(n)^2} \sim N \to \infty ,
\]

as \(N \to \infty\) (which agrees with \(\sigma_N\) defined in (1.23)). We then define the truncated Wick power \(\Psi^2_N\) by

\[
\Psi^2_N = (\Psi_N)^2 - \sigma_N .
\]
A standard computation shows that $\Psi^2 : = \lim_{N \to \infty} : \Psi^2_N :$ belongs to $C([0, T]; W^{-1-\epsilon, \infty}(\mathbb{T}^d))$ almost surely for $\epsilon > 0$. See Lemma 4.1 below.

In the following, we keep our discussion at a formal level\(^{18}\) and only discuss spatial regularities (= differentiability) of various objects without worrying about precise spatial Sobolev spaces that they belong to. We also use the following “rules”\(^{19}\):

- A product of functions of regularities $s_1$ and $s_2$ is defined if $s_1 + s_2 > 0$. When $s_1 > 0$ and $s_1 \geq s_2$, the resulting product has regularity $s_2$.
- A product of stochastic objects (not depending on the unknown) is always well defined, possibly with a renormalization. The product of stochastic objects of regularities $s_1$ and $s_2$ has regularity $\min(s_1, s_2, s_1 + s_2)$.

We now write $u$ in the first order expansion as in\(^{20}\) [54, 12, 23]:

$$u = \Psi + v.$$  \hspace{1cm} (2.14)

Then, it follows from (2.4) and (2.14) that $v$ satisfies

$$\left(\partial_t^2 + \partial_t + 1 - \Delta\right)v = -\left(V \ast (v + \Psi)^2 : (v + \Psi)\right) v - \left(V \ast (v^2 + 2v\Psi + :\Psi^2 : )\right) v.$$

The second term on the right-hand side has regularity\(^{20}\) $-\frac{1}{2}$, inheriting the worse regularity of $\Psi$. In view of one degree of smoothing under the damped wave operator, we expect $v$ to have regularity at most $\frac{1}{2} = (-\frac{1}{2}) + 1$. Then, the product $v\Psi$ is not well defined since $\left(\frac{1}{2} \right) + (-\frac{1}{2}) < 0$.

**Remark 2.3.** Note that the second term on the right-hand side of (2.15) (ignoring $v\Psi$) has regularity $-\frac{1}{2}$ even if $\beta \gg 1$. Namely, the smoothing property of the Bessel potential $V$ does not improve the regularity of this term. Furthermore, we point out, when $\beta > 1$, the purely stochastic term $(V \ast :\Psi^2 : )\Psi$ and the terms $(V \ast v^2 )\Psi$, involving the unknown $v$, have the same regularity $-\frac{1}{2}$. This makes it difficult to apply a higher order expansion as in [43, 63], since the worst part depends not only on $\Psi$ but also on the unknown $v$.

We now proceed with the paracontrolled calculus. The main ingredients for the paracontrolled approach in the parabolic setting, introduced by Gubinelli, Imkeller, and Perkowski\(^{39}\), are (i) a paracontrolled ansatz and (ii) commutator estimates. As pointed out in [43], however, there seems to be no smoothing for a certain relevant commutator for the wave equation. In order to overcome this difficulty, Gubinelli, Koch, and the first author\(^{43}\) introduced the so-called paracontrolled operators (see (2.26) and (2.27) below) in studying SNLW with a quadratic nonlinearity. While our nonlinearity is cubic, the presence of the Bessel potential makes it more convenient to view it as iterated bilinear interactions (as in the Schrödinger case by Bourgain\(^{13}\)). As a result, the (essentially) same paracontrolled operators from [43] will play an important role in our analysis.

---

\(^{18}\)In the following, we directly work on (2.4). A rigorous treatment, however, needs to start with the truncated equation (2.5) and take a limit $N \to \infty$.

\(^{19}\)In the remaining part of the paper, we will justify these rules.

\(^{20}\)Hereafter, we use $a - \epsilon$ (and $a + \epsilon$) to denote $a - \epsilon$ (and $a + \epsilon$, respectively) for arbitrarily small $\epsilon > 0$. If this notation appears in an estimate, then an implicit constant is allowed to depend on $\epsilon > 0$ (and it usually diverges as $\epsilon \to 0$).
In the following, the paraproduct decomposition:

\[ fg = f \otimes g + f \otimes g + f \otimes g \]

(2.16)

plays an important role. See Section 3 for a precise definition. The first term \( f \otimes g \) (and the third term \( f \otimes g \)) is called the paraproduct of \( g \) by \( f \) (the paraproduct of \( f \) by \( g \), respectively) and it is always well defined as a distribution of regularity \( \min(s_2, s_1 + s_2) \). On the other hand, the resonant product \( f \otimes g \) is well defined in general only if \( s_1 + s_2 > 0 \). We also use the notation \( f \gg g := f \otimes g + f \otimes g \).

With this notation, we introduce our paracontrolled ansatz:

\[ v = X + Y, \]

(2.17)

where \( X \) and \( Y \) satisfy

\[
(\partial_t^2 + \partial_t + 1 - \Delta)X = -\left( V \ast ((X + Y)^2 + 2(X + Y)\Psi : \Psi^2 : ) \right) \otimes \Psi,
\]

(2.18)

\[
(\partial_t^2 + \partial_t + 1 - \Delta)Y = -\left( V \ast ((X + Y)^2 + 2(X + Y)\Psi : \Psi^2 : ) \right)(X + Y)
\]

\[
- \left( V \ast ((X + Y)^2 + 2(X + Y)\Psi : \Psi^2 : ) \right) \otimes \Psi.
\]

(2.19)

In view of the paraproduct decomposition (2.16), the right-hand side of the \( X \)-equation (2.18) consists of the worst nonlinear terms in (2.15). We postulate that both \( X \) and \( Y \) have positive regularities \( s_1 \) and \( s_2 \), respectively, with \( 0 < s_1 < s_2 \). If we ignore for now the potentially ill-defined resonant products of the unknowns with \( \Psi \), then we expect that \( X \) has regularity \( \frac{1}{2} - = \left( -\frac{1}{2} - \right) + 1 \) (at best). In the second equation, the worst term is given by the purely stochastic resonant product

\[
(V \ast : \Psi^2 :) \otimes \Psi
\]

(2.20)

which has regularity \( \beta - \frac{3}{2} - \). See Lemma 4.2 below. Thus, we expect that \( Y \) has regularity \( \frac{1}{2} + \) when \( \beta > 1 \) is close to 1.

The main new feature of our formulation (2.18) - (2.19), when compared with the previous works [21, 56, 43], is that the first equation (2.18) (for \( X \)) is nonlinear in the unknowns \( X \) and \( Y \), while the paracontrolled parts in [21, 56, 43] were linear in the unknowns. This makes our analysis different from that in [21, 56, 43]. In these previous works, the main difficulty was to make sense of the resonant product \( \otimes \) (for example \( X \otimes \Psi \) in [43]) in the second equation (2.19) (for \( Y \)), which was overcome using the Duhamel formulation of the \( X \)-equation (and then via the commutator estimates in the parabolic setting and via the paracontrolled operators in the wave case [43]).

In our case, the resonant product with \( \Psi \) in the second term on the right-hand side of the second equation (2.19) is not so much of an issue thanks to the smoothing property of \( V \). On the other hand, we expect from (2.18) that \( X \) has regularity \( \frac{1}{2} - \) and thus \( X \otimes \Psi \) is not well defined since the sum of the regularities is negative. Note that this resonant product \( X \otimes \Psi \) appears in both equations. Furthermore, the smoothing of \( V \) does not help the situation since

---

21We say that a distribution \( f \) is paracontrolled (by a given distribution \( g \)) if there exists \( f' \) such that \( f = f' \otimes g + h \), where \( h \) is a “smoother” remainder. See Definition 3.6 in [39] for a precise definition. Formally speaking, via the decomposition (2.17) with (2.18) and the regularity assumption \( 0 < s_1 < s_2 \), we are postulating \((\partial_t^2 + \partial_t + 1 - \Delta) v \) is paracontrolled by \( \Psi \).
the (ill-defined) resonant product $X \otimes \Psi$ appears inside the convolution with $V$. Our main new idea is to define the resonant product

$$R = X \otimes \Psi$$

as a new unknown and reduce to a system of three unknowns $(X, Y, R)$. More precisely, we substitute the Duhamel formulation of the $X$-equation (2.18) into (2.21) and define $R$ by

$$R = -\mathcal{I} \left( \left( V \ast (Q_{X,Y} + 2R+) : \psi^2 \right) \otimes \psi \right) \otimes \psi$$

where $\mathcal{I} = (\partial_t^2 + \partial_t + 1 - \Delta)^{-1}$ is the Duhamel integral operator given by

$$\mathcal{I} F(t) = \int_0^t D(t - t') F(t') dt'$$

and $Q_{X,Y}$ denotes a good part of $:u^2: ;$ defined by

$$Q_{X,Y} = (X + Y)^2 + 2X \otimes \psi + 2X \otimes \psi + 2Y \psi.$$

Note that all the terms in (2.23) make sense for $0 < s_1 < 1/2 < s_2$ and that $Q_{X,Y}$ has (expected) regularity $-1/2$. Recalling (2.14) and (2.17), we have

$$:u^2: = Q_{X,Y} + 2R+ : \psi^2 :.$$

Due to the paraproduct structure (with the high frequency part given by $\psi$) in the Duhamel integral operator $\mathcal{I}$ in (2.22), we see that the resonant product in (2.22) is not well defined at this point. In order to give a precise meaning to the right-hand side of (2.22), we now recall the paracontrolled operators introduced in [43].

We point out that in the parabolic setting, it is at this step where one would introduce commutators and exploit their smoothing properties. For our dispersive problem, however, such an argument does not seem to work. See [43, Remark 1.17].

Given a function $w$ of positive regularity on $\mathbb{T}^3 \times \mathbb{R}_+$, define

$$\mathcal{J}_\circ (w)(t) := \mathcal{I}(w \otimes \psi)(t)$$

$$= \sum_{n \in \mathbb{Z}^3} e_n \sum_{n = n_1 + n_2 : |n_1| \ll |n_2|} \int_0^t e^{-\frac{t-t'}{2}} \frac{\sin((t-t')|n|)}{|n|} \hat{w}(n_1, t') \hat{\psi}(n_2, t') dt',$$

where $[n]$ is as in (2.7). Here, $|n_1| \ll |n_2|$ signifies the paraproduct $\otimes$ in the definition of $\mathcal{J}_\circ$. As mentioned above, the regularity of $\mathcal{J}_\circ (w)$ is (at best) $1/2$ and thus the resonant product $\mathcal{J}_\circ (w) \otimes \psi$ does not make sense in terms of deterministic analysis.

Proceeding as in [43], we divide the paracontrolled operator $\mathcal{J}_\circ$ into two parts. Fix small $\theta > 0$. Denoting by $n_1$ and $n_2$ the spatial frequencies of $w$ and $\psi$ in (2.25), we define $\mathcal{J}_\circ^{(1)}$ and $\mathcal{J}_\circ^{(2)}$ as the restrictions of $\mathcal{J}_\circ$ onto $\{|n_1| \gtrsim |n_2|^{\theta}\}$ and $\{|n_1| \ll |n_2|^{\theta}\}$. More concretely, we set

$$\mathcal{J}_\circ^{(1)} (w)(t) := \sum_{n \in \mathbb{Z}^3} e_n \sum_{n = n_1 + n_2 : |n_1| \gtrsim |n_2|^\theta} \int_0^t e^{-\frac{t-t'}{2}} \frac{\sin((t-t')|n|)}{|n|} \hat{w}(n_1, t') \hat{\psi}(n_2, t') dt'$$

$$\mathcal{J}_\circ^{(2)} (w)(t) := \sum_{n \in \mathbb{Z}^3} e_n \sum_{n = n_1 + n_2 : |n_1| \ll |n_2|^\theta} \int_0^t e^{-\frac{t-t'}{2}} \frac{\sin((t-t')|n|)}{|n|} \hat{w}(n_1, t') \hat{\psi}(n_2, t') dt'$$

[22] Strictly speaking, the paracontrolled operators introduced in [43] are for the undamped wave equation. Since the local-in-time mapping property remains unchanged, we ignore this minor point.

[23] For simplicity of the presentation, we use the less precise definitions of paracontrolled operators in the remaining part of this introduction. See (7.3), (7.4), and (7.5) for the precise definitions of the paracontrolled operators $\mathcal{J}_\circ^{(1)}$ and $\mathcal{J}_\circ^{(2)}$. 
and \( \mathcal{J}_\ominus^{(2)}(w) := \mathcal{J}_\ominus(w) - \mathcal{J}_\ominus^{(1)}(w) \). As for the first paracontrolled operator \( \mathcal{J}_\ominus^{(1)} \), the lower bound \(|n_1| \gtrsim |n_2|^{\theta}\) and the positive regularity of \( w \) allow us to prove a smoothing property such that the resonant product \( \mathcal{J}_\ominus^{(1)}(w) \odot \Psi \) is well defined. See Lemma 7.1 below.

As noted in [43], the second paracontrolled operator \( \mathcal{J}_\ominus^{(2)} \) does not seem to possess a (deterministic) smoothing property. One of the main novelty in [43] was then to directly study the resonant product \( \mathcal{J}_\ominus^{(2)} \odot \Psi \) in (2.27). See (7.5) for a more precise definition.

\[ \mathcal{J}_\ominus(w)(t) := \mathcal{J}_\ominus^{(2)}(w) \odot \Psi(t) = \sum_{n \in \mathbb{Z}^3} e_n \int_0^t \sum_{n_1 \in \mathbb{Z}^3} \tilde{w}(n_1, t') A_{n, n_1}(t, t') dt', (2.27) \]

where \( A_{n, n_1}(t, t') \) is given by

\[ A_{n, n_1}(t, t') = 1_{[0, t]}(t') \sum_{n-n_1 = n_2+n_3, |n_1| \ll |n_2|^{\theta}, |n_1+n_2| \sim |n_3|} e^{-\frac{1}{2} \sin((t-t')|n_1+n_2|/|n_1+n_2|)} \tilde{\Psi}(n_2, t') \tilde{\Psi}(n_3, t). (2.28) \]

Here, the condition \(|n_1+n_2| \sim |n_3|\) is used to denote the Fourier multiplier corresponding to the resonant product \( \odot \) in (2.27). See (7.5) for a more precise definition.

In [43], by combining stochastic analysis and multilinear dispersion, Gubinelli, Koch, and the first author proved the following almost sure boundedness property of the paracontrolled operator \( \mathcal{J}_\ominus \) defined in (2.27). Given Banach spaces \( B_1 \) and \( B_2 \), we use \( \mathcal{L}(B_1; B_2) \) to denote the space of bounded linear operators from \( B_1 \) to \( B_2 \).

**Lemma 2.4.** Let \( s_3 < 0 \) and \( T > 0 \). Then, there exist small \( \theta = \theta(s_3) > 0 \) and \( \varepsilon > 0 \) such that the paracontrolled operator \( \mathcal{J}_\ominus \) defined in (2.27) belongs to the class:

\[ \mathcal{L}_1(T) := \mathcal{L}(C([0, T]; L^2(\mathbb{T}^3)) \cap C^1([0, T]; H^{-1-\varepsilon}(\mathbb{T}^3)) ; C([0, T]; H^{s_3}(\mathbb{T}^3))), \]

almost surely.

The kernel \( A_{n, n_1}(t, t') \) in (2.28) can be divided into two parts: a stochastic part and a deterministic counter term. See (7.6) below. In order to control a part of the deterministic counter term, the time differentiability of the input function \( w \) was exploited in [43]. Unfortunately, Lemma 2.4 is not suitable for our purpose due to the lack of differentiability in the range of \( \mathcal{L}_1(T) \). One of the terms in (2.22), giving rise to \( \mathfrak{R} \), is given by \( \mathcal{J}_\ominus(V \ast \mathfrak{R}) \). Hence, we need to prove an almost sure mapping property with the same time differentiability for the domain and the range. In Section 7, we prove the following proposition.

**Proposition 2.5.** Let \( s_3 < 0 \) and \( 0 < T \leq 1 \). Then, there exist small \( \theta = \theta(s_3) > 0 \) such that, for any \( q > 1 \), the paracontrolled operator \( \mathcal{J}_\ominus \) defined in (2.27) belongs to

\[ \mathcal{L}_2(q, T) := \mathcal{L}(L^q([0, T]; L^2(\mathbb{T}^3))) ; L^\infty([0, T]; H^{s_3}(\mathbb{T}^3))), \]

almost surely. Furthermore the following tail estimate holds for some \( C, c > 0 \):

\[ P\left( \| \mathcal{J}_\ominus \|_{\mathcal{L}_2(q, T)} > \lambda \right) \leq C \exp\left( - \frac{\lambda}{T^c} \right) \]

(2.30) for any \( \lambda \gg 1 \).

If we define the paracontrolled operator \( \mathcal{J}_\ominus^N \), \( N \in \mathbb{N} \), by replacing \( \Psi \) in (2.27) and (2.28) with the truncated stochastic convolution \( \Psi_N \) in (2.11), then the truncated paracontrolled operators
\(\mathcal{J}_{\otimes, \odot}^N\) converge almost surely to \(\mathcal{J}_{\otimes, \odot}\) in \(L_2(q, T)\). Furthermore, the tail estimate \(2.30\) holds for the truncated paracontrolled operators \(\mathcal{J}_{\otimes, \odot, N}\) with the constants independent of \(N \in \mathbb{N}\).

We are now ready to present the resulting system for the three unknowns \((X, Y, \mathcal{R})\). Putting together (2.18), (2.19), (2.22), (2.24), (2.26), and (2.27), we arrive at the following system:

\[
(\partial^2_t + \partial_t + 1 - \Delta)X = -\left(V * (Q_{X,Y} + 2\mathcal{R} + \Psi^2)\right) \odot \Psi,
\]

\[
(\partial^2_t + \partial_t + 1 - \Delta)Y = -\left(V * (Q_{X,Y} + 2\mathcal{R} + \Psi^2)\right)(X + Y)
- \left(V * (Q_{X,Y} + 2\mathcal{R} + \Psi^2)\right) \odot \Psi,
\]

\[
\mathcal{R} = -I_{\otimes, \odot}^{(1)}\left(V * (Q_{X,Y} + 2\mathcal{R} + \Psi^2)\right) \odot \Psi
- \mathcal{J}_{\otimes, \odot}\left(V * (Q_{X,Y} + 2\mathcal{R} + \Psi^2)\right),
\]

\[(X, \partial_t X, Y, \partial_t Y, \mathcal{R})|_{t=0} = (X_0, X_1, Y_0, Y_1, 0).\]

Here, we included general initial data for \(X\) and \(Y\). By viewing the following random distributions and operator: \(\Psi^2\), \((V * \Psi^2) \odot \Psi\), and \(\mathcal{J}_{\otimes, \odot}\) as predefined deterministic data with certain regularity properties, we prove the following local well-posedness of the system (2.31). Given \(s \in \mathbb{R}\) and \(T > 0\), define \(X^s(T)\) by

\[
X^s(T) = C([0, T]; H^s(\mathbb{T}^3)) \cap C^1([0, T]; H^{s-1}(\mathbb{T}^3)).
\]

**Theorem 2.6.** Let \(V\) be the Bessel potential of order \(\beta > 1\). Let \(\frac{1}{4} < s_1 < \frac{1}{2} < s_2 < 1\) and \(-\frac{1}{2} < s_3 < 0\) satisfy

\[
-3s_1 + s_2 + 2 > \beta > (s_1, s_2, s_3, \beta) > 0 \text{ such that if }
\]

- \(\Psi\) is a distribution-valued function belonging to \(C([0, T]; W^{-\frac{1}{2} - \varepsilon, \infty}(\mathbb{T}^3))\),
- \(\Psi^2\) is a distribution-valued function belonging to \(C([0, T]; W^{-\frac{1}{2} - \varepsilon, \infty}(\mathbb{T}^3))\),
- \((V * \Psi^2) \odot \Psi\) is a distribution-valued function belonging to \(C([0, T]; W^{\beta - \frac{1}{2} - \varepsilon, \infty}(\mathbb{T}^3))\),
- the operator \(\mathcal{J}_{\otimes, \odot}\) belongs to the class \(L_2(\frac{3}{2}, T)\) in (2.29),

then the system (2.31) is locally well-posed in \(H^{s_1}(\mathbb{T}^3) \times H^{s_2}(\mathbb{T}^3) \times \{0\}\). More precisely, given any \((X_0, X_1, Y_0, Y_1) \in H^{s_1}(\mathbb{T}^3) \times H^{s_2}(\mathbb{T}^3)\), there exists \(T > 0\) such that there exists a unique solution \((X, Y, \mathcal{R})\) to the defocusing Hartree S\(\tilde{N}\)LW system (2.31) on \([0, T]\) in the class

\[
Z^{s_1, s_2, s_3}(T) = X^{s_1}(T) \times X^{s_2}(T) \times L^3([0, T]; H^{s_1}(\mathbb{T}^3)).
\]

Furthermore, the solution \((X, Y, \mathcal{R})\) depends continuously on the enhanced data set:

\[
\Xi = (X_0, X_1, Y_0, Y_1, \Psi, \Psi^2; (V * \Psi^2) \odot \Psi, \mathcal{J}_{\otimes, \odot})
\]

in the class:

\[
X_T^{s_1, s_2, \varepsilon} = H^{s_1}(\mathbb{T}^3) \times H^{s_2}(\mathbb{T}^3) \times C([0, T]; W^{-\frac{1}{2} - \varepsilon, \infty}(\mathbb{T}^3)) \times C([0, T]; W^{\beta - \frac{1}{2} - \varepsilon, \infty}(\mathbb{T}^3)) \times L_2(\frac{3}{2}, T).
\]

Note that, given \(\beta > 1\), the condition (2.33) is satisfied by taking both \(s_1\) and \(s_2\) sufficiently close to \(\frac{1}{2}\). Given the a priori regularities of the enhanced data, Theorem 2.6 follows from the standard energy estimate for the damped wave equation (see (8.7) below). Namely, we do not
need to rely on the Strichartz estimates thanks to the strong smoothing of the Bessel potential \( V \). See Section 8 for the proof.

**Remark 2.7.** The choice of the temporal integrability \( L_T^3 \) for \( \mathcal{R} \) and \( L_2(\frac{\alpha}{2}, T) \) comes from the focusing case presented in the next subsection.

### 2.3. Focusing case

In the following, we briefly describe the required modification to prove local well-posedness of the focusing Hartree SdNLW \((2.1)\) for \( \beta \geq 2 \). Since a precise value of \( \sigma > 0 \) does not play any role, we set \( \sigma = 1 \). In the focusing case, we have an extra term \( M_\gamma(u^2)u \) in the equation. From \((2.2),(2.14),(2.17),\) and \((2.24)\), we have

\[
M_\gamma(u^2)u = M_\gamma(Q_{XY} + 2\mathcal{R} + :\Psi^2:) \Psi + M_\gamma(Q_{XY} + 2\mathcal{R} + :\Psi^2:)(X + Y). \tag{2.36}
\]

Then, by including the first term on the right-hand side of \((2.36)\) in the \( X \)-equation and the second term in the \( Y \)-equation, we end up with the system:

\[
\begin{align*}
(\partial_t^2 + \partial_t + 1 - \Delta)X &= \left( V \ast (Q_{XY} + 2\mathcal{R} + :\Psi^2:) \right) \ast \Psi \\
&\quad - M_\gamma(Q_{XY} + 2\mathcal{R} + :\Psi^2:) \Psi, \\
(\partial_t^2 + \partial_t + 1 - \Delta)Y &= \left( V \ast (Q_{XY} + 2\mathcal{R} + :\Psi^2:) \right)(X + Y) \\
&\quad + \left( V \ast (Q_{XY} + 2\mathcal{R} + :\Psi^2:) \right) \ast \Psi \\
&\quad - M_\gamma(Q_{XY} + 2\mathcal{R} + :\Psi^2:) \Psi \tag{2.37}
\end{align*}
\]

\( \mathcal{R} = \mathcal{F}^{(1)}(V \ast (Q_{XY} + 2\mathcal{R} + :\Psi^2:)) \ast \Psi \\
+ \mathcal{F}(V \ast (Q_{XY} + 2\mathcal{R} + :\Psi^2:)) - \mathcal{I}(M_\gamma(Q_{XY} + 2\mathcal{R} + :\Psi^2:) \Psi) \ast \Psi,
\]

\((X, \partial_X X, Y, \partial_Y Y, \mathcal{R})|_{t=0} = (X_0, X_1, Y_0, Y_1, 0)\).

Here, \( \gamma \) is as in Theorem 1.14 and in particular, we have \( \gamma = 3 \) when \( \beta = 2 \). The last term in the \( \mathcal{R} \)-equation puts a restriction on the temporal integrability for \( \mathcal{R} \). By the energy estimate, we can place \( M_\gamma(Q_{XY} + 2\mathcal{R} + :\Psi^2:) \) in \( L^1([0, T]) \) (ignoring the spatial regularity). In order to perform a contraction argument, we need to save some time integrability and thus need to place \( \int \mathcal{R} dx \gamma^{-1} \) in \( L^{1+}([0, T]) \), namely, \( \int \mathcal{R} dx \) in \( L^{2+}([0, T]) \) when \( \gamma = 3 \). This explains the choice \( L_T^3 \) for \( \mathcal{R} \) in \((2.34)\).

In order to handle the last term in the \( \mathcal{R} \)-equation, we also need to introduce the following stochastic term:

\[
\hat{A}(x, t, t') = \sum_{n \in \mathbb{Z}^3} e_n(x) \sum_{\frac{n_1 + n_2}{|n_1| \sim |n_2|}} \frac{e^{-\frac{1}{2} |n'|^2} \sin((t - t') [n_1])}{|n_1|} \hat{\Psi}(n_1, t') \hat{\Psi}(n_2, t) \tag{2.38}
\]

for \( t \geq t' \geq 0 \), where \( |n_1| \sim |n_2| \) signifies the resonant product. Then, we interpret the last term in the \( \mathcal{R} \)-equation as

\[
\mathcal{I}(M_\gamma(Q_{XY} + 2\mathcal{R} + :\Psi^2:) \Psi) \ast \Psi \bigg|_{t=0} = \int_0^t M_\gamma(Q_{XY} + 2\mathcal{R} + :\Psi^2:) \Psi(A(t, t') dt'. \tag{2.39}
\]

We point out that the Fourier transform \( \hat{A}(n, t, t') \) corresponds to \( A_{\mathbb{n},\mathbb{0}}(t, t') \) defined in \((2.28)\) and thus the analysis for \( A \) is closely related to that for the paracontrolled operator \( \mathcal{F}_{\infty} \) in \((2.27)\).

See Lemma 7.2 below.
As a result, we obtain the following local well-posedness of the focusing Hartree SdNLW system (2.37).

**Theorem 2.8.** Let \( V \) be the Bessel potential of order \( \beta \geq 2 \), \( A \in \mathbb{R} \), and \( 2 < \gamma \leq 3 \). Let \( \frac{1}{4} < s_1 < \frac{1}{2} < s_2 < 1 \) and \( -\frac{1}{2} < s_3 < 0 \), satisfying (2.33). Then, there exist \( \theta = \theta(s_3) > 0 \) and \( \varepsilon = \varepsilon(s_1, s_2, s_3, \beta) > 0 \) such that if

1. \( \Psi \) is a distribution-valued function belonging to \( C([0, T]; W^{-\frac{1}{2} - \varepsilon, \infty}(\mathbb{T}^3)) \),
2. \( :\Psi^2: \) is a distribution-valued function belonging to \( C([0, T]; W^{-1 - \varepsilon, \infty}(\mathbb{T}^3)) \),
3. \( \Lambda(t, t') \) is a distribution-valued function belonging to \( L^\infty_t L^3_x(\Delta_2(T); H^{-\varepsilon}(\mathbb{T}^3)) \), where \( \Delta_2(T) \subset [0, T]^2 \) is given by
   \[
   \Delta_2(T) = \{(t, t') \in \mathbb{R}^2_+ : 0 \leq t' \leq t \leq T\},
   \]

- the operator \( \mathcal{J}_{\gamma, \varepsilon} \) belongs to the class \( \mathcal{L}_2(\frac{3}{2}, T) \) in (2.29),

then the system (2.37) is locally well-posed in \( \mathcal{H}^{s_1}(\mathbb{T}^3) \times \mathcal{H}^{s_2}(\mathbb{T}^3) \times \{0\} \). More precisely, given any \( (X_0, X_1, Y_0, Y_1) \in \mathcal{H}^{s_1}(\mathbb{T}^3) \times \mathcal{H}^{s_2}(\mathbb{T}^3) \), there exists \( T > 0 \) such that there exists a unique solution \( (X, Y, \mathcal{R}) \) to the focusing SdNLW system (2.37) on \([0, T]\) in the class \( Z^{s_1, s_2, s_3}(T) \) defined in (2.34). Furthermore, the solution \((X, Y, \mathcal{R})\) depends continuously on the enhanced data set:

\[
\Xi = (X_0, X_1, Y_0, Y_1, \Psi, :\Psi^2:, \Lambda, \mathcal{J}_{\gamma, \varepsilon})
\]

in the class:

\[
\mathcal{Y}^{s_1, s_2, \varepsilon}_T = \mathcal{H}^{s_1}(\mathbb{T}^3) \times \mathcal{H}^{s_2}(\mathbb{T}^3) \times C([0, T]; W^{-\frac{1}{2} - \varepsilon, \infty}(\mathbb{T}^3)) \\
\times C([0, T]; W^{-1 - \varepsilon, \infty}(\mathbb{T}^3)) \times L^\infty_t L^3_x(\Delta_2(T); W^{-\varepsilon, \infty}(\mathbb{T}^3)) \times \mathcal{L}_2(\frac{3}{2}, T)
\]

For \( \beta > \frac{3}{2} \), we can make sense of the resonant product in \((V * :\Psi^2:) \odot \Psi\) in a deterministic manner (given the pathwise regularities of \( \Psi \) and \( :\Psi^2: \)) and thus there is no need to include this term in the enhanced data set.

**Remark 2.9.** By including \((V * :\Psi^2:) \odot \Psi\) in the enhanced data set, we may extend Theorem 2.8 for \( \beta > 1 \) under the condition (2.33). Note, however, that it is not very meaningful to consider the focusing SdNLW (2.1) and thus the system (2.37) for \( \beta < 2 \) in view of Theorem 1.14 since the nonlinearity, especially the terms involving \( M_\gamma \), is derived from the potential energy in the Gibbs measure.

### 3. Notations and Basic Lemmas

In describing regularities of functions and distributions, we use \( \varepsilon > 0 \) to denote a small constant. We often suppress the dependence on such \( \varepsilon > 0 \) in an estimate.

#### 3.1. Sobolev and Besov spaces

Let \( s \in \mathbb{R} \) and \( 1 \leq p \leq \infty \). We define the \( L^2 \)-based Sobolev space \( H^s(\mathbb{T}^d) \) by the norm:

\[
\|f\|_{H^s} = \|\langle n \rangle^s \hat{f}(n)\|_{L^2}.
\]

We also define the \( L^p \)-based Sobolev space \( W^{s, p}(\mathbb{T}^d) \) by the norm:

\[
\|f\|_{W^{s, p}} = \|F^{-1}[\langle n \rangle^s \hat{f}(n)]\|_{L^p}.
\]

When \( p = 2 \), we have \( H^s(\mathbb{T}^d) = W^{s, 2}(\mathbb{T}^d) \).
Let \( \phi : \mathbb{R} \rightarrow [0,1] \) be a smooth bump function supported on \([-\frac{8}{5}, \frac{8}{5}] \) and \( \phi \equiv 1 \) on \([-\frac{5}{4}, \frac{5}{4}] \). For \( \xi \in \mathbb{R}^d \), we set \( \phi_0(\xi) = \phi(|\xi|) \) and
\[
\phi_j(\xi) = \phi(\frac{|\xi|}{2^j}) - \phi(\frac{|\xi|}{2^{j-1}})
\]
for \( j \in \mathbb{N} \). Then, for \( j \in \mathbb{Z}_{\geq 0} := \mathbb{N} \cup \{0\} \), we define the Littlewood-Paley projector \( P_j \) as the Fourier multiplier operator with a symbol \( \varphi_j \) given by
\[
\varphi_j(\xi) = \frac{\phi_j(\xi)}{\sum_{k \in \mathbb{Z}_{\geq 0}} \phi_k(\xi)}.
\]
Note that, for each \( \xi \in \mathbb{R}^d \), the sum in the denominator is over finitely many \( k \)'s. Thanks to the normalization (3.1), we have
\[
f = \sum_{j=0}^{\infty} P_j f.
\]

Let us now recall the definition and basic properties of paraproducts introduced by Bony [8]. See [3, 39] for further details. Given two functions \( f \) and \( g \) on \( \mathbb{T}^d \) of regularities \( s_1 \) and \( s_2 \), we write the product \( fg \) as
\[
fg = f \circ g + f \circ g + f \circ g
\]
\[
:= \sum_{j<k-2} P_j f P_k g + \sum_{|j-k|\leq 2} P_j f P_k g + \sum_{k<j-2} P_j f P_k g. \tag{3.2}
\]

Next, we recall the basic properties of the Besov spaces \( B^{s}_{p,q}(\mathbb{T}^d) \) defined by the norm:
\[
\|u\|_{B^{s}_{p,q}} = \left\| \left\|2^n \|P_j u\|_{L^p} \right\|_{\ell^q(\mathbb{Z}_{\geq 0})} \right\|
\]
We denote the Hölder-Besov space by \( C^s(\mathbb{T}^d) = B^{s}_{\infty,\infty}(\mathbb{T}^d) \). Note that (i) the parameter \( s \) measures differentiability and \( p \) measures integrability, (ii) \( H^s(\mathbb{T}^d) = B^s_{2,2}(\mathbb{T}^d) \), and (iii) for \( s > 0 \) and not an integer, \( C^s(\mathbb{T}^d) \) coincides with the classical Hölder spaces \( C^s(\mathbb{T}^d) \); see [38].

We recall the basic estimates in Besov spaces. See [3, 45] for example.

**Lemma 3.1.** The following estimates hold.

(i) (interpolation) Let \( s, s_1, s_2 \in \mathbb{R} \) and \( p, p_1, p_2 \in (1,\infty) \) such that \( s = \theta s_1 + (1-\theta)s_2 \) and \( \frac{1}{p} = \frac{\theta}{p_1} + \frac{1-\theta}{p_2} \) for some \( 0 < \theta < 1 \). Then, we have\(^\text{24}\)
\[
\|u\|_{W^{s,p}} \lesssim \|u\|_{W^{s_1,p_1}}^{\theta} \|u\|_{W^{s_2,p_2}}^{1-\theta}, \tag{3.3}
\]
(ii) (immediate embeddings) Let \( s_1, s_2 \in \mathbb{R} \) and \( p_1, p_2, q_1, q_2 \in [1,\infty] \). Then, we have
\[
\|u\|_{B^{s_1}_{p_1,q_1}} \lesssim \|u\|_{B^{s_2}_{p_2,q_2}} \quad \text{for } s_1 \leq s_2, p_1 \leq p_2, \text{ and } q_1 \geq q_2,
\]
\[
\|u\|_{B^{s_1}_{p_1,q_1}} \lesssim \|u\|_{B^{s_2}_{p_2,q_2}} \quad \text{for } s_1 < s_2,
\]
\[
\|u\|_{B^{s_1}_{p_1,q_1}} \lesssim \|u\|_{L^{q_1}} \lesssim \|u\|_{B^{s_2}_{p_2,q_2}} \tag{3.4}
\]
(iii) (algebra property) Let \( s > 0 \). Then, we have
\[
\|uv\|_{C^s} \lesssim \|u\|_{C^s} \|v\|_{C^s}. \tag{3.5}
\]
\(^\text{24}\)We use the convention that the symbol \( \lesssim \) indicates that inessential constants are suppressed in the inequality.
(iv) (Besov embedding) Let \(1 \leq p_2 \leq p_1 \leq \infty, q \in [1, \infty], \) and \(s_2 = s_1 + d\left(\frac{1}{p_2} - \frac{1}{p_1}\right).\) Then, we have

\[ \|u\|_{B_{p_1,q}^{s_1}} \lesssim \|u\|_{B_{p_2,q}^{s_2}}. \]

(v) (duality) Let \(s \in \mathbb{R} \) and \(p, p', q, q' \in [1, \infty] \) such that \(\frac{1}{p} + \frac{1}{p'} = \frac{1}{q} + \frac{1}{q'} = 1.\) Then, we have

\[ \left| \int_{\mathbb{T}^d} uv \, dx \right| \leq \|u\|_{B_{p,q}^{s}} \|v\|_{B_{p',q'}^{-s}'}, \] (3.6)

where \(\int_{\mathbb{T}^d} uv \, dx\) denotes the duality pairing between \(B_{p,q}^{s}(\mathbb{T}^d)\) and \(B_{p',q'}^{-s}'(\mathbb{T}^d).\)

(vi) (fractional Leibniz rule) Let \(p, p_1, p_2, p_3, p_4 \in [1, \infty] \) such that \(\frac{1}{p_1} + \frac{1}{p_2} = \frac{1}{p_3} + \frac{1}{p_4} = \frac{1}{p}.\) Then, for every \(s > 0,\) we have

\[ \|uv\|_{B_{p,q}^{s}} \lesssim \|u\|_{B_{p_1,q}^{s_1}} \|v\|_{L^{p_2}} + \|u\|_{L^{p_3}} \|v\|_{B_{p_4,q}^{s}}. \] (3.7)

The interpolation (3.3) follows from the Littlewood-Paley characterization of Sobolev norms via the square function and Hölder’s inequality.

Lemma 3.2 (paraproduct and resonant product estimates). Let \(s_1, s_2 \in \mathbb{R} \) and \(1 \leq p, p_1, p_2, q \leq \infty\) such that \(\frac{1}{p} = \frac{1}{p_1} + \frac{1}{p_2}.\) Then, we have

\[ \|f \otimes g\|_{B_{p,q}^{s_2}} \lesssim \|f\|_{L^{p_1}} \|g\|_{B_{p_2,q}^{s_2}}. \] (3.8)

When \(s_1 < 0,\) we have

\[ \|f \otimes g\|_{B_{p,q}^{s_1+s_2}} \lesssim \|f\|_{B_{p_1,q}^{s_1}} \|g\|_{B_{p_2,q}^{s_2}}. \] (3.9)

When \(s_1 + s_2 > 0,\) we have

\[ \|f \otimes g\|_{B_{p,q}^{s_1+s_2}} \lesssim \|f\|_{B_{p_1,q}^{s_1}} \|g\|_{B_{p_2,q}^{s_2}}. \] (3.10)

The product estimates (3.8), (3.9), and (3.10) follow easily from the definition (3.2) of the paraproduct and the resonant product. See [3, 55] for details of the proofs in the non-periodic case (which can be easily extended to the current periodic setting).

We also recall the following product estimate from [42].

Lemma 3.3. Let \(0 \leq s \leq 1.\)

(i) Let \(1 < p_j, q_j, r < \infty, j = 1, 2\) such that \(\frac{1}{r} = \frac{1}{p_j} + \frac{1}{q_j}.\) Then, we have

\[ \|\langle \nabla \rangle^s (fg)\|_{L^r(\mathbb{T}^3)} \lesssim \|\langle \nabla \rangle^s f\|_{L^{p_1}(\mathbb{T}^3)} \|g\|_{L^{q_1}(\mathbb{T}^3)} + \|f\|_{L^{p_2}(\mathbb{T}^3)} \|\langle \nabla \rangle^s g\|_{L^{q_2}(\mathbb{T}^3)}. \]

(ii) Let \(1 < p, q, r < \infty\) such that \(s \geq 3\left(\frac{1}{p} + \frac{1}{q} - \frac{1}{r}\right).\) Then, we have

\[ \|\langle \nabla \rangle^{-s} (fg)\|_{L^r(\mathbb{T}^3)} \lesssim \|\langle \nabla \rangle^{-s} f\|_{L^{p}(\mathbb{T}^3)} \|\langle \nabla \rangle^s g\|_{L^{q}(\mathbb{T}^3)}. \]

Note that while Lemma 3.3 was shown only for \(s = 3\left(\frac{1}{p} + \frac{1}{q} - \frac{1}{r}\right)\) in [42], the general case \(s \geq 3\left(\frac{1}{p} + \frac{1}{q} - \frac{1}{r}\right)\) follows the embedding \(L^{p_1}(\mathbb{T}^3) \subset L^{p_2}(\mathbb{T}^3),\) \(p_1 \geq p_2.\)
3.2. **On discrete convolutions.** Next, we recall the following basic lemma on a discrete convolution.

**Lemma 3.4.** (i) Let \( d \geq 1 \) and \( \alpha, \beta \in \mathbb{R} \) satisfy
\[
\alpha + \beta > d \quad \text{and} \quad \alpha < d.
\]
Then, we have
\[
\sum_{n=n_1+n_2} \frac{1}{(n_1)^\alpha (n_2)^\beta} \lesssim \langle n \rangle^{-\alpha + \lambda}
\]
for any \( n \in \mathbb{Z}^d \), where \( \lambda = \max(d - \beta, 0) \) when \( \beta \neq d \) and \( \lambda = \varepsilon \) when \( \beta = d \) for any \( \varepsilon > 0 \).

(ii) Let \( d \geq 1 \) and \( \alpha, \beta \in \mathbb{R} \) satisfy \( \alpha + \beta > d \). Then, we have
\[
\sum_{n=n_1+n_2} \frac{1}{(n_1)^\alpha (n_2)^\beta} \lesssim \langle n \rangle^{d - \alpha - \beta}
\]
for any \( n \in \mathbb{Z}^d \).

Namely, in the resonant case (ii), we do not have the restriction \( \alpha, \beta < d \). Lemma 3.4 follows from elementary computations. See, for example, [34, Lemma 4.2] and [57, Lemmas 4.1 and 4.2].

We also need the following lemma, where we establish a uniform bound with respect to the coefficients for a non-integer variable \( n_0 \) defined in (3.12).

**Lemma 3.5.** Let \( \beta \leq \frac{1}{2} \). Then, given \( \varepsilon > 0 \), we have
\[
\sum_{n_1, n_2 \in \mathbb{Z}^3} \frac{1}{(n_1)^2 (n_2)^2 (n_0)^{2\beta} (n_1 - n_2)^{2-2\beta+\varepsilon}} \leq C_\varepsilon < \infty,
\]
uniformly in \( t \gg s > 0 \), where \( n_0 \) is defined by
\[
n_0 = \frac{tn_1 + sn_2}{t + s}.
\]

**Proof.** Given dyadic numbers \( N, M \geq 1 \), we separately estimate the contributions from \( \langle n_1 \rangle \sim N \) and \( \langle n_2 \rangle \sim M \). Note that we have \( n_0 \sim n_1 + \frac{s}{t} n_2 \) under \( t \gg s > 0 \).

- **Case 1:** \( N \gg M \). In this case, we have
\[
\lambda := \langle n_1 \rangle^2 \langle n_2 \rangle^2 \langle n_0 \rangle^{2\beta} \langle n_1 - n_2 \rangle^{2 - 2\beta + \varepsilon} \sim N^{4+\varepsilon} M^2.
\]
  Thus, we have
\[
\text{LHS of (3.11)} \lesssim \sum_{N \gg M, \text{dyadic}} N^{-1-\varepsilon} M \lesssim 1.
\]

- **Case 2:** \( N \sim M \). In this case, we have \( \lambda \sim N^{4+2\beta} \langle n_1 - n_2 \rangle^{2 - 2\beta + \varepsilon} \). Thus, we have
\[
\text{LHS of (3.11)} \lesssim \sum_{N \geq 1, \text{dyadic}} N^{-4-2\beta} \sum_{n_1, n_2 \sim N} \frac{1}{\langle n_1 - n_2 \rangle^{2 - 2\beta + \varepsilon}}
\]
\[
\lesssim \sum_{N \geq 1, \text{dyadic}} N^{-4-2\beta} N^3 N^{3-(2-2\beta+\varepsilon)}
\]
\[
= \sum_{N \geq 1, \text{dyadic}} N^{-\varepsilon} \lesssim 1.
\]
• **Case 3:** $\frac{t}{s} N \gg M \gg N$. In this case, we have $\lambda \sim N^{2+2\beta} M^{4-2\beta+\epsilon}$. Thus, for $\beta \leq \frac{1}{2}$, we have

$$\text{LHS of (3.11)} \lesssim \sum_{M \gg N} N^{1-2\beta} M^{-1+2\beta-\epsilon} \lesssim 1.$$  

• **Case 4:** $\frac{t}{s} N \sim M \gg N$. In this case, we have $\lambda \sim N^2 M^{4-2\beta+\epsilon} \langle n_0 \rangle^{2\beta}$. Recalling $\langle n_0 \rangle \lesssim N$, we have

$$\text{LHS of (3.11)} \lesssim \sum_{N, M \geq 1, \text{dyadic}} N^{-2} M^{-4+2\beta-\epsilon} \sum_{\langle n_2 \rangle \sim M} \sum_{\langle n_1 \rangle \sim N} \frac{1}{\langle n_0 \rangle^{2\beta}} \lesssim 1,$$

provided that $\beta \leq \frac{1}{2}$.

• **Case 5:** $M \gg \frac{t}{s} N$. In this case, we have $\lambda \sim \left( \frac{t}{s} \right)^{2\beta} N^2 M^{4+\epsilon}$. Thus, we have

$$\text{LHS of (3.11)} \lesssim \left( \frac{t}{s} \right)^{2\beta} \sum_{N, M \geq 1, \text{dyadic}} N M^{-1-\epsilon} \lesssim 1,$$

provided that $\beta \leq \frac{1}{2}$. This proves Lemma 3.5. □

### 3.3. Tools from stochastic analysis

We conclude this section by recalling useful lemmas from stochastic analysis. See \[7, 77\] for basic definitions. Let $(H, B, \mu)$ be an abstract Wiener space. Namely, $\mu$ is a Gaussian measure on a separable Banach space $B$ with $H \subset B$ as its Cameron-Martin space. Given a complete orthonormal system $\{e_j\}_{j \in \mathbb{N}} \subset B^*$ of $H^* = H$, we define a polynomial chaos of order $k$ to be an element of the form $\prod_{j=1}^\infty H_{k_j}((x, e_j))$, where $x \in B$, $k_j \neq 0$ for only finitely many $j$’s, $k = \sum_{j=1}^\infty k_j$, $H_{k_j}$ is the Hermite polynomial of degree $k_j$, and $\langle \cdot, \cdot \rangle = B(\langle \cdot, \cdot \rangle_B)$ denotes the $B-B^*$ duality pairing. We then denote the closure of polynomial chaoses of order $k$ under $L^2(B, \mu)$ by $\mathcal{H}_k$. The elements in $\mathcal{H}_k$ are called homogeneous Wiener chaoses of order $k$. We also set

$$\mathcal{H}_{\leq k} = \bigoplus_{j=0}^k \mathcal{H}_j$$

for $k \in \mathbb{N}$.

Let $L = \Delta - x \cdot \nabla$ be the Ornstein-Uhlenbeck operator.\(^{25}\) Then, it is known that any element in $\mathcal{H}_k$ is an eigenfunction of $L$ with eigenvalue $-k$. Then, as a consequence of the hypercontractivity of the Ornstein-Uhlenbeck semigroup $U(t) = e^{tL}$ due to Nelson \[58\], we have the following Wiener chaos estimate \[78, \text{Theorem I.22}\]. See also \[80, \text{Proposition 2.4}\].

**Lemma 3.6.** Let $k \in \mathbb{N}$. Then, we have

$$\|X\|_{L^p(\Omega)} \leq (p - 1)^{\frac{1}{2}} \|X\|_{L^2(\Omega)}$$

for any $p \geq 2$ and any $X \in \mathcal{H}_{\leq k}$.

\(^{25}\)For simplicity, we write the definition of the Ornstein-Uhlenbeck operator $L$ when $B = \mathbb{R}^d$.\]
The following lemma will be used in studying regularities of stochastic objects. We say that a stochastic process $X : \mathbb{R}_+ \to \mathcal{D}'(\mathbb{T}^d)$ is spatially homogeneous if $\{X(\cdot, t)\}_{t \in \mathbb{R}_+}$ and $\{X(x_0 + \cdot, t)\}_{t \in \mathbb{R}_+}$ have the same law for any $x_0 \in \mathbb{T}^d$. Given $h \in \mathbb{R}$, we define the difference operator $\delta_h$ by setting
\[
\delta_h X(t) = X(t + h) - X(t). \tag{3.13}
\]

**Lemma 3.7.** Let $\{X_N\}_{N \in \mathbb{N}}$ and $X$ be spatially homogeneous stochastic processes $\mathbb{R}_+ \to \mathcal{D}'(\mathbb{T}^d)$. Suppose that there exists $k \in \mathbb{N}$ such that $X_N(t)$ and $X(t)$ belong to $\mathcal{H}_{\leq k}$ for each $t \in \mathbb{R}_+$.

(i) Let $t \in \mathbb{R}_+$. If there exists $s_0 \in \mathbb{R}$ such that
\[
\mathbb{E}[|\tilde{X}(n, t)|^2] \lesssim \langle n \rangle^{-d-2s_0}
\]
for any $n \in \mathbb{Z}^d$, then we have $X(t) \in W^{s, \infty}(\mathbb{T}^d)$, $s < s_0$, almost surely. Furthermore, if there exists $\gamma > 0$ such that
\[
\mathbb{E}[|\tilde{X}_N(n, t) - \tilde{X}(n, t)|^2] \lesssim N^{-\gamma} \langle n \rangle^{-d-2s_0}
\]
for any $n \in \mathbb{Z}^d$ and $N \geq 1$, then $X_N(t)$ converges to $X(t)$ in $W^{s, \infty}(\mathbb{T}^d)$, $s < s_0$, almost surely. The following bound also holds:
\[
\mathbb{E}[||X_N(t) - X(t)||_{W^{s, \infty}}^p] \lesssim p^\frac{k_p}{2} N^{-\gamma p}. \tag{3.14}
\]

(ii) Let $T > 0$ and suppose that (i) holds on $[0, T]$. If there exists $\sigma \in (0, 1)$ such that
\[
\mathbb{E}[|\delta_h \tilde{X}(n, t)|^2] \lesssim \langle n \rangle^{-d-2s_0 + \sigma |h|^\sigma},
\]
for any $n \in \mathbb{Z}^d$, $t \in [0, T]$, and $h \in [-1, 1]$ then we have $X \in C^\alpha([0, T]; W^{s, \infty}(\mathbb{T}^d))$, $\alpha < \sigma$ and $s < s_0 - \frac{\sigma}{2}$, almost surely. Furthermore, if there exists $\gamma > 0$ such that
\[
\mathbb{E}[|\delta_h \tilde{X}_N(n, t) - \delta_h \tilde{X}(n, t)|^2] \lesssim N^{-\gamma} \langle n \rangle^{-d-2s_0 + \sigma |h|^\sigma},
\]
for any $n \in \mathbb{Z}^d$, $t \in [0, T]$, $h \in [-1, 1]$, and $N \geq 1$, then $X_N$ converges to $X$ in $C^\alpha([0, T]; W^{s, \infty}(\mathbb{T}^d))$, $\alpha < \sigma$ and $s < s_0 - \frac{\sigma}{2}$, almost surely.

Lemma 3.7 follows from a straightforward application of the Wiener chaos estimate (Lemma 3.6). For the proof, see Proposition 3.6 in [57] and Appendix in [62]. As compared to Proposition 3.6 in [57], we made small adjustments. In studying the time regularity, we made the following modifications: $\langle n \rangle^{-d-2s_0 + 2\sigma} \mapsto \langle n \rangle^{-d-2s_0 + \sigma}$ and $s < s_0 - \sigma \mapsto s < s_0 - \frac{\sigma}{2}$ so that it is suitable for studying the wave equation. Moreover, while the result in [57] is stated in terms of the Hölder-Besov space $C^\alpha(\mathbb{T}^d) = B^s_{\infty, \infty}(\mathbb{T}^d)$, Lemma 3.7 handles the $L^\infty$-based Sobolev space $W^{s, \infty}(\mathbb{T}^d)$. Note that the required modification of the proof is straightforward since $W^{s, \infty}(\mathbb{T}^d)$ and $B^s_{\infty, \infty}(\mathbb{T}^d)$ differ only logarithmically.

Next, we recall the following corollary to the Garsia-Rodemich-Rumsey inequality ([31] Theorem A.1]). See Lemma 2.2 in [44] for the proof. See also Corollary A.5 in [31] for the $\alpha = 2$ case. This lemma is used to obtain the $L^\infty$-regularity of stochastic objects.

**Lemma 3.8.** Let $(E, d)$ be a metric space. Given $u \in C([0, T]; E)$, suppose that there exist $c_0 > 0$, $\theta \in (0, 1)$, and $\alpha > 0$ such that
\[
\int_{t_1}^{t_2} \int_{t_1}^{t_2} \exp \left\{ c_0 \left( \frac{d(u(t), u(s))}{|t - s|^{\theta}} \right)^\alpha \right\} dt ds =: F_{t_1, t_2} < \infty \tag{3.16}
\]
\[26\text{We impose } h \geq -t \text{ such that } t + h \geq 0.\]
for any $0 \leq t_1 \leq t_2 \leq T$ with $t_2 - t_1 \leq 1$. Then, we have
\[
\exp \left\{ \frac{c_0}{C} \left( \sup_{t_1 \leq s < t \leq t_2} \frac{d(u(t), u(s))}{\zeta(t-s)} \right)^{2} \right\} \leq \max(F(t_1, t_2, \varepsilon))
\]
for any $0 \leq t_1 \leq t_2 \leq T$ with $t_2 - t_1 \leq 1$, where $\zeta(t)$ is defined by
\[
\zeta(t) = \int_0^t \tau^{\theta-1} \left\{ \log \left( 1 + \frac{4}{\tau^2} \right) \right\} \frac{1}{\alpha} d\tau.
\]
Lastly, we recall the following Wick’s theorem. See Proposition I.2 in [78].

**Lemma 3.9.** Let $g_1, \ldots, g_{2n}$ be (not necessarily distinct) real-valued jointly Gaussian random variables. Then, we have
\[
\mathbb{E}[g_1 \cdots g_{2n}] = \sum_{k=1}^n \prod_{i=1}^k \mathbb{E}[g_{i_k} g_{j_k}],
\]
where the sum is over all partitions of $\{1, \ldots, 2n\}$ into disjoint pairs $(i_k, j_k)$.

Given $n \in \mathbb{Z}^3$ and $0 \leq t_2 \leq t_1$, define $\sigma_n(t_1, t_2)$ by
\[
\sigma_n(t_1, t_2) := \mathbb{E}[\hat{\Psi}(n, t_1) \hat{\Psi}(-n, t_2)] = e^{-\frac{1}{2}t_1 - \frac{1}{2}t_2} \left( \cos((t_1 - t_2)\|n\|) + \frac{\sin((t_1 - t_2)\|n\|)}{2\|n\|} \right),
\]
where $\Psi$ is as in (2.9). Then, by Wick’s theorem (Lemma 3.9) and (3.17), we have
\[
\mathbb{E}\left[ \left( \hat{\Psi}(n_1, t_1) \hat{\Psi}(n_2, t_1') - 1_{n_1+n_2=0} \cdot \sigma_n(t_1, t_1') \right) \times \left( \hat{\Psi}(n_1', t_2) \hat{\Psi}(n_2', t_2') - 1_{n_1'+n_2'=0} \cdot \sigma_n'(t_2, t_2') \right) \right] = 1_{n_1=n_1'} \cdot 1_{n_2=n_2'} \cdot \sigma_n(t_1, t_2) \sigma_n(t_1', t_2')
\]
for $n_1, n_2, n_1', n_2' \in \mathbb{Z}^3$ and $0 \leq t_2' \leq t_2 \leq t_1' \leq t_1$.

4. ON THE STOCHASTIC TERMS

In this section, we establish the regularity properties of the stochastic objects $\Psi$, $\sigma^2$, and $(V \ast \Psi^2) \ast \Psi$. We study the paracontrolled operators (and $\hat{A}$) in Section 7. First, we go over the regularity properties of the stochastic convolution $\Psi$ and the Wick power $\sigma^2$.

**Lemma 4.1.** Given $k = 1, 2$, let $\Psi^k_N : \Psi^k_N : \Psi^k_N$ denote the truncated Wick power defined in (2.11) for $k = 1$ and [2.13] for $k = 2$, respectively. Then, given any $T, \varepsilon > 0$ and finite $p \geq 1$, $\{\Psi^k_N \}_{N \in \mathbb{N}}$ is a Cauchy sequence in $L^p(\Omega; C([0, T]; W^{-\frac{k}{2} - \varepsilon, \infty}(\mathbb{T}^3)))$, converging to some limit $\Psi^k : \hat{\Psi} \in L^p(\Omega; C([0, T]; W^{-\frac{k}{2} - \varepsilon, \infty}(\mathbb{T}^3)))$. Moreover, $\Psi^k_N$ converges almost surely to the same limit in $C([0, T]; W^{-\frac{k}{2} - \varepsilon, \infty}(\mathbb{T}^3))$. Given any finite $\varepsilon \geq 1$, we have the following tail estimate:
\[
P\left( \| \Psi^k N \|_{L^p \left( W^{-\frac{k}{2} - \varepsilon, \infty}(\mathbb{T}^3) \right)} > \lambda \right) \leq C \exp \left( -c \frac{\lambda^2}{T^\varepsilon} \right)
\]
for any $T > 0$ and $\lambda > 0$. When $q = \infty$, we also have the following tail estimate:
\[
P\left( \| \Psi^k N \|_{L^\infty \left( W^{-\frac{k}{2} - \varepsilon, \infty}(\mathbb{T}^3) \right)} > \lambda \right) \leq C \exp \left( -c \lambda^2 \right)
\]
for any \( j \in \mathbb{Z}_{\geq 0} \) and \( \lambda > 0 \). Moreover, the tail estimates (4.1) and (4.2) also hold for \( :\Psi_N^k:)\), uniformly in \( N \in \mathbb{N} \).

Proof. From (3.17) and (3.18), we have

\[
\mathbb{E} \left[ |:\Psi^k:(n,t)|^2 \right] \lesssim \langle n \rangle^{-3+k} \tag{4.3}
\]

for \( n \in \mathbb{Z}^3 \) and \( 0 \leq t \leq T \). Then, the first part of the claim follows from Lemma 3.7. Indeed, the difference estimate (3.15) for \( \delta_n:\Psi^k:(n,t) \) follows from (4.3) and the mean value theorem as in the proof of Lemma 3.1 in [43]. Note that our stochastic convolution \( \Psi \) in (2.9) is for the damped wave equation and thus is slightly different from that for the undamped wave equation studied in [43]. Furthermore, \( \Psi \) in (2.9) has non-zero random initial data distributed by \( \tilde{\mu} \) in (1.18). This difference, however, is marginal and the argument in the proof of Lemma 3.1 in [43] can be easily modified to establish the convergence results. See also [42, 44].

Next, we prove the tail estimate (4.2). Since \( :\Psi^k:) \) is spatially homogeneous (i.e. its distribution is invariant under spatial translations), we have

\[
\mathbb{E} \left[ :\Psi^k:(n_1,t_1) :\Psi^k:(n_2,t_2) \right] = 0 \tag{4.4}
\]

unless \( n_1 = n_2 \). Indeed, by letting \( F_{t_1,t_2}(x,y) = \mathbb{E} \left[ :\Psi^k:(x,t_1) :\Psi^k:(y,t_2) \right] \), it follows from the spatial homogeneity that

\[
\text{LHS of (4.4)} = \int_{\mathbb{T}^3} \int_{\mathbb{T}^3} F_{t_1,t_2}(x,y)e_{n_1}(x)e_{-n_2}(y)dydx
\]

\[
= \int_{\mathbb{T}^3} \left( \int_{\mathbb{T}^3} F_{t_1,t_2}(0,y-x)e_{-n_2}(y-x)dy \right) e_{n_1-n_2}(x)dx
\]

which equals 0 unless \( n_1 = n_2 \) since the inner integral on the right-hand side is a constant independent of \( x \). This proves (4.4). Now, from (4.3) and (4.4), we have

\[
\mathbb{E} \left[ |(\nabla)^{-\frac{1}{2}-\varepsilon} :\Psi^k(x,t) |^2 \right] = \sum_{n \in \mathbb{Z}^3} \langle n \rangle^{-k-2\varepsilon} \mathbb{E} \left[ |:\Psi^k:(n,t)|^2 \right] \lesssim \sum_{n \in \mathbb{Z}^3} \langle n \rangle^{-3-2\varepsilon} \leq C_\varepsilon \tag{4.5}
\]

for any \( \varepsilon > 0 \), uniformly in \( x \in \mathbb{T}^3 \) and \( t \geq 0 \). Then, Minkowski’s integral inequality and the Wiener chaos estimate (Lemma 3.6), we obtain

\[
\left\| :\Psi^k:\right\|_{L^p\cap W^\frac{1}{2},-\varepsilon,\infty} \leq p^{\frac{1}{2}}T^{\frac{1}{q}} \tag{4.6}
\]

for any sufficiently large \( p \gg 1 \) (depending on \( q \geq 1 \)). The exponential tail estimate (4.1) follows from (4.6) and Chebyshev’s inequality (see also Lemma 4.5 in [86]).

Fix \( j \in \mathbb{Z}_{\geq 0} \) and \( \lambda > 0 \). Then, we have

\[
\mathbb{P} \left( \left\| :\Psi^k: \right\|_{L^\infty([j,j+1]:W^\frac{1}{2},-\varepsilon,\infty)} > \lambda \right) \leq \mathbb{P} \left( \left\| :\Psi^k:(j) \right\|_{W^\frac{1}{2},-\varepsilon,\infty} > \frac{\lambda}{2} \right) + \mathbb{P} \left( \sup_{t \in [j,j+1]} \left| :\Psi^k(t) : - :\Psi^k(j) : \right|_{W^\frac{1}{2},-\varepsilon,\infty} > \frac{\lambda}{2} \right). \tag{4.7}
\]

The first term on the right-hand side of (4.7) is for a fixed time \( t = j \) and thus can be controlled by the right-hand side of (4.2) as above, using (4.5). As for the second term on the right-hand
side of (4.7), a straightforward adaptation of the argument in the proof of [12, Proposition 2.1] to the current three-dimensional setting yields
\[ \| h \|^{-p} \| \delta_h(\Psi^k(t)) \|_{W^{\frac{1}{2} - \epsilon, \infty}} \leq p^\frac{1}{2} \]
for any sufficiently large \( p \gg 1, t \in [j, j + 1] \), and \( |h| \leq 1 \), where \( \delta_h \) is as in (3.13) and \( 0 < \rho < \epsilon \). Then, by applying Lemma 4.5 in [86], we obtain the following exponential bound:
\[ \mathbb{E} \left[ \exp \left\{ \left( \frac{\| : \Psi^k(\tau_2) : - : \Psi^k(\tau_1) : \|_{W^{\frac{1}{2} - \epsilon, \infty}}{|\tau_2 - \tau_1|^{\rho}}}{|2\epsilon|} \right)^\frac{2}{3} \right\} \right] \leq C < \infty, \] (4.8)
uniformly in \( j \leq \tau_1 < \tau_2 \leq j + 1 \) and \( j \in \mathbb{Z}_{\geq 0} \). By integrating (4.8) in \( \tau_1 \) and \( \tau_2 \), this verifies the hypothesis (3.16) of Lemma 3.8 (under an expectation). Finally, applying Lemma 3.8 and then Chebyshev’s inequality, we conclude that
\[ \mathbb{P} \left( \sup_{t \in [j,j+1]} \| : \Psi^k(t) : - : \Psi^k(j) : \|_{W^{\frac{1}{2} - \epsilon, \infty}} > \frac{h}{2} \right) \leq C \exp \left( - c\lambda^\frac{2}{3} \right). \]
This proves (4.2). \( \square \)

Next, we study the regularity of the resonant product \((V_\ast : \Psi^2 : \Psi) \in [2,20]\). Note that when \( \beta > \frac{3}{2} \), we can make sense of this resonant product in the deterministic manner and thus the following lemma is not needed in the focusing case.

**Lemma 4.2.** Let \( V \) be the Bessel potential of order \( \beta > 1 \) and set
\[ Z_N = (V_\ast : \Psi_N^2 : \Psi_N) \]
for \( N \in \mathbb{N} \). Then, given any \( T, \epsilon > 0 \) and finite \( p \geq 1 \), \( \{Z_N\}_{N \in \mathbb{N}} \) is a Cauchy sequence in \( L^p(\Omega; C([0,T]; W^{\beta - \frac{2}{3} - \epsilon, \infty}(\mathbb{T}^3))) \), converging to some limit
\[ Z = (V_\ast : \Psi^2) \in \mathbb{H}_{\leq 3} \]
in \( L^p(\Omega; C([0,T]; W^{\beta - \frac{3}{2} - \epsilon, \infty}(\mathbb{T}^3))) \). Moreover, \( Z_N \) converges almost surely to the same limit in \( C([0,T]; W^{\beta - \frac{3}{2} - \epsilon, \infty}(\mathbb{T}^3)) \). Given any finite \( q \geq 1 \), we have the following tail estimate:
\[ \mathbb{P} \left( \| Z \|_{L^q([j,j+1]; W^{\beta - \frac{3}{2} - \epsilon, \infty})} > \lambda \right) \leq C \exp \left( - c\lambda^\frac{2}{3} \right) \] (4.9)
for any \( T > 0 \) and \( \lambda > 0 \). When \( q = \infty \), we also have the following tail estimate:
\[ \mathbb{P} \left( \| Z \|_{L^{\infty}([j,j+1]; W^{\beta - \frac{3}{2} - \epsilon, \infty})} > \lambda \right) \leq C \exp \left( - c\lambda^\frac{2}{3} \right) \] (4.10)
for any \( j \in \mathbb{Z}_{\geq 0} \) and \( \lambda > 0 \). Moreover, the tail estimates (4.9) and (4.10) also hold for \( Z_N \), uniformly in \( N \in \mathbb{N} \).

**Proof.** Note that \((V_\ast : \Psi^2) \in \mathbb{H}_{\leq 3}\). Thus, in view of Lemma 3.7, it suffices to show
\[ \mathbb{E} [ \tilde{Z}(n,t)^2 ] \leq (n)^{-2\beta}, \] (4.11)
for \( n \in \mathbb{Z}^3 \) and \( 0 \leq t \leq T \). As mentioned above, the difference estimate (3.15) for \( \delta_h \tilde{Z}(n,t) \) follows from (4.11) and the mean value theorem as in the proof of Lemma 3.1 in [13]. Also, an adaptation of the argument in the proof of Lemma 3.1 in [13] yields the claimed convergence.
results. As for the exponential tail estimates (4.9) and (4.10), from the spatial homogeneity of \( Z \) and (4.11), we first obtain
\[
\mathbb{E}[|⟨\nabla⟩^{β} - \frac{3}{2} - ε Z(x, t)|^2] \lesssim \sum_{n ∈ \mathbb{Z}^3} ⟨n⟩^{-3-2ε} \lesssim C_ε
\]
for any \( ε > 0 \), uniformly in \( x ∈ \mathbb{T}^3 \) and \( t ≥ 0 \). Then, we can proceed as in the proof of Lemma 4.1 to conclude the exponential tail estimates (4.9) and (4.10).

In the following, we focus on proving the bound (4.11). Using (2.13), we write \( \hat{Z}(n, t) \) as follows:
\[
\hat{Z}(n, t) = \sum_{n_1, n_2, n_3 ∈ \mathbb{Z}^3} \hat{V}(n_1 + n_2)\left(\hat{Ψ}(n_1, t)\hat{Ψ}(n_2, t) - 1_{n_1+n_2=0}⋅⟨n_1⟩^{-2}\right)\hat{Ψ}(n_3, t)
\]
\[
= \sum_{n_1, n_2, n_3 ∈ \mathbb{Z}^3, |n_3| ≈ |n_1+n_2|} \hat{V}(n_1 + n_2)\hat{Ψ}(n_1, t)\hat{Ψ}(n_2, t)\hat{Ψ}(n_3, t)
\]
\[
+ \sum_{n_1 ∈ \mathbb{Z}^3} 1_{|n| ≈ 1} \hat{V}(0)\left(⟨\hat{Ψ}(n_1, t)⟩^2 - ⟨n_1⟩^{-2}\right)\hat{Ψ}(n, t)
\]
\[
=: \hat{Z}_1(n, t) + \hat{Z}_2(n, t),
\]
where we used \( |n_1 + n_2| ≈ |n_3| \) and \( |n| ≈ 1 \) to signify the resonant product \( ⊗ \) in the definition of \( Z = (V_∗ : Ψ^2) ⊗ Ψ \). From (3.18) with (3.17), we have
\[
\mathbb{E}[|\hat{Z}_2(n, t)|^2] \lesssim 1_{|n| ≈ 1} \sum_{n_1 ∈ \mathbb{Z}^3} \frac{1}{⟨n_1⟩^4} \lesssim 1_{|n| ≈ 1}, \tag{4.13}
\]
verifying (4.11) for \( Z_2 \). We now decompose \( \hat{Z}_1(n, t) \) as
\[
\hat{Z}_1(n, t) = \sum_{n_1, n_2, n_3 ∈ \mathbb{Z}^3} \hat{V}(n_1 + n_2)\hat{Ψ}(n_1, t)\hat{Ψ}(n_2, t)\hat{Ψ}(n_3, t)
\]
\[
+ 2\hat{Ψ}(n, t) \sum_{n_2 ∈ \mathbb{Z}^3} \hat{V}(n + n_2)\left(⟨\hat{Ψ}(n_2, t)⟩^2 - ⟨n_2⟩^{-2}\right)
\]
\[
+ 2\hat{Ψ}(n, t) \sum_{n_2 ∈ \mathbb{Z}^3} \hat{V}(n + n_2)⟨n_2⟩^{-2}
\]
\[
- 1_{n≠0} \hat{V}(2n)⟨\hat{Ψ}(n, t)⟩^2\hat{Ψ}(n, t)
\]
\[
=: \hat{Z}_{11}(n, t) + \hat{Z}_{12}(n, t) + \hat{Z}_{13}(n, t) + \hat{Z}_{14}(n, t). \tag{4.14}
\]
Here, \( Z_{12} \) denotes the renormalized contribution from \( n_3 = n_1, n_2 \), while \( Z_{13} \) is the counter term. From (1.3) and (2.9), we have
\[
\mathbb{E}[|\hat{Z}_{14}(n, t)|^2] \lesssim ⟨n⟩^{-2β-6}, \tag{4.15}
\]
verifying \((4.11)\). Under the condition \(|n + n_2| \sim |n_2|\), we have \(|n_2| \gtrsim |n|\). Then, it follows from \((1.3)\), \((3.17)\), and Lemma 3.4 that

\[
\mathbb{E}[|\hat{Z}_{13}(n, t)|^2] = 4\langle n \rangle^{-2} \left( \sum_{n_2 \in \mathbb{Z}^3} \langle n + n_2 \rangle^{-\beta} \langle n_2 \rangle^{-2} \right)^2 \lesssim \langle n \rangle^{-2\beta} \tag{4.16}
\]

provided that \(\beta > 1\). Similarly, we have

\[
\mathbb{E}[|\hat{Z}_{12}(n, t)|^2] \lesssim \langle n \rangle^{-2} \sum_{n_2 \in \mathbb{Z}^3} \langle n + n_2 \rangle^{-2\beta} \langle n_2 \rangle^{-4} \lesssim \langle n \rangle^{-2\beta - 3} \tag{4.17}
\]

for \(\beta > -\frac{1}{2}\). Finally, we consider the estimate for \(\hat{Z}_{11}(n, t)\). The condition \(|n_1 + n_2| \sim |n_3|\) implies \(|n_1 + n_2| \sim |n_3| \gtrsim |n|\). From \((1.3)\), Wick’s theorem (Lemma 3.9), and Lemma 3.4, we have

\[
\mathbb{E}[|\hat{Z}_{11}(n, t)|^2] = \sum_{n_1, n_2, n_3 \in \mathbb{Z}^3} \sum_{n_1', n_2', n_3' \in \mathbb{Z}^3} \hat{V}(n_1 + n_2) \hat{V}(n_1' + n_2') \times \mathbb{E} \left[ \hat{\Psi}(n_1, t) \hat{\Psi}(n_2, t) \hat{\Psi}(n_3, t) \hat{\Psi}(n_1', t) \hat{\Psi}(n_2', t) \hat{\Psi}(n_3', t) \right] \lesssim \langle n \rangle^{-\beta} \sum_{n_1, n_3 \in \mathbb{Z}^3} \langle n - n_3 \rangle^{-2} \langle n_1 \rangle^{-2} \langle n_2 \rangle^{-2} \langle n_3 \rangle^{-2} \tag{4.18}
\]

for \(\beta > 0\). Putting \((4.12)\) - \((4.18)\) together, we obtain the desired bound \((4.11)\). \(\square\)

**Remark 4.3.** The assumption \(\beta > 1\) was used to estimate \(Z_{13}\) in \((4.16)\), while the other terms can be controlled under \(\beta > 0\). Note that when \(\beta \leq 1\), \((4.16)\) yields

\[
\mathbb{E}[|\hat{Z}_{13}(n, t)|^2] \gtrsim \langle n \rangle^{-2} \left( \sum_{n_2 \in \mathbb{Z}^3} \langle n_2 \rangle^{-\beta - 2} \right)^2 = \infty.
\]

From this, we conclude that \(Z \not\in C([0, T]; D'(\mathbb{T}^3))\) almost surely when \(\beta \leq 1\). See, for example, Subsection 4.4 in [59]. For \(\beta \leq 1\), we introduce a renormalization to remove this problematic term \(Z_{13}\). See \((6.13)\) below.
5. Construction of the Gibbs measures

In this section, we present the construction and non-normalizability of the Gibbs measures. We first discuss the defocusing case (Theorem 1.10) for $\beta > 1$. Then, we present the full proof of Theorem 1.14 in the focusing case. The remaining part of the defocusing case ($0 < \beta \leq 1$) is presented in Section 6. Our proofs rely on the variational formulation of the partition function due to Barashkov-Gubinelli \cite{4}. See Lemma 5.3 and the Boué-Dupuis variational formula (Lemma 5.11) below.

We first consider the defocusing case. In the following, we study the truncated Gibbs measure $\rho_N$ defined in (1.28):

$$d\rho_N = Z_N^{-1} e^{-R_N(u)} d\mu,$$

where $R_N$ is as in (1.27) and $Z_N$ denotes the partition function:

$$Z_N = \int e^{-R_N(u)} d\mu.$$  \hspace{1cm} (5.1)

In what follows, we prove various statements in terms of $\mu$ but they can be trivially upgraded to the corresponding statement for $\tilde{\mu} = \mu_1 \otimes \mu_0$.

First, we state the convergence property of $R_N$.

**Lemma 5.1.** Let $V$ satisfy (1.52) with $\beta > 1$. Then, given any finite $p \geq 1$, $R_N$ defined in (1.27) converges to some $R$ in $L^p(\mu)$ as $N \to \infty$. Moreover, for $\gamma > 0$, $R_N$ defined in (1.46) converges to some $\mathcal{R}$ in $L^p(\mu)$ as $N \to \infty$.

We point out that the proof of Lemma 5.1 does not rely on the positivity of $\hat{V}$. See Subsection 5.1 for the details. Note that Lemma 5.1 implies convergence in measure of $\left\{ e^{-R_N(u)} \right\}_{N \in \mathbb{N}}$ (in the defocusing case). Then, the desired convergence (1.30) of the density follows from a standard argument, once we prove the uniform exponential integrability (1.29). See Remark 3.8 in \cite{85}. See also the proof of Proposition 1.2 in \cite{70}. The same comment applies to the focusing case.

In establishing the uniform exponential integrability bounds (1.30) and (1.48), we employ the variational approach as in \cite{4}. In Subsection 5.2, we briefly go over the setup for the variational formulation of the partition function from \cite{4, 45}. In Subsection 5.3, we then present the uniform exponential integrability (1.29) for $\beta > 1$ in the defocusing case. We then move onto the focusing case. We go over the construction of the focusing Gibbs measure for $\beta > 2$ in Subsection 5.4 and the non-normalizability in Subsection 5.5. In Subsection 5.6, we prove the uniform exponential integrability (1.48) in the weakly nonlinear regime at the critical value $\beta = 2$.

Recall our convention that $\sigma = -1$ in the defocusing case, since a precise value of $\sigma < 0$ does not play an important role.

5.1. Proof of Lemma 5.1. We only consider the case $p = 2$. The convergence for general $p \geq 1$ follows from the $p = 2$ case and the Wiener chaos estimate (Lemma 3.6). Furthermore, in the following, we only show

$$\sup_{N \in \mathbb{N}} \| R_N(u) \|_{L^2(\mu)} < \infty \quad \text{and} \quad \sup_{N \in \mathbb{N}} \| R_N(u) \|_{L^2(\mu)} < \infty$$ \hspace{1cm} (5.2)

since a slight modification of the argument presented below implies the convergence of $\{ R_N \}_{N \in \mathbb{N}}$ and $\{ \mathcal{R}_N \}_{N \in \mathbb{N}}$ in $L^2(\mu)$. 
Define $Q_N(u)$ by

$$Q_N(u) := \int_{\mathbb{T}^3} (V : u_N^2) : u_N^2 : dx - \hat{V}(0) \left( \int_{\mathbb{T}^3} : u_N^2 : dx \right)^2 - 2\alpha_N \quad (5.3)$$

where $\alpha_N$ is as in (1.26). Then, we can write $R_N(u)$ and $\mathcal{R}_N(u)$ in (1.27) and (1.46) as

$$R_N(u) = \frac{1}{4} Q_N(u) + \frac{\hat{V}(0)}{4} \left( \int_{\mathbb{T}^3} : u_N^2 : dx \right)^2, \quad (5.4)$$
$$\mathcal{R}_N(u) = \frac{\sigma}{4} Q_N(u) + \frac{\sigma \hat{V}(0)}{4} \left( \int_{\mathbb{T}^3} : u_N^2 : dx \right)^2 - A \left| \int_{\mathbb{T}^3} : u_N^2 : dx \right|^\gamma. \quad (5.5)$$

By the Wiener chaos estimate (Lemma 3.6), we have

$$\left\| \int_{\mathbb{T}^3} : u_N^2 : dx \right\|_{L^p(\mu)}^p \lesssim C_p \left\| \int_{\mathbb{T}^3} : u_N^2 : dx \right\|_{L^2(\mu)}^p \lesssim C_p \left( \sum_{n \in \mathbb{Z}^3} \langle n \rangle^{-4} \right)^{\frac{p}{2}} < \infty$$

for any finite $p > 0$. Hence, the desired bounds (5.2) follow once we prove

$$\sup_{N \in \mathbb{N}} \| Q_N(u) \|_{L^2(\mu)} < \infty. \quad (5.6)$$

From Parseval’s identity (see (1.25)) with (5.3), (1.24), and (1.26), we have

$$Q_N(u) = \sum_{n_1, n_2, n_3, n_4 \in \mathbb{Z}^3} \hat{V}(n_1 + n_2) \hat{u}_N(n_1) \hat{u}_N(n_2) \hat{u}_N(n_3) \hat{u}(n_4)$$
$$+ 2 \sum_{n_1, n_2 \in \mathbb{Z}^3} \hat{V}(n_1 + n_2) \left( |\hat{u}_N(n_1)|^2 - \langle n_1 \rangle^{-2} \right) \left( |\hat{u}_N(n_2)|^2 - \langle n_2 \rangle^{-2} \right)$$
$$+ 4 \sum_{n_1, n_2 \in \mathbb{Z}^3} \hat{V}(n_1 + n_2) \left( |\hat{u}_N(n_1)|^2 - \langle n_1 \rangle^{-2} \right) \langle n_2 \rangle^{-2}$$
$$- \sum_{n_1 \in \mathbb{Z}^3} \hat{V}(2n_1) |\hat{u}_N(n_1)|^4$$
$$=: Q_{N,1}(u) + Q_{N,2}(u) + Q_{N,3}(u) + Q_{N,4}(u). \quad (5.7)$$

From (1.52) and Wick’s theorem (Lemma 3.9), $Q_{N,1}(u)$ is estimated as follows:

$$\| Q_{N,1}(u) \|_{L^2(\mu)}^2 \lesssim \sum_{n_1, n_2, n_3, n_4 \in \mathbb{Z}^3} \langle n_1 + n_2 \rangle^{-2\beta} \langle n_1 \rangle^{-2} \langle n_2 \rangle^{-2} \langle n_3 \rangle^{-2} \langle n_4 \rangle^{-2}$$
$$+ \sum_{n_1, n_2, n_3, n_4 \in \mathbb{Z}^3} \langle n_1 + n_2 \rangle^{-\beta} \langle n_1 + n_3 \rangle^{-\beta} \langle n_1 \rangle^{-2} \langle n_2 \rangle^{-2} \langle n_3 \rangle^{-2} \langle n_4 \rangle^{-2}$$
By Cauchy’s inequality, symmetry, and Lemma 3.4,
\[
\lesssim \sum_{n_1,n_2,n_3 \in \mathbb{Z}^3} \langle n_1 + n_2 \rangle^{-2\beta} \langle n_1 \rangle^{-2} \langle n_2 \rangle^{-2} \langle n_3 \rangle^{-2} \langle n_1 + n_2 + n_3 \rangle^{-2}
\lesssim \sum_{n_1,n_2 \in \mathbb{Z}^3} \langle n_1 + n_2 \rangle^{-2\beta-1} \langle n_1 \rangle^{-2} \langle n_2 \rangle^{-2}
\lesssim \sum_{n_1 \in \mathbb{Z}^3} \langle n_1 \rangle^{-2-\min(2\beta,2-\varepsilon)} < \infty
\]  
for any small $\varepsilon > 0$, provided that $\beta > \frac{1}{2}$. From (5.7) and (3.18), we have
\[
\|Q_{N,2}(u)\|_{L^2(\mu)}^2 \lesssim \sum_{n_1,n_2 \in \mathbb{Z}^3} \langle n_1 + n_2 \rangle^{-2\beta} \langle n_1 \rangle^{-4} \langle n_2 \rangle^{-4} + \left( \sum_{n_1 \in \mathbb{Z}^3} \langle 2n_1 \rangle^{-\beta} \langle n_1 \rangle^{-4} \right)^2 
\lesssim \left( \sum_{n_1 \in \mathbb{Z}^3} \langle n_1 \rangle^{-4} \right)^2 < \infty
\]  
for $\beta \geq 0$. As for $Q_{N,3}(u)$, we first note that
\[
Q_{N,3}(u) = 4 \sum_{n_1 \in \mathbb{Z}^3} \left( |\tilde{u}_N(n_1)|^2 - \langle n_1 \rangle^{-2} \right) \kappa_N(n_1),
\]  
where $\kappa_N$ is defined in (1.36). Hence, from (3.18) and the uniform boundedness of $\kappa_N$ for $\beta > 1$, we obtain
\[
\|Q_{N,3}(u)\|_{L^2(\mu)}^2 \lesssim \sum_{n_1 \in \mathbb{Z}^3} \kappa(n_1) \langle n_1 \rangle^{-4} \lesssim \sum_{n_1 \in \mathbb{Z}^3} \langle n_1 \rangle^{-4} < \infty.
\]  
Lastly, we have
\[
Q_{N,4}(u) \|_{L^2(\mu)}^2 \lesssim \left( \sum_{n_1 \in \mathbb{Z}^3} \langle n_1 \rangle^{-\beta-4} \right)^2 < \infty.
\]  
Therefore, putting (5.7) - (5.11) together, we obtain (5.6). This proves Lemma 5.1.

**Remark 5.2.** For a potential $V$ satisfying $\hat{V}(n) \gtrsim (n)^{-\beta}$, $n \in \mathbb{Z}^3$, for some $\beta \leq 1$, we have
\[
\lim_{N \to \infty} \|Q_N(u)\|_{L^2(\mu)} = \infty.
\]  
The argument above shows that while $Q_{N,1}$, $Q_{N,2}$, and $Q_{N,4}$ are uniformly bounded in $L^2(\mu)$ for $\beta > \frac{1}{2}$, $Q_{N,3}$ becomes divergent for $\beta \leq 1$ due to the unboundedness of $\kappa_N$. For $\frac{1}{2} < \beta \leq 1$, we can introduce the second renormalization as in (1.38). This precisely removes the divergent term $Q_{N,3}$, allowing us to prove an analogue of Lemma 5.1 for $R_{N}^\circ(u)$ defined in (1.38). For this renormalized potential energy $R_{N}^\circ(u)$, the uniform exponential integrability holds true for $\beta > \frac{1}{2}$. See Section 6.

For $0 < \beta \leq \frac{1}{2}$, the first term $Q_{N,1}$ in (5.7) also becomes divergent. This term, however, constitutes the main contribution for the potential energy and thus can not be removed by a renormalization, causing the singularity of the resulting Gibbs measure to the base Gaussian measure in this case. See Subsection 6.4.
5.2. **Variational formulation.** In order to prove (1.29), we follow the argument in [4,45] and derive a variational formula for the partition function $Z_N$ in (5.1). Let us first introduce some notations. See also Section 4 in [45]. Let $W(t)$ be the cylindrical Wiener process in (2.10). We define a centered Gaussian process $Y(t)$ by

$$Y(t) = \langle \nabla \rangle^{-1} W(t).$$

(5.12)

Then, we have $\text{Law}(Y(1)) = \mu$. By setting $Y_N = \pi_N Y$, we have $\text{Law}(Y_N(1)) = (\pi_N)\#\mu_1$. In particular, we have $\mathbb{E}[Y_N^2(1)] = \sigma_N$, where $\sigma_N$ is as in (1.23).

Next, let $\mathbb{H}_a$ denote the space of drifts, which are the progressively measurable processes that belong to $L^2([0,1]; L^2(\mathbb{T}^3))$, $\mathbb{P}$-almost surely. Given a drift $\theta \in \mathbb{H}_a$, we define the measure $\mathbb{Q}_\theta$ whose Radon-Nikodym derivative with respect to $\mathbb{P}$ is given by the following stochastic exponential:

$$\frac{d\mathbb{Q}_\theta}{d\mathbb{P}} = e^{\int_0^1 \langle \theta(t), dW(t) \rangle - \frac{1}{2} \int_0^1 \|\theta(t)\|^2_{L^2} dt},$$

where $\langle \cdot, \cdot \rangle$ stands for the usual inner product on $L^2(\mathbb{T}^3)$. Then, by letting $\mathbb{H}_c$ denote the subspace of $\mathbb{H}_a$ consisting of drifts such that $\mathbb{Q}_\theta(\Omega) = 1$, it follows from Girsanov’s theorem ([74, Theorems 1.4 and 1.7 in Chapter VIII]) that $W$ is a semi-martingale under $\mathbb{Q}_\theta$ with the following decomposition:

$$W(t) = W_\theta(t) + \int_0^t \theta(t') dt',$$

(5.13)

where $W_\theta$ is now an $L^2(\mathbb{T}^2)$-cylindrical Wiener process under the new measure $\mathbb{Q}_\theta$. Substituting (5.13) in (5.12) leads to the decomposition:

$$Y = Y_\theta + I(\theta),$$

where

$$Y_\theta(t) = \langle \nabla \rangle^{-1} W_\theta(t) \quad \text{and} \quad I(\theta)(t) = \int_0^t \langle \nabla \rangle^{-1} \theta(t') dt'.$$

(5.14)

In the following, we use $\mathbb{E}_{\mathbb{Q}_\theta}$ for an expectation with respect to $\mathbb{Q}_\theta$.

Proceeding as in [4, Lemma 1] and [45, Proposition 4.4], we then have the following variational formula for the partition function $Z_N$ in (5.1).

**Lemma 5.3.** For any $N \in \mathbb{N}$, we have

$$- \log Z_N = \inf_{\theta \in \mathbb{H}_c} \mathbb{E}_{\mathbb{Q}_\theta} \left[ R_N(Y_\theta(1) + I(\theta)(1)) + \frac{1}{2} \int_0^1 \|\theta(t)\|^2_{L^2} dt \right].$$

We state a useful lemma on the pathwise regularity estimates of $Y_\theta(1)$ and $I(\theta)(1)$. See Lemmas 4.6 and 4.7 in [45].

**Lemma 5.4.** (i) Let $V$ be the Bessel potential of order $\beta > 1$. Then, given any finite $p \geq 1$, we have

$$\sup_{\theta \in \mathbb{H}_c} \mathbb{E}_{\mathbb{Q}_\theta} \left[ \|Y_\theta(1)\|_{C^{-\frac{1}{2} - \varepsilon}}^p + \|Y_\theta^2(1) : \|_{C^{-1 - \varepsilon}}^p + \|(V * : Y_\theta^2(1) : Y_\theta(1))\|_{C^{-\frac{1}{2} - \varepsilon}}^p \right] < \infty$$

(5.15)

for any $\varepsilon > 0$.

(ii) For any $\theta \in \mathbb{H}_c$, we have

$$\|I(\theta)(1)\|_{H^1}^2 \leq \int_0^1 \|\theta(t)\|_{L^2}^2 dt.$$
As for (i), the main point is to note that, for any \( \theta \in \mathbb{H}_c \), \( W_\theta \) is a cylindrical Wiener process in \( L^2(\mathbb{T}^3) \) under \( Q_\theta \). Thus, the law of \( Y_\theta(1) = \langle \nabla \rangle^{-1} W_\theta(1) \) under \( Q_\theta \) is always given by \( \mu \), so in particular, it is independent of \( \theta \in \mathbb{H}_c \). This fact is also used in (6.17) below. As for the last term in (5.15), the same argument as in the proof of Lemma 4.2 yields that \( (V* : Y_{\theta}^2(1)) \subset Y_\theta(1) \) is in \( C^{\beta - \frac{1}{2} - \varepsilon}(\mathbb{T}^3) \) almost surely for \( \beta > 1 \). By the paraproduct decomposition (3.2) and Lemma 3.2

we then conclude that \( (V* : Y_{\theta}^2(1))Y_\theta(1) \in C^{-\frac{1}{2} - \varepsilon}(\mathbb{T}^3) \) almost surely for \( \beta > 1 \).

5.3. Exponential integrability in the defocusing case for \( \beta > 1 \). In this section, we consider the defocusing case. We use the variational formulation of the partition function \( Z_N \) (Lemma 5.3) and prove the uniform exponential integrability (1.29) for \( Q \). Since the argument is identical for any finite \( p \geq 1 \), we only present details for the case \( p = 1 \).

Fixing an arbitrary drift \( \theta \in \mathbb{H}_c \), our main goal is to establish a uniform (in \( N \)) lower bound on

\[
W_N(\theta) = \mathbb{E}_{Q_\theta} \left[ R_N(Y_\theta(1) + I(\theta)(1)) + \frac{1}{2} \int_0^1 \|\theta(t)\|_{L_x}^2 dt \right].
\]

(5.16)

Since the drift \( \theta \in \mathbb{H}_c \) is fixed, we suppress the dependence on the drift \( \theta \) henceforth and denote \( Y = Y_\theta(1) \) and \( \Theta = I(\theta)(1) \) with the understanding that an expectation is taken under the measure \( Q_\theta \). We also set \( Y_N = \pi_N Y \) and \( \Theta_N = \pi_N \Theta \). By setting

\[
V_0 = V - \hat{V}(0) = V - 1,
\]

(5.17)

it follows from (1.27), (5.4) and (5.3) that

\[
R_N(Y + \Theta) = \frac{1}{4} Q_N(Y) + \int_{\mathbb{T}^3} (V_0* : Y_N^2 : )Y_N \Theta_N dx + \frac{1}{2} \int_{\mathbb{T}^3} (V_0* : Y_N^2 : ) \Theta_N^2 dx
\]

\[
+ \int_{\mathbb{T}^3} (V_0 * (Y_N \Theta_N)) Y_N \Theta_N dx + \int_{\mathbb{T}^3} (V_0 * \Theta_N^2) Y_N \Theta_N dx
\]

\[
+ \frac{1}{4} \int_{\mathbb{T}^3} (V_0 * \Theta_N^2) \Theta_N^2 dx + \frac{1}{4} \int_{\mathbb{T}^3} \left( Y_N^2 : + 2 Y_N \Theta_N + \Theta_N^2 \right) dx \right)^2.
\]

(5.18)

From (5.7) and Wick’s theorem (Lemma 3.9 and 3.18), we have

\[
\mathbb{E}_{Q_\theta}[Q_{N,1}(Y)] = \mathbb{E}_{Q_\theta}[Q_{N,3}(Y)] = 0,
\]

\[
\mathbb{E}_{Q_\theta}[Q_{N,2}(Y) + Q_{N,4}(Y)] = 2 \sum_{n_1 \in \mathbb{Z}^3} \hat{V}(2n_1) (n_1)^{-4} - 2 \sum_{n_1 \in \mathbb{Z}^3} \hat{V}(2n_1) (n_1)^{-4} = 0.
\]

(5.19)

As a consequence, we have

\[
\mathbb{E}_{Q_\theta}[Q_N(Y)] = 0.
\]

(5.20)

Hence, from (5.16), (5.18), and (5.20), we obtain

\[
W_N(\theta) = \mathbb{E}_{Q_\theta} \left[ \int_{\mathbb{T}^3} (V_0* : Y_N^2 : )Y_N \Theta_N dx + \frac{1}{2} \int_{\mathbb{T}^3} (V_0* : Y_N^2 : ) \Theta_N^2 dx
\]

\[
+ \int_{\mathbb{T}^3} (V_0 * (Y_N \Theta_N)) Y_N \Theta_N dx + \int_{\mathbb{T}^3} (V_0 * \Theta_N^2) Y_N \Theta_N dx
\]

\[
+ \frac{1}{4} \int_{\mathbb{T}^3} (V_0 * \Theta_N^2) \Theta_N^2 dx + \frac{1}{4} \int_{\mathbb{T}^3} \left( Y_N^2 : + 2 Y_N \Theta_N + \Theta_N^2 \right) dx \right)^2.
\]

(5.21)
The main strategy is to bound $\mathcal{W}_N(\theta)$ from below pathwise, uniformly in $N \in \mathbb{N}$ and independently of the drift $\theta$, by utilizing the positive terms:

$$U_N(\theta) = \mathbb{E}_{20} \left[ \frac{1}{4} \int_{T^3} (V_0 * \Theta^2_N) \Theta_N^2 \, dx + \frac{1}{16} \left( \int_{T^3} \Theta_N^2 \, dx \right)^2 + \frac{1}{2} \int_0^1 \| \theta(t) \|_{L^2}^2 \, dt \right]. \quad (5.22)$$

As pointed out in Remark 1.3, the first term on the right-hand side of (5.22) is non-negative and is in fact equal to $\frac{1}{4} \| \Theta_N^2 \|_{H^2}^2$. As for the second term, see Lemma 5.6 below.

In the following, we first state two lemmas, controlling the other terms appearing in (5.21). We now prove the uniform exponential integrability (1.29) in Theorem 1.10. In view of Lemma 5.5, it suffices to establish a finite lower bound on $\mathcal{W}_N(\theta)$ uniformly in $N \in \mathbb{N}$ and $\theta \in \mathbb{H}_c$.

From (5.21), (5.22), Lemmas 5.5 and 5.6 with Lemma 5.4, we obtain

$$\inf_{N \in \mathbb{N}} \inf_{\theta \in \mathbb{H}_c} \mathcal{W}_N(\theta) \geq \inf_{N \in \mathbb{N}} \inf_{\theta \in \mathbb{H}_c} \left\{ - C_0 + \frac{1}{10} U_N(\theta) \right\} \geq - C_0 > -\infty.$$ 

This proves the uniformly exponential integrability (1.29) for $\beta > 1$ and hence Theorem 1.10(i).

We conclude this subsection by presenting the proofs of Lemmas 5.5 and 5.6.

**Lemma 5.5.** Give $\beta > 1$, let the potential $V$ satisfy (1.52). Then, there exist small $\varepsilon > 0$ and a constant $c > 0$ such that

$$\left| \int_{T^3} (V_0 \ast \Theta^2_N) Y_N \Theta_N \, dx \right| \leq c \left( 1 + \| Y_N \|_{C^{1/2 - \varepsilon}} \right) + \frac{1}{100} \left( \| \Theta_N^2 \|_{H^2}^2 + \| \Theta_N \|_{L^2}^4 + \| \Theta_N \|_{H^1}^4 \right). \quad (5.23)$$

$$\left| \int_{T^3} (V_0 \ast Y^2_N) \Theta^2_N \, dx \right| \leq c \left\| Y^2_N \right\|_{C^{1/2 - \varepsilon}}^2 + \frac{1}{100} \| \Theta_N \|_{L^2}^4, \quad (5.24)$$

$$\left| \int_{T^3} (V_0 \ast (Y_N \Theta_N)) Y_N \Theta_N \, dx \right| \leq c \left( 1 + \| Y_N \|_{C^{1/2 - \varepsilon}} \right) + \frac{1}{100} \left( \| \Theta_N \|_{L^2}^4 + \| \Theta_N \|_{H^1}^4 \right), \quad (5.25)$$

$$\left| \int_{T^3} (V_0 \ast Y^2_N) Y_N \Theta_N \, dx \right| \leq c \| (V_0 \ast Y^2_N) Y_N \|_{C^{1/2 - \varepsilon}}^2 + \frac{1}{100} \| \Theta_N \|_{H^1}^4, \quad (5.26)$$

uniformly in $N \in \mathbb{N}$.

**Lemma 5.6.** Given any small $\varepsilon > 0$, there exists $c = c(\varepsilon) > 0$ such that

$$\left\{ \int_{T^3} \left( : Y^2_N : + 2 Y_N \Theta_N + \Theta^2_N \right) \, dx \right\}^2 \geq \frac{1}{4} \| \Theta_N \|_{L^2}^4 - \frac{1}{100} \| \Theta_N \|_{H^1}^4 - c \left\{ \| Y_N \|_{C^{1/2 - \varepsilon}}^2 + \left( \int_{T^3} : Y^2_N : \, dx \right)^2 \right\}, \quad (5.27)$$

uniformly in $N \in \mathbb{N}$. 

We now prove the uniform exponential integrability (1.29) in Theorem 1.10. In view of Lemma 5.3, it suffices to establish a finite lower bound on $\mathcal{W}_N(\theta)$ uniformly in $N \in \mathbb{N}$ and $\theta \in \mathbb{H}_c$.
Proof of Lemma 5.5. From (1.52), Young’s inequality, and the product estimate (Lemma 3.2), we have

\[
\left| \int_{T^3} (V_0 \ast \Theta_N^2) Y_N \Theta_N \, dx \right| \leq \frac{1}{100} \| \Theta_N^2 \|_{H^{-\frac{\beta}{2}}}^2 + c \| Y_N \Theta_N \|_{H^{-\frac{\beta}{2}}}^2 \\
\leq \frac{1}{100} \| \Theta_N^2 \|_{H^{-\frac{\beta}{2}}}^2 + c \| Y_N \|_{C^{\frac{2(1+\epsilon)}{\gamma}-\frac{1}{2}-\epsilon}} + \frac{1}{100} \| \Theta_N \|_{H^{1+2\epsilon}}^2
\]

(5.28)

for \( \beta > 1 \). Then, the estimate (5.23) follows from the interpolation (3.3) and Young’s inequality. Next, we consider the second estimate (5.24). When \( \beta > 1 \), it follows from (3.6) and (3.4) that

\[
\left| \int_{T^3} (V_0 \ast Y_N^2) \Theta_N^2 \, dx \right| \leq \| Y_N^2 \|_{C^{-1-\epsilon}} \| \Theta_N^2 \|_{B_{1,1}^{-\epsilon}} \\
\leq c \| Y_N^2 \|_{C^{-1-\epsilon}} \| \Theta_N^2 \|_{L^1}.
\]

(5.29)

Then, the estimate (5.24) follows from Cauchy’s inequality.

As for (5.25), we have, from (1.52),

\[
\left| \int_{T^3} (V_0 \ast (Y_N \Theta_N)) Y_N \Theta_N \, dx \right| \lesssim \| Y_N \Theta_N \|_{H^{-\frac{\beta}{2}}}^2.
\]

Then, the rest follows as in (5.28), provided that \( \beta > 1 \).

Lastly, from (3.6), (3.4), and Young’s inequality that

\[
\left| \int_{T^3} (V_0 \ast Y_N^2) Y_N \Theta_N \, dx \right| \leq \| (V_0 \ast Y_N^2) Y_N \|_{C^{-\frac{1}{2}-\epsilon}} \| \Theta_N \|_{B_{1,1}^{\frac{1}{2}+\epsilon}} \\
\leq c \| (V_0 \ast Y_N^2) Y_N \|_{C^{-\frac{1}{2}-\epsilon}}^2 + \frac{1}{100} \| \Theta_N \|_{H^1}^2.
\]

(5.30)

Here, the condition \( \beta > 1 \) is needed to guarantee the finiteness of the first term on the right-hand side of (5.30). See Lemma 5.4. This completes the proof of Lemma 5.5. □

Next, we present the proof of Lemma 5.6.

Proof of Lemma 5.6. From Cauchy’s inequality, there exists a constant \( C > 0 \) such that

\[
(a + b + c)^2 \geq \frac{1}{2} c^2 - C(a^2 + b^2)
\]

for any real numbers \( a, b, c \). Thus, we have

\[
\left\{ \left( \int_{T^3} (Y_N^2 : +2Y_N \Theta_N + \Theta_N^2) \, dx \right) \right\}^2 \\
\geq \frac{1}{2} \left( \int_{T^3} \Theta_N^2 \, dx \right)^2 - C_0 \left( \int_{T^3} Y_N^2 \, dx \right)^2 + \left( \int_{T^3} Y_N \Theta_N \, dx \right)^2
\]

(5.31)

for some \( C_0 > 0 \). From (3.6), (3.4), (3.3), and Young’s inequality, we have

\[
\left| \int_{T^3} Y_N \Theta_N \, dx \right|^2 \leq \| Y_N \|_{C^{-\frac{1}{2}-\epsilon}}^2 \| \Theta_N \|_{H^{\frac{1}{2}+2\epsilon}}^2 \lesssim \| Y_N \|_{C^{-\frac{1}{2}-\epsilon}} ^2 \| \Theta_N \|_{L^2}^{1-4\epsilon} \| \Theta_N \|_{H^{1+4\epsilon}}^{1+4\epsilon} \\
\leq c \| Y_N \|_{C^{-\frac{1}{2}-\epsilon}}^2 + \frac{1}{4C_0} \| \Theta_N \|_{L^2}^4 + \frac{1}{100C_0} \| \Theta_N \|_{H^1}^2.
\]

(5.32)

Hence, (5.27) follows from (5.31) and (5.32). □
5.4. Exponential integrability for the focusing case: the non-endpoint case $\beta > 2$. In this subsection, we present the construction of the focusing Hartree Gibbs measure $\rho$ in (1.50) in the non-endpoint case $\beta > 2$ (Theorem 1.14(i)). In view of Lemma 5.1 and the comments following the lemma, it suffices to prove the uniform exponential integrability (1.48).

In the focusing case, the potential energy $\frac{1}{4} \int_{T^3} (V_0 * \Theta_N^2) \Theta_N^2 dx$ has a wrong sign. Thus, we need to reprove (5.23) in Lemma 5.5 without using the potential energy.

**Lemma 5.7.** Let $V$ satisfy (1.52) with $\beta \geq 2$. Then, there exist small $\varepsilon > 0$ and a constant $c > 0$ such that

$$\left| \int_{T^3} (V_0 * \Theta_N^2) Y_N \Theta_N dx \right| \leq c \| Y_N \|_{C^{-\frac{1}{2}-\varepsilon}} + \frac{1}{100} \left( \| \Theta_N \|^2_{L^2} + \| \Theta_N \|^2_{H^1} \right),$$

(5.33)

uniformly in $N \in \mathbb{N}$.

**Proof.** From (3.6), (3.7), and Sobolev’s inequality with $\beta \geq 2$, we have

$$\text{LHS of (5.33)} \leq \| Y_N \|_{C^{-\frac{1}{2}-\varepsilon}} \| (V_0 * \Theta_N^2) \Theta_N \|_{B_{1,1}^1}$$

$$\leq \| Y_N \|_{C^{-\frac{1}{2}-\varepsilon}} \| \Theta_N^2 \|_{H^{\frac{1}{2}-\beta+2\varepsilon}} \| \Theta_N \|_{H^{\frac{1}{2}+2\varepsilon}}$$

$$\leq \| Y_N \|_{C^{-\frac{1}{2}-\varepsilon}} \| \Theta_N \|_{H^{\frac{1}{2}}} \| \Theta_N \|_{H^{\frac{1}{2}+2\varepsilon}}.$$ 

Then, (5.33) follows from (3.3) and Young’s inequality. 

**Lemma 5.8.** Let $0 < \gamma < 3$ and $A > 0$. There exist small $\varepsilon > 0$ and a constant $c > 0$ such that

$$A \left| \int_{T^3} (Y_N^2 : +2Y_N \Theta_N + \Theta_N^2) dx \right|^\gamma$$

$$\geq \frac{A}{4} \| \Theta_N \|^2_{L^2} - \frac{1}{100} \| \Theta_N \|^2_{H^1} - c \left( \| Y_N \|^2_{C^{\frac{1}{2}-\gamma}} + \int_{T^3} Y_N^2 : dx \right)^\gamma,$$

(5.34)

uniformly in $N \in \mathbb{N}$.

**Proof.** Note that there exists a constant $C > 0$ such that

$$|a + b + c|^\gamma \geq \frac{1}{2} |c|^\gamma - C (|a|^\gamma + |b|^\gamma),$$

(5.35)

for any $a, b, c \in \mathbb{R}$. Indeed, if $|c|^\gamma < 2C(|a|^\gamma + |b|^\gamma)$, (5.35) is trivial. By $|c|^\gamma \geq 2C (|a|^\gamma + |b|^\gamma)$, by $|c| \geq (2C)^{\frac{1}{\gamma}} \max(|a|, |b|)$ and the triangle inequality, we have

$$|a + b + c| \geq |c| - |a| - |b| \geq (1 - 2(2C)^{-\frac{1}{\gamma}}) |c| \geq 2^{-\frac{1}{\gamma}} |c|,$$

provided that a constant $C > 0$ is sufficiently large. Hence, we obtain (5.35).

By (5.35), there exists a constant $C_0 > 0$ such that

$$A \left| \int_{T^3} (Y_N^2 : +2Y_N \Theta_N + \Theta_N^2) dx \right|^\gamma$$

$$\geq \frac{A}{2} \left( \int_{T^3} \Theta_N^2 dx \right)^\gamma - C_0 A \left( \int_{T^3} Y_N^2 : dx \right)^\gamma,$$

(5.36)

From (3.6), (3.4), (3.3), and Young’s inequality, we have

$$\left| \int_{T^3} Y_N \Theta_N dx \right|^\gamma \leq \| Y_N \|^\gamma_{C^{-\frac{1}{2}-\varepsilon}} \| \Theta_N \|^\gamma_{B_{1,1}^{1,\gamma}} \leq \| Y_N \|^\gamma_{C^{-\frac{1}{2}-\varepsilon}} \| \Theta_N \|^\gamma_{L^2} \| \Theta_N \|^2_{H^{1,\gamma} \frac{2(1+4\gamma)}{1+4\gamma}}$$

$$\leq c \| Y_N \|^\gamma_{C^{-\frac{1}{2}-\varepsilon}} + \frac{1}{400} \| \Theta_N \|^2_{L^2} + \frac{1}{1000} \| \Theta_N \|^2_{H^1},$$

(5.37)
provided that \(0 < \gamma < \frac{3+4\varepsilon}{1+4\varepsilon}\), namely \(0 < \gamma < 3\) and \(0 < \varepsilon \ll 1\). Hence, (5.34) follows from (5.36) and (5.37).

We now present the proof of the uniform exponential integrability (1.48) for \(\beta > 2\), using the variational formulation. As in the previous section, we only consider the case \(p = 1\). Set

\[
\mathcal{W}_N(\theta) = \mathbb{E}_{Q_0} \left[ -\mathcal{R}_N(Y_\theta(1) + I(\theta)(1)) + \frac{1}{2} \int_0^1 \|\theta(t)\|^2_{L^2} dt \right],
\]

where \(\mathcal{R}_N(u)\) is as in (5.5). In view of Lemma 5.8, we also set

\[
\mathcal{U}_N(\theta) = \mathbb{E}_{Q_0} \left[ \frac{A}{4} \int_{T^3} \Theta_N^2 dx \right] + \frac{1}{2} \int_0^1 \|\theta(t)\|^2_{L^2} dt.
\]

In the focusing case, the potential energy \(\int_{T^3} (V_0 * \Theta_N^2) \Theta_N^2 dx\) appears with a wrong sign and thus we need to control this term by \(\mathcal{U}_N\) in (5.39). When \(1 < \beta < 3\), it follows from Sobolev’s inequality, (3.3), and Young’s inequality that

\[
\left| \int_{T^3} (V_0 * \Theta_N^2) \Theta_N^2 dx \right| \lesssim \|\Theta_N^2\|^2_{H^{-\frac{\gamma}{2}}/2} \lesssim \|\Theta_N\|^4_{L^{2+\gamma}} \lesssim \|\Theta_N\|^{1+\beta}_{L^2} \|\Theta_N\|^{3-\beta}_H
\]

\[
\leq c_0 + \frac{A}{100} \|\Theta_N\|^{2\gamma}_{L^2} + \frac{1}{100} \|\Theta_N\|^{2}_H,
\]

provided that \(\gamma \geq \frac{\beta+1}{2+\varepsilon}\) and \(A > 0\) is sufficiently large. When \(\beta = 3\), (5.40) holds with a strict inequality \(\gamma > \frac{\beta+1}{2+\varepsilon} = 2\). When \(\beta > 3\), applying Hausdorff-Young’s inequality twice, we have

\[
\left| \int_{T^3} (V_0 * \Theta_N^2) \Theta_N^2 dx \right| \leq \|V_0 * \Theta_N^2\|_{L^\infty} \|\Theta_N\|^2_{L^2} \leq \langle n \rangle^{-\beta} \|\Theta_N\|_{L^2} \|\Theta_N\|^2_{L^2}
\]

\[
\lesssim \|\Theta_N\|_{L^2} \|\Theta_N\|^2_{L^2} \leq \|\Theta_N\|_{L^2}.
\]

From (5.38) and (5.39) with Lemmas 5.4, 5.5, 5.7, and 5.8, (5.40), and (5.41), and \(\max(\frac{\beta+1}{2+\varepsilon}, 2) \leq \gamma < 3\) with \(\gamma \geq 2\) when \(\beta = 3\), we obtain

\[
\inf_{N \in \mathbb{N}} \inf_{\theta \in \mathcal{H}_\varepsilon} \mathcal{W}_N(\theta) \geq \inf_{N \in \mathbb{N}} \inf_{\theta \in \mathcal{H}_\varepsilon} \left\{ -C_0 + \frac{1}{10} \mathcal{U}_N(\theta) \right\} \geq -C_0 > -\infty.
\]

Therefore, from an analogue of Lemma 5.3 for \(\mathcal{R}_N(u)\), we conclude the uniform exponential integrability (1.48), provided that \(\frac{\beta+1}{2+\varepsilon} < 3\), namely, \(\beta > 2\).

5.5. Non-normalizability of the focusing Gibbs measure. In this subsection, we prove the non-normalizability of the focusing Hartree Gibbs measure for \(\beta < 2\) with any \(\sigma > 0\) (Theorem 1.14(ii)) and for \(\beta = 2\) with \(\sigma \gg 1\) (Theorem 1.14(iii.a)). When \(\beta < 2\), the non-normalizability follows from the next proposition.

**Proposition 5.9.** Given \(1 < \beta < 2\), let \(V\) be the Bessel potential of order \(\beta\). Then, for any \(\sigma > 0\), there exists \(K > 0\) such that

\[
\lim_{L \to \infty} \liminf_{N \to \infty} \mathbb{E} \left[ \exp \left( \min \left( \sigma R_N(u), L \right) \right) \cdot 1_{\{|\int_{T^3} u_N^2 dx| \leq K\}} \right] = \infty,
\]

where \(R_N(u)\) is as in (1.27).

We first present the proof of Theorem 1.14(ii) by assuming Proposition 5.9.
Proof of Theorem 1.14 (ii). It follows from (1.27) and (1.46) that
\[ \sigma R_N(u) = \mathcal{R}_N(u) + A \left| \int_{T^3} :u_N^2 : dx \right|^{\gamma}. \]
Noting that
\[ 1_{{\{|\cdot| \leq K}\}}(x) \leq \exp(-A|x|^\gamma) \exp(AK^\gamma) \]
for any $K > 0$, $\gamma > 0$, and $A > 0$, we have, for any $L > 0$,
\[
\mathbb{E}[e^{\mathcal{R}_N(u)}] = \mathbb{E} \left[ \exp \left( \sigma R_N(u) - A \left| \int_{T^3} :u_N^2 : dx \right|^{\gamma} \right) \right] \\
\geq \mathbb{E} \left[ \exp \left( \min (\sigma R_N(u), L) - A \left| \int_{T^3} :u_N^2 : dx \right|^{\gamma} \right) \right] \\
\geq \exp(-AK^\gamma) \mathbb{E} \left[ \exp \left( \min (\sigma R_N(u), L) \right) \cdot 1_{\{|\int_{T^3} :u_N^2 : dx| \leq K\}} \right].
\]
Then, (1.51) follows from Proposition 5.9.

Remark 5.10. (i) Proposition 5.9 holds true at the critical value $\beta = 2$, provided that $\sigma \gg 1$. See Remark 5.14. Then, the argument above proves Theorem 1.14 (iii.a).

(ii) Proposition 5.9 and Part (i) of this remark establish the non-normalizability of the focusing Hartree Gibbs measure $\rho$ in (1.44) with a Wick-ordered $L^2$-cutoff, considered by Bourgain [13], (a) for $\beta < 2$ with any $\sigma > 0$ and (b) for $\beta = 2$ with $\sigma \gg 1$. In view of (5.42), the construction of the focusing Hartree Gibbs measure $\rho$ in (1.44) with a Wick-ordered $L^2$-cutoff in the weakly nonlinear regime ($0 < \sigma \ll 1$) at the critical value $\beta = 2$ follows from the corresponding construction for the focusing Gibbs measure in (1.50) presented in Subsection 5.6.

The rest of the section is devoted to the proof of Proposition 5.9. We first note that
\[
\mathbb{E} \left[ \exp \left( \min (\sigma R_N(u), L) \right) \cdot 1_{\{|\int_{T^3} :u_N^2 : dx| \leq K\}} \right] \\
\geq \mathbb{E} \left[ \exp \left( \min (\sigma R_N(u), L) \cdot 1_{\{|\int_{T^3} :u_N^2 : dx| \leq K\}} \right) \right] - \mathbb{P} \left( \left| \int_{T^3} :u_N^2 : dx \right| > K \right) \\
\geq \mathbb{E} \left[ \exp \left( \min (\sigma R_N(u), L) \cdot 1_{\{|\int_{T^3} :u_N^2 : dx| \leq K\}} \right) \right] - 1,
\]
and thus it suffices to prove
\[
\lim_{L \to \infty} \lim_{N \to \infty} \mathbb{E} \left[ \exp \left( \min (\sigma R_N(u), L) \cdot 1_{\{|\int_{T^3} :u_N^2 : dx| \leq K\}} \right) \right] = \infty.
\]

As in the previous subsections, we will use a variational formulation. In this part, however, we take a drift $\theta$ depending on $Y$ and thus we need to use a variational formula, where an expectation is taken with respect to the underlying probability $\mathbb{P}$, rather than the modified one $\mathbb{Q}_\theta$ (as in Lemma 5.3). For this purpose, we first recall the Boué-Dupuis variational formula [9, 87]; in particular, see Theorem 7 in [87].

Lemma 5.11. Let $Y(t) = (\nabla)^{-1} W(t)$ be as in (5.12). Fix $N \in \mathbb{N}$. Suppose that $F : C^\infty(T^3) \to \mathbb{R}$ is measurable such that $\mathbb{E}[|F(\pi_N Y(1))|^p] < \infty$ and $\mathbb{E}[|e^{-F(\pi_N Y(1))}|^q] < \infty$ for some $1 < p, q < \infty$ with $\frac{1}{p} + \frac{1}{q} = 1$. Then, we have
\[
- \log \mathbb{E}[e^{-F(\pi_N Y(1))}] = \inf_{\theta \in \mathbb{R}_a} \mathbb{E} \left[ F(\pi_N Y(1) + \pi_N I(\theta)(1)) + \frac{1}{2} \int_0^1 \|\theta(t)\|^2_{L^2_x} dt \right],
\]
where $I(\theta)$ is as in (5.14) and the expectation $\mathbb{E} = \mathbb{E}_\mathcal{P}$ is an expectation with respect to the underlying probability measure $\mathcal{P}$.

In our current context, Lemma 5.11 together with Lemma 5.1 yields

where the expectation $\mathbb{E} = \mathbb{E}_\mathcal{P}$ is an expectation with respect to the underlying probability measure $\mathcal{P}$.

Let $R$ be a real-valued Schwartz function such that $\int_{\mathbb{R}^3} |\hat{f}(\xi)|^2 d\xi = 1$. Define a function $f_M$ on $\mathbb{T}^3$ by

$$f_M(x) := M^{-\frac{3}{2}} \sum_{|n| > M/2} \hat{f}(\frac{n}{M}) e_n,$$

where $\hat{f}$ denotes the Fourier transform on $\mathbb{R}^3$ defined by

$$\hat{f}(\xi) = \frac{1}{(2\pi)^{\frac{3}{2}}} \int_{\mathbb{R}^3} f(x) e^{-i\xi \cdot x} dx.$$

Then, a direct computation yields the following lemma.

**Lemma 5.12.** Let $0 < \beta < 3$. Then, given any $\alpha > 0$, we have

$$\int_{\mathbb{T}^3} f_M^2 dx = 1 + O(M^{-\alpha}),$$

$$\int_{\mathbb{T}^3} (|\nabla|^{-1} f_M)^2 dx \lesssim M^{-2},$$

$$\int_{\mathbb{T}^3} (V * f_M^2) f_M^2 dx \sim M^{3-\beta}.$$

**Proof.** Define a function $F_M$ on $\mathbb{R}^3$ by

$$F_M(x) := M^{\frac{3}{2}} f(Mx).$$

Then, by the Poisson summation formula, we have

$$f_M(x) = (2\pi)^{\frac{3}{2}} \sum_{k \in \mathbb{Z}^3} F_M(x + 2\pi k) = \sum_{k \in \mathbb{Z}^3} T_k f(x),$$

where

$$T_k f(x) := (2\pi)^{\frac{3}{2}} M^{\frac{3}{2}} f(M(x + 2\pi k)).$$

Since $f$ is a Schwartz function, if $|x| \leq \pi$ and $k \in \mathbb{Z}^3 \setminus \{0\}$, we have

$$|f(M(x + 2\pi k))| \lesssim (M|k|)^{-\alpha - 3}$$

Recall our convention of using the normalized Lebesgue measure $d\mathcal{L}_3 = (2\pi)^{-3} dx$ on $\mathbb{T}^3 \cong [-\pi, \pi]^3$. For simplicity of notation, we use $dx$ to denote the standard Lebesgue measure $\mathbb{R}^3$ and the normalized Lebesgue measure on $\mathbb{T}^3$ in the following.
for any $\alpha > 0$, from which we obtain, for $k \in \mathbb{Z}^3 \setminus \{0\}$,

$$
\int_{\mathbb{T}^3} (T_k f(x))^2 \, dx \lesssim |k|^{-2\alpha - 6} M^{-2\alpha - 3}.
$$

(5.52)

For $k = 0$, we have

$$
\int_{\mathbb{T}^3} (T_0 f(x))^2 \, dx = \int_{|x| \leq \pi M} f^2(x) \, dx = 1 - \int_{|x| > \pi M} f^2(x) \, dx = 1 - O(M^{-\alpha}).
$$

(5.53)

Hence, it follows from (5.50), (5.52), and (5.53) that

$$
\left| \int_{\mathbb{T}^3} f_M^2(x) \, dx - 1 \right|
\leq \left| \sum_{k,j \in \mathbb{Z}^3} \int_{\mathbb{T}^3} T_k f(x) T_j f(x) \, dx - 1 \right|
\leq \left| \int_{\mathbb{T}^3} (T_0 f(x))^2 \, dx - 1 + 2 \sum_{k \neq 0} \int_{\mathbb{T}^3} T_0 f(x) T_k f(x) \, dx + \sum_{k,j \neq 0} \int_{\mathbb{T}^3} T_k f(x) T_j f(x) \, dx \right|
\lesssim M^{-\alpha} \left( 1 + M^{-\frac{3}{2}} \sum_{k \neq 0} |k|^{-\alpha - 3} + M^{-\alpha - 3} \sum_{k,j \neq 0} |k|^{-\alpha - 3} |j|^{-\alpha - 3} \right)
\lesssim M^{-\alpha},
$$

for any $\alpha > 0$. This proves (5.47).

By Plancherel’s identity, (5.46), and (5.47), we have

$$
\int_{\mathbb{T}^3} \langle \nabla \rangle^{-1} f_M(x) \, dx = \sum_{|n| > M/2} M^{-3} \left| \hat{f} \left( \frac{n}{M} \right) \right|^2 \frac{1}{(n^2)^2}
\lesssim M^{-5} \sum_{n \in \mathbb{Z}^3} \left| \hat{f} \left( \frac{n}{M} \right) \right|^2
= M^{-2} \| f_M \|_{L^2}^2
\lesssim M^{-2}.
$$

This proves (5.48).

It remains to prove (5.49). By Hausdorff-Young’s inequality, (5.50), (5.52), and (5.53), we have

$$
\sup_{n \in \mathbb{Z}^3} \left( (1 + |n|) \left| \hat{f}_M(n) - (T_0 f)(n) \right| \right)
\lesssim \left\| (1 + \Delta^2) (f_M - (T_0 f))^2 \right\|_{L^1}
= \left\| (1 + \Delta^2) \left( 2T_0 f \sum_{k \neq 0} T_k f + \sum_{k,j \neq 0} T_k f T_j f \right) \right\|_{L^1}
\lesssim M^{-\alpha + \frac{\beta}{2}} \lesssim M^{-\alpha}
$$

(5.54)
for any $\tilde{\alpha} > 0$ such that $\tilde{\alpha} > \alpha + \frac{\gamma}{2}$. Hence, Plancherel’s identity, (5.51), (5.54), and Hausdorff-Young’s inequality with (5.47) and (5.53) yields that

$$\int_{\mathbb{T}^3} (V * f_M^2)f_M^2 dx - \sum_{n \in \mathbb{Z}^3} \hat{V}(n)|(T_0f)^2(n)|^2$$

$$= \left| \sum_{n \in \mathbb{Z}^3} \hat{V}(n)\left(|\hat{f}_M^2(n)|^2 - |(T_0f)^2(n)|^2\right) \right|$$

$$\lesssim \sum_{n \in \mathbb{Z}^3} \langle n \rangle^{-\beta - 4}\left((1 + |n|^4)|\hat{f}_M(n) - (T_0f)^2(n)|\right)\left(|\hat{f}_M^2(n)| + |(T_0f)^2(n)|\right)$$

$$\lesssim \sum_{n \in \mathbb{Z}^3} M^{-a} \langle n \rangle^{-\beta - 4}$$

$$\lesssim M^{-a}.$$

By the assumption, $\hat{f}_M^2 = \hat{f} * \hat{f}$ is an even Schwartz function with supp $\hat{f}_M^2 \subset \{||\xi|| \leq 2\}$ and $\hat{f}_M^2(0) = 1$. Moreover, from (5.51), we have $\langle (T_0f)^2(\xi) = (2\pi)^3 \hat{f}^2(\xi) \rangle$. Thus, we have

$$\frac{1}{2} \cdot 1_{\{||\cdot|| \leq c_1 M\}}(\xi) \leq |(T_0f)^2(\xi) | \leq c_2 \cdot 1_{\{||\cdot|| \leq 2M\}}(\xi)$$

for some $c_1, c_2 > 0$. Thus, we obtain

$$\sum_{n \in \mathbb{Z}^3} \hat{V}(n)\langle (T_0f)^2(n) \rangle^2 \lesssim \sum_{|n| \leq M} \langle n \rangle^{-\beta} \lesssim M^{3-\beta},$$

$$\sum_{n \in \mathbb{Z}^3} \hat{V}(n)\langle (T_0f)^2(n) \rangle^2 \gtrsim \sum_{|n| \leq c_1 M} \langle n \rangle^{-\beta} \sim M^{3-\beta}. \tag{5.56}$$

Therefore, from (5.55) and (5.56), we obtain (5.49). $\square$

Let $Y$ be as in (5.12). We define $Z_M$ and $\tilde{\sigma}_M$ by

$$Z_M := \sum_{|n| \leq M} Y(\frac{1}{2})(n)e_n \quad \text{and} \quad \tilde{\sigma}_M := \mathbb{E}[Z_M^2(x)]. \tag{5.57}$$

Note that $\tilde{\sigma}_M$ is independent of $x \in \mathbb{T}^3$ thanks to the spatial translation invariance of $Z_M$.

**Lemma 5.13.** Let $M \gg 1$ and let $1 < p < \infty$. Then, we have

$$\tilde{\sigma}_M \sim M,$$  

$$\mathbb{E}\left[\int_{\mathbb{T}^3} |Z_M|^p dx\right] \leq C(p)M^{\frac{p}{2}}, \tag{5.58}$$  

$$\mathbb{E}\left[\left(\int_{\mathbb{T}^3} Z_M^2 dx - \tilde{\sigma}_M\right)^2\right] + \mathbb{E}\left[\left(\int_{\mathbb{T}^3} Y_N Z_M dx - \int_{\mathbb{T}^3} Z_M^2 dx\right)^2\right] \lesssim 1, \tag{5.59}$$

$$\mathbb{E}\left[\left(\int_{\mathbb{T}^3} Y_N f_M dx\right)^2\right] + \mathbb{E}\left[\left(\int_{\mathbb{T}^3} Z_M f_M dx\right)^2\right] \lesssim M^{-2} \tag{5.60}$$

for any $N \geq M$.

**Proof.** From (5.57) and (5.12), we have

$$\tilde{\sigma}_M = \sum_{n \in \mathbb{Z}^3} \mathbb{E}[|\hat{Z}_M(n)|^2] \sim \sum_{|n| \leq M} \frac{1}{\langle n \rangle^2} \sim M.$$
yielding (5.58). The second estimate (5.59) follows from Minkowski’s integral inequality, the Wiener chaos estimate (Lemma 3.6), and (5.58).

By the independence of \( \{ |\hat Z_M(n)|^2 - \mathbb{E}[|Z_M(n)|^2]\} \), where \( \Lambda_0 \) as in (1.19), we have

\[
\mathbb{E}\left[ \left( \int_{T^3} Z_M^2 \, dx - \bar{\sigma}_M \right)^2 \right] = \mathbb{E}\left[ \left( \sum_{n \in \mathbb{Z}^3} \left( |\hat Z_M(n)|^2 - \mathbb{E}[|\hat Z_M(n)|^2] \right) \right)^2 \right] 
\sim \sum_{n \in \mathbb{Z}^3} \frac{1}{\langle n \rangle^4} \lesssim 1.
\]

Using the independence of \( B_n(1) - B_n(\frac{1}{2}) \) and \( B_n(\frac{1}{2}) \), we obtain

\[
\mathbb{E}\left[ \left( \int_{T^3} Y_N Z_M \, dx - \int_{T^3} Z_M^2 \, dx \right)^2 \right] = \mathbb{E}\left[ \left( \sum_{n \in \mathbb{Z}} \left( \hat Y_N(n) \hat Z_M(n) - |\hat Z_M(n)|^2 \right) \right)^2 \right] 
\leq \sum_{n \in \mathbb{Z}^3} \frac{1}{\langle n \rangle^4} \lesssim 1.
\]

This proves (5.60).

Lastly, from (5.48), we have

\[
\mathbb{E}\left[ \left( \int_{T^3} Y_N f_M \, dx \right)^2 \right] = \mathbb{E}\left[ \left( \sum_{|n| \leq N} \hat Y_N(n) \hat f_M(n) \right)^2 \right] = \sum_{|n| \leq N} \frac{1}{\langle n \rangle^2} |\hat f_M(n)|^2 
\lesssim \int_{T^3} (\langle \nabla \rangle^{-1} f_M(x))^2 \, dx \lesssim M^{-2}.
\]

A similar computation shows the same bound holds for the second term in (5.61). □

We are now ready to prove Proposition 5.9.

**Proof of Proposition 5.9.** For \( M \gg 1 \), we set \( f_M, Z_M, \) and \( \bar{\sigma}_M \) as in (5.46) and (5.57). We choose a drift \( \theta = \theta^0 \) for (5.45), defined by

\[
\theta^0(t) = 2 \cdot 1_{t > \frac{1}{2}} \langle \nabla \rangle (-Z_M + \sqrt{\bar{\sigma}_M} f_M)
\]

such that

\[
\Theta^0 := I(\theta^0)(1) = \int_0^1 \langle \nabla \rangle^{-1} \theta^0(t) \, dt = -Z_M + \sqrt{\bar{\sigma}_M} f_M.
\]

Furthermore, define \( Q(u) \) by

\[
Q(u) := \frac{1}{4} \int_{T^3} (V_0 + u^2) \, u^2 \, dx = \frac{1}{4} \| u^2 \|_{H^{-\frac{3}{2}}}
\]

where \( V_0 = V - \hat V(0) \) as in (5.17).
Let us first make some preliminary computations. From (5.63), (5.64), and Young’s inequality, we have
\[
Q(\Theta^0) - \tilde{\sigma}_M^2 Q(f_M)
\]
\[
= - \int_{T^3} (V_0 * (\sqrt{\sigma_M f_M})^2) \sqrt{\sigma_M f_M} Z_M dx + \frac{1}{2} \int_{T^3} (V_0 * (\sqrt{\sigma_M f_M})^2) Z_M^2 dx
\]
\[
+ \int_{T^3} (V_0 * (\sqrt{\sigma_M f_M} Z_M)) \sqrt{\sigma_M f_M} Z_M dx - \int_{T^3} (V_0 * Z_M^2) \sqrt{\sigma_M f_M} Z_M dx
\]
\[
+ Q(Z_M)
\]
(5.65)
\[
\geq -\delta \sigma_M^2 Q(f_M) - C_\delta \int_{T^3} (V_0 * (\sqrt{\sigma_M f_M})^2) Z_M^2 dx + (1 - \delta)Q(Z_M)
\]
\[
\geq -\delta \sigma_M^2 Q(f_M) - C_\delta \int_{T^3} (V_0 * (\sqrt{\sigma_M f_M})^2) Z_M^2 dx
\]
for any 0 < \delta < 1. From Lemmas 5.12 and 5.13, we have
\[
\mathbb{E} \left[ \int_{T^3} (V_0 * (\sqrt{\sigma_M f_M})^2) Z_M^2 dx \right] = \int_{T^3} (V_0 * (\sqrt{\sigma_M f_M})^2) \sigma_M dx
\]
\[
\lesssim \sigma_M^2 \|f_M\|_{L^2}^2 \lesssim M^2.
\]
(5.66)

Then, for any measurable set E with \(\mathbb{P}(E) > \frac{1}{2}\) and any \(L \gg \sigma \cdot \sigma_M^2 Q(f_M)\), it follows from (5.65), (5.66), (5.58), and (5.49) that
\[
\mathbb{E} \left[ \min \left( \frac{\sigma}{2} Q(\Theta^0), L \right) \cdot 1_E \right] \geq \sigma (1 - \delta) \sigma_M^2 Q(f_M) \mathbb{P}(E) - C'_\delta \sigma M^2 \gtrsim \sigma M^{5-\beta},
\]
(5.67)
provided that 0 < \beta < 3.

Recall that both \(\tilde{Z}_M\) and \(\tilde{f}_M\) are supported on \(\{|n| \leq M\}\). Then, by Lemma 5.4 (5.62), (5.63), and Lemmas 5.12 and 5.13, we have
\[
\mathbb{E} [\|\Theta^0\|_{L^1}] \leq \mathbb{E} \left[ \int_0^1 \|\theta^0(t)\|_{L^2}^2 dt \right] \lesssim M^2 \mathbb{E} [\|\Theta^0\|_{L^2}^2] \lesssim M^3.
\]
(5.68)

We now impose \(\beta > 1\). Then, it follows from (5.18) and Lemmas 5.5 and 5.6 that
\[
\sigma R_N(Y + \Theta^0) \geq \frac{\sigma}{2} Q(\Theta^0)
\]
\[
- c(\sigma) \left( 1 + \|Y_N\|_{C^{-\frac{1}{2} - \epsilon}} + \|Y_N^2 : Y_N^2_{\sigma} : Y_N\|_{C^{-\frac{1}{2} - \epsilon}} + \|(V_0 : Y_N^2_{\sigma}) Y_N\|_{C^{-\frac{1}{2} - \epsilon}} \right)
\]
\[
+ \frac{\sigma}{32} \|\Theta^0\|_{L^2}^4 - c_0 \|\Theta^0\|_{H^1}^2 - \frac{\sigma}{4} \|Q_N(Y)\|,
\]
(5.69)
where \(c_0\) is independent of \(\sigma > 0\). Suppose that
\[
\mathbb{P} \left( \left| \int_{T^3} (Y_N^2 : Y_N + 2Y_N \Theta^0 + (\Theta^0)^2) dx \right| \leq K \right) > \frac{1}{2},
\]
(5.70)
uniformly in \(M \gg 1\) and \(N \geq M\), and \(L \gg \sigma \cdot \sigma_M^2 Q(f_M) \sim \sigma M^{5-\beta}\). Then, putting together, (5.45), (5.67), (5.68), (5.69) with Lemma 5.1 (in particular (5.6)), there exist constants

\footnote{From (5.63) and \(N > M\), we have \(\pi_N \Theta^0 = \Theta^0\).}
$C_1, C_2, C_3 > 0$ such that
\[
- \log \mathbb{E} \left[ \exp \left( \min (\sigma R_N(u), L) \mathbf{1}_{\{|f_{33} : u_N^2 | dx| \leq K\}} \right) \right]
\leq \mathbb{E} \left[ - \min (\sigma R_N(Y + \Theta^0), L) \mathbf{1}_{\{|f_{33} : (Y_N^2 + 2Y_N \Theta^0 + (\Theta^0)^2) dx| \leq K\}} + \frac{1}{2} \int_{0}^{1} \| \theta^0(t) \|^2_{L^2} dt \right]
\leq \mathbb{E} \left[ - \min \left( \frac{\alpha}{\beta} Q(\Theta^0), L \right) \mathbf{1}_{\{|f_{33} : (Y_N^2 + 2Y_N \Theta^0 + (\Theta^0)^2) dx| \leq K\}} \right]
+ c(\sigma) \left( 1 + \| Y_N \|_{C^{-1} - \epsilon} + \| Y_N^2 \|_{C^{-1} - \epsilon} + \|(V_0 \ast Y_N^2) Y_N\|_{C^{-1} - \epsilon} + 1 \right)
\leq - \sigma C_1 M^{5-\beta} + C_2 M^3 + C_3
\]
for any $N \geq M \gg 1$. Therefore, we conclude from (5.43) and (5.71) that
\[
\lim_{L \to \infty} \lim_{N \to \infty} \mathbb{E} \left[ \exp \left( \min (\sigma R_N(u), L) \mathbf{1}_{\{|f_{33} : u_N^2 | dx| \leq K\}} \right) \right]
\geq \exp \left( \sigma C_1 M^{5-\beta} - C_2 M^3 - C_3(\sigma) \right) \to \infty
\]
as $M \to \infty$, provided that $\beta < 2$. This proves (5.44) by assuming (5.70).

Now, it remains to prove (5.70) for some $K \gg 1$, namely,
\[
P \left( \left| \int_{T^3} \left( : Y_N^2 : + 2Y_N \Theta^0 + (\Theta^0)^2 \right) dx \right| > K \right) \leq \frac{1}{2},
\]
uniformly in $M \gg 1$ and $N \geq M$. From (5.63), Lemmas 5.4 and 5.13 with (5.47), we have
\[
\mathbb{E} \left[ \left| \int_{T^3} \left( : Y_N^2 : + 2Y_N \Theta^0 + (\Theta^0)^2 \right) dx \right|^2 \right]
\leq \mathbb{E} \left[ \left( \int_{T^3} : Y_N^2 : dx \right)^2 \right] + \mathbb{E} \left[ \left( - \int_{T^3} Y_N Z_M dx + \int_{T^3} f_M dx \right)^2 \right]
\leq \bar{\sigma}_M \mathbb{E} \left[ \left( \int_{T^3} : Y_N^2 : dx \right)^2 \right] + \mathbb{E} \left[ \left( \int_{T^3} Y_N Z_M dx \right)^2 \right] + \mathbb{E} \left[ \left( \int_{T^3} f_M^2 dx \right)^2 \right]
\leq 1,
\]
provided that $\alpha > 1$. Then, by choosing $K \gg 1$, the bound (5.73) follows from Chebyshev’s inequality. This concludes the proof of Proposition 5.9. \qed

Remark 5.14. When $\beta = 2$, (5.72) still holds true as long as $\sigma \gg 1$, thus yielding (5.44) in the strongly nonlinear regime at the critical value $\beta = 2$. 

5.6. Focusing Gibbs measure at the critical value $\beta = 2$. We consider the focusing Hartree Gibbs measure at the critical value $\beta = 2$. In the previous section, we prove the non-normalizability for $\beta = 2$ in the strongly nonlinear regime ($\sigma \gg 1$); see Remarks 5.10 and 5.14. In this subsection, we show that the focusing Gibbs measure is indeed normalizable for $\beta = 2$ in the weakly nonlinear regime (i.e. $0 < \sigma \ll 1$).

Let $\beta = 2$. In view of (5.40), we set $\gamma = 3$ in (1.46). More precisely, we consider the following renormalized potential energy:

$$R_N(u) = \frac{\sigma}{4} \int_{T^3} (V \ast : u_N^2 : ) : u_N^2 : dx - A \left| \int_{T^3} : u_N^2 : dx \right|^3 - \frac{1}{2} \alpha_N,$$  \hfill (5.74)

where $\sigma > 0$ is a small constant. Then, it suffices to prove

$$\inf_{N \in \mathbb{N}} \inf_{\theta \in H_c} \mathbb{E}_{\mathcal{Q}_\sigma} \left[ - R_N(Y_\theta(1) + I(\theta)(1)) + \frac{1}{2} \int_0^1 \|\theta(t)\|_{L_x^2}^2 dt \right] > -\infty. \hfill (5.75)$$

In the following, we use the same notations as in Subsections 5.3 and 5.4. The main difficulty comes from the failure of Lemma 5.8 when $\gamma = 3$. See the case (5.78) below.

From (5.74), Lemmas 5.5, 5.6, and 5.7, and (5.40) with Lemma 5.4, we reduce (5.75) to showing

$$\sup_{N \in \mathbb{N}} \sup_{\theta \in H_c} \mathbb{E} \left[ c_0 \sigma \|\Theta_N\|_{L_x^2}^6 - A \int_{T^3} \left( : Y_N^2 : + 2 Y_N \Theta_N + \Theta_N^2 \right) dx \right]^3 - \frac{1}{4} \|\Theta_N\|_{L_x^1}^2 < \infty. \hfill (5.76)$$

Suppose that we have

$$\|\Theta_N\|_{L_x^2}^2 \gg \int_{T^3} Y_N \Theta_N dx.$$

Then, from (5.35), there exists a constant $c > 0$ such that

$$\left| \int_{T^3} \left( : Y_N^2 : + 2 Y_N \Theta_N + \Theta_N^2 \right) dx \right|^3 \geq c \left( \int_{T^3} \Theta_N^2 dx \right)^3 - c \left( \int_{T^3} : Y_N^2 : dx \right)^3. \hfill (5.77)$$

Hence, by choosing $\sigma > 0$ sufficiently small, (5.76) follows from (5.77) and Lemma 5.4.

Next, we consider the case:

$$\|\Theta_N\|_{L_x^2}^2 \lesssim \int_{T^3} Y_N \Theta_N dx. \hfill (5.78)$$

Define the sharp frequency projections \{\Pi_j\}_{j \in \mathbb{N}} by setting $\Pi_1 = \pi_1$ and $\Pi_j = \pi_{2^j} - \pi_{2^{j-1}}$ for $j \geq 2$. Then, write $\Theta_N$ as

$$\Theta_N = \sum_{j=0}^{\infty} (\lambda_j \Pi_j Y_N + w_j),$$

where

$$\lambda_j := \begin{cases} \frac{\Theta_N \Pi_j Y_N}{\|\Pi_j Y_N\|_{L_x^2}}, & \text{if } \|\Pi_j Y_N\|_{L_x^2} \neq 0, \\ 0, & \text{otherwise,} \end{cases} \quad \text{and} \quad w_j := \Pi_j \Theta_N - \lambda_j \Pi_j Y_N.$$  \hfill \footnote{This case works even for $\sigma = 1$ simply by taking $A \gg 1$.}
Note that \( w_j \) is orthogonal to \( \Pi_j Y_N \) and \( Y_N \) in \( L^2(\mathbb{T}^3) \). Thus, we have
\[
\| \Theta_N \|_{L^2}^2 = \sum_{j=0}^{\infty} \left( \lambda_j^2 \| \Pi_j Y_N \|_{L^2}^2 + \| w_j \|_{L^2}^2 \right),
\] (5.79)
\[
\int_{\mathbb{T}^3} Y_N \Theta_N \, dx = \sum_{j=0}^{\infty} \lambda_j \| \Pi_j Y_N \|_{L^2}^2.
\] (5.80)

Hence, from (5.78), (5.79), and (5.80), we have
\[
\sum_{j=0}^{\infty} \lambda_j^2 \| \Pi_j Y_N \|_{L^2}^2 \lesssim \sum_{j=0}^{\infty} \lambda_j \| \Pi_j Y_N \|_{L^2}^2.
\] (5.81)

Fix \( j_0 \in \mathbb{N} \) (to be chosen later). By Cauchy-Schwarz inequality and (5.79), we have
\[
\left| \sum_{j=j_0+1}^{\infty} \lambda_j \| \Pi_j Y_N \|_{L^2}^2 \right| \leq \left( \sum_{j=0}^{\infty} \lambda_j^2 \| \Pi_j Y_N \|_{L^2}^2 \right)^{1/2} \left( \sum_{j=j_0+1}^{\infty} 2^{-2j} \| \Pi_j Y_N \|_{L^2}^2 \right)^{1/2}
\leq \left( \sum_{j=0}^{\infty} 2^{2j} \| \Pi_j \Theta_N \|_{L^2}^2 \right)^{1/2} \left( \sum_{j=j_0+1}^{\infty} 2^{-2j} \| \Pi_j Y_N \|_{L^2}^2 \right)^{1/2}
\sim \| \Theta_N \|_{H^1} \left( \sum_{j=j_0+1}^{\infty} 2^{-2j} \| \Pi_j Y_N \|_{L^2}^2 \right)^{1/2}.
\] (5.82)

Moreover, from Cauchy-Schwarz inequality and (5.81) followed by Cauchy’s inequality, we have
\[
\left| \sum_{j=0}^{j_0} \lambda_j \| \Pi_j Y_N \|_{L^2}^2 \right| \leq \left( \sum_{j=0}^{\infty} \lambda_j^2 \| \Pi_j Y_N \|_{L^2}^2 \right)^{1/2} \left( \sum_{j=0}^{j_0} \| \Pi_j Y_N \|_{L^2}^2 \right)^{1/2}
\leq C \left| \sum_{j=0}^{\infty} \lambda_j \| \Pi_j Y_N \|_{L^2}^2 \right| \left( \sum_{j=0}^{j_0} \| \Pi_j Y_N \|_{L^2}^2 \right)^{1/2}
\leq \frac{1}{2} \left| \sum_{j=0}^{\infty} \lambda_j \| \Pi_j Y_N \|_{L^2}^2 \right| + C' \sum_{j=0}^{j_0} \| \Pi_j Y_N \|_{L^2}^2.
\] (5.83)

Hence, from (5.82) and (5.83), we conclude that
\[
\left| \sum_{j=0}^{\infty} \lambda_j \| \Pi_j Y_N \|_{L^2}^2 \right| \lesssim \| \Theta_N \|_{H^1} \left( \sum_{j=j_0+1}^{\infty} 2^{-2j} \| \Pi_j Y_N \|_{L^2}^2 \right)^{1/2} + \sum_{j=0}^{j_0} \| \Pi_j Y_N \|_{L^2}^2.
\] (5.84)

Now, write as follows:
\[
\sum_{j=j_0+1}^{\infty} 2^{-2j} \| \Pi_j Y_N \|_{L^2}^2 = \sum_{j=j_0+1}^{\infty} 2^{-2j} \int_{\mathbb{T}^3} : (\Pi_j Y_N)^2 : \, dx + \sum_{j=j_0+1}^{\infty} 2^{-2j} E \left[ (\Pi_j Y_N)^2 \right].
\] (5.85)

For the first term, it follows from (5.12) and (3.18) that
\[
E \left[ \left( \sum_{j=j_0+1}^{\infty} 2^{-2j} \int_{\mathbb{T}^3} : (\Pi_j Y_N)^2 : \, dx \right)^2 \right] \sim \sum_{j=j_0+1}^{\infty} 2^{-5j} \sim 2^{-5j_0}.
\]
Set an almost surely finite constant \( B_1(\omega) \) by
\[
B_1(\omega) = \left( \sum_{j_0=0}^{\infty} 2^{j_0} \left( \sum_{j=j_0+1}^{\infty} 2^{-2j} \int_{\mathbb{T}^3} : (\Pi_j Y_N)^2 : \, dx \right)^2 \right)^{\frac{1}{2}}. 
\]
(5.86)
By the Wiener chaos estimate (Lemma [3.6]), we see that \( \mathbb{E} [B_1^p] \leq C_p < \infty \) for any finite \( p \geq 1 \).

From (5.85) and (5.86), we obtain
\[
\sum_{j=j_0+1}^{\infty} 2^{-2j} \| \Pi_j Y_N \|^2_{L^2} \lesssim 2^{-2j_0} B_1(\omega) + 2^{-j_0}. 
\]
(5.87)
Similarly, we have
\[
\sum_{j=0}^{j_0} \| \Pi_j Y_N \|^2_{L^2} = \sum_{j=0}^{j_0} \int_{\mathbb{T}^3} : (\Pi_j Y_N)^2 : \, dx + \sum_{j=0}^{j_0} \mathbb{E} [(\Pi_j Y_N)^2] \lesssim B_2(\omega) + 2^{j_0}
\]
for some \( B_2(\omega) \geq 0 \), satisfying \( \mathbb{E} [B_2^p] \leq C_p < \infty \) for any finite \( p \geq 1 \).

Hence, from (5.84) with (5.87) and (5.88) that
\[
\sum_{j=0}^{\infty} \lambda_j \| \Pi_j Y_N \|^2_{L^2} \lesssim \left( 2^{-\frac{1}{2}j_0} + 2^{-j_0} B_1^2(\omega) \right) \| \Theta_N \|_{H^1} + B_2(\omega) + 2^{j_0}.
\]

By choosing \( 2^{j_0} \sim \| \Theta_N \|^\frac{3}{2}_{H^1} \), it follows from (5.78) and (5.80) and Cauchy’s inequality that
\[
\| \Theta_N \|^6_{L^2} \lesssim \| \Theta_N \|^2_{H^1} + B_1^3(\omega) + B_2^3(\omega). 
\]
(5.89)
Therefore, by taking \( \sigma > 0 \) sufficiently small, the desired bound (5.76) in this case follows from (5.89).

6. Further analysis in the defocusing case: \( 0 < \beta \leq 1 \)

6.1. Construction of the defocusing Gibbs measure: \( \frac{1}{2} < \beta \leq 1 \). In this subsection, we present the proof of Theorem 1.10 (ii.a) for \( \frac{1}{2} < \beta \leq 1 \). As pointed out in Remark 1.12, we introduce another renormalization and consider a new renormalized potential energy \( R_N^\beta(u) \) in (1.38).

Then, as in the case \( \beta > 1 \), it suffices to prove the uniform exponential integrability (1.40) for this new potential energy \( R_N^\beta(u) \).

We first extend the estimates (5.23) and (5.24) in Lemma 5.5 to the range \( 0 < \beta \leq 1 \).

**Lemma 6.1.** Let \( V \) be the Bessel potential of order \( 0 < \beta \leq 1 \). Then, there exist small \( \varepsilon > 0 \) and a constant \( c > 0 \) such that
\[
\left| \int_{\mathbb{T}^3} (V_0 \ast \Theta_N^2) Y_N \Theta_N \, dx \right| \leq c \left( 1 + \| Y_N \|^c_{\dot{C}^{-\frac{3}{2} - \varepsilon}} \right)
\]
\[+ \frac{1}{100} \left( \| \Theta_N \|^2_{H^{-\frac{3}{2}}} + \| \Theta_N \|^4_{L^2} + \| \Theta_N \|^2_{H^1} \right),
\]
(6.1)
\[
\left| \int_{\mathbb{T}^3} (V_0 \ast : Y_N^2:) \Theta_N^2 \, dx \right| \leq c \| : Y_N^2 : \|_{\dot{C}^{-1 - \varepsilon}} + \frac{1}{100} \left( \| \Theta_N \|^2_{L^2} + \| \Theta_N \|^2_{H^1} \right),
\]
(6.2)
uniformly in \( N \in \mathbb{N} \).
Proof. The second estimate (6.2) follows from a small modification of (5.29). From (3.6), (3.7), (3.3), and Young’s inequality, we have

\[ \left| \int_{\mathbb{T}^3} (V_0 * Y_N^2) \Theta_N^2 dx \right| \leq \| : Y_N^2 : c_1 - \varepsilon \| \Theta_N^4 \| p_{1,1}^{1 + \beta + \varepsilon} \]

\[ \lesssim \| : Y_N^2 : c_1 - \varepsilon \| \Theta_N \| L^2 \| \Theta_N \| H^{1 - \beta + 2\varepsilon} \]

\[ \lesssim \| : Y_N^2 : c_1 - \varepsilon \| \Theta_N \| L^2 \| \Theta_N \| H^{1 - \beta + 2\varepsilon} \] (6.3)

\[ \leq c \| Y_N^2 : c_1 - \varepsilon \| \frac{1}{100} \| \Theta_N \| ^4 \frac{1}{L^2} + \frac{1}{100} \| \Theta_N \| ^2 \] verifying (6.2) when \( 0 < \beta \leq 1 \).

As for the first estimate (6.1), it suffices to control \( \| (V_0 * \Theta_N^2) \Theta_N \| _{W^{1/2, 1}} \), using the terms appearing in (5.22). From (1.12) and (5.17), there exists a constant \( K_0 > 0 \) such that \( V_+ := V_0 + K_0 > 0 \). Then, we have

\[ \| (V_0 * \Theta_N^2) \Theta_N \| _{W^{1/2, 1}} \leq \| (V_+ * \Theta_N^2) \Theta_N \| _{W^{1/2, 1}} + K_0 \left( c + \| \Theta_N \| _{H^1} + \| \Theta_N \| _{L^2} \right) ^{1 - \varepsilon_0} \] (6.4)

for some \( 0 < \varepsilon_0 < 1 \). Letting

\[ Q(\Theta_N) := \int_{\mathbb{T}^3} (V_+ * \Theta_N^2) \Theta_N^2 dx, \]

we have

\[ Q(\Theta_N) \leq \left| \int_{\mathbb{T}^3} (V_0 * \Theta_N^2) \Theta_N^2 dx \right| + K_0 \| \Theta_N \| ^4 \frac{1}{L^2}. \] (6.5)

We also note that

\[ \| V_+ * \Theta_N^2 \| _{L^2} \lesssim \| \Theta_N \| _{H^{-\beta}} + K_0 \| \Theta_N \| _{L^2} \lesssim \| \Theta_N \| _{H^{-\beta}} + K_0 \| \Theta_N \| _{L^2} \]

\[ \lesssim Q^\frac{1}{2}(\Theta_N) + K_0 \| \Theta_N \| _{L^2} \] (6.6)

Given \( \lambda > 0 \), from (6.6), we have

\[ \| (V_+ * \Theta_N^2) \Theta_N \| _{L^1} = \int_{\mathbb{T}^3} | V_+ * \Theta_N^2 | | \Theta_N | dx \]

\[ \lesssim \int_{\mathbb{T}^3} | V_+ * \Theta_N^2 | (\lambda + \lambda^{-1} \Theta_N) dx \]

\[ \lesssim \lambda Q^\frac{1}{2}(\Theta_N) + \| \Theta_N \| _{L^2}^2 + \lambda^{-1} Q(\Theta_N). \]

By choosing \( \lambda \sim Q^\frac{1}{2}(\Theta_N) \), we obtain

\[ \| (V_+ * \Theta_N^2) \Theta_N \| _{L^1} \lesssim Q^\frac{3}{2}(\Theta_N) + \| \Theta_N \| _{L^2}^2. \] (6.7)

Moreover, we have

\[ \| (V_+ * \Theta_N^2) \Theta_N \| _{W^{1,1}} \leq \int_{\mathbb{T}^3} | V_+ * \Theta_N^2 | | \nabla \Theta_N | dx + \int_{\mathbb{T}^3} | V_+ * (\Theta_N \nabla \Theta_N) | | \Theta_N | dx \]

\[ \lesssim \int_{\mathbb{T}^3} | V_+ * \Theta_N^2 | | \nabla \Theta_N | dx + \int_{\mathbb{T}^3} | \Theta_N | | \nabla \Theta_N | | V_+ | \Theta_N | dx \]

\[ \lesssim (Q^\frac{3}{2}(\Theta_N) + \| \Theta_N \| _{L^2}^2) \| \Theta_N \| _{H^1} + \| \Theta_N | V_+ | \Theta_N | \| _{L^2} \| \Theta_N \| _{H^1}, \] (6.8)
where we used (6.6) in the last step. By Cauchy’s inequality, we have
\[
\|\Theta_N[(V_+ \ast |\Theta_N|)]^2\|_{L^2}^2 = \int_{\mathbb{T}^3} (V_+ \ast |\Theta_N|)^2(x) \Theta_N^2(x) \, dx \\
= \iiint V_+(x-y)V_+(x-z)|\Theta_N(y)||\Theta_N(z)| \, dy \, dz \, \Theta_N^2(x) \, dx \\
\lesssim \iiint V_+(x-y)V_+(x-z)(\Theta_N^2(y) + \Theta_N^2(z)) \, dy \, dz \, \Theta_N^2(x) \, dx
\]
(6.9)

Hence, by interpolating (6.7) and (6.10), we have
\[
\|(V_+ \ast \Theta_N^2) \Theta_N\|_{W^{1,1}} \lesssim \left(Q \frac{\|\Theta_N\|^2}{\|\Theta_N\|_{L^2}^2} + \|\Theta_N\|_{H^1}^{1+\varepsilon}\right) \|\Theta_N\|_{H^1}^{1-\varepsilon_0}
\]
(6.11)
for some $0 < \varepsilon_0 < 1$. Finally, the desired estimate (6.1) follows from (6.4), (6.5), (6.7), (6.11), and Young’s inequality.

In order to handle (5.25) and (5.26) for $\beta \leq 1$, we need to introduce a further renormalization. Namely, we need to use $R_N^0$ in (1.38) instead of $R_N$ in (1.27). The additional term in (1.38) is divided into the following three terms:
\[
- \int_{\mathbb{T}^3} (K_N^{1/2} \ast Y_N)^2 \, dx, \quad -2 \int_{\mathbb{T}^3} (K_N \ast Y_N) \, dx, \quad \text{and} \quad - \int_{\mathbb{T}^3} (K_N \ast \Theta_N) \, dx
\]
(6.12)
where $K_N$ and $K_N^{1/2}$ are defined in (1.37) in terms of the multiplier $\kappa_N(n)$. One can easily check that the first term in (6.12) is 0 under an expectation. By writing the second term in (6.12) as
\[
-2 \int_{\mathbb{T}^3} (K_N \ast Y_N) \, dx = -2 \sum_{n \in \mathbb{Z}^3} (\kappa_N(n) \hat{Y}_N(n)) \overline{\Theta_N(n)},
\]
we see that this term in particular cancels the divergent contribution from the left-hand side of (5.26), coming from $(V_0 \ast Y_N^2) \ast Y_N$ (which corresponds to $Z_{13}$ defined in (4.14)). In view of Remark 4.3 with (4.13), (4.15), (4.17), and (4.18), it follows from Lemma 3.7 and the paraproduct decomposition (3.2) that the renormalized cubic term:
\[
[(V_0 \ast Y_N^2) \ast Y_N], \quad V_0 \ast Y_N^2 : Y_N - 2K_N \ast Y_N
\]
(6.13)
belongs to $C^{\beta - \frac{3}{2} - \varepsilon}(\mathbb{T}^3)$ with a uniform bound in $N \in \mathbb{N}$, provided that $0 < \beta \leq 1$. See also Appendix B. Then, by modifying (5.30), we have
\[
\left| \int_{\mathbb{T}^3} [(V_0 \ast Y_N^2 \ast Y_N)]^\circ \, dx \right| \leq \|(V_0 \ast Y_N^2 \ast Y_N)]^\circ\|_{C^{\beta - \frac{3}{2} - \varepsilon}} \|\Theta_N\|_{C^{\beta - \frac{3}{2} - \varepsilon}}
\]
(6.14)
\[
\leq c \|(V_0 \ast Y_N^2 \ast Y_N)]^\circ\|^2_{C^{\beta - \frac{3}{2} - \varepsilon}} + \frac{1}{100} \|\Theta_N\|_{H^1}^2,
\]
provided that $\beta > \frac{1}{2}$.
The third term in (6.12) removes the divergence for $\beta \leq 1$ in
\[
\int_{T^3} (V_0 * (Y_N \Theta_N)) Y_N \Theta_N dx = \sum_{n_1 + n_2 + n_3 + n_4 = 0, n_1 + n_2 \neq 0} \tilde{V}(n_1 + n_2) \tilde{Y}_N(n_1) \tilde{\Theta}_N(n_2) \tilde{Y}_N(n_3) \tilde{\Theta}_N(n_4),
\]
coming from the case $n_1 + n_3 = 0$. We set
\[
\int_{T^3} [(V_0 * (Y_N \Theta_N)) Y_N \Theta_N]^2 dx := \int_{T^3} (V_0 * (Y_N \Theta_N)) Y_N \Theta_N dx - \int_{T^3} (K_N * \Theta_N) \Theta_N dx. \tag{6.15}
\]
Define a function $\gamma_N$ on $T^3 \times T^3$ by its Fourier coefficient:
\[
\tilde{\gamma}_N(n_2, n_4) := \sum_{n_1 \in \mathbb{Z}^3 \setminus \{n_2\}} \langle n_1 + n_2 \rangle^{-\beta} \left( \tilde{Y}_N(n_1) \tilde{Y}_N(-n_1 - n_2 - n_4) - \mathbf{1}_{n_2 + n_4 = 0} \langle n_1 \rangle^{-2} \right). \tag{6.16}
\]
Then, with $\tilde{\Theta}_N(x) = \Theta_N(-x)$, it follows from Parseval’s identity, (3.3), and Young’s inequality that
\[
|\int_{T^3 \times T^3} \gamma_N(x, y) \tilde{\Theta}_N(x) \tilde{\Theta}_N(y) dx dy | \leq C \| \gamma_N \|_{H^{-1+\varepsilon}(T^3 \times T^3)}^2 + 100 \left( \| \Theta_N \|_{H^{-1}(T^3)}^2 + \| \Theta_N \|_{L^2(T^3)}^4 \right).
\]
Note that $\gamma_N \in \mathcal{H}_2$. Then, in view of the Wiener chaos estimate (Lemma 3.6), it suffices to bound the second moment of $\| \gamma_N \|_{H^{-1+\varepsilon}(T^3 \times T^3)}$. By symmetry, we assume $|n_2| \geq |n_4|$. Then, from (6.16), Young’s inequality, and Lemma 3.4 we have
\[
\mathbb{E}_{Q^u} \left[ \| \gamma_N \|_{H^{-1+\varepsilon}(T^3 \times T^3)}^2 \right] \lesssim \sum_{n_1, n_2, n_4 \in \mathbb{Z}^3, |n_2| \geq |n_4|} \frac{1}{\langle n_2 \rangle^{2-2\varepsilon} \langle n_4 \rangle^{2-2\varepsilon} \langle n_1 + n_2 \rangle^{2\beta} \langle n_1 + n_2 + n_4 \rangle^2} \frac{1}{\langle n_1 \rangle^2} \lesssim 1,
\]
uniformly in $N \in \mathbb{N}$, provided that $\beta > \frac{1}{2}$.

Putting everything together, we conclude that, with an additional renormalization (1.38), an analogue of Lemma 5.5 holds for $\beta > \frac{1}{2}$ and thus, in view of Lemma 5.3 we conclude the uniform exponential integrability (1.40) for $R^u_N(u)$. Finally, together with Remark 5.2 this proves (1.32), allowing us to construct the limiting Gibbs measure $\tilde{\rho}$ in (1.41) for $\beta > \frac{1}{2}$. 

6.2. Tightness for $0 < \beta \leq \frac{1}{2}$. In the remaining part of this section, we consider the case $0 < \beta \leq \frac{1}{2}$. In this subsection, we extend the uniform exponential integrability and prove tightness of the truncated Gibbs measures $\{\rho_N\}_{N \in \mathbb{N}}$ for $0 < \beta \leq \frac{1}{2}$. In this case, the estimate (6.14) fails since $[(V_0 * : Y_N^2 :) Y_N]^\circ$ defined in (6.13) is too irregular. This forces us to introduce a further renormalization (see (6.23)), in an analogous manner to the case of the $\Phi_3^4$-measure studied in [4]. The resulting measure will not be absolutely continuous with respect to the base Gaussian free field $\mu$; see Subsection 6.4. We point out that this extra renormalization appears only at the level of the measure. In the following, we use the following short-hand notations: $\mathcal{Y}$ field renormalization (see (6.23)), in an analogous manner to the case of the $\Phi_3^4$-measure studied in [4].

The Ito product formula yields

$$
E \left[ \int_{T^3} [(V_0 * : Y_N^2 :) Y_N]^\circ \Theta_N dx \right] = E \left[ \int_0^1 \int_{T^3} [(V_0 * : Y_N(t)^2 :) Y_N(t)]^\circ \dot{\Theta}_N(t) dt \right],
$$

where we have $\dot{\Theta}_N(t) = \langle \nabla \rangle^{-1} \pi_N \theta(t)$ by the definition (5.14). Define $\mathcal{Y}_N$ with $\mathcal{Y}_N(0) = 0$ by its time derivative:

$$
\dot{\mathcal{Y}}_N(t) = (1 - \Delta)^{-1} [(V_0 * : Y_N(t)^2 :) Y_N(t)]^\circ
$$

and set $\mathcal{Y}_N = \pi_N \mathcal{Y}_N$. Then, we perform a change of variables:

$$
\mathcal{Y}_N(t) := \dot{\Theta}(t) + \dot{\mathcal{Y}}_N(t)
$$

with $\mathcal{Y}_N(0) = 0$ and set $\mathcal{Y}_N = \pi_N \mathcal{Y}_N$. Then, from (6.18), (6.19), and (6.20), we have

$$
E \left[ \int_{T^3} [(V_0 * : Y_N^2 :) Y_N]^\circ \Theta_N dx + \frac{1}{2} \int_0^1 \|\theta(t)\|_L^2 dt \right]
= \frac{1}{2} E \left[ \int_0^1 \|\mathcal{Y}_N(t)\|_{H^1}^2 dt \right] - C_N,
$$

where the divergent constant $C_N$ is given by

$$
C_N := \frac{1}{2} E \left[ \int_0^1 \|\mathcal{Y}_N(t)\|_{H^1}^2 dt \right] \longrightarrow \infty,
$$

as $N \to \infty$ for $\beta \leq \frac{1}{2}$. The divergence in (6.22) can be easily seen from the spatial regularity $\beta + \frac{1}{2} - \varepsilon$ of $\dot{\mathcal{Y}}_N(t)$ (with a uniform bound in $N \in \mathbb{N}$) for $0 < \beta \leq \frac{1}{2}$.

This motivates us to introduce a further renormalization:

$$
R_N^\circ(u) = R_N^\circ(u) + C_N,
$$

where $R_N^\circ(u)$ and $C_N$ are as in (1.38) and (6.22), respectively. With a slight abuse of notation, we define the truncated Gibbs measure $\rho_N$ in this case by

$$
d\rho_N(u) = Z_N^{-1} e^{-R_N^\circ(u)} d\mu(u),
$$

where the partition function $Z_N$ is given by

$$
Z_N = \int e^{-R_N^\circ(u)} d\mu.
$$

Then, by the Boué-Dupuis variational formula (Lemma 5.11), we have

$$
- \log Z_N = \inf_{\theta \in \mathbb{H}_a} E \left[ R_N^\circ(Y(1) + J(\theta)(1)) + \frac{1}{2} \int_0^1 \|\theta(t)\|_L^2 dt \right] (6.26)
$$
for any $N \in \mathbb{N}$. By setting

$$W_N^\omega(\theta) = \mathbb{E}\left[ R_N^\omega(Y(1) + I(\theta)(1)) + \frac{1}{2} \int_0^1 \|\theta(t)\|^2_{L^2} dt \right], \quad (6.27)$$

it follows from (5.16) and (5.21) with (1.38), (6.13), (6.15), (6.21), and (6.23) that

$$W_N^\omega(\theta) = \mathbb{E}\left[ \frac{1}{2} \int_{T^3} (V_0 \ast : Y_N^2:) \Theta_N^2 dx + \int_{T^3} [(V_0 \ast (Y_N \Theta_N)) Y_N \Theta_N]^{\circ} dx 
+ \int_{T^3} (V_0 \ast \Theta_N^2) Y_N \Theta_N dx + \frac{1}{4} \int_{T^3} (V_0 \ast \Theta_N^2) \Theta_N^2 dx 
+ \frac{1}{4} \left\{ \int_{T^3} \left( Y_N^2 : + Y_N \Theta_N + \Theta_N^2 \right) \right\}^2 
+ \frac{1}{2} \int_0^1 \|\hat{\theta}(t)\|^2_{H^1} dt \right], \quad (6.28)$$

We also set

$$\Upsilon_N = \Upsilon_N(1) = \pi_N \Upsilon^N(1) \quad \text{and} \quad \Xi_N = \Xi_N(1) = \pi_N \Xi^N(1). \quad (6.29)$$

In view of the change of variables (6.20), we view $\hat{\theta}$ as a drift and study each term in (6.28) by writing $\Theta_N$ as

$$\Theta_N = \Upsilon_N - \Xi_N. \quad (6.30)$$

The positive terms for the current problem are given by

$$\mathcal{U}_N^\omega(\theta) = \mathbb{E}\left[ \frac{1}{8} \int_{T^3} (V_0 \ast \Upsilon_N^2) \Upsilon_N^2 dx + \frac{1}{32} \left( \int_{T^3} \Upsilon_N^2 dx \right)^2 + \frac{1}{2} \int_0^1 \|\hat{\Upsilon}_N(t)\|^2_{H^1} dt \right]. \quad (6.31)$$

As for the first term on the right-hand side of (6.31), see Lemma 6.2 below.

In the following, we state several lemmas, controlling the terms appearing in (6.28).

**Lemma 6.2.** Let $V$ be the Bessel potential of order $0 < \beta \leq \frac{1}{2}$ and $V_0$ be as in (5.17). Then, there exist small $\varepsilon > 0$ and a constant $c > 0$ such that

$$\int_{T^3} (V_0 \ast \Theta_N^2) \Theta_N^2 dx \geq \frac{1}{2} \int_{T^3} (V_0 \ast \Upsilon_N^2) \Upsilon_N^2 dx - \frac{1}{1000} \|\Upsilon_N\|_{L^2}^4 - c \|\Xi_N\|_{C^{\beta + \frac{1}{2} - \varepsilon}}^4 \quad (6.32)$$

and

$$\left\{ \int_{T^3} \left( Y_N^2 : + 2 Y_N \Theta_N + \Theta_N^2 \right) dx \right\}^2 \geq \frac{1}{8} \|\Upsilon_N\|_{L^2}^4 - \frac{1}{100} \|\Upsilon_N\|_{H^1}^2 - c \left\{ 1 + \|\Upsilon_N\|_{C^{\alpha - \frac{1}{2} - \varepsilon}} + \left( \int_{T^3} Y_N^2 : dx \right)^2 + \|\Xi_N\|_{C^{\beta + \frac{1}{2} - \varepsilon}}^c \right\} \quad (6.33)$$

for $\Theta_N = \Upsilon_N - \Xi_N$ as in (6.30), uniformly in $N \in \mathbb{N}$.

**Proof.** The first estimate (6.32) can be easily seen from

$$\|\Upsilon_N + \Xi_N\|_{H^{-\frac{\alpha}{2}}} \lesssim \|\Upsilon_N\|_{L^2}^2 + \|\Xi_N\|_{C^{\beta + \frac{1}{2} - \varepsilon}}^2.$$
The second estimate (6.33) follows from a slight modification of the proof of Lemma 5.6. Indeed, it follows from (5.31) along with the following two estimates:

\[
\frac{1}{2} \left( \int_{\mathbb{T}^3} \Theta_N^2 dx \right)^2 = \frac{1}{2} \left( \int_{\mathbb{T}^3} \mathcal{Y}_N^2 dx - 2 \int_{\mathbb{T}^3} \mathcal{Y}_N \mathcal{Z}_N dx + \int_{\mathbb{T}^3} \mathcal{Z}_N^2 dx \right)^2 \\
\geq \frac{1}{5} \| \mathcal{Y}_N \|_{L^2}^4 - C \| \mathcal{Z}_N \|_{L^2}^4
\]

and

\[
\left| \int_{\mathbb{T}^3} \mathcal{Y}_N \Theta_N dx \right|^2 \leq \| \mathcal{Y}_N \|_{C^{-\frac{1}{2}-\varepsilon}}^2 \left( \| \mathcal{Y}_N \|_{H^{\frac{1}{2}+2\varepsilon}}^2 + \| \mathcal{Z}_N \|_{C^{\frac{1}{2}+2\varepsilon}}^2 \right) \\
\leq C \| \mathcal{Y}_N \|_{C^{-\frac{1}{2}-\varepsilon}}^4 + \frac{1}{100C_0} \| \mathcal{Y}_N \|_{L^2}^4 + \frac{1}{100C_0} \| \mathcal{Y}_N \|_{H^1}^4 + \| \mathcal{Z}_N \|_{C^{\frac{1}{2}+\varepsilon}}^4.
\]

This proves Lemma 6.2.

Lemma 6.3. Let \( V \) be the Bessel potential of order \( 0 < \beta \leq \frac{1}{2} \) and \( V_0 \) be as in (5.17). Then, there exist small \( \varepsilon > 0 \) and a constant \( C > 0 \) such that

\[
\left| \int_{\mathbb{T}^3} (V_0 \ast \Theta_N^2) \mathcal{Y}_N \Theta_N dx \right| \leq C \left( 1 + \| \mathcal{Y}_N \|_{C^{-\frac{1}{2}-\varepsilon}}^4 + \| \mathcal{Z}_N \|_{C^{\beta+\frac{1}{2}-\varepsilon}}^4 \right) \\
+ \frac{1}{100} \left( \| \mathcal{Y}_N \|_{H^{\frac{1}{2}}}^2 + \| \mathcal{Y}_N \|_{L^2}^2 + \| \mathcal{Y}_N \|_{H^1}^2 \right),
\]

\[
\left| \int_{\mathbb{T}^3} (V_0 \ast : \mathcal{Y}_N^2 \mathcal{Y}_N^2) \Theta_N^2 dx \right| \leq C \| \mathcal{Y}_N \|_{C^{-\varepsilon}} \left( \| \mathcal{Y}_N \|_{H^{\frac{1}{2}}}^2 + \| \mathcal{Y}_N \|_{L^2}^2 + \| \mathcal{Y}_N \|_{H^1}^2 \right)
+ \| (V_0 \ast : \mathcal{Y}_N^2 \mathcal{Y}_N^2) \mathcal{Z}_N \|_{C^{\beta-\varepsilon}} \\
+ \frac{1}{100} \left( \| \mathcal{Y}_N \|_{L^2}^2 + \| \mathcal{Y}_N \|_{H^1}^2 \right)
\]

for \( \Theta_N = \mathcal{Y}_N - \mathcal{Z}_N \) as in (6.30), uniformly in \( N \in \mathbb{N} \). Furthermore, the stochastic terms \( (V_0 \ast : \mathcal{Y}_N^2 \mathcal{Y}_N^2) \mathcal{Z}_N \) and \( (V_0 \ast : \mathcal{Y}_N^2 \mathcal{Y}_N^2) \mathcal{Z}_N \) have uniformly bounded \( \mathbb{E} \) moments under the \( C^{\beta-\varepsilon} \) norm.

Proof. In the following, we focus on proving the estimates (6.34) and (6.35). See Appendix E for analysis on the stochastic terms \( (V_0 \ast : \mathcal{Y}_N^2 \mathcal{Y}_N^2) \mathcal{Z}_N \) and \( (V_0 \ast : \mathcal{Y}_N^2 \mathcal{Y}_N^2) \mathcal{Z}_N \).

We prove (6.34) and (6.35) by replacing each \( \Theta_N \) with \( \mathcal{Y}_N \) or \( \mathcal{Z}_N \) and carrying out case-by-case analysis. When all the occurrences of \( \Theta_N \) are replaced by \( \mathcal{Y}_N \), the estimates (6.34) and (6.35) follow from Lemma 6.1. From (B.2) and Lemma 3.7, we have \( \mathcal{Z}_N \in C^{\beta+\varepsilon} (\mathbb{T}^3) \) almost surely with a uniform bound in \( N \in \mathbb{N} \).

From (3.6), (3.7), and Lemma 3.2 (with \( \beta > 2\varepsilon \)), we have

\[
\left| \int_{\mathbb{T}^3} (V_0 \ast \mathcal{Y}_N^2) \mathcal{Y}_N \mathcal{Z}_N dx \right| \leq \| V_0 \ast \mathcal{Y}_N^2 \|_{L^1} \| \mathcal{Y}_N \mathcal{Z}_N \|_{C^{-\varepsilon}} \leq \| \mathcal{Y}_N \|_{H^{\frac{1}{2}}} \| \mathcal{Y}_N \|_{H^1} \| \mathcal{Z}_N \|_{C^{\beta+\varepsilon}}.
\]

Then, (6.34) in this case follows from (3.3) and Young’s inequality. Similarly, we have

\[
\left| \int_{\mathbb{T}^3} (V_0 \ast (\mathcal{Y}_N \mathcal{Z}_N)) \mathcal{Y}_N (\mathcal{Y}_N - \mathcal{Z}_N) dx \right| \\
\leq \| \mathcal{Y}_N \|_{H^{\frac{1}{2}}} \| \mathcal{Y}_N \|_{H^{\frac{1}{2}}} \| \mathcal{Y}_N \mathcal{Z}_N \|_{C^{\beta+\varepsilon}} \leq \| \mathcal{Y}_N \|_{H^{\frac{1}{2}}} \| \mathcal{Y}_N \|_{H^{\frac{1}{2}}} \| \mathcal{Z}_N \|_{C^{\beta+\varepsilon}}.
\]
Then, (3.3) and Young’s inequality yields (6.34) in this case. The remaining case (with $V_0 \ast \mathcal{Z}_N^\beta$) follows in an analogous manner since $V_0 \ast \mathcal{Z}_N^\beta \in C^\infty(T^3)$.

The second estimate (6.35) for $(V_0^* : Y_N^2 : \mathcal{Z}_N^\beta Y_N$ follows from (3.6), (3.3), and Young’s inequality.

Lastly, we estimate the contribution from the renormalized term defined in (6.15). Given small $\varepsilon > 0$, define an integral operator $T_N$ by

$$T_N f(x) = \int_{T^3} k_N(x, y) f(y) dy \quad (6.36)$$

with the kernel $k_N$ given by

$$k_N(x, y) = (\nabla_x)^{-1+\varepsilon} (\nabla_y)^{-1+\varepsilon} \mathcal{Y}_N(x, y), \quad (6.37)$$

where $\mathcal{Y}_N$ is defined in (6.16). Then, the following estimate holds.

**Lemma 6.4.** Let $V$ be the Bessel potential of order $0 < \beta \leq 1 \over 2$. Then, there exist small $\varepsilon > 0$ and a constant $c > 0$ such that

$$\int_{T^3} [(V_0 \ast (Y_N \Theta_N)) Y_N \Theta_N^\beta] \, dx \leq c \left( 1 + \| T_N \|_{L^2(L^2)} + \| (V_0 \ast (Y_N \mathcal{Z}_N^\beta)) Y_N \mathcal{Z}_N^\beta \|_{C_{\beta-1-\varepsilon}} \right)$$

$$+ \left( \| (V_0 \ast (Y_N \mathcal{Z}_N^\beta)) Y_N^\alpha \|_{C_{\beta-1-\varepsilon}} \right)^2$$

$$+ \frac{1}{100} \left( \| Y_N \|^2_{L^2} + \| Y_N \|^2_{H^1} \right), \quad (6.38)$$

for $\Theta_N = \mathcal{Y}_N - \mathcal{Z}_N$ as in (6.30), uniformly in $N \in \mathbb{N}$. Here, $[(V_0 \ast (Y_N \mathcal{Z}_N^\beta)) Y_N^\alpha]$ is defined by

$$[(V_0 \ast (Y_N \mathcal{Z}_N^\beta)) Y_N^\alpha] := (V_0 \ast (Y_N \mathcal{Z}_N^\beta)) Y_N - K_N \ast \mathcal{Z}_N, \quad (6.39)$$

where $K_N$ is as in (1.37). Furthermore, the expectation of the first term, containing the stochastic terms $T_N$, $[(V_0 \ast (Y_N \mathcal{Z}_N^\beta)) Y_N^\alpha]^\circ$, and $[(V_0 \ast (Y_N \mathcal{Z}_N^\beta)) Y_N^\alpha]^\circ$, is uniformly bounded in $N \in \mathbb{N}$.

**Proof.** As in the proof of Lemma 6.3, we prove (6.38) by performing case-by-case analysis. The contribution from the case when both $\Theta_N$’s are replaced by $\mathcal{Z}_N$ is clearly bounded by $\| [(V_0 \ast (Y_N \mathcal{Z}_N^\beta)) Y_N \mathcal{Z}_N^\beta] \|_{C_{(\beta-1-\varepsilon)}}$. From (6.15) and (6.39) with (6.30), we have

$$\left| \int_{T^3} [(V_0 \ast (Y_N \mathcal{Z}_N^\beta)) Y_N Y_N^\beta] \, dx \right| \leq \int_{T^3} [(V_0 \ast (Y_N \mathcal{Z}_N^\beta)) Y_N^\beta] \, T_N \, dx$$

$$\leq \| [(V_0 \ast (Y_N \mathcal{Z}_N^\beta)) Y_N^\alpha] \|_{C_{(\beta-1-\varepsilon)}} \| T_N \|_{H^1}. \quad (6.40)$$

Then, Cauchy’s inequality yields (6.38) in this case. By the symmetry, the contribution from $[(V_0 \ast (Y_N \mathcal{Y}_N^\beta)) Y_N \mathcal{Z}_N^\beta]^\circ$ is also bounded by (6.40).

It remains to consider the case $\Theta_N = \mathcal{Y}_N$ for both entries. Suppose that, for $\beta > 0$, $T_N$ defined in (6.36) is bounded on $L^2(T^3)$. Then, with $\tilde{\mathcal{Y}}_N(x) = \mathcal{Y}_N(-x)$, it follows from Parseval’s identity, the (assumed) boundedness of $T_N$, (3.3), and Young’s inequality that

$$\left| \int_{T^3} [(V_0 \ast (Y_N \mathcal{Y}_N)) Y_N \mathcal{Y}_N^\beta] \, dx \right| \leq \int_{T^3} \mathcal{Y}_N(x, y) \tilde{\mathcal{Y}}_N(x) \tilde{\mathcal{Y}}_N(y) dy dx$$

$$= \int_{T^3} T_N (\nabla)^{-1-\varepsilon} \tilde{\mathcal{Y}}_N(x) \cdot (\nabla)^{-1-\varepsilon} \tilde{\mathcal{Y}}_N(x) \, dx$$

$$\leq \| T_N \|_{L^2(L^2)} \| \mathcal{Y}_N \|^2_{H^1-\varepsilon}$$

$$\leq C \| T_N \|^2_{L^2(L^2)} + \frac{1}{100} \left( \| \mathcal{Y}_N \|^2_{H^1(T^3)} + \| \mathcal{Y}_N \|^2_{L^2(T^3)} \right).$$
This proves (6.38) in this case.

We now need to show that the expectation of the first term on the right-hand side of (6.39), containing the stochastic terms $T_N$, $((V_0 * (Y_N \mathcal{F} N)) Y_N Y_N) \mathcal{F} N$, and $((V_0 * (Y_N \mathcal{F} N)) Y_N) \mathcal{F} N$, is uniformly bounded in $N \in \mathbb{N}$. As for the stochastic terms $((V_0 * (Y_N \mathcal{F} N)) Y_N Y_N) \mathcal{F} N$ and $((V_0 * (Y_N \mathcal{F} N)) Y_N) \mathcal{F} N$, see Appendix [3] In the remaining part of this proof, we focus on proving the boundedness of $T_N$ on $L^2(\mathbb{T}^3)$ (under a high moment). In the following, all the estimates are uniform in $N \in \mathbb{N}$.

Suppose that there exists some $0 < \alpha < 3$ such that

$$|x - y|^{2\alpha} \mathbb{E}[k_N^2(x, y)] \lesssim 1$$

(6.41)

for any $x, y \in \mathbb{T}^3 \cong [-\pi, \pi]^3$, uniformly in $N \in \mathbb{N}$. Then, by the Wiener chaos estimate (Lemma 3.6), we have

$$\mathbb{E}\left[\left\|\frac{1}{\sqrt{\pi}} e^{-\frac{|x|^2}{2}} - \frac{1}{\sqrt{\pi}} e^{-\frac{|y|^2}{2}}\right\|^2_{L_2^q L_6^p}\right] < \infty$$

for any finite $q \geq 1$ and $\varepsilon > 0$. Thus, for $1 < p < q < \frac{3}{2}$ and $\frac{1}{r} = \frac{1}{p} - \frac{1}{q}$, we have

$$\mathbb{E}\left[\left\|\frac{1}{\sqrt{\pi}} e^{-\frac{|x|^2}{2}} - \frac{1}{\sqrt{\pi}} e^{-\frac{|y|^2}{2}}\right\|^2_{L_2^q L_6^p}\right] \leq \mathbb{E}\left[\left\|\frac{1}{\sqrt{\pi}} e^{-\frac{|x|^2}{2}} - \frac{1}{\sqrt{\pi}} e^{-\frac{|y|^2}{2}}\right\|^2_{L_2^q L_6^p}\right] < \infty.$$
\textbf{Case 1:} \(0 < s \leq t \leq 1\). From (6.16) and (3.18), we have

\[
\mathbb{E}\left[\tilde{Y}(n, m)\tilde{Y}(n', m')\right] = \mathbb{E}\left[\sum_{n_1 \in \mathbb{Z}^3, \ n_1 \neq n} (n + n_1)^{-\beta} \left(\tilde{Y}_N(n_1)\tilde{Y}_N(-n_1 - n - m) - 1_{n+m=0} \cdot (n_1)^{-2}\right)\right] \\
\times \sum_{n_1' \in \mathbb{Z}^3, \ n_1' \neq n'} (n' + n_1')^{-\beta} \left(\tilde{Y}_N(n_1')\tilde{Y}_N(-n_1' - n' - m') - 1_{n'+m'=0} \cdot (n_1')^{-2}\right) \\
= 1_{n+m+n'+m'=0} \sum_{n_1 \in \mathbb{Z}^3, \ |n_1|, |n_1+n+m| \leq N} \frac{\tilde{V}(n + n_1)\tilde{V}(n' - n_1)}{(n_1)^2(n + m + n_1)^2} \\
+ 1_{n+m+n'+m'=0} \sum_{n_1 \in \mathbb{Z}^3, \ |n_1|, |n_1+n+m| \leq N} \frac{\tilde{V}(n + n_1)\tilde{V}(m' - n_1)}{(n_1)^2(n + m + n_1)^2} + \text{l.o.t.} \tag{6.44}
\]

Here, “l.o.t.” denotes the lower order terms coming from \(n_1 = -n\) or \(n_1' = -n'\). Hence, by ignoring the lower order terms in (6.44) (which can be estimated easily), we have

\[
\mathbb{E}\left[(p_t \otimes p_s) \ast \mathbb{Y}(N)^2(x, y)\right] = \sum_{n, m, n', m' \in \mathbb{Z}^3} e^{-t|m|^2 + |n|^2} e^{-s|m'|^2 + |m'|^2} \mathbb{E}\left[\tilde{Y}(n, m)\tilde{Y}(n', m')\right] e_{n+n'}(x) e_{m+m'}(y) \\
= \sum_{n, m, n', m' \in \mathbb{Z}^3} e^{-t|m|^2 + |n|^2} e^{-s|m|^2 + |m'|^2} (I + \Pi) e_{n+n'}(x - y) \\
= \left(\sum_{|n_1|, |n_2| \leq N} \frac{1}{(n_1)^2(n_2)^2}\right) \left(\sum_{k \in \mathbb{Z}^3} \tilde{V}(k) \exp\left(-t|k - n_1|^2 - s|k - n_2|^2\right) e_k(x - y)\right)^2 \\
= \sum_{|n_1|, |n_2| \leq N} \frac{\exp\left(-2t\frac{s}{t+s}|n_1 - n_2|^2\right)}{(n_1)^2(n_2)^2} \\
\times \left(\sum_{k \in \mathbb{Z}^3} \tilde{V}(k) \exp\left(-t + s\right) |k - \frac{tn_1 + sn_2}{t + s}|^2 e_k(x - y)\right)^2. \tag{6.45}
\]

Fix \(\delta > 0\) small. We first consider the case \(s \gtrsim t^\frac{1}{2}\). Recall that \(e^{-t|k - k_0|^2}\) is the Fourier transform of the periodization of \(e^{-ix \cdot k_0} p_t^\mathbb{R}^3(x)\), where \(p_t^\mathbb{R}^3\) is the heat semigroup on \(\mathbb{R}^3\). Then, from the Poisson summation formula, we have

\[
\left|\sum_{k \in \mathbb{Z}^3} \tilde{V}(k) \exp\left(-t + s\right) |k - \frac{tn_1 + sn_2}{t + s}|^2 e_k(x - y)\right| \\
\lesssim \sum_{k \in \mathbb{Z}^3} \left(|\mathbb{W}\mathbb{R}^3| \ast \mathbb{W}^2\right)(x - y + 2\pi k) \\
\lesssim |x - y|^\beta - 3 \tag{6.46}
\]
for any \( x, y \in \mathbb{T}^3 \cong [-\pi, \pi]^3 \), where \( V^{\mathbb{R}^3} \) is the Bessel potential of order \( \beta \) on \( \mathbb{R}^3 \). In the last step, we used the well-known asymptotics of the Bessel potential on \( \mathbb{R}^3 \): \( V^{\mathbb{R}^3}(x) \sim |x|^\beta - 3 \) as \( x \to 0 \) and \( V^{\mathbb{R}^3}(x) \sim |x|^\beta - 2 \) as \( |x| \to \infty \); see (4.2) and (4.3) in [2].

We also have
\[
\exp \left( -2 \frac{ts}{t+s} |n_1 - n_2|^2 \right) \lesssim s^{-1-\varepsilon} (n_1 - n_2)^{-2-2\varepsilon}. \tag{6.47}
\]

Hence, from (6.45), (6.46), and (6.47) with \( s \geq t^{\frac{3}{2}} \), we obtain (6.43), provided that \( \alpha > 3 - \beta \) and \( \frac{3\varepsilon}{2} < 1 - 2\varepsilon \). The last condition is guaranteed by choosing sufficiently small \( \varepsilon > 0 \).

Next, we consider the case \( x > 0 \). Then, from Lemma 3.4, we have
\[
\left| \sum_{k \in \mathbb{Z}^3} \hat{V}(k) \exp \left( -(t+s)|k - n_0|^2 \right) c_k(x-y) \right| \lesssim t^{-\frac{3}{2} - \varepsilon} (n_0)^{-\beta}, \tag{6.48}
\]

where \( n_0 = \frac{tn_1 + sn_2}{t+s} \). We also have
\[
\exp \left( -2 \frac{ts}{t+s} |n_1 - n_2|^2 \right) \lesssim s^{-1+\beta - \frac{1}{2} \varepsilon} (n_1 - n_2)^{-2+2\beta - \varepsilon}. \tag{6.49}
\]

Therefore, from (6.48), (6.49), and Lemma 3.5 with \( t^{-1} \ll s^{-\delta} \), we obtain
\[
\text{RHS of (6.45)} \lesssim \sum_{n_1, n_2} \frac{t^{-3-2\varepsilon} s^{-1+\beta - \frac{1}{2} \varepsilon}}{\langle n_1 \rangle^2 \langle n_2 \rangle^2 \langle n_0 \rangle^2 \langle n_1 - n_2 \rangle^{2+2\beta - \varepsilon}} \lesssim t^{-3-2\varepsilon} s^{-1+\beta - \frac{1}{2}} \lesssim s^{-1+2\varepsilon} t^{1+2\varepsilon},
\]

provided that \( \frac{5}{2} \varepsilon + (2 + 4\varepsilon)\delta \leq \beta \leq \frac{1}{2} \). This proves (6.43) in this case.

- **Case 2:** \( t \geq s \geq 1 \). In this case, the bound (6.43) follows from (6.45), (6.46), and (6.47) with \( s^{-1-\varepsilon} \leq 1 \).

- **Case 3:** \( t \geq 1 \geq s > 0 \). In this case, from (6.48), (6.49), and Lemma 3.5, we have
\[
\text{RHS of (6.45)} \lesssim \sum_{n_1, n_2} \frac{s^{-1+\beta - \frac{1}{2} \varepsilon}}{\langle n_1 \rangle^2 \langle n_2 \rangle^2 \langle n_0 \rangle^2 \langle n_1 - n_2 \rangle^{2-2\beta + \varepsilon}} \lesssim s^{-1+\beta - \frac{1}{2}} \lesssim s^{-1+2\varepsilon},
\]

provided that \( \frac{5}{2} \varepsilon \leq \beta \leq \frac{1}{2} \). This completes the proof of Lemma 6.4.

Putting everything together, we conclude from (6.27), (6.31), and Lemmas 6.2, 6.3, and 6.4 with Lemmas 5.4 and B.1 that
\[
\inf_{N \in \mathbb{N}} \inf_{\theta \in \mathbb{B}_a} W_N^\infty(\theta) \geq \inf_{N \in \mathbb{N}} \inf_{\theta \in \mathbb{B}_a} \left\{ - C_0 + \frac{1}{10} \mathcal{U}_N^\infty(\theta) \right\} \geq -C_0 > -\infty. \tag{6.50}
\]

Then, the uniform exponential integrability (1.42) for \( R_N^\infty(u) \) defined in (6.23) follows from the Boué-Dupuis variational formula (6.26).

**Remark 6.5.** As mentioned in Section 1, the uniform exponential integrability (1.42) holds only for the first moment but not for higher moments. This is because, in the renormalization (6.23), the constant \( C_N \) was introduced to cancel a divergent interaction in computing the first moment, (which is not suitable for higher moments).
Finally, we prove tightness of the truncated Gibbs measures $\{\rho_N\}_{N \in \mathbb{N}}$. Fix small $\varepsilon > 0$ and let $B_R \subset H^{-\frac{1}{2}-\varepsilon}(\mathbb{T}^3)$ be the closed ball of radius $R > 0$ centered at the origin. Then, by Rellich's compactness lemma, we see that $B_R$ is compact in $H^{-\frac{1}{2}-2\varepsilon}(\mathbb{T}^3)$. In the following, we establish a uniform bound on $\rho_N(B_R^c)$, $N \in \mathbb{N}$, by assuming that a unique limit $Z = \lim_{N \to \infty} Z_N \in (0, \infty)$ exists. We will prove this latter fact in the next subsection. See (6.57).

Given $M \gg 1$, let $F$ be a bounded smooth non-negative function such that $F(u) = 0$ if $\|u\|_{H^{-\frac{1}{2}-\varepsilon}} > R$ and $F(u) = M$ if $\|u\|_{H^{-\frac{1}{2}-\varepsilon}} \leq \frac{R}{2}$. Then, we have

$$\rho_N(B_R^c) \leq Z_N^{-1} \int e^{-F(u) - R_N^\infty(u)} d\mu \leq \int e^{-F(u) - R_N^\infty(u)} d\mu =: \tilde{Z}_N, \quad (6.51)$$

uniformly in $N \gg 1$. Under the change of variables (6.20), define $\tilde{R}_N^\infty(Y + \mathcal{Y}^N - 3N)$ by

$$\tilde{R}_N^\infty(Y + \mathcal{Y}^N - 3N) = \frac{1}{2} \int_{\mathbb{T}^3} (V_0 * :Y^2_N:)\Theta_N^2 dx + \int_{\mathbb{T}^3} [(V_0 * (Y \Theta_N))^\ast Y_N \Theta_N] dx$$

$$+ \int_{\mathbb{T}^3} (V_0 * \Theta_N^2)Y_N \Theta_N dx + \frac{1}{4} \int_{\mathbb{T}^3} (V_0 * \Theta_N^2) \Theta_N^2 dx$$

$$+ \frac{1}{4} \left\{ \int_{\mathbb{T}^3} Y_N^2 : + 2Y_N \Theta_N + \Theta_N^2 \right\} dx, \quad (6.52)$$

where $Y_N = \pi_N Y$ and $\Theta_N = \pi_N \Theta = \pi_N (\mathcal{Y}^N - 3N)$. Then, by the Boué-Dupuis formula (Lemma 5.11)\[3\] we have

$$- \log \tilde{Z}_N = \inf_{\mathcal{Y}^N \in \mathcal{H}_a} \mathbb{E} \left[ F(Y + \mathcal{Y}^N - 3N) ight.$$

$$+ \tilde{R}_N^\infty(Y + \mathcal{Y}^N - 3N) + \frac{1}{2} \int_0^1 \|\mathcal{Y}(t)\|_{H^2}^2 dt \bigg]. \quad (6.53)$$

Recall that $Y - 3N \in \mathcal{H}_{< 3}$. Then, by the Wiener chaos estimate (Lemma 3.6) and Chebyshev’s inequality, we have, for some $c > 0$,

$$\mathbb{P}\left( \|Y + \mathcal{Y}^N - 3N\|_{H^{-\frac{1}{2}-\varepsilon}} > \frac{R}{2} \right) \leq \mathbb{P}\left( \|Y - 3N\|_{H^{-\frac{1}{2}-\varepsilon}} > \frac{R}{4} \right) + \mathbb{P}\left( \|\mathcal{Y}\|_{H^1} > \frac{R}{4} \right)$$

$$\leq e^{-cR^2} + \frac{16}{R^2} \mathbb{E}\left[ \|\mathcal{Y}\|_{H^1}^2 \right], \quad (6.54)$$

uniformly in $N \in \mathbb{N}$ and $R \gg 1$. Thus, by choosing $M = \frac{1}{64} R^2 \gg 1$, it follows from the definition of $F$, (6.54), and Lemma 5.4 that

$$\mathbb{E}\left[ F(Y + \mathcal{Y}^N - 3N) \cdot 1 \left\{ \|Y + \mathcal{Y}^N - 3N\|_{H^{-\frac{1}{2}-\varepsilon}} \leq \frac{R}{2} \right\} \right] \geq \frac{M}{2} - \frac{16M}{R^2} \mathbb{E}\left[ \|\mathcal{Y}\|_{H^1}^2 \right]$$

$$\geq \frac{M}{2} - \frac{1}{4} \mathbb{E}\left[ \int_0^1 \|\mathcal{Y}(t)\|_{H^2}^2 dt \right]. \quad (6.55)$$

Then, from (6.53), (6.55), and repeating the computation leading to (6.50), we obtain

$$- \log \tilde{Z}_N \geq \frac{M}{2} + \inf_{\mathcal{Y}^N \in \mathcal{H}_a} \mathbb{E} \left[ \tilde{R}_N^\infty(Y + \mathcal{Y}^N - 3N) + \frac{1}{4} \int_0^1 \|\mathcal{Y}(t)\|_{H^2}^2 dt \right]$$

$$\geq \frac{M}{4}, \quad (6.56)$$

\[3\] Here, we apply the Boué-Dupuis formula (Lemma 5.11) for $F$ on rough functions but this can be justified by a limiting argument. A similar comment applies in the following.
uniformly \( N \in \mathbb{N} \) and \( M = \frac{1}{64} R^2 \gg 1 \). Therefore, given any small \( \delta > 0 \), by choosing \( R = R(\delta) \gg 1 \) and setting \( M = \frac{1}{64} R^2 \gg 1 \), we obtain, from (6.51) and (6.56),

\[
\sup_{N \in \mathbb{N}} \rho_N(B'_R) < \delta.
\]

This proves tightness of the truncated Gibbs measures \( \{\rho_N\}_{N \in \mathbb{N}} \).

6.3. **Uniqueness of the limiting Gibbs measure for** \( 0 < \beta \leq \frac{1}{2} \). When \( \beta > \frac{1}{2} \), the uniform exponential integrability combined with Lemma 5.1 and Remark 5.2 allowed us to conclude the convergence of the truncated Gibbs measures. This argument, however, fails for \( 0 < \beta \leq \frac{1}{2} \) due to the non-convergence of \( \{R_N^\infty\}_{N \in \mathbb{N}} \), which can be seen from the proof of Lemma 5.1 (see the term \( Q_{N,1} \)). Nonetheless, the tightness of the truncated Gibbs measures \( \{\rho_N\}_{N \in \mathbb{N}} \), proven in the previous subsection, together with Prokhorov’s theorem implies existence of a weakly convergent subsequence. In this subsection, we prove uniqueness of the limiting Gibbs measure, which allows us to conclude the weak convergence of the whole sequence \( \{\rho_N\}_{N \in \mathbb{N}} \).

**Proposition 6.6.** Let \( 0 < \beta \leq \frac{1}{2} \). Let \( \{\rho_{N_k^1}\}_{k=1}^{\infty} \) and \( \{\rho_{N_k^2}\}_{k=1}^{\infty} \) be two weakly convergent subsequences of the truncated Gibbs measures \( \{\rho_N\}_{N \in \mathbb{N}} \) defined in (6.24), converging weakly to \( \rho^{(1)} \) and \( \rho^{(2)} \) as \( k \to \infty \), respectively. Then, we have \( \rho^{(1)} = \rho^{(2)} \).

**Proof.** By taking a further subsequence, we may assume that \( N_k^1 \geq N_k^2, k \in \mathbb{N} \). We first show that

\[
\lim_{k \to \infty} Z_{N_k^1} = \lim_{k \to \infty} Z_{N_k^2}, \tag{6.57}
\]

where \( Z_N \) is as in (6.25). Let \( Y = Y(1) \) be as in (5.12). Recall the change of variables (6.20) from the previous section and let \( \tilde{R}^\infty_N(Y + \Upsilon^N - \Upsilon_N) \) be as in (6.52). Then, by the Boué-Dupuis formula (Lemma 5.11), we have

\[
-\log Z_{N_k}^j = \inf_{\Upsilon_N^j \in \mathcal{H}_a} \mathbb{E} \left[ \tilde{R}^\infty_N(Y + \Upsilon_N^j - \Upsilon_N^j) + \frac{1}{2} \int_0^1 \|\dot{\Upsilon}_N^j(t)\|_{H^2_x}^2 dt \right] \tag{6.58}
\]

for \( j = 1, 2 \) and \( k \in \mathbb{N} \). Recall that \( Y \) and \( \Upsilon_N \) do not depend on the drift \( \Upsilon^N \) in the Boué-Dupuis formula (6.58).

Given \( \delta > 0 \), let \( \Upsilon_N^2 \) be an almost optimizer for (6.58). \[31\]

\[
-\log Z_{N_k}^j \geq \mathbb{E} \left[ \tilde{R}^\infty_N(Y + \Upsilon_N^2 - \Upsilon_N^2) + \frac{1}{2} \int_0^1 \|\dot{\Upsilon}_N^2(t)\|_{H^2_x}^2 dt \right] - \delta. \tag{6.59}
\]

\[31\] For an almost optimizer \( \Upsilon_N^2 \) of the minimization problem (6.58), we may assume that \( \Upsilon_N^2 = \pi_{N_k^2} Y_N^2 \). We, however, do not use this fact in view of a more general minimization problem (6.68) below.
Then, by choosing \( Y_{N_k}^{1} = Y_{N_k}^{2} := \pi_{N_k}^2 Y_{N_k}^{N_k} \), we have

\[
- \log Z_{N_k}^{1} + \log Z_{N_k}^{2} \leq \inf_{\tilde{Y}_{N_k} \in H_a} \mathbb{E} \left[ \tilde{R}^{\infty}_{N_k}(Y + \tilde{Y}_{N_k}^{1} - 3_{N_k}^{1}) + \frac{1}{2} \int_0^1 \| \tilde{Y}_{N_k}^{1}(t) \|^2_{H^2} dt \right] - \mathbb{E} \left[ \tilde{R}^{\infty}_{N_k}(Y + \tilde{Y}_{N_k}^{2} - 3_{N_k}^{2}) + \frac{1}{2} \int_0^1 \| \tilde{Y}_{N_k}^{2}(t) \|^2_{H^2} dt \right] + \delta
\]

\[
\leq \mathbb{E} \left[ \tilde{R}^{\infty}_{N_k}(Y + \tilde{Y}_{N_k}^{2} - 3_{N_k}^{2}) + \frac{1}{2} \int_0^1 \| \tilde{Y}_{N_k}^{2}(t) \|^2_{H^2} dt \right] + \delta
\]

where \( \tilde{R}^{\infty} \) is defined by

\[
\tilde{R}^{\infty}(Y + \tilde{3} - 3) = \frac{1}{2} \int_{T^3} (V_0 * : Y^2 : \tilde{0}^2 dx + \int_{T^3} [(V_0 * (Y \tilde{0})) Y \tilde{\Theta}] dx + \int_{T^3} (V_0 * \tilde{0}^2) Y \tilde{\Theta} dx + \frac{1}{4} \int_{T^3} (V_0 * \tilde{0}^2 \tilde{\Theta}) dx \]

\[
+ \frac{1}{4} \left\{ \int_{T^3} (Y^2 + 2Y \tilde{\Theta} + \tilde{\Theta}^2) dx \right\}^2
\]

for \( \tilde{\Theta} = Y - 3 \). At the last equality in (6.60), we used the fact that \( \pi_{N_k}^1 \tilde{Y}_{N_k}^{N_k} = \tilde{Y}_{N_k}^{N_k} \) under the assumption \( N_k^1 \geq N_k^2 \).

In the following, we discuss how to estimate the difference

\[
\mathbb{E} \left[ \tilde{R}^{\infty}(Y_{N_k}^{1} + \tilde{Y}_{N_k}^{2} - 3_{N_k}^{1}) - \tilde{R}^{\infty}(Y_{N_k}^{2} + \tilde{Y}_{N_k}^{2} - 3_{N_k}^{2}) \right].
\]

The main point is that differences appear only for \( Y \)-terms and \( \tilde{3} \)-terms (creating a negative power of \( N_k^2 \)). The contribution from the first term on the right-hand side in (6.61) is given by

\[
\mathbb{E} \left[ \frac{1}{2} \int_{T^3} (V_0 * : Y_{N_k}^{2} : - : Y_{N_k}^{2} : \tilde{Y}_{N_k}^{2}) \right] \]

\[
- \mathbb{E} \left[ \frac{1}{2} \int_{T^3} (V_0 * : Y_{N_k}^{2} : - : Y_{N_k}^{2} : \tilde{Y}_{N_k}^{2}) \right] (2\tilde{Y}_{N_k}^{N_k} - 3_{N_k}^{1}) 3_{N_k}^{1} \]

\[
- \mathbb{E} \left[ \frac{1}{2} \int_{T^3} (V_0 * : Y_{N_k}^{2} : (2\tilde{Y}_{N_k}^{N_k} - 3_{N_k}^{1} - 3_{N_k}^{2})) (3_{N_k}^{1} - 3_{N_k}^{2}) \right].
\]

By slightly modifying the analysis in Subsections 6.1 and 6.2, we can bound each term in (6.63) by

\[
(N_k^2)^{-a} \left( C(Y_{N_k}^{1}, Y_{N_k}^{2}, 3_{N_k}^{1}, 3_{N_k}^{2}) + \mathcal{U}_{N_k}^{\infty} \right) \lesssim (N_k^2)^{-a} \left( 1 + \mathcal{U}_{N_k}^{\infty} \right),
\]

for some small \( a > 0 \), where \( \mathcal{U}_{N_k}^{\infty} \) is given by (6.31) with \( \tilde{Y}_{N} = \tilde{Y}_{N_k}^{N_k} \) and \( Y = Y_{N_k}^{N_k} \) and \( C(Y_{N_k}^{1}, Y_{N_k}^{2}, 3_{N_k}^{1}, 3_{N_k}^{2}) \) denotes certain high moments of various stochastic terms involving \( Y_{N_k}^{i} \) and \( \tilde{3}_{N_k}^{j} \), \( j = 1, 2 \). For example, proceeding as in (6.3) together with Hölder’s inequality in \( \omega \), we
can estimate the first term in (6.63) by
\[ \lesssim \mathbb{E} \left[ \| : Y_{N_k^1}^2 : - : Y_{N_k^2}^2 : \| c^{-1-\epsilon} \| \mathcal{Y}_{N_k^1} \|_{L^2}^{1+\beta-2\epsilon} \| \mathcal{Y}_{N_k^2} \|_{H^1}^{1-\beta+2\epsilon} \right] \]
\[ \lesssim \| : Y_{N_k^1}^2 : - : Y_{N_k^2}^2 : \| \mathcal{Y}_{N_k^1} \|_{L^2}^{1+\beta-2\epsilon} \mathcal{C}_{\beta \epsilon} \| \mathcal{Y}_{N_k^2} \|_{L^2}^{1-\beta+2\epsilon} \]
\[ \lesssim (N_k^2)^{-a} \| \mathcal{Y}_{N_k^1} \|_{L^2}^{1+\beta-2\epsilon} \| \mathcal{Y}_{N_k^2} \|_{L^2}^{1-\beta+2\epsilon} \]
\[ \lesssim (N_k^2)^{-a} \left( 1 + \mathcal{U}_{N_k}^\infty \right) , \]
where the third inequality follows from a modification of the proof of Lemma 4.1 and (3.14) in Lemma 3.7. By modifying the proofs of Lemmas 6.3 and B.1 we can also estimate the other two terms in (6.63) by (6.64).

Similarly, the contribution to the difference (6.62) from the third, fourth, and fifth terms in (6.61) can also be estimated by (6.64). As for the contribution from the second term in (6.61), we need to check that the difference \( T_{N_k^1} - T_{N_k^2} \) of the operator \( T_N \) defined in (6.36) gives a decay \( (N_k^2)^{-a} \). It follows from (6.44) that in studying the difference \( T_{N_k^1} - T_{N_k^2} \), we have an extra condition \( \max(|n_1|,|n_2|) > N_k^2 \) in (6.45), which allows us to gain a small negative power of \( N_k^2 \). Thus, we can also bound the contribution from the second term in (6.61) by (6.64). Hence, we conclude that (6.62) is bounded by (6.64).

It follows from (a slight modification of) Lemmas 6.2 [6.3] and 6.4 together with Lemmas 4.1, 4.2 and B.1 that \( C(Y_{N_k^1},Y_{N_k^2},3_{N_k^1},3_{N_k^2}) \) in (6.64) is uniformly bounded in \( N_k^1 \) and \( N_k^2 \), \( k \in \mathbb{N} \). Furthermore, from the discussion in Subsection 6.2 (see (6.50), (6.59), and (6.58), we have
\[ \sup_{k \in \mathbb{N}} \mathcal{U}_{N_k}^\infty \leq 10C_0 + 10 \sup_{k \in \mathbb{N}} \mathbb{E} \left[ \mathcal{R}_{N_k}^{\infty}(Y + \mathcal{Y}_{N_k^1}^2 - 3_{N_k^1}) + \frac{1}{2} \int_0^1 \| \mathcal{Y}_{N_k}^1(t) \|_{H^1}^2 \, dt \right] \]
\[ \leq 10(C_0 + \delta) + 10 \sup_{k \in \mathbb{N}} \mathbb{E} \left[ \mathcal{R}_{N_k}^{\infty}(Y + 0 - 3_{N_k^1}) + \frac{1}{2} \right] \]
\[ \lesssim 1. \] (6.65)
Therefore, we conclude that
\[ \mathbb{E} \left[ \mathcal{R}_{N_k}^{\infty}(Y_{N_k^1} + \mathcal{Y}_{N_k^1}^2 - 3_{N_k^1}) - \mathcal{R}_{N_k}^{\infty}(Y_{N_k^2} + \mathcal{Y}_{N_k^2}^2 - 3_{N_k^2}) \right] \lesssim (N_k^2)^{-a} \rightarrow 0 \] (6.66)
as \( k \rightarrow \infty \). Since the choice of \( \delta > 0 \) was arbitrary, we obtain, from (6.60) and (6.66),
\[ \lim_{k \rightarrow \infty} Z_{N_k^1} \geq \lim_{k \rightarrow \infty} Z_{N_k^2} . \]
By symmetry, we then conclude (6.57).

Next, we show \( \rho^{(1)} = \rho^{(2)} \). This claim follows from a small variation of the argument presented above. For this purpose, it suffices to prove that for every bounded Lipschitz continuous function \( F : \mathcal{C}^{-100}(\mathbb{T}^3) \rightarrow \mathbb{R} \), we have
\[ \lim_{k \rightarrow \infty} \int \exp(F(u)) \, d\rho_{N_k^1} \geq \lim_{k \rightarrow \infty} \int \exp(F(u)) \, d\rho_{N_k^2} . \]
In view of (6.57), it suffices to show
\[
\limsup_{k \to \infty} \left[ -\log \left( \int \exp(F(u) - R_{N_k}^\infty(u))d\mu \right) + \log \left( \int \exp(F(u) - R_{N_k}^\infty(u))d\mu \right) \right] \leq 0. \tag{6.67}
\]

As before, we assume \( N_k^1 \geq N_k^2, k \in \mathbb{N} \), without loss of generality. By the Boué-Dupuis formula (Lemma 5.11), we have
\[
-\log \left( \int \exp(F(u) - R_{N_k}^\infty(u))d\mu \right) = \inf_{\mathcal{Y}^{N_k} \in \mathcal{M}_a} \mathbb{E} \left[ -F(Y + \mathcal{Y}^{N_k} - 3N_k^1) + \mathcal{R}_{N_k}^\infty(Y + \mathcal{Y}^{N_k} - 3N_k^1) + \frac{1}{2} \int_0^1 \left\| \dot{\mathcal{Y}}^{N_k}(t) \right\|_{H_2}^2 dt \right]. \tag{6.68}
\]

Given \( \delta > 0 \), let \( \mathcal{Y}^{N_k} \) be an almost optimizer for (6.68) with \( j = 2 \):
\[
-\log \left( \int \exp(F(u) - R_{N_k}^\infty(u))d\mu \right) \geq \mathbb{E} \left[ -F(Y + \mathcal{Y}^{N_k} - 3N_k^1) + \mathcal{R}_{N_k}^\infty(Y + \mathcal{Y}^{N_k} - 3N_k^1) + \frac{1}{2} \int_0^1 \left\| \dot{\mathcal{Y}}^{N_k}(t) \right\|_{H_2}^2 dt \right] - \delta.
\]

Then, by choosing \( \mathcal{Y}^{N_k} = \pi_{N_k}^1 \mathcal{Y}^{N_k} \) and proceeding as in (6.60), we have
\[
-\log \left( \int \exp(F(u) - R_{N_k}^\infty(u))d\mu \right) + \log \left( \int \exp(F(u) - R_{N_k}^\infty(u))d\mu \right) \leq \mathbb{E} \left[ -F(Y + \mathcal{Y}^{N_k} - 3N_k^1) + \mathcal{R}_{N_k}^\infty(Y + \mathcal{Y}^{N_k} - 3N_k^1) + \frac{1}{2} \int_0^1 \left\| \dot{\mathcal{Y}}^{N_k}(t) \right\|_{H_2}^2 dt \right] - \delta
\]
\[
- \mathbb{E} \left[ -F(Y + \mathcal{Y}^{N_k} - 3N_k^1) + \mathcal{R}_{N_k}^\infty(Y + \mathcal{Y}^{N_k} - 3N_k^1) + \frac{1}{2} \int_0^1 \left\| \dot{\mathcal{Y}}^{N_k}(t) \right\|_{H_2}^2 dt \right] + \delta
\]
\[
\leq \text{Lip}(F) \cdot \mathbb{E} \left[ \left\| \pi_{N_k}^1 \mathcal{Y}^{N_k} + 3N_k^1 - 3N_k^2 \right\|_{C^{-100}} \right] + \mathbb{E} \left[ \mathcal{R}^\infty(Y_{N_k}^1 + \pi_{N_k}^1 \mathcal{Y}^{N_k} - 3N_k^1) - \mathcal{R}^\infty(Y_{N_k}^2 + \pi_{N_k}^1 \mathcal{Y}^{N_k} - 3N_k^2) \right] + \delta, \tag{6.69}
\]
where \( \pi_{N_k}^1 = \text{Id} - \pi_{N_k} \). We can proceed as before to show that the second term on the right-hand side of (6.69) satisfies (6.66). Here, we need to use the boundedness of \( F \) in showing an analogue of (6.65) in the current context.

By writing
\[
\mathbb{E} \left[ \left\| \pi_{N_k}^1 \mathcal{Y}^{N_k} + 3N_k^1 - 3N_k^2 \right\|_{C^{-100}} \right] \leq \mathbb{E} \left[ \left\| \pi_{N_k}^1 \mathcal{Y}^{N_k} \right\|_{C^{-100}} \right] + \mathbb{E} \left[ \left\| 3N_k^1 - 3N_k^2 \right\|_{C^{-100}} \right],
\]
we see from Footnote 32 that the second term on the right-hand side tends to 0 as \( k \to \infty \). As for the first term, from Lemma 5.4 and (an analogue of) (6.65), we obtain
\[
\mathbb{E} \left[ \left\| \pi_{N_k}^1 \mathcal{Y}^{N_k} \right\|_{C^{-100}} \right] \leq (N_k^2)^{-a} \left\| \mathcal{Y}^{N_k} \right\|_{L_2^2 H^1} \leq (N_k^2)^{-a} \left( \sup_{k \in \mathbb{N}} u_{N_k}^\infty \right)^{\frac{1}{2}} \to 0
\]
as \( k \to \infty \). Since the choice of \( \delta > 0 \) was arbitrary, we conclude (6.67) and hence \( \rho^{(1)} = \rho^{(2)} \) by symmetry. This completes the proof of Proposition 6.6. \( \square \)
6.4. Singularity of the defocusing Gibbs measure for $0 < \beta \leq \frac{1}{2}$. In this subsection, we prove that the Gibbs measure $\rho$ for $0 < \beta \leq \frac{1}{2}$ is singular with respect to the reference Gaussian free field $\mu$. While our proof is inspired by the discussion in Section 4 of [5], we directly prove singularity without referring to the shifted measure. In Appendix C, we show that the Gibbs measure is indeed absolutely continuous with respect to the shifted measure, namely, the law of $Y(1) - \mathcal{Z}(1) + \mathcal{W}(1)$, where the auxiliary process $\mathcal{W} = \mathcal{W}(Y)$ is defined in (C.1).

Given $N \in \mathbb{N}$, define $A_N$ and $B_N$ by

$$A_N := \sum_{|n| \leq N} \langle n \rangle^{-2\beta - 2} \sim \begin{cases} \log N, & \text{if } \beta = \frac{1}{2}, \\ N^{1-2\beta}, & \text{if } \beta < \frac{1}{2}, \end{cases}$$

(6.70)

and

$$B_N := (\log N)^{-\frac{1}{4}} A_N^{-\frac{1}{2}} \sim \begin{cases} (\log N)^{-\frac{1}{4}}, & \text{if } \beta = \frac{1}{2}, \\ (\log N)^{-\frac{1}{4}} N^{\frac{1}{2}}, & \text{if } \beta < \frac{1}{2}. \end{cases}$$

(6.71)

**Proposition 6.7.** Let $0 < \beta \leq \frac{1}{2}$, $\varepsilon > 0$, and $R^0_N$ be as in (1.38). Then, there exists a strictly increasing sequence $\{N_k\}_{k=1}^\infty \subset \mathbb{N}$ such that the set

$$S := \{ u \in H^{-\frac{1}{2}-\varepsilon} (\mathbb{T}^3) : \lim_{k \to \infty} B_{N_k}^0 R_{N_k}^0 (u) = 0 \}$$

has $\mu$-full measure: $\mu(S) = 1$. Furthermore, we have

$$\rho(S) = 0.$$  

(6.72)

In particular, the Gibbs measure $\rho$ and the Gaussian free field $\mu$ are mutually singular for $0 < \beta \leq \frac{1}{2}$.

**Proof.** By repeating the computation as in Subsection 5.1, we have

$$\| R_N^0 (u) \|_{L^2(\mu)}^2 \lesssim \sum_{|n| \leq N} \langle n \rangle^{-2\beta - 2} = A_N.$$  

(6.73)

Then, from (6.71) and (6.73), we have

$$\lim_{N \to \infty} B_N \| R_N^0 (u) \|_{L^2(\mu)} \lesssim \lim_{N \to \infty} (\log N)^{-\frac{1}{4}} = 0.$$  

Hence, there exists a subsequence such that

$$\lim_{k \to \infty} B_{N_k}^0 R_{N_k}^0 (u) = 0$$

almost surely with respect to $\mu$.

Define $G_k(u)$ by

$$G_k(u) = B_{N_k}^0 R_{N_k}^0 (u) - \| u \|_{C^{-\frac{1}{2}-\varepsilon}}^{10}$$

for some small $\varepsilon > 0$. In the following, we show that $e^{G_k(u)}$ tends to 0 in $L^1(\rho)$. This will imply that there exists a subsequence of $G_k(u)$ tending to $-\infty$, almost surely with respect to the Gibbs measure $\rho$. Recalling the almost sure boundedness of $\| u \|_{C^{-\frac{1}{2}-\varepsilon}}^{10}$ under the Gibbs measure $\rho$, this shows that $B_{N_k}^0 R_{N_k}^0$ tends $\rho$-almost surely to $-\infty$ along this subsequence, which in turn yields (6.72).
Let $\phi$ be a smooth bump function as in Subsection 3.1. By Fatou’s lemma, the weak convergence of $\rho_M$ to $\rho$, and the boundedness of $\phi$, we have

$$\int e^{G_k(u)} d\rho(u) \leq \liminf_{K \to \infty} \int \phi \left( \frac{G_k(u)}{K} \right) e^{G_k(u)} d\rho(u)$$

$$= \liminf_{K \to \infty} \lim_{M \to \infty} \int \phi \left( \frac{G_k(u)}{K} \right) e^{G_k(u)} d\rho_M(u)$$

$$\leq \lim_{M \to \infty} \int e^{G_k(u)} d\rho_M(u) =: Z^{-1} \lim_{M \to \infty} C_{M,k},$$

provided that $\lim_{M \to \infty} C_{M,k}$ exists. Here, $Z = \lim_{M \to \infty} Z_M$ denotes the partition function for $\rho$, which is well defined thanks to (6.57). In the following, we show that the right-hand side of (6.74) tends to 0 as $k \to \infty$.

As in the previous subsection, we proceed with the change of variables (6.20): $\hat{Y}^M(t) := \hat{\Theta}(t) + \hat{3}_M(t)$. Then, by the Boué-Dupuis formula (Lemma 5.11), we have

$$- \log C_{M,k} = \inf_{\hat{Y}^M \in H_0} \mathbb{E} \left[ -B_{N,k} R^\circ R_{N,k} (Y + \hat{Y}^M - \hat{3}_M) + \|Y + \hat{Y}^M - \hat{3}_M\|_{C^{-\frac{1}{2}} - \varepsilon}^{10} + \hat{R}^\circ (Y + \hat{Y}^M - \hat{3}_M) + \frac{1}{2} \int_0^1 \|\hat{Y}^M(t)\|_{H_2}^2 dt \right]$$

$$= \inf_{\hat{Y}^M \in H_0} \hat{\mathcal{V}}^\circ_M(Y^M),$$

where $\hat{R}^\circ_N$ is defined in (6.52). Let $Q_N := Q_N - Q_{N,3}$, where $Q_N$ and $Q_{N,3}$ are as in (5.3) and (5.7). Then, from (1.38), (6.18), (6.13), and (6.15), we have

$$R^\circ_{N,k} (Y + \hat{Y}^M - \hat{3}_M)$$

$$= \frac{1}{4} Q^\circ_{N,k} (Y) + \int_{T^3} [(V_0 \ast Y_{N,k}^2) Y_{N,k}]^\circ \Theta_{N,k} dx$$

$$+ \frac{1}{2} \int_{T^3} (V_0 \ast Y_{N,k}^2) \Theta_{N,k}^2 dx + \int_{T^3} [(V_0 \ast (Y_{N,k} \Theta_{N,k})) Y_{N,k} \Theta_{N,k}]^\circ dx$$

$$+ \int_{T^3} (V_0 \ast \Theta_{N,k}^2) Y_{N,k} \Theta_{N,k} dx + \frac{1}{4} \int_{T^3} (V_0 \ast \Theta_{N,k}^2) \Theta_{N,k}^2 dx$$

$$+ \frac{1}{4} \left\{ \int_{T^3} \left( Y_{N,k}^2 + 2Y_{N,k} \Theta_{N,k} + \Theta_{N,k}^2 \right) dx \right\}^2$$

for $N_k \leq M$, where $\Theta_{N,k}$ is given by

$$\Theta_{N,k} := \pi_{N,k} \Theta = \pi_{N,k} \hat{Y}^M - \pi_{N,k} \hat{3}_M.$$  

(6.77)

We can handle the contribution from the last two terms on the right-hand side of (6.75) as in Subsection 6.2 (see (6.50)) and obtain

$$\mathbb{E} \left[ \hat{R}^\circ_M (Y + \hat{Y}^M - \hat{3}_M) + \frac{1}{2} \int_0^1 \|\hat{Y}^M(t)\|_{H_2}^2 dt \right] \geq -C_0 + \frac{1}{10} U_M^\circ,$$

(6.78)

where $U_M^\circ$ is given by (6.31) with $Y_N = \pi_M Y^M$ and $Y^N = \hat{Y}^M$. The main contribution to (6.75) comes from the first term. More precisely, under an expectation, the second term on the right-hand side of (6.76) gives a (negative) divergent contribution; see (6.84) below. From (5.19), the first term on the right-hand side of (6.76) gives 0 under an expectation, while we can bound the
other terms (excluding the first and second terms) as in Subsection 6.2 and obtain
\[
\mathbb{E}\left[ R_{N_k}^2(Y + \mathcal{M} - 3_M) - \frac{1}{4} Q_{N_k}^2(Y) - \int_{T^3} [(V_0 : Y_{N_k}^2) Y_{N_k}]^\circ \Theta_{N_k} \, dx \right] \lesssim C(Y_{N_k}, \pi_{N_k} 3_M) + U_{N_k}^\infty \lesssim 1 + U_{N_k}^\infty
\]
(6.79)
where \(C(Y_{N_k}, \pi_{N_k} 3_M)\) denotes certain high moments of various stochastic terms involving \(Y_{N_k}\) and \(3_{N_k}\) and \(U_{N_k}^\infty = U_{N_k}^\infty (\pi_{N_k} \mathcal{M})\) is given by (6.31) with \(\Upsilon_N = \Upsilon = \pi_{N_k} \mathcal{M}\):
\[
U_{N_k}^\infty = \mathbb{E}\left[ \frac{1}{8} \int_{T^3} (V_0 * (\pi_{N_k} \mathcal{M})^2)(\pi_{N_k} \mathcal{M})^2 \, dx \right]
+ \frac{1}{32} \left( \int_{T^3} (\pi_{N_k} \mathcal{M})^2 \, dx \right)^2 + \frac{1}{2} \int_0^1 \| \partial_t (\pi_{N_k} \mathcal{M})(t) \|_{H^1}^2 \, dt \right].
\]
(6.80)
Note that, in view of the smallness of \(B_{N_k}\) in (6.75), the second and third terms in (6.80) can be controlled by the positive terms \(U_{M_k}^\infty\) coming from the last two terms in (6.75). On the other hand, the first term on the right-hand side of (6.80) can not be controlled by the corresponding potential energy \(\frac{1}{2} \int_{T^3} (V_0 * \Upsilon_M)^2 \, dx\) in \(U_{M_k}^\infty\). Here, the second term on the right-hand side of (6.75) comes to the rescue. From Sobolev’s inequality, the interpolation (3.3) (with \(0 = \theta \cdot 1 + (1 - \theta)(-\frac{1}{2} - 2\varepsilon)\) for differentiability), and Young’s inequality, we have
\[
\int_{T^3} (V_0 * (\pi_{N_k} \mathcal{M})^2)(\pi_{N_k} \mathcal{M})^2 \, dx = \| (\pi_{N_k} \mathcal{M})^2 \|_{H^{-\beta \frac{1}{2}}}^2 \lesssim \| \pi_{N_k} \mathcal{M} \|_{L^{2+\gamma}}^4
\]
\[
\lesssim \| \pi_{N_k} \mathcal{M} \|_{H^{\frac{1}{4} + \gamma}}^4 \| \pi_{N_k} \mathcal{M} \|_{C^{-\frac{1}{2} - \varepsilon}}^8
\]
\[
\lesssim 1 + \| \mathcal{M} \|_{H^1}^2 + \| \mathcal{M} \|_{C^{-\frac{1}{2} - \varepsilon}}^{10}
\]
(6.81)
Hence, from (6.71), (6.75), (6.78), (6.79), and (6.81) with the following bound:
\[
\| Y + \mathcal{M} - 3_M \|_{C^{-\frac{1}{2} - \varepsilon}}^{10} \gtrsim \| \mathcal{M} \|_{C^{-\frac{1}{2} - \varepsilon}}^{10} - \| Y \|_{C^{-\frac{1}{2} - \varepsilon}}^{10} - \| 3_M \|_{C^{-\frac{1}{2} - \varepsilon}}^{10}
\]
we obtain
\[
\hat{W}_{M,k}^\infty (\mathcal{M}) \geq -B_{N_k} \mathbb{E}\left[ \int_{T^3} [(V_0 : Y_{N_k}^2) Y_{N_k}]^\circ \Theta_{N_k} \, dx \right] - C_1 + \frac{1}{20} U_{M_k}^\infty
\]
(6.82)
for any \(1 \ll N_k \leq M\).

It remains to estimate the contribution from the second term on the right-hand side of (6.76). Let us first state a lemma whose proof is presented at the end of this subsection.

**Lemma 6.8.** Let \(0 < \beta < 1\). Then, we have
\[
\mathbb{E}\left[ \int_0^1 \int_{T^3} (1 - \Delta) \hat{3}_N(t) \cdot (\hat{3}_N - 3_M)(t) \, dx \, dt \right] \lesssim 1
\]
(6.83)
for \(1 \leq N \leq M\), where \(\hat{3}_N = \pi_N \hat{3}_N\).

\(^{33}\)Recall the notation \(\Upsilon_M = \pi_M \Upsilon^M\).
By (6.18), (6.19), (6.77), Lemma 6.8, Cauchy’s inequality, (6.10), and (6.70), we have
\[
\mathbb{E} \left[ \int_{\mathbb{T}^3} \left[ (V_0 \ast : Y_N^2 \cdot Y_N \right)^2 \right] dx \right] = \mathbb{E} \left[ \int_0^1 \int_{\mathbb{T}^3} \left[ (V_0 \ast : Y_N(t)^2 \cdot Y_N(t)]^2 \Theta_N(t) dt \right] \right]
\]
\[
= \mathbb{E} \left[ \int_0^1 \int_{\mathbb{T}^3} (1 - \Delta) \tilde{\mathcal{N}}(t) \cdot (\tilde{\mathcal{N}}_M(t)) dx dt \right]
\]
\[
- \mathbb{E} \left[ \int_0^1 \| \tilde{\mathcal{N}}_M(t) \| H^2 \right] dt + \frac{1}{2} \mathbb{E} \left[ \int_0^1 \| \tilde{Y}_M(t) \| H^2 dt \right]
\]
\[
\leq C - \frac{1}{2} \mathbb{E} \left[ \int_0^1 \| \tilde{\mathcal{N}}_M(t) \| H^2 dt \right] + \frac{1}{2} \mathbb{E} \left[ \int_0^1 \| \tilde{Y}_M(t) \| H^2 dt \right]
\]
\[
\leq C - cA_N + \frac{1}{2} \mathbb{E} \left[ \int_0^1 \| \tilde{Y}_M(t) \| H^2 dt \right]
\]
for $1 \leq N \leq M$. Thus, putting (6.75), (6.82), and (6.84) together, we have
\[
- \log C_{M,k} \geq \inf_{\tilde{Y}_M \in \mathbb{H}_a} \left\{ cB_N A_N - C_2 + \frac{1}{40} U_{M_k}^2 \right\} \geq cB_N A_N - C_2.
\]
Hence, from (6.85) with (6.70) and (6.71), we obtain
\[
C_{M,k} \gtrsim \begin{cases} \exp \left( - c(\log N_k)^{\frac{1}{2}} \right), & \text{if } \beta = \frac{1}{2}, \\ \exp \left( - c(\log N_k)^{-\frac{1}{2}} N_k^{\frac{1}{2} - \beta + \frac{1}{2}} \right), & \text{if } 0 < \beta < \frac{1}{2} \end{cases}
\]
for $1 \ll N_k \ll M$, uniformly in $M \in \mathbb{N}$. Therefore, by taking limits in $M \to \infty$ and then $k \to \infty$, we conclude from (6.74) and (6.86) that
\[
\lim_{k \to \infty} \int e^{G_k(u)} d\rho(u) = 0
\]
as desired. This completes the proof of Proposition 6.7.

We conclude this subsection by presenting the proof of Lemma 6.8.

Proof of Lemma 6.8. In the following, we drop the time variable. Let
\[
\hat{Y}_N(n_1) \hat{Y}_N(n_2) := \hat{Y}_N(n_1) \hat{Y}_N(n_2) - \mathbf{1}_{n_1 + n_2 = 0} \cdot \langle n_1 \rangle^{-2}.
\]
Then, proceeding as in (4.12) and (4.14) with (6.19), (6.13), and (1.37), we have
\[
\hat{\mathcal{N}}_N(n) = \langle n \rangle^{-2} \left( \sum_{n_1, n_2, n_3 \in \mathbb{Z}^3 \atop n = n_1 + n_2 + n_3} \tilde{V}_0(n_1 + n_2)(\hat{Y}_N(n_1) \hat{Y}_N(n_2) : \hat{Y}_N(n_3) - 2\kappa_N(n) \hat{Y}_N(n)) \right)
\]
\[
\hat{\mathcal{N}}_N(n) = \langle n \rangle^{-2} \left( \sum_{n_1, n_2, n_3 \in \mathbb{Z}^3 \atop n = n_1 + n_2 + n_3} \tilde{V}_0(n_1 + n_2)(\hat{Y}_N(n_1) \hat{Y}_N(n_2) : \hat{Y}_N(n_3) \right)
\]
\[
+ 2 \langle n \rangle^{-2} \hat{V}_0(n) \sum_{n_1 \in \mathbb{Z}^3 \atop |n_1| \leq N} \langle n_1 \rangle \left( |\hat{Y}_N(n_1)|^2 - \langle n_1 \rangle^{-2} \right)
\]
\[
- \langle n \rangle^{-2} \hat{V}_0(2n) \langle \hat{Y}_N(n) \rangle^2 \langle \hat{Y}_N(n) \rangle
\]
\[
= \hat{\mathcal{N}}_{N,1}(n) + \hat{\mathcal{N}}_{N,2}(n) + \hat{\mathcal{N}}_{N,3}(n)
\]
for $|n| \leq N$. By repeating the proof of Lemma 4.2, we have

$$\mathbb{E}\left[|\hat{3}_{N,1}(n)|^2\right] \sim \langle n \rangle^{-2\beta-4}. \quad (6.89)$$

Also, by a computation analogous to (4.17) and (4.15), we have

$$\mathbb{E}\left[|\hat{3}_{N,2}(n)|^2\right] + \mathbb{E}\left[|\hat{3}_{N,3}(n)|^2\right] \lesssim \langle n \rangle^{-2\beta-6}. \quad (6.90)$$

Hence, from (6.88), (6.89), and (6.90), we have

$$\mathbb{E}\left[\int_{\mathbb{T}^3} (1 - \Delta)\hat{3}_N \cdot (\hat{3}_N - \hat{3}_M) \, dx\right]$$

$$= \mathbb{E}\left[\sum_{n \in \mathbb{Z}^3} \langle n \rangle^2 \hat{3}_N(n) \left(\hat{3}_N(n) - \hat{3}_M(n)\right)\right]$$

$$= \sum_{n \in \mathbb{Z}^3} \langle n \rangle^2 \mathbb{E}\left[\hat{3}_{N,1}(n)\left(\hat{3}_{N,1}(n) - \hat{3}_{M,1}(n)\right)\right] + O\left(\sum_{n \in \mathbb{Z}^3} \langle n \rangle^{2\beta-2} \langle n \rangle^{-\beta-3}\right)$$

$$= \sum_{n \in \mathbb{Z}^3} \langle n \rangle^2 \mathbb{E}\left[\hat{3}_{N,1}(n)\left(\hat{3}_{N,1}(n) - \hat{3}_{M,1}(n)\right)\right] + O(1) \quad (6.91)$$

for $\beta > 0$.

We now write $\hat{3}_{M,1}(n) - \hat{3}_{N,1}(n)$ as follows:

$$\hat{3}_{M,1}(n) - \hat{3}_{N,1}(n)$$

$$= \sum_{j,k,\ell \in \{1,2,3\}} \sum_{\{j,k,\ell\} \neq \{1,2,3\}} \tilde{V}_0(n_1 + n_2)(\hat{Y}_M(n_1)\hat{Y}_M(n_2))\hat{Y}_M(n_3)$$

$$+ \sum_{j,k,\ell \in \{1,2,3\}} \sum_{\{j,k,\ell\} \neq \{1,2,3\}} \tilde{V}_0(n_1 + n_2)(\hat{Y}_M(n_1)\hat{Y}_M(n_2))\hat{Y}_M(n_3)$$

$$+ \sum_{n_1,n_2,n_3 \in \mathbb{Z}^3} \tilde{V}_0(n_1 + n_2)(\hat{Y}_M(n_1)\hat{Y}_M(n_2))\hat{Y}_M(n_3)$$

$$=: I(n) + II(n) + III(n).$$

By the independence of $\{\hat{Y}(n)\}_{n \in \Lambda_0}$ where the index set $\Lambda_0$ is as in (1.19), we have

$$\mathbb{E}\left[\hat{3}_{N,1}(n)III(n)\right] = \mathbb{E}\left[\hat{3}_{N,1}(n)\right] \cdot \mathbb{E}\left[III(n)\right] = 0 \quad (6.92)$$

for any $n \in \mathbb{Z}^3$. We also have

$$\mathbb{E}\left[\hat{3}_{N,1}(n)I(n)\right] = 0 \quad (6.93)$$
for any $n \in \mathbb{Z}^3$ since only one of the frequencies is larger than $N$ in size. Noting that there are exactly two frequencies larger than $N$, we have

$$\mathbb{E} \left[ \hat{\mathcal{J}}_{N,1}(n) \right] = 0$$

(6.94)

for any $n \in \mathbb{Z}^3$ since, under the condition $|n_2 + n_3||n_3 + n_1| \neq 0$ in $\Pi$, the only possible non-zero contribution $\Pi$ comes from $|n_1|, |n_2| > N$ with $n_1 + n_2 = 0$ in $\Pi$ but $\hat{\nu}_0(n_1 + n_2) = \hat{\nu}_0(0) = 0$ in this case.

The desired bound (6.83) then follows from (6.91), (6.92), (6.93), (6.94), and integrating in time. \hspace{1cm} \Box

7. Paracontrolled operators

In this section, we study the mapping properties of the paracontrolled operators $\mathcal{J}_{(1)}^{(1)}$ and $\mathcal{J}_{(\omega)}^{(1)}$ defined in (2.26) and (2.27), respectively. Then, we briefly discuss the regularity property of the stochastic term $\mathcal{A}$ defined in (2.38) at the end of this section.

We first consider the regularity property of the paracontrolled operator $\mathcal{J}_{(1)}^{(1)}$ defined in (2.26). By writing out the frequency relation $|n_2|^{\theta} \lesssim |n_1| \ll |n_2|$ in a more precise manner, we have

$$\mathcal{J}_{(1)}^{(1)}(w)(t) = \sum_{n \in \mathbb{Z}^3} c_n \sum_{n=n_1+n_2} \sum_{\theta_k+c_0 \leq j \leq k-2} \varphi_j(n_1) \varphi_k(n_2) \times \int_0^t e^{-\frac{(t-t')}{2}} \sin((t-t')|n|) \hat{w}(n_1, t') \hat{\varphi}(n_2, t') dt',$n

(7.1)

where $c_0 \in \mathbb{R}$ is some fixed constant. In the following, we establish the mapping property of $\mathcal{J}_{(1)}^{(1)}$ in a deterministic manner by using a pathwise regularity of $\varphi$.

Lemma 7.1. Let $s > 0$ and $T > 0$. Then, given small $\theta > 0$, there exists small $\varepsilon = \varepsilon(s, \theta) > 0$ such that the following deterministic estimate holds for the paracontrolled operator $\mathcal{J}_{(1)}^{(1)}$ defined in (2.26):

$$\| \mathcal{J}_{(1)}^{(1)}(w) \|_{L_T^\infty H^s_T H^3_T} \lesssim \| w \|_{L_T^\infty H^s_T H^3_T} \| \varphi \|_{L_T^\infty W^\frac{1}{2} - \varepsilon, \infty}.$$  

(7.2)

In particular, $\mathcal{J}_{(1)}^{(1)}$ belongs almost surely to the class

$$\mathcal{L}_3(T) = \mathcal{L}(L^2([0, T]; H^s(\mathbb{T}^3)), C([0, T]; H^s + 3\varepsilon(\mathbb{T}^3)))).$$

Moreover, by letting $\mathcal{J}_{(\omega)}^{(1)}$, $N \in \mathbb{N}$, denote the paracontrolled operator in (2.26) with $\varphi$ replaced by the truncated stochastic convolution $\varphi_N$ in (2.11), the truncated paracontrolled operator $\mathcal{J}_{(\omega)}^{(1)}$ converges almost surely to $\mathcal{J}_{(1)}^{(1)}$ in $\mathcal{L}_3(T)$.

Lemma 7.1 follows from a slight modification of the proof of Lemma 5.1 in [43]. We present the argument for readers' convenience.

Proof. Under $|n_2|^{\theta} \lesssim |n_1| \ll |n_2|$ with $n = n_1 + n_2$, we have $\langle n \rangle \sim \langle n_2 \rangle$. Thus, we have

$$\langle n \rangle^{\frac{1}{2} + 3\varepsilon} \langle n_2 \rangle^{-1} \lesssim \langle n_1 \rangle^{\frac{1}{2} + 3\varepsilon} \langle n_2 \rangle^{-\frac{1}{2} - 2\varepsilon} \lesssim \langle n_1 \rangle^{s-\varepsilon} \langle n_2 \rangle^{-\frac{1}{2} - 2\varepsilon}$$

(7.3)

by choosing $\varepsilon = \varepsilon(s, \theta) > 0$ sufficiently small.
Letting \( \hat{w}_j(n_1, t') = \varphi_j(n_1) \hat{w}(n_1, t') \) and \( \hat{\Psi}_k(n_2, t') = \varphi_k(n_2) \hat{\Psi}(n_2, t') \), it follows from \( (7.1) \) and \( (7.3) \) with the trivial embedding \( (3.4) \) that

\[
\| \mathcal{G}^{(1)}_\otimes (w)(t) \|_{H^\frac{1}{2}+\epsilon} \lesssim \int_0^t \sum_{j,k=0}^\infty 2^{(s-\epsilon)j} 2^{(\frac{1}{2}-2\epsilon)k} \| \hat{w}_j(n_1, t') \hat{\Psi}_k(n_2, t') \|_{L^2_n} \, dt'
\]

\[
\lesssim \int_0^t \sum_{j,k=0}^\infty 2^{(s-\epsilon)j} 2^{(\frac{1}{2}-2\epsilon)k} \| w_j(t') \|_{L^2_n} \| \Psi_k(t') \|_{L^\infty_x} \, dt'
\]

\[
\lesssim \| w \|_{L^2_t H^s_x} \| \Psi \|_{L^2_t(B^{\frac{1}{2}-2\epsilon}_{\infty,1})_x}
\]

\[
\lesssim \| w \|_{L^2_t H^s_x} \| \Psi \|_{L^2_t \dot{W}^{\frac{1}{2}-\epsilon,\infty}_x}
\]

for any \( t \in [0, T] \), which shows \( (7.2) \). The continuity in time of \( \mathcal{G}^{(1)}_\otimes (w) \) and the convergence of \( \mathcal{G}^{(1),N}_\otimes \) follow from modifying the computation above. We omit the details. \( \square \)

Next, we present the proof of Proposition 2.5 on the paracontrolled operator \( \mathcal{I}_{\otimes,\otimes} \) in \( (2.27) \).

By writing out the frequency relations more carefully as in \( (7.1) \), we have

\[
\mathcal{I}_{\otimes,\otimes}(w)(t) = \sum_{n \in \mathbb{Z}^3} e_n \int_0^t \sum_{j=0}^\infty \sum_{n_1 \in \mathbb{Z}^3} \varphi_j(n_1) \hat{w}(n_1, t') A_{n,n_1}(t, t') \, dt',
\]

(7.4)

where \( A_{n,n_1}(t, t') \) is given by

\[
A_{n,n_1}(t, t') = \mathbf{1}_{[0,t]}(t') \sum_{k=0}^\infty \sum_{\ell,m=0}^\infty \sum_{n-n_1=n_2+n_3} \varphi_k(n_2) \varphi_\ell(n_1 + n_2) \varphi_m(n_3)
\]

\[
\times e^{-\frac{t-t'}{2}} \frac{\sin((t-t') [n_1 + n_2])}{[n_1 + n_2]} \hat{\Psi}(n_2, t') \hat{\Psi}(n_3, t).
\]

(7.5)

For simplicity of notations, however, we use \( (2.27) \) and \( (2.28) \) in the following, with the understanding that the frequency relations \( |n_1| \ll |n_2|^\theta \) and \( |n_1 + n_2| \sim |n_3| \) are indeed characterized by the use of smooth frequency cutoff functions as in \( (7.4) \) and \( (7.5) \).

Recall from the definition \( (2.9) \) that \( \hat{\Psi}(n_2, t') \) and \( \hat{\Psi}(n_3, t) \) in \( (2.28) \) are uncorrelated unless \( n_2 + n_3 = 0 \), i.e. \( n = n_1 \). This leads to the following decomposition of \( A_{n,n_1} \):

\[
A_{n,n_1}(t, t') = \mathbf{1}_{[0,t]}(t') \sum_{n-n_1=n_2+n_3} \left( \begin{array}{c}
1_{|n_1| \ll |n_2|^\theta} \\
1_{|n_1 + n_2| \sim |n_3|}
\end{array} \right)
\times \left( \hat{\Psi}(n_2, t') \hat{\Psi}(n_3, t) - \mathbf{1}_{n_2+n_3=0} \cdot \sigma_{n_2}(t, t') \right)
\]

\[
+ \mathbf{1}_{[0,t]}(t') \cdot \mathbf{1}_{n=n_1} \cdot \sum_{n_2 \in \mathbb{Z}^3} \left( \begin{array}{c}
1_{|n| \ll |n_2|^\theta}
\end{array} \right) \sigma_{n_2}(t, t')
\]

\[
=: A_{n,n_1}^{(1)}(t, t') + A_{n,n_1}^{(2)}(t, t').
\]

(7.6)

The second term \( A_{n,n_1}^{(2)} \) is a (deterministic) “counter term” for the case \( n_2 + n_3 = 0 \). For this second term, the condition \( |n_1 + n_2| \sim |n_3| \) reduces to \( |n + n_2| \sim |n_2| \) which is automatically satisfied under \( |n| \ll |n_2|^\theta \) for small \( \theta > 0 \).
In view of (3.17), the sum in \( n_2 \) for the second term \( A_{n,n_1}^{(2)} \) is not absolutely convergent. Hence, we need to exploit the dispersive nature of the problem. Proceeding as in [13] with (3.17) and (7.6), we decompose \( A_{n,n_1}^{(2)}(t,t') \) as

\[
A_{n,n_1}^{(2)}(t,t') = 1_{[0,t]}(t') \cdot e^{-(t-t')} \sum_{n_2 \in \mathbb{Z}^3} \frac{\sin((t-t')|n + n_2|)}{|n + n_2|} \frac{\cos((t-t')|n_2|)}{\langle n_2 \rangle^2} \\
+ 1_{[0,t]}(t') \cdot e^{-(t-t')} \sum_{n_2 \in \mathbb{Z}^3} \frac{\sin((t-t')|n + n_2|)}{|n + n_2|} \cdot \frac{\sin((t-t')|n_2|)}{2 \langle n_2 \rangle^2} \\
+ 1_{[0,t]}(t') \cdot e^{-(t-t')} \sum_{n_2 \in \mathbb{Z}^3} \frac{\sin((t-t')|n + n_2|)}{|n + n_2|} \cdot \frac{\sin((t-t')|n_2|)}{2 \langle n_2 \rangle^2}
\]

\[
=: A_n^{(3)}(t,t') + A_n^{(4)}(t,t') + A_n^{(5)}(t,t'). \tag{7.7}
\]

We denote the contribution to \( J_{\odot\odot}(w) \) from \( 1_{n=n_1} \cdot A_n^{(j)} \) by \( J_{\odot\odot}^{(j)}(w) \) for \( j = 3, 4, 5 \):

\[
J_{\odot\odot}^{(j)}(w)(t) := \sum_{n \in \mathbb{Z}^3} e_n \int_0^t \hat{w}(n,t') A_n^{(j)}(t,t') dt'. \tag{7.8}
\]

The analysis for \( j = 4, 5 \) is analogous to that in [13]. As for the \( j = 3 \) case, while the argument in [13] relied on the time differentiability of the input function \( w \), we present an argument without using the time differentiability of \( w \).

We now present the proof of Proposition 2.5. Part of the argument follows closely the proof of Proposition 1.11 in [13].

**Proof of Proposition 2.5** Fix \( q > 1 \) and let \( q' \) be its Hölder conjugate. First, we consider the contribution to \( J_{\odot\odot} \) from \( A_{n,n_1}^{(1)} \) in (7.6) and denote it by \( J_{\odot\odot}^{(1)} \). Then, from (2.27) and (7.6), we have

\[
\| J_{\odot\odot}^{(1)}(w)(t) \|_{H^s_{t,x}} \leq \left\| \int_0^t \langle n \rangle^{s_3} \sum_{n_1 \in \mathbb{Z}^3} \hat{w}(n_1,t') A_{n,n_1}^{(1)}(t,t') dt' \right\|_{L^2_t} \\
\lesssim \|w\|_{L^q_t L^q_x} \| \langle n \rangle^{s_3} A_{n,n_1}^{(1)}(t,t') \|_{L^q_t([0,T];L^2_{x_{n,n_1}})}.
\tag{7.9}
\]

Note that the conditions \( |n_1| \ll |n_2| \) for some small \( \theta > 0 \) and \( |n_1 + n_2| \sim |n_3| \) imply \( |n_2| \sim |n_3| \gg |n_1| \). Moreover, with the condition \( n - n_1 = n_2 + n_3 \), we have \( |n_2| \sim |n_3| \gg |n| \).
Then, from (7.6), (3.17), and (3.18), we have

\begin{align}
\mathbb{E}\left[\langle n \rangle^{s_3} A^{(1)}_{n,n_1}(t, t') \right] & \leq \sum_{n, n_1} \langle n \rangle^{2s_3} \mathbb{E} \left[ \sum_{n \sim n_1} \sum_{n_2, n_3} \frac{\sin((t - t')(n_1 + n_2)) \sin((t - t')(n_1 + n_3))}{n_1 + n_2} \right] \\
& \times \left( \hat{\Psi}(n_2, t') \hat{\Psi}(n_3, t) - 1_{n_2 + n_3 = 0} \cdot \sigma_{n_2}(t, t') \right) \\
& \times \left( \hat{\Psi}(n'_2, t') \hat{\Psi}(n'_3, t) - 1_{n'_2 + n'_3 = 0} \cdot \sigma_{n'_2}(t, t') \right)
\end{align}

(7.10)

uniformly in $0 \leq t' \leq t \leq T$, provided that $2s_3 + 3\theta < 0$, where, at the second inequality, we used the fact that non-zero contribution appears only when $n_2 = n'_2$ or $n_2 = n'_3$. Hence, from Minkowski’s integral inequality, Lemma 3.6, and (7.10), we conclude that

\begin{align}
\left\| \langle n \rangle^{s_3} A^{(1)}_{n,n_1}(t, t') \right\|_{L^p(m \circ \hat{\mathcal{A}}^2_{n,n_1})} \lesssim T^{\frac{3}{p}} p
\end{align}

(7.11)

for any finite $p \geq 2$ and $t \in [0, T]$. A similar argument yields the following difference estimate; there exists small $\sigma_0 > 0$ such that

\begin{align}
\left\| \langle n \rangle^{s_3} A^{(1)}_{n,n_1}(t_1, t') - \langle n \rangle^{s_3} A^{(1)}_{n,n_1}(t_2, t') \right\|_{L^p([0,T] ; \mathcal{E}^2_{n,n_1})} \lesssim T^{\frac{3}{p}} |t_1 - t_2|^{\sigma_0}
\end{align}

(7.12)

for any finite $p \geq 2$ and $t_1, t_2 \in [0, T]$. See, for example, the proof of Proposition 1.11 in [43]. By Kolmogorov’s continuity criterion, we conclude that

\begin{align}
\langle n \rangle^{s_3} A^{(1)}_{n,n_1}(\cdot, t') \in L^\infty([0,T])
\end{align}

(7.13)

The desired mapping property then follows from (7.9) and (7.13). The tail estimate (2.30) for $\gamma^{(1)}_{\circ, \circ}$ follows from (7.11), (7.12), and the Garsia-Rodemich-Rumsey inequality (Lemma 3.8) as in the proof of Lemma 4.1.

Next, we consider $\gamma^{(3)}_{\circ, \circ}$ defined in (7.8). This is a deterministic operator with the kernel given by $A^{(3)}_{n}(t, t')$ in (7.7). Hence, once we show its boundedness, the tail estimate (2.30) is automatically satisfied. The same comment applies to $\gamma^{(4)}_{\circ, \circ}$ and $\gamma^{(5)}_{\circ, \circ}$ studied below. In this case,
we show
\[ \mathcal{A}^{(3)}_{\otimes, \otimes} \in \mathcal{L}(L^q([0, T]; L^2(\mathbb{T}^3)); L^\infty([0, T]; L^2(\mathbb{T}^3))) \] (7.14)
for any \( q > 1 \). In the following, we only consider \( 1 < q \leq 2 \).

Define \( K_n \) by
\[ K_n(t) = 1_{[0,1]}(t) \cdot e^{-t} \sum_{n_2 \in \mathbb{Z}^3} \frac{\sin(t([n + n_2] + [n_2]))}{2[n + n_2](n_2)^2}. \] (7.15)
Then, from (7.7), we have
\[ A^{(3)}_n(t, t') = 1_{[0,1]}(t') \cdot K_n(t - t') \] (7.16)
for \( 0 \leq t \leq 1 \). Thus, we have
\[ \mathcal{A}^{(3)}_n(t) = 1_{[0,1]}(t) \cdot \sum_{n \in \mathbb{Z}^3} e_n \int_0^t (1_{[0,1]}(t') \cdot \hat{w}(n, t')) K_n(t - t') dt'. \] (7.17)
for \( 0 \leq t \leq T \leq 1 \).

From (7.15), we have
\[ \hat{K}_n(\tau) = \frac{1}{\sqrt{2\pi}} \int_0^1 K_n(t)e^{-it\tau} dt \]
\[ = \frac{1}{4i\sqrt{2\pi}} \sum_{\sigma \in \{1, -1\}} \sum_{n_2 \in \mathbb{Z}^3} \frac{1}{\|n + n_2\|} \|n_2\|^2 \]
\[ \times \frac{\exp\left(i\sigma([n + n_2] + [n_2]) - \tau\right) - 1}{i(\sigma([n + n_2] + [n_2]) - \tau) - 1}. \]
In the following, we only bound the contribution from \( \sigma = 1 \). The contribution from \( \sigma = -1 \) can be estimated in an analogous manner. Let
\[ \phi_{n, \tau}(n_2) := \|n + n_2\| + \|n_2\| - \tau. \]
Then, for \( N \geq 4 \) dyadic and \( \tau \geq 1 \), we have
- If \( N \ll \tau \), then \#\{\( n_2 \in \mathbb{Z}^3 : \phi_{n, \tau}(n_2) \sim N \} \lesssim N\tau^2 \). In this case, we have \( |n_2| \sim \tau \).
- If \( N \sim \tau \), then \#\{\( n_2 \in \mathbb{Z}^3 : \phi_{n, \tau}(n_2) \sim N \} \lesssim \tau^3 \). In this case, we have \( |n_2| \lesssim \tau \).
- If \( N \gg \tau \), then \#\{\( n_2 \in \mathbb{Z}^3 : \phi_{n, \tau}(n_2) \sim N \} \lesssim N^3 \). In this case, we have \( \phi_{n, \tau}(n_2) \sim \tau \).
Hence, we have
\[
|\hat{\kappa}_n(\tau)| \lesssim \sum_{n_2 \in \mathbb{Z}^3, \phi_{n,\tau}(n_2) \leq 4} \frac{1}{(n_2)^3} + \sum_{N \ll \tau \text{ dyadic}} \sum_{n_2 \in \mathbb{Z}^3, \phi_{n,\tau}(n_2) \sim N} \frac{1}{(n_2)^3} \frac{1}{N} \\
+ \sum_{N \sim \tau \text{ dyadic}} \sum_{n_2 \in \mathbb{Z}^3, \phi_{n,\tau}(n_2) \sim N} \frac{1}{(n_2)^3} \frac{1}{\tau} + \sum_{N \gg \tau \text{ dyadic}} \sum_{n_2 \in \mathbb{Z}^3, \phi_{n,\tau}(n_2) \sim N} \frac{1}{N^4} 
\tag{7.18}
\]
uniformly in \( n \) with \(|n| \ll |n_2|^\theta \), when \( \tau \geq 1 \). When \( \tau \leq 1 \), we have \( \phi_{n,\tau}(n_2) \gtrsim \langle n_2 \rangle \gg 1 \) and thus
\[
|\hat{\kappa}_n(\tau)| \lesssim \sum_{n_2 \in \mathbb{Z}^3} \frac{1}{(n_2)^3} \max(\langle n_2 \rangle, \langle \tau \rangle) \lesssim \frac{\log(\tau)}{\langle \tau \rangle},
\tag{7.19}
\]
uniformly in \( n \in \mathbb{Z}^3 \) with \(|n| \ll |n_2|^\theta \). From (7.18) and (7.19), we conclude that \( \hat{\kappa}_n \in L^q(\mathbb{R}^3) \) for any \( q > 1 \). Then, by Hausdorff-Young’s inequality, we obtain
\[
\left\|(1_{[0,T]} \cdot \hat{\omega}(n, \cdot)) \ast \kappa_n\right\|_{L^\infty} \lesssim \left\|\hat{W}_n \hat{\kappa}_n\right\|_{L^1} \lesssim \left\|\hat{W}_n\right\|_{L^q} \left\|\hat{\kappa}_n\right\|_{L^q} \lesssim \|W_n\|_{L^q}
\tag{7.20}
\]
for any \( 1 < q \leq 2 \), uniformly in \( n \in \mathbb{Z}^3 \), where \( W_n = 1_{[0,T]} \cdot \hat{\omega}(n) \). Therefore, from (7.17), (7.20), and Minkowski’s integral inequality, we conclude that
\[
\left\|\mathcal{S}^{(3)}(w)\right\|_{L^\infty L^2} \lesssim \left\|\left(1_{[0,T]} \cdot \hat{\omega}(n, \cdot)\right) \ast \kappa_n\right\|_{L^\infty} \lesssim \left\|\hat{\omega}(n, \cdot)\right\|_{L^q} \|w\|_{L^q L^2}
\]
for any \( 1 < q \leq 2 \). This proves (7.14).

Lastly, we consider \( \mathcal{S}^{(4)} \) and \( \mathcal{S}^{(5)} \) defined in (7.8). These are deterministic operators with the kernels given by \( \mathcal{A}^{(4)}(t, t') \) and \( \mathcal{A}^{(5)}(t, t') \) in (7.7). Hence, once we show their boundedness, the tail estimate (2.30) is automatically satisfied. For now, we assume that there exists some small \( \varepsilon > 0 \) such that
\[
\|\langle n \rangle^{-\varepsilon} \mathcal{A}^{(j)}(t, t')\|_{\ell^2_n} \lesssim 1
\tag{7.21}
\]
for any \( 0 \leq t' \leq t \leq T \leq 1 \), \( j = 4, 5 \), and show
\[
\mathcal{S}^{(j)} \in L^1([0, T]; L^2(\mathbb{T}^3)) \cap L^\infty([0, T]; H^{s_3}(\mathbb{T}^3)), \quad j = 4, 5.
\]
From (7.8) and (7.21), we have
\[
\|\mathcal{S}^{(j)}(w)\|_{L^\infty L^2} = \left\| \int_0^t \langle n \rangle^{s_3} \hat{\omega}(n, t') \mathcal{A}^{(j)}(t, t') dt' \right\|_{L^\infty L^2_n} \lesssim \|w\|_{L^1_n L^2} \sup_{n \in \mathbb{Z}^3} \langle n \rangle^{s_3 + \varepsilon} \lesssim \|w\|_{L^1_n L^2}
\]
provided that \( \varepsilon \leq -s_3 \). By noting that \( \|n + n_2\| \sim \langle n_2 \rangle \gg \langle n \rangle \) under \(|n| \ll |n_2|^\theta \), we see that (7.21) is easily verified for \( j = 5 \).
The sum for $A_n^{(4)}(t, t')$ in (7.1) is not absolutely convergent. As in [43], we exploit the symmetry $n_2 \leftrightarrow -n_2$ and the oscillatory nature of the sine kernel. Set

$$\Theta^{\pm}(n, n_2) := \left| n \pm n_2 \right| - \left| n_2 \right| = \pm \left( n, n_2 \right) \frac{n_2}{n_2^2}.$$  

(7.22)

Then, noting that $\left| n \pm n_2 \right| \sim \left| n_2 \right|$ under $|n| \ll |n_2|^\theta$, it follows from (2.7) and the mean value theorem that

$$\Theta^{\pm}(n, n_2) = \left| n \right|^2 \frac{\left| n \right| - \left| n_2 \right|}{\left| n \pm n_2 \right|} \pm \left( n, n_2 \right) \frac{n_2}{n_2^2}.$$  

(7.23)

Write

$$\sum_{n_2 \in \mathbb{Z}^3 \setminus \{0\}} F(n_2) = \sum_{n_2 \in \Lambda} (F(n_2) + F(-n_2)),$$

where the index $\Lambda$ is as in (1.19). Then, from (7.7), (7.22), the mean value theorem, and (7.23), we have

$$A_n^{(4)}(t, t') = e^{-(t-t')} \sum_{n_2 \in \Lambda \atop |n| \ll |n_2|^{\theta}} \sin((t - t')(\left| n + n_2 \right| - \left| n_2 \right|)) \sin((t - t')(\left| n - n_2 \right| - \left| n_2 \right|))$$

$$- e^{-(t-t')} \sum_{n_2 \in \Lambda \atop |n| \ll |n_2|^{\theta}} \sin((t - t')(\left| n - n_2 \right| - \left| n_2 \right|)) \left( \frac{1}{\left| n + n_2 \right|} - \frac{1}{\left| n - n_2 \right|} \right)$$

$$+ e^{-(t-t')} \sum_{n_2 \in \Lambda \atop |n| \ll |n_2|^{\theta}} \frac{1}{2\left| n + n_2 \right| \left| n_2 \right|} \left\{ \sin \left( (t - t') \left( \frac{\left| n, n_2 \right|}{\left| n_2 \right|} + \Theta^{+}(n, n_2) \right) \right) - \sin \left( (t - t') \left( \left| n, n_2 \right| - \Theta^{-}(n, n_2) \right) \right) \right\}$$

$$+ O \left( \sum_{n_2 \in \Lambda \atop |n| \ll |n_2|^{\theta}} \frac{\left( n \right) \left( n_2 \right)^2}{\left| n_2 \right|} \right)$$

$$\lesssim \sum_{n_2 \in \Lambda \atop |n| \ll |n_2|^{\theta}} \frac{1}{\left| n + n_2 \right| \left| n_2 \right|} \left( \frac{\left( n \right) \left( n_2 \right)^2}{\left| n_2 \right|} \right) + \sum_{n_2 \in \Lambda \atop |n| \ll |n_2|^{\theta}} \frac{\left( n \right) \left( n_2 \right)^2}{\left| n_2 \right|}$$

$$\lesssim \left( n \right)^{\delta}$$

for any $0 \leq t' \leq t \leq 1$ and $0 < \delta \leq 1$. This proves (7.21) for $j = 4$.

This completes the proof of Proposition [2.5] \(\square\)

We conclude this section by briefly discussing the regularity property of the stochastic term $\hat{A}$ defined in (2.38). For this purpose, we first define its truncated version:

$$A_N(x, t, t') = \sum_{n \in \mathbb{Z}^3} e_n(x) \sum_{n_1, n_2 \atop |n_1| \ll |n_2|} e^{-\frac{t-t'}{2} \sin((t - t')(\left| n_1 \right|)} \tilde{\Psi}_N(n_1, t') \tilde{\Psi}_N(n_2, t).$$  

(7.25)
Lemma 7.2. Let $\mathcal{A}_N(t,t')$ be as in (7.25). Fix finite $q \geq 2$. Then, given any $T, \varepsilon > 0$ and finite $p \geq 1$, $\{\mathcal{A}_N\}_{N \in \mathbb{N}}$ is a Cauchy sequence in $L^p(\Omega; L^\infty_0 L^q_t(\Delta_2(T); H^{-\varepsilon}(\mathbb{T}^3)))$, converging to some limit $\mathcal{A}$ (formally defined by (2.38)) in $L^p(\Omega; L^\infty_0 L^q_t(\Delta_2(T); H^{-\varepsilon}(\mathbb{T}^3)))$, where $\Delta_2(T)$ is as in (2.40). Moreover, $\mathcal{A}_N$ converges almost surely to the same limit in $L^\infty_0 L^q_t(\Delta_2(T); H^{-\varepsilon}(\mathbb{T}^3))$. Furthermore, we have the following uniform tail estimate:

$$P\left( \|\mathcal{A}_N\|_{L^\infty_0 L^q_t(\Delta_2(T); H^{-\varepsilon})} > \lambda \right) \leq C \exp\left(-\frac{\lambda}{T^{\frac{3}{2}}}\right)$$  \hspace{1cm} (7.26)

for any $0 < T \leq 1$, $\lambda \gg 1$, and $N \in \mathbb{N} \cup \{\infty\}$, where $\mathcal{A}_\infty = \mathcal{A}$.

Proof. In the following, we simply study the regularity of $\mathcal{A}$, i.e. when $N = \infty$. The claimed convergence and the tail estimate (7.26) follow from a standard argument and the fact that $\mathcal{A}_N \in \mathcal{H}_{\leq 2}$, $N \in \mathbb{N} \cup \{\infty\}$. By comparing (2.38) with (2.28), we have

$$\tilde{\mathcal{A}}(n, t) = \mathcal{A}_{n,0}(t, t')$$

for $(t, t') \in \Delta_2(T)$. Thus, from (7.6) and (7.7), we can write

$$\tilde{\mathcal{A}}(n, t, t') = \tilde{\mathcal{A}}^{(1)}(n, t, t') + 1_{n=0} \cdot \left( \tilde{\mathcal{A}}^{(3)}(0, t, t') + \tilde{\mathcal{A}}^{(4)}(0, t, t') + \tilde{\mathcal{A}}^{(5)}(0, t, t') \right),$$

where $\tilde{\mathcal{A}}^{(1)}(n, t, t') = \mathcal{A}^{(1)}_{n,0}(t, t')$ and $\tilde{\mathcal{A}}^{(j)}(n, t, t') = \mathcal{A}^{(j)}_{n,0}(t, t')$, $j = 3, 4, 5$.

From (7.10), we have

$$E\left[ \|\tilde{\mathcal{A}}^{(1)}(n, t, t')\|^2 L^q([0,T]) \right] \lesssim \langle n \rangle^{-3} T^\frac{3}{2}$$

for $n \in \mathbb{Z}^3$ and $0 \leq t' \leq t \leq T$. Note that, in (2.38), $t'$ appears in $\sin((t-t')[n_0])$ and $\Psi(n_1, t')$. Then, proceeding as in the proof of Lemma 3.1 in [43], we obtain

$$E\left[ \|\tilde{\mathcal{A}}^{(1)}(n, t, t') - \tilde{\mathcal{A}}^{(1)}(n, t, t')\|^2 L^q([0,T]) \right] \lesssim \langle t_1 - t_2 \rangle^{\sigma_0} \langle n \rangle^{-3+3\sigma_0} T^\frac{3}{2}$$

for some small $\sigma_0 > 0$. Then, by (a variant of) Lemma 3.7, we conclude that $\mathcal{A}^{(1)} \in L^\infty_0 L^q_t(\Delta_2(T); H^{-\varepsilon}(\mathbb{T}^3))$ almost surely. The exponential tail estimate (7.26) for $\mathcal{A}^{(1)}$ follows from adapting the proof of Lemma 4.1 using Lemma 3.8.

It remains to estimate the deterministic terms $\mathcal{A}^{(j)}$, $j = 3, 4, 5$, which appear only at the zeroth frequency. Let $\phi$ be a smooth bump function in Section 3 and set $\phi T(t) = \phi(T^{-1}t)$. Then, from (7.16), (7.18), (7.19), Hausdorff-Young’s inequality, and Young’s inequality, we have

$$\|\tilde{\mathcal{A}}^{(3)}(0, t, t')\|_{L^\infty_0 L^q_t(\Delta_2(T))} \leq \|\mathcal{K}_0\|_{L^q} \lesssim \|\phi T \mathcal{K}_0\|_{L^\infty_q} \lesssim \|\phi T\|_{L^q_t} \lesssim T^\frac{1}{2}$$

for small $\varepsilon > 0$. From (7.24), we have

$$\|\tilde{\mathcal{A}}^{(4)}(0, t, t')\|_{L^\infty_0 L^q_t(\Delta_2(T))} \lesssim T^\frac{1}{2}. \hspace{1cm} (7.27)$$

In view of a faster decay in $n_2$ for $j = 5$ in (7.7), the estimate (7.27) trivially holds for $\tilde{\mathcal{A}}^{(5)}$. \hfill $\Box$

8. Local well-posedness of Hartree SdNLW

In this section, we present the proofs of Theorems 2.6 and 2.8 on local well-posedness of the renormalized Hartree SdNLW systems (2.31) and (2.37) in the defocusing case and the focusing case, respectively.
• **Defocusing case for \( \beta > 1 \).** We first treat the defocusing case (2.31). By writing (2.31) in the Duhamel formulation (for \( X \) and \( Y \)), we have
\[
X = \Phi_1(X, Y, \Re)
\]
\[
:= S(t)(X_0, X_1) - \mathcal{I}( (V * (Q_{X,Y} + 2\Re + :\Psi^2:)) \otimes \Psi ), \]
\[
Y = \Phi_2(X, Y, \Re)
\]
\[
:= S(t)(Y_0, Y_1) - \mathcal{I}( (V * (Q_{X,Y} + 2\Re + :\Psi^2:))(X + Y) ) - \mathcal{I}( (V * (Q_{X,Y} + 2\Re + :\Psi^2:)) \otimes \Psi ), \tag{8.1}
\]
\[
\Re = \Phi_3(X, Y, \Re)
\]
\[
:= -\mathcal{J}^{(1)}( V * (Q_{X,Y} + 2\Re + :\Psi^2:) ) \otimes \Psi - \mathcal{J}^{(1)}( V * (Q_{X,Y} + 2\Re + :\Psi^2:) ),
\]
where \( S(t)(f, g) = \partial_t \mathcal{D}(t)f + \mathcal{D}(t)(f + g) \) and \( \mathcal{D}(t) \) is as in (2.6). In the following, we assume that \(-\frac{1}{2} < s_3 < 0 < s_1 < \frac{1}{2} < s_2 < 1 \). Given \( 0 < T \leq 1 \), let \( Z^{s_1, s_2, s_3}(T) \) be as in (2.34). Given an enhanced data set \( \Xi \) as in (2.35), we set
\[
\Xi(\Psi) = (\Psi, :\Psi^2:, (V * :\Psi^2:) \otimes \Psi, \mathcal{J}^{(1)}(\Xi))
\]
and
\[
\|\Xi(\Psi)\|_{\mathcal{X}_1} := \|\Psi\|_{\sum_1 -1-\epsilon, \infty} + \| :\Psi^2: \|_{\sum_1 -1-\epsilon, \infty} + \|(V * :\Psi^2:) \otimes \Psi\|_{\sum_1 -1-\epsilon, \infty} + \|\mathcal{J}^{(1)}(\Xi)\|_{L^2(T)} \tag{8.2}
\]
for some small \( \epsilon = \epsilon(\beta, s_1, s_2, s_3) > 0 \). We assume
\[
\|\Xi(\Psi)\|_{\mathcal{X}_1} \leq K \tag{8.3}
\]
for some \( K \geq 1 \).

We first establish preliminary estimates. By Sobolev’s inequality, we have
\[
\|f^2\|_{H^{-a}} \lesssim \|f^2\|_{L^{\frac{6}{1+2a}}} = \|f\|_{L^{\frac{12}{1+2a}}} \lesssim \|f\|_{H^{\frac{3-2a}{2}}} \tag{8.4}
\]
for any \( 0 \leq a < \frac{3}{2} \). By (1.3), (2.23), (8.4), Lemma 3.2, Lemma 3.3, and Hölder’s inequality with (8.3), we have
\[
\|V * Q_{X,Y}\|_{L^\infty_t H_{H^\alpha}^{-s_1+s_2+s_1+\frac{1}{2}}} \lesssim \|(X + Y)^2\|_{L^\infty_t H_{H^\alpha}^{-s_1+s_2+\frac{1}{2}}} + \|X \otimes \Psi\|_{L^\infty_t H_{H^\alpha}^{-s_1+s_2+s_1+\frac{1}{2}}} + \|Y \otimes \Psi\|_{L^\infty_t H_{H^\alpha}^{-s_2+s_1+s_1+\frac{1}{2}}} \lesssim \left( \|X\|_{L^\infty_t H_x^{\max(1-s_1+s_2+\alpha, \epsilon)}}^2 + \|Y\|_{L^\infty_t H_x^{\max(1-s_2+s_1+\alpha, \epsilon)}}^2 \right) \|\Psi\|_{L^\infty_t H_x^{\frac{1}{2}+\epsilon}} \|\Psi\|_{L^\infty_t W_x^{\frac{1}{2}-\epsilon, \infty}} \lesssim \left( \|X\|_{X^{s_1}(T)}^2 + \|Y\|_{X^{s_2}(T)}^2 + K^2 \right), \tag{8.5}
\]
provided that \( \beta \geq \max(-s_1 + s_2 + 1 + \epsilon, -3s_1 + s_2 + 2) \), \( s_1 \geq \epsilon \), and \( s_2 \geq \frac{1}{2} + 2\epsilon \). When \( \beta > 1 \), these conditions are satisfied for \( 0 < s_1 < \frac{1}{2} < s_2 \) such that \( s_2 - s_1 > 0 \) is sufficiently close to 0.
We also record the following estimate, which follows from Sobolev’s and Hölder’s inequality:

\[
\|fg\|_{H^{s_2-1}} \lesssim \|fg\|_{L^6_x L^{\frac{3}{2}}_t} \lesssim \|f\|_{L^6_x L^{\frac{3}{2}}_t} \|g\|_{L^6_x L^{\frac{3}{2}}_t} \lesssim \|f\|_{H^{s_1}} \|g\|_{H^{-s_1+s_2+\frac{1}{2}}} \tag{8.6}
\]

for any \(0 \leq s_1 < s_2 \leq 1\). Lastly, we recall the energy estimate:

\[
\left\| \int_0^T \mathcal{D}(t - t') F(t') dt' \right\|_{X^s(T)} \lesssim \|F\|_{L^1_T H^{s-1}}. \tag{8.7}
\]

We now estimate \(\Phi_1(X, Y, \mathfrak{R})\) in (8.1). By the energy estimate (8.7), Lemma 3.2, and (8.5) with (8.3), we have

\[
\|\Phi_1(X, Y, \mathfrak{R})\|_{X^s(T)} \\
\lesssim \|(X_0, X_1)\|_{H^{s_1}} + \|(V * (Q_{X,Y} + 2\mathfrak{R} + :\Psi^2:) ) \|_{L^1_T H^{s_1}} \\
\lesssim \|(X_0, X_1)\|_{H^{s_1}} + T^{\frac{3}{2}} \|V * (Q_{X,Y} + 2\mathfrak{R} + :\Psi^2:) \|_{L^2_T L^2_x} \|\Psi\|_{L^\infty_T W^{\frac{1}{2}, -\infty}_x} \tag{8.8}
\]

provided that \(\beta \geq \max(-s_3, 1 + \varepsilon)\) and \(s_1 < \frac{1}{2} - \varepsilon\).

Next, we estimate \(\Phi_2(X, Y, \mathfrak{R})\) in (8.1). By the energy estimate (8.7), (8.6), Lemma 3.2, and (8.5) with (8.3), we have

\[
\|\Phi_2(X, Y, \mathfrak{R})\|_{X^s(T)} \\
\lesssim \|(Y_0, Y_1)\|_{H^{s_2}} + \|(V * (Q_{X,Y} + 2\mathfrak{R} + :\Psi^2:) ) (X + Y)\|_{L^1_T H^{s_2}} \\
+ \|(V * (Q_{X,Y} + 2\mathfrak{R} + :\Psi^2:) ) \|_{L^1_T H^{s_2}} \\
\lesssim \|(Y_0, Y_1)\|_{H^{s_2}} + T^{\frac{3}{2}} \|V * (Q_{X,Y} + 2\mathfrak{R})\|_{L^2_T H^{s_2}} \left( \|X\|_{L^\infty_T H^{s_1}} + \|Y\|_{L^\infty_T H^{s_1}} \right) \tag{8.9}
\]

provided that \(\beta \geq \max(1 + \varepsilon, s_2 + \frac{1}{2} + 4\varepsilon, -s_1 + s_2 - s_3 + \frac{1}{2})\) and \(s_1 + 2\varepsilon \leq s_2 \leq 1\).
Finally, we estimate \( \Phi_3(X, Y, \mathfrak{R}) \) in (8.1). By Lemma 3.2, Lemma 7.1 (in particular (7.2)), and (8.5) with (8.3), we have
\[
\| \Phi_3(X, Y, \mathfrak{R}) \|_{L^{3,2}_{x}} \leq \left\| J^{(1)}(V \ast (Q_{X,Y} + 2\mathfrak{R} + : \Psi^2 :)) \odot \Psi \right\|_{L^{3,2}_{x}} \\
+ \left\| J_{\odot,\odot}(V \ast (Q_{X,Y} + 2\mathfrak{R} + : \Psi^2 :)) \right\|_{L^{3,2}_{x}} \\
\lesssim T_{\frac{1}{2}} \left\| J^{(1)}(V \ast (Q_{X,Y} + 2\mathfrak{R} + : \Psi^2 :)) \right\|_{L^{3,2}_{W,\frac{3}{2},H_x^{\frac{1}{2} + \varepsilon,\infty}}} \\
+ T_{\frac{1}{2}} K \left\| V \ast (Q_{X,Y} + 2\mathfrak{R} + : \Psi^2 :) \right\|_{L^{3,2}_{L^2}} \\
\lesssim T_{\frac{2}{3}} K^2 \left\| V \ast (Q_{X,Y} + 2\mathfrak{R} + : \Psi^2 :) \right\|_{L^{3,2}_{W,\frac{3}{2},H_x^{0}}} \\
+ T_{\frac{2}{3}} K \left\| V \ast (Q_{X,Y} + 2\mathfrak{R} + : \Psi^2 :) \right\|_{L^{3,2}_{L^2}} \\
\lesssim T_{\frac{2}{3}} K^2 \left( \| (X, Y, \mathfrak{R}) \|_{Z^{1,s_2,s_3}(T)}^2 + K^2 \right)
\] (8.10)
for some small positive \( s_0 = s_0(\varepsilon) \sim \varepsilon \), provided that \( \beta \geq \max(-s_3 + s_0, 1 + s_0) \).

By repeating a similar computation, we also obtain the following difference estimate:
\[
\| \Phi(X, Y, \mathfrak{R}) - \Phi(X, Y, \mathfrak{R}) \|_{Z^{1,s_2,s_3}(T)} \\
\lesssim T_{\frac{1}{2}} K^2 \left( \| (X, Y, \mathfrak{R}) \|_{Z^{1,s_2,s_3}(T)} + \| (X, Y, \mathfrak{R}) \|_{Z^{1,s_2,s_3}(T)}^2 + K^2 \right)
\] (8.11)
where \( \Phi := (\Phi_1, \Phi_2, \Phi_3) \). Let \( B_R \subset Z^{1,s_2,s_3}(T) \) be the closed ball of radius \( R \sim \| (X_0, X_1) \|_{H^1} + \| (Y_0, Y_1) \|_{H^2}, \) centered at the origin. Then, by choosing \( T = T(K, R) > 0 \) sufficiently small, we conclude from (8.8), (8.9), (8.10), and (8.11) that \( \Phi = (\Phi_1, \Phi_2, \Phi_3) \) is a contraction on the closed ball \( B_R \). A similar computation yields continuous dependence of the solution \( (X, Y, \mathfrak{R}) \) on the enhanced data set \( \Xi \) measured in the \( \lambda_{1,s_2}^{\beta_1 \cdot \varepsilon} \) norm. This concludes the proof of Theorem 2.6.

**Focusing case for \( \beta \geq 2 \).** We conclude this section by briefly going over the required modifications in the focusing case. In view of the Gibbs measure construction (Theorem 1.14), we take \( 2 < \gamma \leq 3 \) sufficiently close to 3 (and \( \gamma = 3 \) when \( \beta = 2 \)). As mentioned in Section 11, a precise value of \( \sigma > 0 \) does not play any role in the local well-posedness argument, so we simply set \( \sigma = 1 \) and consider the system (2.37). By writing (2.37) in the Duhamel formulation, we have
\[
X = \Psi_1(X, Y, \mathfrak{R}) \\
= S(t)(X_0, X_1) + \mathcal{I}
\left( (V \ast (Q_{X,Y} + 2\mathfrak{R} + : \Psi^2 :)) \odot \Psi \right) \\
- \mathcal{I}
\left( M_{\gamma}(Q_{X,Y} + 2\mathfrak{R} + : \Psi^2 :) \Psi \right),
\]
\[
Y = \Psi_2(X, Y, \mathfrak{R}) \\
= S(t)(Y_0, Y_1) + \mathcal{I}
\left( (V \ast (Q_{X,Y} + 2\mathfrak{R} + : \Psi^2 :))(X + Y) \right) \\
+ \mathcal{I}
\left( (V \ast (Q_{X,Y} + 2\mathfrak{R} + : \Psi^2 :)) \odot \Psi \right) \\
- \mathcal{I}
\left( M_{\gamma}(Q_{X,Y} + 2\mathfrak{R} + : \Psi^2 :) (X + Y) \right),
\]
\[
\mathfrak{R} = \Psi_3(X, Y, \mathfrak{R}) \\
= \mathcal{J}^{(1)}(V \ast (Q_{X,Y} + 2\mathfrak{R} + : \Psi^2 :)) \odot \Psi
\]
where the last term in the \( R \) equation is interpreted as \( (2.39) \).

Comparing with \( (8.1) \) from the defocusing case, it suffices to estimate the last terms in each equation. Given an enhanced data set \( \Xi \) as in \( (2.41) \), we set

\[
\Xi(\Psi) = (\Psi, :\Psi^2:, A, I_{0,0})
\]

for some \( K \) and

\[
\| \Xi(\Psi) \|_{Y^1_T} := \| \Psi \|_{C^1_T W^{-\epsilon,\infty}_x} + \| :\Psi^2: \|_{C^1_T W^{-\epsilon,\infty}_x} + \| A \|_{L^\infty_T L^1_0(\Delta_\gamma(T); W^{-\epsilon,\infty}_x)} + \| I_{0,0} \|_{L^2_0 T}^3
\]

for some small \( \epsilon = \epsilon(\beta, s_1, s_2, s_3) > 0 \). We assume

\[
\| \Xi(\Psi) \|_{Y^1_T} \leq K
\]

for some \( K \geq 1 \).

By the energy estimate \( (8.7) \), \( (2.2) \), and \( (8.14) \), we have

\[
\left\| \mathcal{I}(M_\gamma(Q_{X,Y} + 2R + :\Psi^2:)\Psi) \right\|_{X^{s_1}(T)} \lesssim \left\| M_\gamma(Q_{X,Y} + 2R + :\Psi^2:)\Psi \right\|_{L^1_T H^{1}_{s_1,1}}
\]

\[
\lesssim \left\| Q_{X,Y} + 2R + :\Psi^2: \right\|_{L^\infty_T L^1_0(\Delta_\gamma(T); W^{-\epsilon,\infty}_x)} \left\| :\Psi^2: \right\|_{L^\infty_T H^{1}_{s_1,1}}
\]

\[
\lesssim T^{\frac{4-\gamma}{3}} K \left\| Q_{X,Y} + 2R + :\Psi^2: \right\|_{L^\infty_T H^{1}_{s_1,1}}
\]

\[
\lesssim T^{\frac{4-\gamma}{3}} K \left( \left\| (X,Y, R) \right\|_{Z^{s_1,s_2,s_3}(T)}^2 + K^2 \right)^{\frac{\gamma}{2}}
\]

Similarly, we have

\[
\left\| \mathcal{I}(M_\gamma(Q_{X,Y} + 2R + :\Psi^2:)(X+Y)) \right\|_{X^{s_2}(T)} \lesssim T^{\frac{4-\gamma}{3}} \left( \left\| (X,Y, R) \right\|_{Z^{s_1,s_2,s_3}(T)}^2 + K^2 \right)^{\frac{\gamma}{2}} \left\| (X,Y, R) \right\|_{Z^{s_1,s_2,s_3}(T)}
\]

By Minkowski’s integral inequality and the proceeding as in \( (8.15) \), we have

\[
\left\| \mathcal{I}(M_\gamma(Q_{X,Y} + 2R + :\Psi^2:)\Psi) \right\|_{L^1_T H^{s_3}}
\]

\[
\leq \int_0^T \left| M_\gamma(Q_{X,Y} + 2R + :\Psi^2:)(t') \right| \cdot \left\| A(t, t') \right\|_{L^1_T H^{s_3}} dt'
\]

\[
\leq K \left\| Q_{X,Y} + 2R + :\Psi^2: \right\|_{L^\infty_T H^{1}_{s_1,1}}
\]

\[
\lesssim T^{\frac{4-\gamma}{3}} K \left( \left\| (X,Y, R) \right\|_{Z^{s_1,s_2,s_3}(T)}^2 + K^2 \right)^{\frac{\gamma}{2}}
\]

Since \( \gamma \leq 3 \), we have a small power of \( T \) in \( (8.15) \), \( (8.16) \), and \( (8.17) \). Furthermore, since \( \gamma \geq 2 \), \( |x|^{\gamma-1} x \) is differentiable with a locally bounded derivative and thus difference estimates also hold for these extra terms. Therefore, proceeding as in the defocusing case, we can show that \( \bar{\Psi} := (\Psi_1, \Psi_2, \Psi_3) \) is a contraction on the ball \( B_R \subset Z^{s_1,s_2,s_3}(T) \) of radius \( R \sim \left\| (X_0, X_1) \right\|_{H^{s_1}} + \left\| (Y_0, Y_1) \right\|_{H^{s_2}} \). This proves Theorem 2.8 in the focusing case.
9. Invariant Gibbs dynamics

In this section, we present the proof of Theorem 2.1 by applying Bourgain’s invariant measure argument [10, 12]. In Subsection 9.1, we first study the truncated dynamics and establish a long time a priori bound on the solutions (Proposition 9.4). In Subsection 9.2, we then prove almost sure global well-posedness of the Hartree SdNLW and invariance of the Hartree Gibbs measure. Our presentation closely follows those in [85, 20, 66], in particular [66], where a renormalization was required on the nonlinearity. We, however, point out that a certain part of the argument from [66] in the two-dimensional setting can not be applied to the current three-dimensional setting. More precisely, in estimating the difference of two solutions, the authors in [66] applied the product estimates (such as Lemma 3.3) to bound the difference of the enhanced data sets with two different initial data. Such an estimate, however, fails in the three-dimensional setting due to the lower regularity of the noise. We overcome this issue by going back to the original idea of Bourgain [12]; see Lemma 9.7.

In the following, we only consider the focusing case ($\sigma > 0$). A straightforward modification yields the corresponding result for the defocusing case. Furthermore, we restrict our attention to the non-endpoint case $\beta > 2$ and assume $\sigma = 1$ for simplicity. The same argument applies to the critical case $\beta = 2$ with $0 < \sigma \ll 1$.

In the remaining part of this section, we fix some notations. Let $V$ be the Bessel potential of order $\beta > 2$. We also fix $A > 0$ sufficiently large and $\gamma > 0$, satisfying $\max\left(\frac{\beta + 1}{\beta - 1}, 2\right) \leq \gamma < 3$ with $\gamma > 2$ when $\beta = 3$, such that the focusing Hartree measure $\rho$ in (1.50) is constructed as the limit of the truncated Gibbs measures $\rho_N$ in (1.47) as in Theorem 1.14. With these parameters and $\mu_0$ as in (1.17), the Gibbs measure $\vec{\rho} = \rho \otimes \mu_0$ for the focusing Hartree SdNLW (2.1) is constructed as the limit of the truncated Gibbs measures:

$$\vec{\rho}_N = \rho_N \otimes \mu_0$$  \hspace{1cm} (9.1)

for the truncated focusing Hartree SdNLW (2.3); see Remark 1.9.

By assumption, the Gaussian field $\vec{\mu} = \mu_1 \otimes \mu_0$ in (1.18) and hence the (truncated) Gibbs measures are independent of (the distribution of) the space-time white noise $\xi$ in (2.1) and (2.3). Hence, we can write the probability space $\Omega$ as

$$\Omega = \Omega_1 \times \Omega_2$$  \hspace{1cm} (9.2)

such that the random Fourier series in (1.20) depend only on $\omega_1 \in \Omega_1$, while the cylindrical Wiener process $W$ in (2.10) depends only on $\omega_2 \in \Omega_2$. In view of (9.2), we also write the underlying probability measure $\mathbb{P}$ on $\Omega$ as $\mathbb{P} = \mathbb{P}_1 \otimes \mathbb{P}_2$, where $\mathbb{P}_j$ is the marginal probability measure on $\Omega_j$, $j = 1, 2$.

With the decomposition (9.2) in mind, we set

$$\Psi(t; \vec{u}_0, \omega_2) = \partial_t \mathcal{D}(t)u_0 + \mathcal{D}(t)(u_0 + u_1) + \sqrt{2} \int_0^t \mathcal{D}(t - t')dW(t', \omega_2),$$

$$\vec{\Psi}(t; \vec{u}_0, \omega_2) = \left(\Psi(t; \vec{u}_0, \omega_2), \partial_t \Psi(t; \vec{u}_0, \omega_2)\right),$$

$$\Psi_N(t; \vec{u}_0, \omega_2) = \pi_N \Psi(t; \vec{u}_0, \omega_2)$$

for $\vec{u}_0 = (u_0, u_1) \in \mathcal{H}^{-\frac{1}{2} - \varepsilon}(T^3)$ and $\omega_2 \in \Omega_2$. We may suppress the dependence on $t$ and $\omega_2$ and write $\Psi(\vec{u}_0)$, etc.

In the following, we fix $\frac{1}{4} < s_1 < \frac{1}{2} < s_2 < 1$ and $-\frac{1}{2} < s_3 < 0$ as in (the proof of) Theorem 2.8.
9.1. On the truncated dynamics. In this subsection, we study the truncated focusing Hartree SdNLW \([2.3]\). While local well-posedness of the truncated equation \((2.3)\) follows from a small modification of the proof of Theorem \([2.8]\) we present a simple argument to prove local well-posedness of \((2.3)\).

Given \(N \in \mathbb{N}\), let \(\bar{u}_0 = (u_0, u_1)\) be a pair of random distributions such that \(\text{Law}((u_0, u_1)) = \tilde{\rho}_N = \rho_N \otimes \mu_0\). Let \(u_N\) be a solution to the truncated equation \((2.3)\) with \((u_N, \partial_t u_N)|_{t=0} = \bar{u}_0\). Then, by writing \(u_N = \Psi(\bar{u}_0) + v_N\), we see that

\[
\begin{align*}
\partial_t^2 v_N + \partial_t v_N + (1 - \Delta) v_N &- \pi_N((V * ((\pi_N v_N)^2 + 2(\pi_N v_N)\Psi + :\Psi_N^2:))(\pi_N v_N + \Psi)) \\
+ M_\gamma((\pi_N v_N)^2 + 2(\pi_N v_N)\Psi + :\Psi_N^2:))(\pi_N v_N + \Psi) &= 0,
\end{align*}
\]

(9.3)

where \(\Psi_N = \Psi_N(\bar{u}_0) = \pi_N \Psi(\bar{u}_0)\) and \(:\Psi_N^2:\) and \(M_\gamma\) are as in \((2.13)\) and \((2.2)\), respectively.

For each fixed \(N \in \mathbb{N}\), \(\Psi_N\) is smooth (in \(x\)). By viewing the stochastic terms in \((9.4)\) as perturbations, it suffices to study the following damped NLW with deterministic perturbations:

\[
\begin{align*}
\partial_t^2 v_N + \partial_t v_N + (1 - \Delta) v_N &- \pi_N((V * ((\pi_N v_N)^2 + 2(\pi_N v_N)f + f^2 - \sigma_N))(\pi_N v_N + f)) \\
+ M_\gamma((\pi_N v_N)^2 + 2(\pi_N v_N)f + f^2 - \sigma_N)(\pi_N v_N + f) &= 0,
\end{align*}
\]

(9.5)

where \((v_0, v_1) \in \mathcal{H}^1(\mathbb{T}^3)\), \(\sigma_N\) is as in \((1.23)\), and \(f \in L^\infty(\mathbb{R}_+; L^\infty(\mathbb{T}^3))\) is a given deterministic function.

**Lemma 9.1.** Let \(N \in \mathbb{N}\). Given any \((v_0, v_1) \in \mathcal{H}^1(\mathbb{T}^3)\) and \(f \in L^\infty([0, 1]; L^\infty(\mathbb{T}^3))\) with

\[
\|(v_0, v_1)\|_{\mathcal{H}^1} \leq R \quad \text{and} \quad \|f\|_{L^\infty([0, 1]; L^\infty)} \leq K
\]

for some \(R, K > 0\), there exist \(\tau = \tau(R, K, N) > 0\) and a unique solution \(v_N\) to \((9.5)\) on \([0, \tau]\), satisfying the bound:

\[
\|v_N\|_{X^1(\tau)} \lesssim R + K,
\]

where \(X^1(\tau)\) is as in \((2.32)\). Moreover, the solution \(v_N\) is unique in \(X^1(\tau)\).

While the local existence time depends on \(N \in \mathbb{N}\), Lemma 9.1 suffices for our purpose. We also point out that the unconditional uniqueness statement for \(v_N\) plays an important role in Proposition 9.4. See Remark 9.5 below.

**Proof.** By writing \((9.5)\) in the Duhamel formulation, we have

\[
v_N(t) = \partial_t \mathcal{D}(t)v_0 + \mathcal{D}(t)(v_0 + v_1)
\]

\[
+ \int_0^t \mathcal{D}(t - t')\pi_N((V * (\pi_N v_N)^2 + 2(\pi_N v_N)f + f^2 - \sigma_N))(\pi_N v_N + f))(t')dt'
\]

\[
- \int_0^t \mathcal{D}(t - t')(M_\gamma((\pi_N v_N)^2 + 2(\pi_N v_N)f + f^2 - \sigma_N)(\pi_N v_N + f))(t')dt'
\]

\[
= : \Phi_N(v_N)(t),
\]

\[
\text{where} \quad \Phi_N(v_N)(t) = \int_0^t \mathcal{D}(t - t')(M_\gamma((\pi_N v_N)^2 + 2(\pi_N v_N)f + f^2 - \sigma_N)(\pi_N v_N + f))(t')dt',
\]

\[
\text{for some} \quad R, K > 0.
\]
where $D(t)$ is as in (2.8). Let $0 < \tau \leq 1$. Then, from (2.8), (8.7), and Sobolev’s inequality, with (2.2) and $\gamma \geq 2$, we have
\[
\|\Phi_N(v_N)\|_{X^1(\tau)} \lesssim \|(v_0, v_1)\|_{H^1} + T\|V \ast ((\pi_N v_N)^2 + 2(\pi_N v_N)f + f^2 - \sigma_N)\|_{L^p_t L^q_x} + \|f\|_{L^p_t L^q_x} \lesssim R + T\|v_N\|_{L^p_x H^{\frac{\gamma - 1}{2}}_x} + \|f\|_{L^p_x H^{\frac{\gamma - 1}{2}}_x} + \sigma_N \gamma^{-1} \|v_N\|_{L^p_x H^{\frac{\gamma}{2}}_x} + \|f\|_{L^p_x L^q_x} \lesssim R + K,
\]
where the last step holds by choosing $\tau = \tau(R, K, N) > 0$ sufficiently small. A difference estimate also follows in a similar manner since $\gamma \geq 2$. Hence, we conclude that $\Phi_N$ is a contraction on the ball $B_{C_0}(R + K) \subset X^1(\tau)$ for some $C_0 > 0$. At this point, the uniqueness holds only in the ball $B_{C_0}(R + K)$ but by a standard continuity argument, we can extend the uniqueness to hold in the entire $X^1(\tau)$. We omit details.  

\[ \square \]

**Remark 9.2.** From the proof, we see that $\tau = \tau(R, K, N) \sim (R + K + N)^{-\theta}$ for some $\theta > 0$.

Before proceeding further, let us introduce some notations. Given the cylindrical Wiener process $W$ in (2.10), by possibly enlarging the probability space $\Omega_2$, there exists a family of translations $\tau_0 : \Omega_2 \to \Omega_2$ such that
\[
W(t, \tau_0(\omega_2)) = W(t + t_0, \omega_2) - W(t_0, \omega_2)
\]
for $t, t_0 \geq 0$ and $\omega_2 \in \Omega_2$. Denote by $\Phi^N(t)$ the stochastic flow map to the truncated equation (2.3) given in Lemma 9.1 (which is not necessarily global at this point). Namely,
\[
\hat{u}_N(t) = \Phi^N(t)(\hat{u}_0, \omega_2)
\]
is the solution to (2.3) with $\hat{u}_N|_{t=0} = \hat{u}_0$ and Law($\hat{u}_0$) = $\hat{\rho}_N$. We now extend $\Phi^N(t)$ as
\[
\Phi^N(t)(\hat{u}_0, \omega_2) = (\Phi^N(t)(\hat{u}_0, \omega_2), \tau(t_2)) \quad \text{for some } t_2 \geq 0.
\]
Note that by the uniqueness of the solution to (2.3), we have
\[
\Phi^N(t_1 + t_2)(\hat{u}_0, \omega_2) = \Phi^N(t_2)(\Phi^N(t_1)(\hat{u}_0, \omega_2), \tau_1(\omega_2)) = \Phi^N(t_2)\Phi^N(t_1)(\hat{u}_0, \omega_2) \quad \text{for } t_1, t_2 \geq 0.
\]
for $t_1, t_2 \geq 0$ as long as the flow is well defined.

Next, by exploiting invariance of the truncated Gibbs measure $\hat{\rho}_N$, we construct global-in-time solutions to (2.3) almost surely with respect to the truncated Gibbs measure $\hat{\rho}_N$ in (9.1).

**Lemma 9.3.** Let $N \in \mathbb{N}$. Then, the truncated focusing Hartree SdNLW (2.3) is almost surely globally well-posed with respect to the random initial data distributed by the truncated Gibbs measure $\hat{\rho}_N$ in (9.1). Furthermore, $\hat{\rho}_N$ is invariant under the resulting dynamics.

**Proof.** We first discuss the (formal) invariance of the truncated Gibbs measure $\hat{\rho}_N$ under the truncated dynamics (2.3). Given $N \in \mathbb{N}$, let $\pi_N = \text{Id} - \pi_N$. We define the marginal probability measures $\hat{\mu}_N$ and $\hat{\mu}_N^\perp$ on $\pi_N H^{\frac{\gamma}{2} - \epsilon}(\mathbb{T}^3)$ and $\pi_N^\perp H^{\frac{\gamma}{2} - \epsilon}(\mathbb{T}^3)$, respectively, as the induced probability measures under the following maps:
\[
\omega_1 \in \Omega_1 \mapsto (\pi_N u_{\omega_1}, \pi_N v_{\omega_1})
\]
for $\tilde{\mu}_N$ and
\[ \omega_1 \in \Omega_1 \mapsto (\pi_N^1 u^{\omega_1}, \pi_N^1 v^{\omega_1}) \]
for $\tilde{\mu}_N^1$, where $u^{\omega_1}$ and $v^{\omega_1}$ are as in (1.20) with $\omega$ replaced by $\omega_1$ in view of the decomposition (9.2). Then, we have
\[ \tilde{\mu} = \tilde{\mu}_N \otimes \tilde{\mu}_N^1. \quad (9.8) \]
From (9.1) with (1.18), (1.47), and (9.8), we then have
\[ \tilde{\nu}_N = \tilde{\nu}_N^1 \otimes \tilde{\nu}_N^2, \quad (9.9) \]
where $\tilde{\nu}_N$ is given by
\[ d\tilde{\nu}_N = \tilde{Z}_N^{-1} e^{R_N(u)} d\tilde{\mu}_N \]
with the density $R_N$ as in (1.46).

By writing the decomposition (9.3) as
\[ u_N = \Psi(\tilde{u}_0) + v_N = (\Psi_N(\tilde{u}_0) + v_N) + \Psi_N^1(\tilde{u}_0), \]
where $\Psi_N^1(\tilde{u}_0) = \pi_N^1 \Psi(\tilde{u}_0)$, we see that the high frequency part $\pi_N^1 u_N = \pi_N^1 \Psi(\tilde{u}_0)$ satisfies the following linear dynamics:
\[ \partial_t^2 \Psi_N^1(\tilde{u}_0) + \partial_t \Psi_N^1(\tilde{u}_0) + (1 - \Delta) \Psi_N^1(\tilde{u}_0) = \sqrt{2} \pi_N^1 x. \quad (9.10) \]
It is easy to check that the Gaussian measure $\tilde{\mu}_N^1$ is invariant under the dynamics of (9.10), say, by studying (9.10) for each frequency $|n| > N$ on the Fourier side.

The low frequency part $\pi_N u_N$ satisfies
\[ \partial_t^2 \pi_N u_N + \partial_t \pi_N u_N + (1 - \Delta) \pi_N u_N - \pi_N N(\pi_N u_N) = \sqrt{2} \pi_N x, \quad (9.11) \]
where
\[ N(\pi_N u_N) = (V* (\pi_N u_N)^2 : ) \pi_N u_N - M \gamma (\pi_N u_N)^2 : u_N. \]
By writing (9.11) in the Ito formulation with $(u_N^1, u_N^2) = (\pi_N u_N, \partial_t \pi_N u_N)$, it is easy to see that the generator $\mathcal{L}_N^2$ for (9.11) can be written as $\mathcal{L}_N^2 = \mathcal{L}_N^1 + \mathcal{L}_N^2$, where $\mathcal{L}_N^1$ denotes the generator for the undamped NLW with the truncated nonlinearity:
\[ d\left( \begin{array}{c} u_N^1 \\ u_N^2 \\ \end{array} \right) + \left\{ \begin{array}{cc} 0 & -1 \\ 1 - \Delta & 0 \\ \end{array} \right\} \left( \begin{array}{c} u_N^1 \\ u_N^2 \\ \end{array} \right) + \left( -\pi_N N(\pi_N u_N) \right) dt = 0 \quad (9.12) \]
and $\mathcal{L}_N^2$ denotes the generator for the Ornstein-Uhlenbeck process (for the second component $u_N^2$):
\[ d\left( \begin{array}{c} u_N^1 \\ u_N^2 \\ \end{array} \right) = \left( \begin{array}{c} 0 \\ -u_N^2 dt + \sqrt{2} \pi_N dW \end{array} \right). \quad (9.13) \]

By recalling that the Ornstein-Uhlenbeck process preserves the standard Gaussian measure, we conclude that $\tilde{\nu}_N$ is invariant under the linear dynamics (9.13) since the measure $\tilde{\nu}_N$ is nothing but the white noise measure (projected onto the low frequencies $\{|n| \leq N\}$) on the second component $u_N^2$. As for (9.12), we note that it is a Hamiltonian equation with the Hamiltonian:
\[ \mathcal{E}_N^2(u_N^1, u_N^2) = \frac{1}{2} \int_{T^3} |(\nabla) u_N^1|^2 dx + \frac{1}{2} \int_{T^3} (u_N^2)^2 dx - R_N(u_N^1), \]
where $\mathcal{R}_N$ is as in (1.46) (with $\sigma = 1$). Then, from the conservation of the Hamiltonian $\mathcal{E}_N^0(u^1_N, u^2_N)$ and Liouville’s theorem (on a finite-dimensional phase space), we conclude that $\nu_N$ is invariant under the dynamics of (9.12). Therefore, we conclude that

$$(L^N)^*\nu_N = (L_1^N)^*\nu_N + (L_2^N)^*\nu_N = 0.$$ 

This shows invariance of $\nu_N$ under (9.11).

Therefore, from (9.9) and the invariance of $\hat{\mu}_N$ and $\nu_N$ under (9.10) and (9.11), respectively, we conclude that the truncated Gibbs measure $\hat{\rho}_N$ in (9.1) is formally invariant under the dynamics of the truncated focusing Hartree SdNLW (2.3). Here, by the formal invariance, we mean that the $\hat{\rho}_N$-measure of a measurable set is preserved under the truncated dynamics (2.3) as long as the flow is well defined. In view of the translation invariance of the law of the Brownian motions $\{B_n\}_{n \in \mathbb{Z}^3}$ in (2.10), we also conclude formal invariance of $\hat{\rho}_N \otimes \mathbb{P}_2$ under the extended stochastic flow map $\hat{\Phi}^N(t)$ defined in (9.6).

Next, by exploiting this formal invariance of $\rho_N \otimes \mathbb{P}_2$, we establish almost sure global well-posedness of (2.3). By arguing as in [10, 22, 66], it suffices to show “almost” almost sure global existence. Namely, we prove that, given any $T \geq 1$ and $\kappa > 0$, there exists $\Sigma_{T, \kappa} \subset H^{-\frac{1}{2} - \varepsilon}(\mathbb{T}^3) \times \Omega_2$ such that $\rho_N \otimes \mathbb{P}_2((\Sigma_{T, \kappa}) \subset < \kappa$ and for any $(\bar{u}_0, \omega_2) \in \Sigma_{T, \kappa}$, there exists a solution $u_N$ to (2.3) on the time interval $[0, T]$.

We follow the ideas from [10, 66]. Given $T \geq 1$ and $\kappa > 0$, let

$$K \sim c_N \left( \log \frac{T}{\kappa} + \log C_N \right)^\frac{1}{2} \quad (9.14)$$

for some suitable $c_N, C_N > 0$ Then, with $\tau = \tau(0, K, N) > 0$ as in Lemma 9.1, we set

$$\Sigma_{T, \kappa} = \bigcap_{j=0}^{[T/\tau]} \left\{ (\bar{u}_0, \omega_2) \in H^{-\frac{1}{2} - \varepsilon}(\mathbb{T}^3) \times \Omega_2 : \|\Psi_N(\hat{\Phi}_N^j(\bar{u}_0, \omega_2))\|_{L^\infty_{\tau,x}} \leq K \right\}.$$ 

By the definition of $\Sigma_{T, \kappa}$ and the local well-posedness argument (Lemma 9.1), we see that, given any $(\bar{u}_0, \omega_2) \in \Sigma_{T, \kappa}$, the corresponding solution $u_N$ to (2.3) exists on $[0, T]$.

By Bernstein’s inequality, we have

$$\|\Psi_N(\bar{u}_0, \omega_2)\|_{L^\infty_{\tau,x}} \lesssim N^{\frac{1}{2} + \varepsilon} \|\Psi_N(\bar{u}_0, \omega_2)\|_{L^\infty_{\tau,x} \cdot W^{-\frac{1}{2} - \varepsilon, \infty}}.$$ 

Then, from the (formal) invariance of $\hat{\rho}_N \otimes \mathbb{P}_2$ under the extended stochastic flow map $\hat{\Phi}^N(t)$ in (9.6), Remark 9.2, Cauchy-Schwarz inequality with Theorem 1.14 (in particular, the bound (4.18), Lemma 4.4, and (9.14), we have

$$\rho_N \otimes \mathbb{P}_2((\Sigma_{T, \kappa}) \lesssim \frac{T}{\tau} \rho_N \otimes \mathbb{P}_2((u_0, \omega_2) : \|\Psi_N(\bar{u}_0, \omega_2)\|_{L^\infty_{\tau,x}} > K) \lesssim C_N T \rho_N \otimes \mathbb{P}_2((u_0, \omega_2) : \|\Psi_N(\bar{u}_0, \omega_2)\|_{L^\infty_{\tau,x}} > K) \lesssim C_N T \cdot C e^{-c_N K^2} \ll \kappa.$$ 

This proves the desired “almost” almost sure global existence, and thus almost sure global well-posedness of the truncated focusing Hartree SdNLW (2.3). Since the dynamics is now globally well defined almost surely with respect to $\hat{\rho}_N$, we conclude invariance of the truncated Gibbs measure $\hat{\rho}_N$ from the formal invariance of $\hat{\rho}_N$ discussed above.

We now establish a long time a priori bound on the solutions to the truncated equation (2.3),
Proposition 9.4. Let \( i \in \mathbb{N} \) and \( N \in \mathbb{N} \). Then, there exists a \( \tilde{\rho}_N \otimes \mathbb{P}_2 \)-measurable set \( \Sigma_N^i \subset \mathcal{H}^{-\frac{1}{2} - \varepsilon}(\mathbb{T}^3) \times \Omega_2 \) such that

\[
\tilde{\rho}_N \otimes \mathbb{P}_2((\mathcal{H}^{-\frac{1}{2} - \varepsilon}(\mathbb{T}^3) \times \Omega_2) \setminus \Sigma_N^i) \leq 2^{-i}.
\]  
(9.15)

Moreover, there exists \( C > 0 \) such that for any \( (\tilde{u}_0, \omega_2) \in \Sigma_N^i \) and \( t \geq 0 \), we have

\[
\| \Phi^N(t)(\tilde{u}_0, \omega_2) \|_{\mathcal{H}^{-\frac{1}{2} - \varepsilon}} \leq C(i + \log(1 + t)).
\]  
(9.16)

**Proof.** We follow the argument in [66]. Given \( (\tilde{u}_0, \omega_2) \in \mathcal{H}^{-\frac{1}{2} - \varepsilon}(\mathbb{T}^3) \times \Omega_2 \), we set

\[
\Psi_N = \Psi_N(\tilde{u}_0, \omega_2)
\]  
(9.17)

and define the enhanced data set \( \Xi(\Psi_N(\tilde{u}_0, \omega_2)) \) by

\[
\Xi(\Psi_N(\tilde{u}_0, \omega_2)) = (\Psi_N, :\Psi_2^N ::, \mathfrak{A}_N, \mathfrak{G}_N^T),
\]  
(9.18)

where \( :\Psi_2^N ::, \mathfrak{A}_N, \mathfrak{G}_N^T \) are defined in \([2.13], (7.25)\), and Proposition 2.5 respectively, with the substitution (9.17).

Given \( i, j, N \in \mathbb{N} \) and \( D \gg 1 \), define a set \( B_{ij}^N(D) \) by

\[
B_{ij}^N(D) = \left\{ (\tilde{u}_0, \omega_2) \in \mathcal{H}^{-\frac{1}{2} - \varepsilon}(\mathbb{T}^3) \times \Omega_2 : \right. \\
\left. \| \Xi(\tilde{u}_0, \omega_2) \|_C([0,1]; \mathcal{H}^{-\frac{1}{2} - \varepsilon}) \leq D(i + j), \right. \\
\left. \| \Xi(\Psi_N(\tilde{u}_0, \omega_2)) \|_Y \leq D(i + j), \right. \\
\left. \| \Xi(\Psi_M(\tilde{u}_0, \omega_2)) - \Xi(\Psi_N(\tilde{u}_0, \omega_2)) \|_Y \leq M^{-\varepsilon}D(i + j) \text{ for any } M \leq N \right\},
\]  
(9.19)

where \( \| \Xi(\Psi) \|_Y \) is as in \([8.13]\). Then, by Theorem 1.14, Cauchy-Schwarz inequality, Lemma 4.1, and Proposition 2.5, we have

\[
\tilde{\rho}_N \otimes \mathbb{P}_2((\mathcal{H}^{-\frac{1}{2} - \varepsilon}(\mathbb{T}^3) \times \Omega_2) \setminus B_{ij}^N(D)) \\
\leq C \left\| e^{R_N(u)} \right\|_{L^2(\mu)}(\tilde{\mu} \otimes \mathbb{P}_2((\mathcal{H}^{-\frac{1}{2} - \varepsilon}(\mathbb{T}^3) \times \Omega_2) \setminus B_{ij}^N(D)))^{\frac{1}{2}}
\]  
(9.20)

\[
\leq C \exp(-cD(i + j)).
\]

It follows from a slight modification of (the proof of) Theorem 2.8 that

\[
\Phi^N(t)(B_{ij}^N(D)) \subset \left\{ \tilde{u} \in \mathcal{H}^{-\frac{1}{2} - \varepsilon}(\mathbb{T}^3) : \| \tilde{u} \|_{\mathcal{H}^{-\frac{1}{2} - \varepsilon}} \leq D(i + j + 1) \right\}
\]  
(9.21)

for any \( 0 \leq t \leq \tau \), where \( \tau \) is given by

\[
\tau = (D(i + j))^{-\theta}
\]  
(9.22)

for some \( \theta > 0 \). Indeed, by decomposing the first component \( \Phi_1^N(t)(\tilde{u}_0, \omega_2) \) of \( \Phi^N(t)(\tilde{u}_0, \omega_2) \) as in \([2.14], (2.17)\):

\[
\Phi_1^N(t)(\tilde{u}_0, \omega_2) = \Psi(t; \tilde{u}_0, \omega_2) + X_N(t) + Y_N(t),
\]  
(9.23)

\footnote{The third condition in (9.19) is used in the proof of Proposition 9.6 below.}
we see that $X_N$, $Y_N$, and $\mathcal{R}_N := X_N \otimes \Psi_N(\tilde{u}_0, \omega_2)$ satisfy the following system:

$$(\partial_t^2 + \partial_t + 1 - \Delta)X_N = \pi_N\left((V \ast (Q_{X_N,Y_N} + 2\mathcal{R}_N + :\Psi_N^2:) \otimes \Psi_N\right)$$

$$(\partial_t^2 + \partial_t + 1 - \Delta)Y_N = \pi_N\left((V \ast (Q_{X_N,Y_N} + 2\mathcal{R}_N + :\Psi_N^2:) (X_N + Y_N)\right)$$

$$+ \pi_N\left((V \ast (Q_{X_N,Y_N} + 2\mathcal{R}_N + :\Psi_N^2:) \otimes \Psi_N\right)$$

$$- M_N(Q_{X_N,Y_N} + 2\mathcal{R}_N + :\Psi_N^2:) (X_N + Y_N),$$

$\mathcal{R}_N = \mathcal{G}^{(1),N}_0 (V \ast (Q_{X_N,Y_N} + 2\mathcal{R}_N + :\Psi_N^2:) \otimes \Psi_N + \mathcal{G}^{(1),N}_0 (V \ast (Q_{X_N,Y_N} + 2\mathcal{R}_N + :\Psi_N^2:) \right)$$

$$- \mathcal{I}(M_N(Q_{X_N,Y_N} + 2\mathcal{R}_N + :\Psi_N^2:) \otimes \Psi_N,$$

$$\quad (X_N, \partial_t X_N, Y_N, \partial_t Y_N; \mathcal{R}_N)|_{t=0} = (0, 0, 0, 0),$$

where $M_N$ is as in (2.2), $Q_{X_N,Y_N}$ is as in (2.23) with $\Psi$ replaced by $\Psi_N = \Psi_N(\tilde{u}_0, \omega_2)$, and $\mathcal{G}^{(1),N}_0$ is as in Lemma 7.1 with the substitution (9.17). Then, by repeating the proof of Theorem 2.8 (see (8.8) - (8.10) and (8.15) - (8.17) with the uniform boundedness of $\pi_N$, $(\tilde{u}_0, \omega_2) \in B_{N}^{ij}(D)$ (see (9.19), (9.26), we have

$$\| (X_N, Y_N, \mathcal{R}_N) \|_{Z^{1+\varepsilon_3}(\tau)} \leq \tau^{\frac{2}{3}} \left( \| (X_N, Y_N, \mathcal{R}_N) \|_{Z^{1+\varepsilon_3}(\tau)} + K^3 \right)$$

$$+ \tau^{\frac{4}{3}} \left( \| (X_N, Y_N, \mathcal{R}_N) \|_{Z^{1+\varepsilon_3}(\tau)} + K \right)^{2\gamma - 1}$$

$$\lesssim (D(i + j))^{1-\gamma} \left( \| (X_N, Y_N, \mathcal{R}_N) \|_{Z^{1+\varepsilon_3}(\tau)} + (D(i + j))^{2} \right)$$

$$+ (D(i + j))^{-\frac{4}{3} + \gamma} \left( \| (X_N, Y_N, \mathcal{R}_N) \|_{Z^{1+\varepsilon_3}(\tau)} + (D(i + j)) \right)^{2\gamma - 1},$$

where $K = \| (\Xi(\Psi_N(\tilde{u}_0, \omega_2)) \|_{L^\infty} + 1$. Then, by taking sufficiently large $\theta \gg 1$ and $D \gg 1$ (independent of $i, j, N \in \mathbb{N}$), a standard continuity argument with (9.25) yields

$$\| (X_N, Y_N, \mathcal{R}_N) \|_{Z^{1+\varepsilon_3}(\tau)} \leq 1.$$
uniformly in $i,j,N \in \mathbb{N}$, provided that $D \gg 1$. Moreover, from (9.27) and (9.21) with the flow property (9.7), we have
\[
\|\Phi^N(t)(\tilde{u}_0, \omega_2)\|_{H^{-\frac{1}{2}-\epsilon}} \leq D(i + j + 1)
\] (9.29)
for $(\tilde{u}_0, \omega_2) \in \Sigma_N^{i,j}$ and $0 \leq t \leq 2^j$.

Finally, we set
\[
\Sigma_N^i = \bigcap_{j=1}^{\infty} \Sigma_N^{i,j}.
\] (9.30)

Then, (9.15) and follow from (9.28). The growth bound (9.16) follows from (9.29). □

**Remark 9.5.**

(i) In the proof of Proposition 9.4, we used two different decompositions (9.3) and (9.23) for the solution $u_N$ to the truncated equation (2.3). The former was used to obtain (9.28), while the latter was used to obtain (9.29). The unconditional uniqueness statement for $v_N$ in Lemma 9.1 was essential to conclude that these solutions given by the two different decompositions coincide.

(ii) Note that the power in the growth bound (9.16) comes from the fact that the enhanced data set $\Xi(\Psi_N(\tilde{u}_0, \omega_2))$ in (9.18) belongs to $H_{\leq 2}$ in the focusing case. In the defocusing case, the associated enhanced data set belongs to $H_{\leq 3}$ and thus we need to replace the right-hand side of (9.16) by $C(i + \log(1 + t))^{\frac{3}{2}}$.

9.2. **Proof of Theorem 2.1.** In this subsection, by an approximation argument, we first prove almost sure global well-posedness of the focusing Hartree SdNLW (2.1). Given $i \in \mathbb{N}$, define a set $\Sigma^i$ by
\[
\Sigma^i = \limsup_{N \to \infty} \bigcup_{M=1}^{\infty} \bigcap_{N=M}^{\infty} \Sigma_N^i.
\] (9.31)

Then, from (9.31), Theorem 1.14 and (9.15), we have
\[
\tilde{\rho} \otimes \mathbb{P}_2(\Sigma^i) = \lim_{N \to \infty} \tilde{\rho} \otimes \mathbb{P}_2\left( \bigcup_{M=1}^{\infty} \Sigma_M^i \right)
\geq \limsup_{N \to \infty} \tilde{\rho} \otimes \mathbb{P}_2(\Sigma_N^i) = \lim_{N \to \infty} \tilde{\rho}_N \otimes \mathbb{P}_2(\Sigma_N^i)
\geq 1 - 2^{-i}.
\]

Hence, by setting
\[
\Sigma = \bigcup_{i=1}^{\infty} \Sigma^i,
\] (9.32)
we obtain
\[
\tilde{\rho} \otimes \mathbb{P}_2(\Sigma) = 1.
\]

Fix $(\tilde{u}_0, \omega_2) \in \Sigma$. Then, it follows from (9.32), (9.31), (9.30), and (9.27) that there exist $i \in \mathbb{N}$ and an increasing sequence $\{N_k\}_{k \in \mathbb{N}}$ such that
\[
(\tilde{u}_0, \omega_2) \in \Sigma_N^i_k = \bigcap_{j=1}^{\infty} \bigcap_{t=0}^{[2^j/\tau]} (\Phi_N^k(\ell \tau))^{-1}(B_{N_k}^{i,j}(D))
\] (9.33)
for any $k \in \mathbb{N}$, where $\tau = \tau(i,j,D) > 0$ is as in (9.22).
In the next proposition, we prove convergence of the solutions \( \{ \Phi_{N_k}(\bar{u}_0, \omega_2) \}_{k \in \mathbb{N}} \) along this particular subsequence \( N_k = N_k(\bar{u}_0, \omega_2) \). In Corollary 9.9, we establish convergence of the entire sequence \( \{ \Phi_{N}(\bar{u}_0, \omega_2) \}_{N \in \mathbb{N}} \). See also Remark 9.8.

**Proposition 9.6.** Let \( (\bar{u}_0, \omega_2) \in \Sigma, i \in \mathbb{N}, \) and \( \{N_k\}_{k \in \mathbb{N}} \) be as above. Then, \( \{ \Phi_{N_k}(\bar{u}_0, \omega_2) \}_{k \in \mathbb{N}} \) is a Cauchy sequence in \( C(\mathbb{R}_+; \mathcal{H}^{1+\epsilon}(\mathbb{T}^3)) \) endowed with the compact-open topology (in time).

Before proceeding to the proof of Proposition 9.6, we first show the following stability result. See [12, p.442].

**Lemma 9.7.** Fix \( i, j, N \in \mathbb{N} \) and \( (\bar{u}_0, \omega_2) \in B^i,j_N(D) \). Suppose that \( \bar{v}_0 = (v_0, v_1) \in \mathcal{H}^{1+\epsilon}(\mathbb{T}^3) \) satisfies

\[
\|\bar{u}_0 - \bar{v}_0\|_{\mathcal{H}^{1+\epsilon}} < \frac{1}{10}. \tag{9.34}
\]

Then, we have

\[
\|\Phi_N(\cdot)(\bar{u}_0, \omega_2) - \Phi_N(\cdot)(\bar{v}_0, \omega_2)\|_{C(\mathbb{R}_+; \mathcal{H}^{1+\epsilon})} \lesssim \|\bar{u}_0 - \bar{v}_0\|_{\mathcal{H}^{1+\epsilon}}, \tag{9.35}
\]

where \( \tau = \tau(i, j, D) > 0 \) is as in (9.22).

**Proof.** Let \( (\bar{u}_0, \omega_2) \in B^i,j_N(D) \). By writing (9.24) in the Duhamel formulation, we have

\[
X_N = \Gamma_1^N(X_N, Y_N, \mathfrak{R}_N) := I\left(\pi_N\left( (V(\mathcal{Q}_{X_N} + 2\mathfrak{R}_N + \Psi^2_N) \otimes \Psi_N ) \right) \right)
- I\left(M_q(Q_{X_N}, Y_N + 2\mathfrak{R}_N + \Psi^2_N) \otimes \Psi_N \right),
\]

\[
Y_N = \Gamma_2^N(X_N, Y_N, \mathfrak{R}_N) := I\left(\pi_N\left( (V(\mathcal{Q}_{X_N} + 2\mathfrak{R}_N + \Psi^2_N) \otimes \Psi_N ) \right) \right)
+ I\left(M_q(Q_{X_N}, Y_N + 2\mathfrak{R}_N + \Psi^2_N) \otimes \Psi_N \right),
\]

\[
\mathfrak{R}_N = \Gamma_3^N(X_N, Y_N, \mathfrak{R}_N) := \mathcal{J}_{(1)\otimes N}^N\left( (V(\mathcal{Q}_{X_N} + 2\mathfrak{R}_N + \Psi^2_N) \otimes \Psi_N ) \right)
+ \mathcal{J}_{(2)\otimes N}^N\left( (V(\mathcal{Q}_{X_N} + 2\mathfrak{R}_N + \Psi^2_N) \otimes \Psi_N ) \right)
- I\left(M_q(Q_{X_N}, Y_N + 2\mathfrak{R}_N + \Psi^2_N) \otimes \Psi_N \right),
\]

where \( \Psi_N = \Psi_N(\bar{u}_0, \omega_2) \) and the enhanced data set \( \Xi(\Psi_N(\bar{u}_0, \omega_2)) \) in (9.18) is constructed as in the proof of Proposition 9.4. Proceeding as in Section 3 (see also (9.25)), we see that \( \bar{\Gamma}_N = (\Gamma_1^N, \Gamma_2^N, \Gamma_3^N) \) is a contraction on the ball \( B_1 \subset Z^{a_1,a_2,a_3}(\tau) \), where \( \tau = \tau(i, j, D) \) is as in (9.22). Thus, we have

\[
\bar{\Gamma}_N(X_N, Y_N, \mathfrak{R}_N) = (X_N, Y_N, \mathfrak{R}_N). \tag{9.36}
\]

Then, by (9.36), we have

\[
\Phi_1^N(t)(\bar{u}_0, \omega_2) = \Psi(t; \bar{u}_0, \omega_2) + X_N(t) + Y_N(t)
= \Psi(t; \bar{u}_0, \omega_2) + \Gamma_1^N(X_N, Y_N, \mathfrak{R}_N)(t) + \Gamma_2^N(X_N, Y_N, \mathfrak{R}_N)(t). \tag{9.37}
\]

Now, let us now study the truncated equation (2.3) with the initial data \( \bar{v}_0 \) (for fixed \( \omega_2 \in \Omega_2 \)). One way is to use the decomposition (9.23) with \( \bar{u}_0 \) replaced by \( \bar{v}_0 \) and study the resulting system by introducing a new enhanced data set \( \Xi(\Psi_N(\bar{v}_0, \omega_2)) \). This is how the argument in [66] proceeds in the two-dimensional setting. In the current three-dimensional setting, however, we can not
obtain a difference estimate on the two enhanced data set $\Xi(\Psi_N(\vec{u}_0, \omega_2))$ and $\Xi(\Psi_N(\vec{v}_0, \omega_2))$ to conclude (9.35) due to the low regularity of the noise.

In the following, by making use of the assumption (9.34), we study the truncated equation (2.3) with the initial data $\vec{v}_0$ without introducing a new enhanced data set. Namely, we decompose the first component $\Phi^N(t)(\vec{v}_0, \omega_2)$ of $\Phi^N(t)(\vec{v}_0, \omega_2)$ as

$$
\Phi^N(t)(\vec{v}_0, \omega_2) = \Psi(t; \vec{u}_0, \omega_2) + \tilde{X}_N(t) + \tilde{Y}_N(t). 
$$

(9.38)

Note that the initial data of the stochastic convolution on the right-hand side of (9.38) is $\vec{u}_0$, not $\vec{v}_0$. By writing $\vec{v}_0 = \vec{u}_0 + (\vec{v}_0 - \vec{u}_0)$, we have

$$
\Psi(t; \vec{v}_0, \omega_2) = \Psi(t; \vec{u}_0, \omega_2) + \partial_t \mathcal{D}(t)(v_0 - u_0) + \mathcal{D}(t)(v_0 - u_0 + v_1 - u_1). 
$$

(9.39)

In the following, we set up a fixed point problem by including the last two terms on the right-hand side of (9.39) as the linear part of $\tilde{X}_N$.

Define $\Gamma^N_1$ by

$$
\Gamma^N_1(X_N, Y_N, \mathcal{R}_N) := \partial_t \mathcal{D}(t)(v_0 - u_0) + \mathcal{D}(t)(v_0 - u_0 + v_1 - u_1)
+ \Gamma^N_1(X_N, Y_N, \mathcal{R}_N),
$$

(9.40)

where $\mathcal{D}(t)$ is as in (2.6). Then, the decomposition (9.38) leads to the following fixed point problem:

$$(\tilde{X}_N, \tilde{Y}_N, \tilde{\mathcal{R}}_N) = \tilde{\Gamma}_N(\tilde{X}_N, \tilde{Y}_N, \tilde{\mathcal{R}}_N),$$

(9.41)

where $\tilde{\Gamma}_N = (\tilde{\Gamma}_1^N, \tilde{\Gamma}_2^N, \tilde{\Gamma}_3^N)$. We point out that the enhanced data set appearing in (9.41) is $\Xi(\Psi_N(\vec{u}_0, \omega_2))$, coming from $\vec{u}_0$. From (9.40), we have

$$
\tilde{\Gamma}_N^N(\tilde{X}_N, \tilde{Y}_N, \tilde{\mathcal{R}}_N) - \tilde{\Gamma}_1^N(\tilde{X}_N, \tilde{Y}_N, \tilde{\mathcal{R}}_N) = \Gamma^N_1(\tilde{X}_N, \tilde{Y}_N, \tilde{\mathcal{R}}_N) - \Gamma^N_1(\tilde{X}_N, \tilde{Y}_N, \tilde{\mathcal{R}}_N).
$$

Then, in view of (9.34), we see that $\tilde{\Gamma}_N = (\tilde{\Gamma}_1^N, \tilde{\Gamma}_2^N, \tilde{\Gamma}_3^N)$ is also a contraction on the ball $B_1 \subset Z^{1.2.3}(\tau)$ (by possibly making $\tau > 0$ slightly smaller).

From (9.36), (9.41), (9.40), and the difference estimate for $\tilde{\Gamma}_N$ (see (8.11) in the defocusing case with $N = \infty$), we have

$$
\| (X_N, Y_N, \mathcal{R}_N) - (\tilde{X}_N, \tilde{Y}_N, \tilde{\mathcal{R}}_N) \|_{Z^{1.2.3}(\tau)} 
\leq C \| \vec{u}_0 - \vec{v}_0 \|_{H^1} + \| \tilde{\Gamma}_N(X_N, Y_N, \mathcal{R}_N) - \tilde{\Gamma}_N(\tilde{X}_N, \tilde{Y}_N, \tilde{\mathcal{R}}_N) \|_{Z^{1.2.3}(\tau)} 
\leq C \| \vec{u}_0 - \vec{v}_0 \|_{H^1} + \frac{1}{2} \| (X_N, Y_N, \mathcal{R}_N) - (\tilde{X}_N, \tilde{Y}_N, \tilde{\mathcal{R}}_N) \|_{Z^{1.2.3}(\tau)},
$$

which implies that

$$
\| (X_N, Y_N, \mathcal{R}_N) - (\tilde{X}_N, \tilde{Y}_N, \tilde{\mathcal{R}}_N) \|_{Z^{1.2.3}(\tau)} \lesssim \| \vec{u}_0 - \vec{v}_0 \|_{H^1}. 
$$

(9.42)

Finally, from (9.37), (9.38), and (9.42), we conclude that

$$
\| \Phi^N(t)(\vec{u}_0, \omega_2) - \Phi^N(t)(\vec{v}_0, \omega_2) \|_{C, H^1} 
\leq \| X_N - \tilde{X}_N \|_{C, H^1} + \| Y_N - \tilde{Y}_N \|_{C, H^1} 
\lesssim \| \vec{u}_0 - \vec{v}_0 \|_{H^1}.
$$

This proves (9.35). \hfill \Box

We are now ready to prove Proposition 9.6.
Proof of Proposition 9.6: Fix $T > 0$. We prove that there exists small $\delta > 0$ such that
\[
\|\Phi_{N_k}(\cdot)(\tilde{u}_0, \omega_2) - \Phi_{N_k'}(\cdot)(\tilde{u}_0, \omega_2)\|_{C_T H^s_z} \lesssim N_k^{-\delta}
\] (9.43)
for any $k' \geq k \geq 1$.

Let $j \in \mathbb{N}$ be such that $2^{j-1} \leq T < 2^j$ and $\tau = \tau(i, j, D) > 0$ be as in (9.22). First, we estimate the difference on the time interval $[0, \tau]$. We decompose $\Phi_{N_k}(t)(\tilde{u}_0, \omega_2)$ as in (9.23) with $N$ replaced by $N_k$. Proceeding as in (9.25), we have
\[
\max \left( \| (X_{N_k}, Y_{N_k}, \mathfrak{R}_{N_k}) \|_{Z^{s_1, s_2, s_3}(\tau)}, \| (X_{N_k'}, Y_{N_k'}, \mathfrak{R}_{N_k'}) \|_{Z^{s_1, s_2, s_3}(\tau)} \right) \leq 1
\] (9.44)
for the solutions $(X_{N_k}, Y_{N_k}, \mathfrak{R}_{N_k})$ and $(X_{N_k'}, Y_{N_k'}, \mathfrak{R}_{N_k'})$ to (9.24) with $N = N_k$ and $N = N_k'$, respectively. Then, proceeding as in (8.5) with (9.44), we have
\[
\| V * (Q X_{N_k}, Y_{N_k}, R_{N_k}) - Q X_{N_k'}, Y_{N_k'}) \|_{L^\infty_t H^s_z} \lesssim \| (X_{N_k} + Y_{N_k'})^2 - (X_{N_k'} + Y_{N_k'})^2 \|_{L^\infty_t H^s_z - \beta-s_1-s_2+\frac{1}{2}}
\] (9.45)
for any $k' \geq k \geq 1$. Hence, by repeating the calculations as in (8.8) and (8.15) with (9.45), (9.44), and the difference estimate assumption in (9.19), we have
\[
\| X_{N_k} - X_{N_k'} \|_{Z^{s_1}(\tau)} \lesssim \| \pi_{N_k} \left( (V * (Q X_{N_k}, Y_{N_k} + 2 R_{N_k} + : \Psi_{N_k}^2)) \Psi_{N_k} \right) \|_{L^1_t H^s_z}^{-1}
\] (9.46)

where $\pi_{N_k}$ denotes the projection onto the space $Z^{s_1, s_2, s_3}(\tau)$.
for any $k' \geq k \geq 1$. The difference estimates for $Y_{N_k} - Y_{N_{k'}}$ and $\mathfrak{R}_{N_k} - \mathfrak{R}_{N_{k'}}$ can be established in a similar manner. Hence, we obtain

$$
\| (X_{N_k}, Y_{N_k}, \mathfrak{R}_{N_k}) - (X_{N_{k'}}, Y_{N_{k'}}, \mathfrak{R}_{N_{k'}}) \|_{Z^{s_1, s_2, s_3}(\tau)} \lesssim N_k^{-\delta}
$$

(9.46)

for any $k' \geq k \geq 1$. From (9.23), we have

$$
\Phi^{N_k}(t) (\bar{u}_0, \omega_2) - \Phi^{N_{k'}}(t) (\bar{u}_0, \omega_2) = X_{N_k}(t) - X_{N_{k'}}(t) + Y_{N_k}(t) - Y_{N_{k'}}(t).
$$

(9.47)

Therefore, from (9.46) and (9.47), we obtain

$$
\| \Phi^{N_k}(\cdot) (\bar{u}_0, \omega_2) - \Phi^{N_{k'}}(\cdot) (\bar{u}_0, \omega_2) \|_{C_t, H^{s_1}} \lesssim N_k^{-\delta}
$$

(9.48)

for any $k' \geq k \geq 1$. This shows (9.43) on $[0, \tau]$.

Given $\tau \leq t \leq 2^j$, we can write it uniquely as $t = \ell \tau + t_1$ for some $\ell \in \mathbb{N}$ and $t_1 \in [0, \tau)$. With (9.7), we have

$$
\Phi^{N_k}(t)(\bar{u}_0, \omega_2) - \Phi^{N_{k'}}(t)(\bar{u}_0, \omega_2) = \Phi^{N_k}(t_1) \Phi^{N_k}(\ell \tau)(\bar{u}_0, \omega_2) - \Phi^{N_{k'}}(t_1) \Phi^{N_{k'}}(\ell \tau)(\bar{u}_0, \omega_2)
$$

(9.49)

$$
= \left( \Phi^{N_k}(t_1) \Phi^{N_k}(\ell \tau)(\bar{u}_0, \omega_2) - \Phi^{N_k}(t_1) \Phi^{N_{k'}}(\ell \tau)(\bar{u}_0, \omega_2) \right) + \left( \Phi^{N_k}(t_1) \Phi^{N_{k'}}(\ell \tau)(\bar{u}_0, \omega_2) - \Phi^{N_{k'}}(t_1) \Phi^{N_{k'}}(\ell \tau)(\bar{u}_0, \omega_2) \right)
$$

$$
=: I + II.
$$

Since $(\bar{u}_0, \omega_2) \in \Sigma_{N_{k'}}$, it follows from (9.33) that $\Phi^{N_{k'}}(\ell \tau)(\bar{u}_0, \omega_2) \in B_{N_{k'}}^{1, j}(D)$. Hence, by repeating the computation above, we have

$$
\| I \|_{C(I_\ell; H^{s_1})} \lesssim N_k^{-\delta}
$$

(9.50)

for any $k' \geq k \geq 1$, where $I_{\ell'} = [\ell \tau, (\ell + 1) \tau] \cap [0, T]$.

Next, we estimate $I$ in (9.49) and conclude (9.43) on $I_{\ell'}$ in an iterative manner. When $\ell = 1$, it follows from Lemma 9.7 and (9.48) that

$$
\| I \|_{C(I_1; H^{s_1})} \lesssim \| \Phi^{N_k}(\tau)(\bar{u}_0, \omega_2) - \Phi^{N_{k'}}(\tau)(\bar{u}_0, \omega_2) \|_{H^{s_1}}
$$

$$
\leq C_N N_k^{-\delta}
$$

(9.51)

for any $k' \geq k \geq 1$. From (9.49), (9.50), and (9.51), we obtain (9.43) on $[\tau, 2 \tau]$. By repeating this argument, we obtain

$$
\| I \|_{C(I_{\ell}; H^{s_1})} \lesssim \| \Phi^{N_k}(\ell \tau)(\bar{u}_0, \omega_2) - \Phi^{N_{k'}}(\ell \tau)(\bar{u}_0, \omega_2) \|_{H^{s_1}}
$$

$$
\leq C_{\ell} N_k^{-\delta}
$$

(9.52)

for any $k' \geq k \geq 1$. From (9.49), (9.50), and (9.52), we obtain (9.43) on the time interval $I_{\ell'}$ for $\ell = 1, \ldots, \left\lfloor \frac{2^j}{\tau} \right\rfloor$. This completes the proof of Proposition 9.6.

**Remark 9.8.** In Proposition 9.6, we proved that, given $(u_0, \omega_2) \in \Sigma$, a subsequence $\{\Phi^{N_k}(\bar{u}_0, \omega_2)\}_{k \in \mathbb{N}}$ converges to some limit in $C(\mathbb{R}_+; H^{-\frac{1}{2}, -\varepsilon}(T^3))$. In fact, a slight modification of the proof of Proposition 9.6 establishes the convergence of the solution $(X_{N_k}, Y_{N_k}, \mathfrak{R}_{N_k})$ to (9.24) with $N = N_k$, emanating from $(\bar{u}_0, \omega_2)$, in $Z^{s_1, s_2, s_3}(T)$ for any $T > 0$ to a limit $(X, Y, \mathfrak{R})$, satisfying the focusing Hartree SdNLW system (2.37) with the zero initial data and the enhanced data set $\Xi(\Psi)$ in (8.12) given as the limit of the enhanced data set $\Xi(\Psi_{N_k}(\bar{u}_0, \omega_2))$ in (9.18), which is guaranteed to exist thanks to (9.33) and the difference estimate assumption in (9.19).
This claim on $[0, \tau]$ can be easily seen from (9.46). Denote by $\tilde{X}_N(u_0, \omega_2)$ the solution $(X_N, Y_N, R_N)$ to (9.24), emanating from $(\tilde{u}_0, \omega_2)$. For $\tau \leq t \leq 2^{j}$, write $t = \ell \tau + t_1$ as before. Then, we can estimate the difference $\tilde{X}_{N_k}(u_0, \omega_2) - \tilde{X}_{N_{k'}}(u_0, \omega_2)$ by writing

$$\tilde{X}_{N_k}(t)(u_0, \omega_2) - \tilde{X}_{N_{k'}}(t)(u_0, \omega_2) = \left(\tilde{X}_{N_k}(t_1)(\tilde{\Phi}^{N_k}(\ell \tau)(u_0, \omega_2)) - \tilde{X}_{N_k}(t_1)(\tilde{\Phi}^{N_{k'}}(\ell \tau)(u_0, \omega_2))\right)$$
$$+ \left(\tilde{X}_{N_k}(t_1)(\tilde{\Phi}^{N_k}(\ell \tau)(u_0, \omega_2)) - \tilde{X}_{N_{k'}}(t_1)(\tilde{\Phi}^{N_{k'}}(\ell \tau)(u_0, \omega_2))\right)$$

$$=: III + IV.$$

Compare this with (9.49). As for IV, noting that both terms have the same initial data $\tilde{\Phi}^{N_{k'}}(\ell \tau)(u_0, \omega_2)$ at time $\ell \tau$, we can repeat the analysis leading to (9.46). As for III, we can apply the estimate (9.42) in the proof of Lemma 9.7 and then the conclusion of Proposition 9.6.

Proposition 9.6 shows that given any $(u_0, \omega_2) \in \Sigma$, there exists a subsequence $N_k = N_k(u_0, \omega_2) \in \mathbb{N}$ such that $\{\Phi^{N_k}(u_0, \omega_2)\}_{k \in \mathbb{N}}$ converges to some limit. We now show that the entire sequence $\{\Phi^N(u_0, \omega_2)\}_{N \in \mathbb{N}}$ converges (to a unique limit, which we can denote by $(u, \partial_t u)$ without ambiguity).

**Corollary 9.9.** Let $(u_0, \omega_2) \in \Sigma$. Then, the entire sequence $\{\Phi^N(u_0, \omega_2)\}_{N \in \mathbb{N}}$ converges to some limit $(u, \partial_t u)$ in $C(\mathbb{R}^+; H^{-\frac{1}{2} - \varepsilon}(T^3))$ endowed with the compact-open topology (in time).

**Proof.** We use the same notations as in the proof of Proposition 9.6. Denote by $\tilde{\Phi}(u_0, \omega_2)$ the limit of $\Phi^{N_k}(u_0, \omega_2)$ as $k \to \infty$, constructed in Proposition 9.6. Fix $T > 0$. By writing

$$\Phi^N(t)(u_0, \omega_2) - \Phi(t)(u_0, \omega_2) = \left(\Phi^N(t)(u_0, \omega_2) - \Phi^{N_k}(t)(u_0, \omega_2)\right)$$
$$+ \left(\Phi^{N_k}(t)(u_0, \omega_2) - \Phi(t)(u_0, \omega_2)\right),$$

we see that the second term tends to 0 in $C([0, T]; H^{-\frac{1}{2} - \varepsilon}(T^3))$, as $k \to \infty$.

From (9.33) and (9.19), we have

$$\|\Xi(\Psi_N(\tilde{\Phi}^{N_k}(\ell \tau)(u_0, \omega_2))) - \Xi(\Psi_N(\tilde{\Phi}^{N_{k'}}(\ell \tau)(u_0, \omega_2)))\|_{Y_1^\ell} \leq N^{-\varepsilon}D(i + j),$$
$$\|\Xi(\Psi_N(\tilde{\Phi}^{N_k}(\ell \tau)(u_0, \omega_2)))\|_{Y_1^\ell} \leq 2D(i + j)$$

for any $1 \leq N \leq N_k$ and $\ell = 0, \ldots, [\frac{2}{\tau}]$. Then, we can estimate the first term on the right-hand side of (9.53) by repeating the computation in the proof of Proposition 9.6 with $(N_k, N_{k'})$ replaced by $(N, N_k)$. \(\square\)

Finally, we show invariance of the focusing Hartree Gibbs measure $\bar{\rho}$ in (1.55) for the limiting process $u = (u, \partial_t u)$. Fix $F \in C_b(H^{-\frac{1}{2} - \varepsilon}(T^3); \mathbb{R})$ and $t > 0$. It follows from (9.2), the bounded convergence theorem with Corollary 9.9, the strong convergence of $\tilde{\rho}_N$ to $\bar{\rho}$ (Theorem 1.14), and
FOCUSING $\Phi^4_3$-MODEL WITH A HARTREE-TYPE NONLINEARITY

This shows invariance of $\rho_N$. This concludes the proof of Theorem 2.1.

APPENDIX A. ON THE PARABOLIC STOCHASTIC QUANTIZATION OF THE FOCUSING HARTREE GIBBS MEASURE

In this section, we consider the parabolic stochastic quantization of the focusing Hartree Gibbs measure $\rho$ constructed in Theorem 1.14 associated with the energy functional $E^\sharp(u)$ in (1.53). More precisely, we study the following focusing Hartree stochastic nonlinear heat equation (SNLH) on $T^3$:

$$\partial_t u + (1 - \Delta) u - \sigma (V^* : u^2:) u + M_{\gamma} (: u^2:) u = \sqrt{2} \xi,$$  
(A.1)

where $\sigma > 0$ and $M_{\gamma}$ is as in (2.2).

**Theorem A.1.** Let $\sigma > 0$. Let $V$ be the Bessel potential of order $\beta \geq 2$, where we also assume that $\sigma > 0$ is sufficiently small when $\beta = 2$. Then, the focusing Hartree SNLH (A.1) on the three-dimensional torus $T^3$ is almost surely globally well-posed with respect to the random initial data distributed by the focusing Hartree Gibbs measure $\rho$ in (1.50). Furthermore, the Gibbs measure $\rho$ is invariant under the resulting dynamics.

Here, we made a somewhat informal statement in the spirit of Theorem 1.2. A rigorous statement needs to be given in terms of a limiting procedure as in Theorem 2.1 which we omit.

As in the wave case, the main task is to prove local well-posedness of (A.1). Once this is achieved, then the rest follows from Bourgain’s invariant measure argument whose detail we omit. Thus, we only prove local well-posedness of (A.1) in the following.

**Remark A.2.** The defocusing/focusing nature of the problem does not play an important role in the local well-posedness argument. By simply setting $\sigma < 0$ in (A.1) and $A = 0$ in (2.2), our argument below proves an analogue of Theorem A.1 in the defocusing case for $\beta > 1$. See Proposition A.3 below.

In the defocusing case, by adapting the well-posedness argument [21, 39, 47, 56] for the parabolic $\Phi^4_3$-model (1.16), we expect that an analogue of Theorem A.1 can be extended to $\beta > 0$.

Let $\Psi$ be the stochastic convolution, satisfying

$$\begin{cases}
\partial_t \Psi + (1 - \Delta) \Psi = \sqrt{2} \xi \\
\Psi|_{t=0} = \phi_0 \quad \text{with } \text{Law}(\phi_0) = \mu.
\end{cases}$$

Then, by repeating the arguments, Lemmas 4.1 and 4.2 for $\Psi$, $:\Psi^2:,$ and $(V^* : \Psi^2:) \otimes \Psi$ extend to the parabolic setting when $\beta > 1$.
We proceed with the following first order expansion:

\[ u = \Psi + v. \]  

(A.2)

Then, it follows from (A.1) and (A.2) that the residual term \( v \) satisfies

\[ (\partial_t + 1 - \Delta)v = \mathcal{N}_1(v) + \mathcal{N}_2(v), \]

(A.3)

where \( \mathcal{N}_1(v) \) and \( \mathcal{N}_2(v) \) are given by

\[
\mathcal{N}_1(v) := \sigma(V * (v^2 + 2v\Psi + :\Psi^2:))(v + \Psi), \\
\mathcal{N}_2(v) := -M_\gamma(v^2 + 2v\Psi + :\Psi^2:)(v + \Psi).
\]

(A.4)

Here, \((V * :\Psi^2:)\Psi\) in \( \mathcal{N}_1(v) \) is interpreted as

\[ (V * :\Psi^2:)\Psi = (V * :\Psi^2:) \odot \Psi + (V * :\Psi^2:) \odot \Psi + (V * :\Psi^2:) \odot \Psi, \]

where the second term on the right-hand side is given a meaning via stochastic analysis for \( 1 < \beta \leq \frac{3}{2} \).

Since \( \Psi \sim -\frac{1}{2} - \), we expect that \( v \) has regularity \( \frac{3}{2} - \). Hence, \( v\Psi \) is well defined and thus a straightforward computation yields the following local well-posedness of (A.3).

**Proposition A.3.** Let \( \beta > 1, \sigma \in \mathbb{R} \setminus \{0\}, 2 < \gamma \leq 3, \) and \( A \in \mathbb{R} \). Given \( s < \frac{3}{2} \) sufficiently close to \( \frac{3}{2} \), there exists \( \varepsilon = \varepsilon(s) > 0 \) such that if

- \( \Psi \) is a distribution-valued function belonging to \( C([0, T]; C^{-\frac{1}{2} - \varepsilon, \infty}(\mathbb{T}^3)) \),
- \( :\Psi^2: \) is a distribution-valued function belonging to \( C([0, T]; C^{-1 - \varepsilon, \infty}(\mathbb{T}^3)) \),
- \((V * :\Psi^2:) \odot \Psi \) is a distribution-valued function belonging to \( C([0, T]; C^{3 - \frac{3}{2} - \varepsilon, \infty}(\mathbb{T}^3)) \),

then the Hartree SNLH (A.3) is locally well-posed in \( C^s(\mathbb{T}^3) \). More precisely, given any \( v_0 \in C^s(\mathbb{T}^3) \), there exists \( T > 0 \) such that a unique solution \( v \) to (A.3) exists on the time interval \([0, T]\) in the class \( C([0, T]; C^s(\mathbb{T}^3)) \). Furthermore, the solution \( v \) depends continuously on the enhanced data set:

\[ \Xi = (v_0, \Xi(\Psi)) := (v_0, \Psi, :\Psi^2:, (V * :\Psi^2:) \odot \Psi) \]

(A.5)

in the class \( C^s(\mathbb{T}^3) \times \mathcal{X}_T^s \), where

\[ \mathcal{X}_T^s := C([0, T]; C^{-\frac{1}{2} - \varepsilon}(\mathbb{T}^3)) \times C([0, T]; C^{-1 - \varepsilon}(\mathbb{T}^3)) \times C([0, T]; C^{3 - \frac{3}{2} - \varepsilon}(\mathbb{T}^3)). \]

(A.6)

When \( \beta > \frac{3}{2} \), the resonant product \((V * :\Psi^2:) \odot \Psi\) makes sense in the deterministic manner and thus we do not include this term in the enhanced data set.

Before proceeding to the proof of Proposition A.3, we first recall the Schauder estimate for the heat equation. Let \( P(t) = e^{-t(1-\Delta)} \) denote the linear heat propagator defined as a Fourier multiplier operator:

\[ P(t)f = \sum_{n \in \mathbb{Z}^d} e^{-t(n)^2} \hat{f}(n)e_n \]

for \( t \geq 0 \). Then, we have the following Schauder estimate on \( \mathbb{T}^d \).

**Lemma A.4.** Let \( -\infty < s_1 \leq s_2 < \infty \). Then, we have

\[ \|P(t)f\|_{C^{s_2}} \lesssim t^{\frac{s_1 - s_2}{2}} \|f\|_{C^{s_1}} \]

(A.7)

for any \( t > 0 \).
The bound \((A.7)\) on \(T^d\) follows from the decay estimate for the heat kernel on \(\mathbb{R}^d\) (see Lemma 2.4 in [3]) and the Poisson summation formula to pass such a decay estimate to \(T^d\).

**Proof of Proposition A.3.** Define a map \(\Phi\) by

\[
\Phi(v)(t) = P(t)v_0 + \int_0^t P(t-t')\left(\mathcal{N}_1(v) + \mathcal{N}_2(v)\right)(t')dt'.
\]

Let \(0 < T \leq 1\). We assume

\[
\|\Xi(\Psi)\|_{X_T^1} \leq K
\]

for some \(K \geq 1\), where \(\Xi(\Psi)\) and \(X_T^1\) are as in \((A.5)\) and \((A.6)\).

From Lemma 3.2 \((A.4)\), \((A.4)\), \((A.5)\), and \((A.6)\), we have

\[
\left\| \int_0^t P(t-t')\mathcal{N}_1(v)(t')dt' \right\|_{L_T^\infty C_x^s} \lesssim T^\theta \left( \|v^2 + 2v\Psi\|_{L_T^\infty C_x^{1-\beta+2\epsilon}} + \|V^* : \Psi^2 : \|_{L_T^\infty C_x^{1-\beta+2\epsilon}} \right.

+ \|\left(V^* : \Psi^2 : \right) \Psi\|_{L_T^\infty C_x^{1-\beta + 2\epsilon}}

\]

\[
\lesssim T^\theta \left( \|v\|_{L_T^\infty C_x^s}^3 + K^3 \right)
\]

for \(\beta > 1\) and \(\frac{1}{2} + 2\epsilon \leq s < \frac{3}{2} - \epsilon\). Similarly, we have

\[
\left\| \int_0^t P(t-t')\mathcal{N}_2(v)(t')dt' \right\|_{L_T^\infty C_x^s} \lesssim T^\theta \|\mathcal{M}_\gamma(v^2 + 2v\Psi + : \Psi^2 : )\|_{L_T^\infty} + \|\Psi\|_{L_T^\infty C_x^{1-\beta + 2\epsilon}}

\]

\[
\lesssim T^\theta \|v^2 + 2v\Psi + : \Psi^2 : \|_{L_T^\infty C_x^{1-\beta + 2\epsilon}}
\]

\[
\lesssim T^\theta \left( \|v\|_{L_T^\infty C_x^s}^5 + K^5 \right)
\]

since \(\gamma \leq 3\). Hence, from \((A.8)\), \((A.10)\), and \((A.11)\), we have

\[
\|\Phi(v)\|_{L_T^\infty C_x^s} \lesssim \|v_0\|_{C_x^s} + T^\theta \left( \|v\|_{L_T^\infty C_x^s}^5 + K^5 \right).
\]

Moreover, since \(\gamma > 2\), \(\mathcal{N}_2(v)\) in \((A.4)\) is Lipschitz continuous with respect to \(v\) and thus a similar computation also yields a difference estimate:

\[
\|\Phi(v_1) - \Phi(v_2)\|_{L_T^\infty C_x^s} \lesssim T^\theta \left( \|v_1\|_{L_T^\infty C_x^s} + \|v_2\|_{L_T^\infty C_x^s} + K \right) \|v_1 - v_2\|_{L_T^\infty C_x^s}.
\]

Therefore, local well-posedness of \((A.3)\) follows from a contraction argument with \((A.12)\) and \((A.13)\). An analogous computation shows that the solution \(v\) depends continuously on the enhanced data set \(\Xi\) in \((A.5)\). \(\square\)

**APPENDIX B. ON THE REGULARITIES OF THE STOCHASTIC TERMS**

In the following, we study the regularities of the stochastic terms, appearing in Subsection 6.2. From \((6.19)\) and \((6.13)\), we have

\[
\tilde{\mathcal{X}}_N = (1 - \Delta)^{-1} \left[ [V_0 * : Y_N^2 : ]Y_N \right]^0
\]

\[
= (1 - \Delta)^{-1} \left( [V_0 * : Y_N^2 : ]Y_N - 2\mathcal{K}_N * Y_N \right).
\]
In view of (1.36) and (1.37), we see that the subtraction of
\[ 2K_N \ast Y_N = 2\hat{Y}_N(n, t) \sum_{n_1 \in \mathbb{Z}^3} \hat{V}(n + n_1)\langle n_1 \rangle^{-2}, \]
removes the divergent term in \((V_0 \ast Y_N^2) \ast Y_N\) (which corresponds to \(Z_{13}\) defined in (4.14)). See Remark 4.3. Then, by repeating the proof of Lemma 4.2 and taking into account the smoothing by \((1 - \Delta)^{-1}\), we have
\[
E[\hat{3}_N(n, t)]^2 \sim \langle n \rangle^{-2\beta - 4} \tag{B.1}
\]
for \(0 < \beta \leq 1\) and \(0 \leq t \leq 1\); see the proof of Lemma 6.8. Thus, by Minkowski’s integral inequality, we have
\[
E[|\hat{3}_N(n)|^2] \sim \langle n \rangle^{-2\beta - 4} \tag{B.2}
\]
where \(3_N = 3_N(1)\) is as in (6.29).

**Lemma B.1.** Let \(V_0, Y_N\), and \(3_N\) be as in Section 6 and let \(0 < \beta \leq \frac{1}{2}\). Then, given any \(\varepsilon > 0\) and finite \(p \geq 1\), we have
\[
E\left[\left\| (V_0 \ast Y_N^2) : 3_N^2 \right\|_{C^{\beta - 1 - \varepsilon}}^p \right] \leq C_{p,\varepsilon} \langle n \rangle^{-1}, \tag{B.3}
\]
\[
E\left[\left\| (V_0 \ast Y_N^2) \hat{3}_N^2 \right\|_{C^{\beta - 1 - \varepsilon}}^p \right] \leq C_{p,\varepsilon} \langle n \rangle^{-1}, \tag{B.4}
\]
\[
E\left[\left\| (V \ast (Y_N \hat{3}_N)) Y_N \hat{3}_N \right\|_{C^{\beta - 1 - \varepsilon}}^p \right] \leq C_{p,\varepsilon} \langle n \rangle^{-1}, \tag{B.5}
\]
\[
E\left[\left\| (V \ast (Y_N \hat{3}_N)) \hat{3}_N \right\|_{C^{\beta - 1 - \varepsilon}}^p \right] \leq C_{p,\varepsilon} \langle n \rangle^{-1}, \tag{B.6}
\]
uniformly in \(N \in \mathbb{N}\). Here, the third term is defined as in (6.15) (with \(\Theta_N\) replaced by \(3_N\)), while the fourth term is defined in (6.39).

**Proof.** By Proposition 3.6 in [57], we only compute the second moment of the Fourier coefficient of each stochastic term. With \(Q_1 = (V_0 \ast Y_N^2) \hat{3}_N^2\), we have
\[
E[|\hat{Q}_1(n)|^2] = E\left[\sum_{n_1 + n_2 + n_3 + n_4} \langle n_1 + n_2 \rangle^{-\beta} : \hat{Y}_N(n_1) \hat{Y}_N(n_2) : \hat{3}_N(n_3) \hat{3}_N(n_4) \right] \\
\times E\left[\sum_{m_1 + m_2 + m_3 + m_4} \langle m_1 + m_2 \rangle^{-\beta} : \hat{Y}_N(m_1) \hat{Y}_N(m_2) : \hat{3}_N(m_3) \hat{3}_N(m_4) \right],
\]
where we used the notation introduced in (6.87). In order to compute the expectation above, we need to take all possible pairings between \((n_1, n_2, n_3, n_4)\) and \((m_1, m_2, m_3, m_4)\). By Jensen’s inequality, however, we see that it suffices to consider the case \(n_j = m_j, j = 1, \ldots, 4\). See the discussion on \(Y_N\) in Section 4 of [57]. See also Section 10 in [46]. Hence, from (B.2), we have
\[
E[|\hat{Q}_1(n)|^2] \lesssim \sum_{n_1 + n_2 + n_3 + n_4} \frac{1}{(n_1 + n_2)^{2\beta} \langle n_1 \rangle^2 \langle n_2 \rangle^2 \langle n_3 \rangle^{2\beta + 4} \langle n_4 \rangle^{2\beta + 4}}.
\]
By applying Lemma 3.4 iteratively, we have
\[
E[|\hat{Q}_1(n)|^2] \lesssim \sum_{n_3, n_4 \in \mathbb{Z}} \frac{1}{(n - n_3 - n_4)^{1+2\beta} \langle n_3 \rangle^{2\beta + 4} \langle n_4 \rangle^{2\beta + 4}} \lesssim \langle n \rangle^{-3 - 2(\beta - 1)}.
\]
By applying Proposition 3.6 in [57], we obtain (B.3). The second estimate (B.4) follows in a similar manner.

Let \( Q_3 = (V_0 \ast (Y_N \mathcal{Z}_N))Y_N \mathcal{Z}_N^o \). Then, proceeding as above with Jensen’s inequality and Lemma 3.4, we have

\[
\mathbb{E}|Q_3(n)|^2 \lesssim \sum_{n_1+n_2+n_3+n_4} \frac{1}{(n_1 + n_2)^2(n_1)2(2\beta+4)(n_4)^2}\lesssim \sum_{n_3,n_4 \in \mathbb{Z}} \frac{1}{(n-n_3)^22^\beta(2\beta+4)(n_4)^2}\lesssim (n)^{-3-2(\beta-1)}.
\]

Similarly, with \( Q_4 = [(V_0 \ast (Y_N \mathcal{Z}_N))Y_N]^o \), we have

\[
\mathbb{E}|Q_4(n)|^2 \lesssim \sum_{n_1+n_2+n_3} \frac{1}{(n_1 + n_2)^2(n_1)2(2\beta+4)(n_3)^2}\lesssim \sum_{n_3 \in \mathbb{Z}} \frac{1}{(n-n_3)^22^\beta(2\beta+4)(n_3)^2}\lesssim (n)^{-3-2(\beta-1)}.
\]

Therefore, these estimates with Proposition 3.6 in [57] yield (B.5) and (B.6). □

**Appendix C. Absolute Continuity with Respect to the Shifted Measure**

In this section, we prove that the defocusing Hartree Gibbs measure \( \rho \) for \( 0 < \beta \leq \frac{1}{2} \) is absolutely continuous with respect to the shifted measure \( \text{Law}(Y(1) - \mathcal{Z}(1) + \mathcal{W}(1)) \), where \( Y \) is as in (5.12), \( \mathcal{Z} \) is defined as the limit of the antiderivative of \( \mathcal{Z} \) in (6.19), and the auxiliary process \( \mathcal{W} \) is defined by

\[
\mathcal{W}(t) = (1 - \Delta)^{-1} \int_0^t \langle \nabla \rangle^{-\frac{1}{2}} \left( \langle \nabla \rangle^{-\frac{1}{2}} \mathcal{W}(t') \right)^{19} dt'
\]

for some small \( \varepsilon > 0 \). For the proof, we construct a drift as in the discussion in Section 3 of [5]. Note that the coercive term \( \mathcal{W} \) is introduced to guarantee global existence of a drift on the time interval \([0, 1] \). See Lemma C.2 below.

First, we present the following general lemma, giving a criterion for absolute continuity.

**Lemma C.1.** Let \( \mu_n \) and \( \rho_n \) be probability measures on a Polish space \( X \). Suppose that \( \mu_n \) and \( \rho_n \) converge weakly to \( \mu \) and \( \rho \), respectively. Furthermore, suppose that for every \( \varepsilon > 0 \), there exist \( \delta(\varepsilon) > 0 \) and \( \eta(\varepsilon) > 0 \) with \( \delta(\varepsilon), \eta(\varepsilon) \to 0 \) as \( \varepsilon \to 0 \) such that for every continuous function \( F : X \to \mathbb{R} \) with \( 0 < \inf F \leq F \leq 1 \) satisfying

\[
\mu_n(\{ F \leq \varepsilon \}) \geq 1 - \delta(\varepsilon)
\]

for any \( n \geq n_0(F) \), we have

\[
\limsup_{n \to \infty} \int F(u) d\rho_n(u) \leq \eta(\varepsilon).
\]

Then, \( \rho \) is absolutely continuous with respect to \( \mu \).

**Proof.** By the inner regularity, it suffices to show that for every compact set \( K \subset X \) with \( \mu(K) = 0 \), we have \( \rho(K) = 0 \). Consider the family of Lipschitz functions:

\[
\chi^{K,\varepsilon}_m(u) := \max(\varepsilon, 1 - md(u, K))
\]

(C.3)
for \( m \in \mathbb{N} \) and small \( \varepsilon_* > 0 \), where \( d(u, K) \) denotes the distance between \( u \) and \( K \). Then, we have

\[
0 < \varepsilon_* = \inf \chi_m^{K,\varepsilon_*} \leq \chi_m^{K,\varepsilon_*} \leq 1. \tag{C.4}
\]

It follows from (C.3) that

\[
\int \chi_m^{K,\varepsilon_*}(u) d\mu(u) \leq \varepsilon_* + \int 1_{\{d(u, K) < \ell_m\}}(u) d\mu(u) =: \varepsilon_* + \ell_m \tag{C.5}
\]

and that \( \ell_m \to 0 \) as \( m \to \infty \). Given \( \varepsilon > 0 \), let \( m = m(\varepsilon) \in \mathbb{N} \) and \( \varepsilon_* = \varepsilon_*(\varepsilon) > 0 \) be such that \( \frac{2(\varepsilon_* + \ell_m)}{\varepsilon} < \delta(\varepsilon) \). Let \( S^{K,\varepsilon} := \{ \chi_m^{K,\varepsilon} > \varepsilon \} \). By Markov’s inequality, the weak convergence of \( \mu_n \)

to \( \mu \), and (C.5), we have

\[
\mu_n(S^{K,\varepsilon}) \leq \frac{1}{\varepsilon} \int \chi_m^{K,\varepsilon_*}(u) d\mu_n(u) \leq \frac{2(\varepsilon_* + \ell_m)}{\varepsilon} < \delta(\varepsilon)
\]
for any \( \varepsilon > 0 \) and sufficiently large \( n \gg 1 \). Therefore, by our hypothesis (C.2) with (C.4) and (C.6), we obtain

\[
\limsup_{n \to \infty} \int \chi_m^{K,\varepsilon_*}(u) d\rho_n(u) \leq \eta(\varepsilon)
\]
for \( \varepsilon > 0 \). Hence, it follows from (C.3), the weak convergence of \( \rho_n \) to \( \rho \), and (C.7) that

\[
\rho(K) \leq \int \chi_m^{K,\varepsilon_*}(u) d\rho(u) = \lim_{n \to \infty} \int \chi_m^{K,\varepsilon_*}(u) d\rho_n(u) \leq \eta(\varepsilon).
\]

By taking \( \varepsilon \to 0 \), we conclude that \( \rho(K) = 0 \). \( \square \)

By regarding \( \hat{S}^N \) in (6.19) and \( \hat{W} \) in (C.1) as functions on \( Y \), we write them as

\[
\hat{S}^N(Y)(t) := (1 - \Delta)^{-1}[(V_0 * : Y_N^2(t))Y_N(t)]^\circ, \tag{C.8}
\]

\[
\hat{W}(Y)(t) := (1 - \Delta)^{-1} \int_0^t \langle \nabla \rangle^{-\frac{3}{2} - \varepsilon} \langle \nabla \rangle^{-\frac{3}{2} - \varepsilon} Y(t') \rangle^{19} dt', \tag{C.9}
\]
and we set \( \hat{S}_N(Y) = \pi_N \hat{S}^N(Y) \). Then, from (C.8), and (6.13), we have

\[
\hat{S}_N(Y + \Theta) - \hat{S}_N(Y) = (1 - \Delta)^{-1}\pi_N \hat{S}_N(Y, \Theta), \tag{C.10}
\]
where \( \hat{S}_N(Y, \Theta) \) is given by

\[
P_N(Y, \Theta) := (V_0 * : Y_N^2)\Theta_N + 2((V_0 * (Y_N \Theta_N))Y_N - K_N \Theta_N)
+ (V_0 * \Theta_N^2)Y_N + 2(V_0 * (\Theta_N Y_N))\Theta_N + (V_0 * \Theta_N^2)\Theta_N.
\]

Here, \( K_N \) is as in (1.37) and \( \Theta_N = \pi_N \Theta \).

Next, we state a lemma on the construction of a drift \( \Theta \).

**Lemma C.2.** Let \( V \) be the Bessel potential of order \( \beta > 0 \). Let \( \hat{Y} \in L^2([0, 1]; H^1(\mathbb{T}^3)) \). Then, given any \( N \in \mathbb{N} \), the Cauchy problem for \( \Theta \):

\[
\begin{align*}
\Theta - (1 - \Delta)^{-1}\pi_N P_N(Y, \Theta) + \pi_N \hat{W}(Y + \Theta) - \hat{Y} &= 0 \\
\Theta(0) &= 0
\end{align*}
\]

is almost surely globally well-posed in \( H^1(\mathbb{T}^3) \) on the time interval \([0, 1]\). Moreover, if \( \|\hat{Y}\|_{L^p_t([0, 1]; H^1)} \leq M \) for some \( M > 0 \), then, for any \( 1 \leq p < \infty \), there exists \( C = C(M, p) > 0 \) such that

\[
\mathbb{E}\left[\|\Theta\|_{L^p_t([0, 1]; H^1)}^p\right] \leq C(M, p), \tag{C.13}
\]
where \( C(M, p) \) is independent of \( N \in \mathbb{N} \).
We first prove the absolute continuity of the defocusing Hartree Gibbs measure \( \rho \) with respect to \( \text{Law}(Y(1) - \mathcal{Z}(1) + \mathcal{W}(1)) \) by assuming Lemma C.2. We present the proof of Lemma C.2 at the end of this section. Let \( \delta(L) \) and \( R(L) \) satisfy \( \delta(L) \to 0 \) and \( R(L) \to \infty \) as \( L \to \infty \), which will be specified later. In view of Lemma C.1, it suffices to show that if \( F : C^{-100}(\mathbb{R}^3) \to \mathbb{R} \) is a bounded continuous function with \( F \geq 0 \) and

\[
\mathbb{P}\left( \{ F(Y(1) - \mathcal{Z}_N(1) + \mathcal{W}_N(1)) \geq L \} \right) \geq 1 - \delta(L),
\]

where \( \mathcal{W}_N = \pi_N \mathcal{W} \), then we have

\[
\limsup_{N \to \infty} \int \exp(-F(u)) d\rho_N(u) \leq \exp(-R(L)).
\]

For simplicity, we use the same short-hand notations as in Subsection 6.2; for instance, \( Y = Y(1) \), \( \mathcal{Z} = \mathcal{Z}(1) \), and \( \mathcal{W} = \mathcal{W}(1) \). By the Boué-Dupuis formula (Lemma 5.11) and (6.20), we have

\[
-\log\left( \int \exp(-F(u) - R_N(u)) d\mu(u) \right)
\]

\[
= \inf_{Y_N \in \mathbb{H}_a} \mathbb{E}\left[ F(Y + Y_N - \mathcal{Z}_N) + \hat{R}_N(Y + Y_N - \mathcal{Z}_N) + \frac{1}{2} \int_0^1 \| \hat{Y}(t) \|^2_{H^1} dt \right],
\]

where \( \hat{R}_N \) is as in (6.52). It follows from Lemmas 6.2 6.3 and 6.4 with Lemmas 5.4 and B.1 (see (6.50)) that

\[
-\log\left( \int \exp(-F(u) - R_N(u)) d\mu(u) \right)
\]

\[
\geq \inf_{Y_N \in \mathbb{H}_a} \mathbb{E}\left[ F(Y + Y_N - \mathcal{Z}_N) + \frac{1}{20} \int_0^1 \| \hat{Y}_N(t) \|^2_{H^1} dt \right] - C_1
\]

for some constant \( C_1 > 0 \). For \( Y_N \in \mathbb{H}_a \), let \( \Theta^N \) be the solution to (C.12) with \( \hat{Y} \) replaced by \( Y_N \). For any \( M > 0 \), define the stopping time \( \tau_M \) as

\[
\tau_M = \min \left\{ 1, \min \left\{ \tau : \int_0^\tau \| \hat{Y}_N(s) \|^2_{H^1} ds = M \right\} \right\},
\]

where \( C(M, 2) \) is the constant appearing in (C.13) with \( p = 2 \). Let \( \Theta^N_M(t) = \Theta^N(\min(t, \tau_M)) \). It follows from (C.10) and (C.12) with \( Y^N(0) = \Theta^N_M(0) = \mathcal{W}_N(0) = 0 \) that

\[
Y + Y_N - \mathcal{Z}_N = Y + \Theta^N_M - \mathcal{Z}_N(Y + \Theta^N_M) + \mathcal{W}_N(Y + \Theta^N_M)
\]

(C.18)

on the set \( \{ \tau_M = 1 \} \).

Since \( \| \hat{\Theta}^N_M \|^2_{L^2([0, 1]; H^1)} \) is bounded by \( 2C(M, 2) \), Girsanov’s theorem yields that \( \text{Law}(Y + \Theta^N_M) \) is absolutely continuous with respect to \( \text{Law}(Y) \). Moreover, by Cauchy-Schwarz inequality, we have

\[
\mathbb{P}\left( \{ Y + \Theta^N_M \in E \} \right) \leq C_M \left( \mathbb{P}\left( \{ Y \in E \} \right) \right)^{\frac{1}{2}}
\]

(C.19)

for any measurable set \( E \).
From (C.16), (C.18), and the non-negativity of $F$, we have
\[
- \log \left( \int \exp(-F(u) - R_N^\omega(u)) d\mu(u) \right)
\geq \inf_{\mathcal{F}} \mathbb{E} \left[ (F(Y + \Theta_M^N - 3N(Y + \Theta_M^N) + W_N(Y + \Theta_M^N))
\right.
\left. + \frac{1}{20} \int_0^1 \|\dot{\Theta}^N(t)\|^2_{H_2^2} dt \right]_1^{\{\tau_M = 1\}}
\]
\[
+ \left( F(Y + \Theta_M^N - 3N(Y + \Theta_M^N) + W_N(Y + \Theta_M^N)) \cdot 1_{\{\tau_M = 1\}}
\right.
\left. + \frac{1}{20} \int_0^1 \|\dot{\Theta}^N(t)\|^2_{H_2^2} dt \cdot 1_{\{\tau_M < 1\}} \right] - C_1
\]

From (C.17) followed by (C.19) and (C.14),
\[
\geq \inf_{\mathcal{F}} \mathbb{E} \left[ L \cdot 1_{\{\tau_M = 1\}} \cap (F(Y + \Theta_M^N - 3N(Y + \Theta_M^N) + W_N(Y + \Theta_M^N)) \geq L)
\right.
\left. + \frac{M}{20} 1_{\{\tau_M < 1\}} \cap \left( \int_0^1 \|\dot{\Theta}^N_M(t)\|^2_{H_2^2} dt < 2C(M,2) \right) \right] - C_1
\]
\[
\geq \inf_{\mathcal{F}} \mathbb{E} \left[ L \left( \mathbb{P}({\tau_M = 1}) - C_M \delta(L)^{\frac{1}{2}} \right)
\right.
\left. + \frac{M}{20} \mathbb{P}({\tau_M < 1}) \cap \left\{ \int_0^1 \|\dot{\Theta}^N_M(t)\|^2_{H_2^2} dt < 2C(M,2) \right\} \right] - C_1. \quad (C.20)
\]

Since (C.13) yields that $\mathbb{E}[\|\dot{\Theta}^N_M\|^2_{L^2([0,1];H_2^2)}] \leq C(M,2)$, Markov’s inequality gives
\[
\mathbb{P} \left( \int_0^1 \|\dot{\Theta}^N_M(t)\|^2_{H_2^2} dt \geq 2C(M,2) \right) < \frac{1}{2},
\]
and thus we have
\[
\mathbb{P} \left( \{\tau_M < 1\} \cap \left\{ \int_0^1 \|\dot{\Theta}^N_M(t)\|^2_{H_2^2} dt < 2C(M,2) \right\} \right) \geq \mathbb{P}(\{\tau_M < 1\}) - \frac{1}{2}. \quad (C.21)
\]
Hence, by choosing $M = 20L$, it follows from (C.20) and (C.21) that
\[
- \log \left( \int \exp(-F(u) - R_N^\omega(u)) d\mu(u) \right)
\geq \inf_{\mathcal{F}} \left\{ L \left( \mathbb{P}({\tau_M = 1}) - C'_L \delta(L)^{\frac{1}{2}} \right) + L \left( \mathbb{P}({\tau_M < 1}) - \frac{1}{2} \right) \right\} - C_1
\]
\[
= L \left( \frac{1}{2} - C'_L \delta(L)^{\frac{1}{2}} \right) - C_1.
\]
Therefore, by choosing $\delta(L) > 0$ such that $C'_L \delta(L)^{\frac{1}{2}} \to 0$ as $L \to \infty$, this shows (C.15) with
\[
R(L) = L \left( \frac{1}{2} - C'_L \delta(L)^{\frac{1}{2}} \right) - C_1 + \log Z,
\]
where \( Z = \lim_{N \to \infty} Z_N \) denotes the normalization constant for the defocusing Hartree Gibbs measure \( \rho \).

We conclude this section by presenting the proof of Lemma C.2.

**Proof of Lemma C.2.** For simplicity, we only consider \( 0 < \beta \leq \frac{1}{2} \), which is the relevant case in this section. First, we estimate each term on the right-hand side of \((C.11)\). From Lemma 3.3, we have

\[
\| (V_b : \Theta_N(t)) \|_{H_x} \lesssim \| V_b : \Theta_N(t) \|_{W_x^{1,\infty}} \| \Theta_N(t) \|_{H_x^{\beta}}
\]

provided that \( \beta \geq \varepsilon > 0 \). For the second term on the right-hand side of \((C.11)\), we define \( Y_N \) by replacing \( Y_N = Y_N(1) \) in \((6.16)\) with \( Y_N(t) \). We also define \( T_N \) by \((6.36)\) and \((6.37)\), where we replaced \( Y_N \) in \((6.37)\) with \( Y_N \). Then, by duality we have

\[
\| (V_b (Y_N(t) \Theta_N(t))) Y_N(t) - K_N \Theta_N(t) \|_{H_x^{-1}}
= \sup_{\| h \|_{H_x^{\beta}} = 1} \left| \int_{T^3 \times T^3} \langle \langle \nabla \rangle^{1-\varepsilon} \Theta_N(t) \rangle \cdot \langle \langle \nabla \rangle^{1-\varepsilon} h(x) \rangle \right| \]

\[
\leq \| T_N \|_{L(L^2,L^2)} \| \Theta(t) \|_{H_x^{\beta}}
\]

for \( \varepsilon > 0 \), where \( \Theta_N(x,t) = \Theta_N(-x,t) \). By Lemma 3.3 (i) and (ii) and Sobolev’s inequality, we have

\[
\| (V_b \Theta_N(t)) Y_N(t) \|_{H_x^{-1}} \lesssim \| V_b \Theta_N(t) \|_{W_x^{\frac{1}{2} + \frac{3}{2(1-\varepsilon)}}} \| Y_N(t) \|_{W_x^{-\frac{1}{2} - \varepsilon, \frac{1}{2}}}
\]

\[
\lesssim \| \Theta_N(t) \|_{W_x^{-\beta + \frac{3}{2} + \varepsilon, \frac{1}{2}}} \| \Theta_N(t) \|_{L_x^6} \| Y_N(t) \|_{W_x^{-\frac{1}{2} - \varepsilon, \infty}}
\]

\[
\lesssim \| Y_N(t) \|_{W_x^{-\frac{1}{2} - \varepsilon, \infty}} \| \Theta(t) \|_{H_x^{\beta}}^2
\]

for \( 0 \leq \beta \leq \frac{1}{2} \) and \( 0 < \varepsilon < 1 \). By Sobolev’s inequality and Lemma 3.3, we have

\[
\| (V_b (\Theta_N Y_N(t))) \Theta_N(t) \|_{H_x^{-1}} \lesssim \| (V_b (\Theta_N(t) Y_N(t))) \Theta_N(t) \|_{W_x^{-\frac{1}{2} \frac{3}{2}}}
\]

\[
\lesssim \| V_b (\Theta_N(t) Y_N(t)) \|_{W_x^{-\frac{1}{2} \frac{3}{2}}} \| \Theta_N(t) \|_{W_x^{-\frac{1}{2} \frac{3}{2}}}
\]

\[
\lesssim \| \Theta_N(t) \|_{W_x^{-\frac{1}{2} \frac{3}{2}}} \| Y_N(t) \|_{W_x^{-\frac{1}{2} - \varepsilon, \infty}} \| \Theta(t) \|_{H_x^{\beta}}^2
\]

\[
\lesssim \| Y_N(t) \|_{W_x^{-\frac{1}{2} - \varepsilon, \infty}} \| \Theta(t) \|_{H_x^{\beta}}^2
\]

for \( \beta \geq \varepsilon > 0 \). Lastly, we have

\[
\| (V_b \Theta_N(t)) \Theta_N(t) \|_{H_x^{-1}} \lesssim \| \Theta_N(t) \|_{L_x^3} \| \Theta(t) \|_{H_x^{\beta}}^3
\]

\[
\| (1 - \Delta)^{-1} P_N(Y(t), \Theta(t)) \|_{H_x^{\beta}} \lesssim \| P_N(Y(t), \Theta(t)) \|_{H_x^{-1}}
\]

\[
\lesssim \left( \| Y_N(t) \|_{W_x^{-1 - \delta, \infty}} + \| T_N \|_{L(L^2)} \right) \| \Theta(t) \|_{H_x^{\beta}}
\]

\[
+ \| Y_N(t) \|_{W_x^{-\frac{1}{2} - \varepsilon, \infty}} \| \Theta(t) \|_{H_x^{\beta}}^2 + \| \Theta(t) \|_{H_x^{\beta}}^3.
\]
Moreover, from (C.1), we have
\[
\|\tilde{W}_N(Y(t) + \Theta(t))\|_{H^1_x} \lesssim \|\nabla\|^{-\frac{1}{2} - \varepsilon} Y(t)\|_{L^2_x} + \|\nabla\|^{-\frac{1}{2} - \varepsilon} \Theta(t)\|_{L^2_x}
\lesssim \|Y(t)\|_{W^{\frac{1}{2} - \varepsilon, \infty}} + \|\Theta(t)\|_{H^1_x}^{19}
\] (C.28)
for \(\varepsilon > 0\). Therefore, by studying the integral formulation of (C.12), a contraction argument in \(L^\infty([0, T]; H^1(\mathbb{T}^3))\) for some \(T > 0\) with (C.27) and (C.28) yields local well-posedness. Here, the local existence time \(T\) depends on \(\|\Theta(0)\|_{H^1_x}, \|\tilde{Y}\|_{L^2_x H^1_x}\), and the following terms:
\[
\|Y_N\|_{L^\infty_T W^{1,2 - \varepsilon, \infty}_x}, \quad \|\Sigma_Y^2\| : L^\infty_T W^{\frac{1}{2} - \varepsilon, \infty}_x, \quad \text{and} \quad \|T_N^2\|_{L^2_T \mathcal{L}(L^2; L^2)}
\]
whose almost sure boundedness follows from a small modification of the proofs of Lemmas 5.4 and 6.4.

Next, we prove global existence on \([0, 1]\). It follows from (C.12) with (C.9) that
\[
\frac{1}{2} \frac{d}{dt} \|\Theta(t)\|_{H^1_x}^2 = \int_{\mathbb{T}^3} P_N(Y(t), \Theta(t)) \Theta_N(t) \, dx
- \int_{\mathbb{T}^3} (\nabla\|^{-\frac{1}{2} - \varepsilon} (Y(t) + \Theta(t)))^{19} (\nabla\|^{-\frac{1}{2} - \varepsilon} \Theta(t)) \, dx
+ \int_{\mathbb{T}^3} \langle \nabla \rangle \Theta(t) \langle \nabla \rangle \hat{Y}(t) \, dx.
\] (C.29)

From (C.11), Lemma 6.1 and (C.23), we have
\[
\int_{\mathbb{T}^3} P_N(Y(t), \Theta(t)) \Theta_N(t) \, dx \lesssim \|\Theta(t)\|_{H^1_x}^2 + \|\Theta(t)\|_{L^2_x}^4
+ \int_{\mathbb{T}^3} (V * \Theta_N^4(t)) \Theta_N^2(t) \, dx + C_0(Y_N(t))
\] (C.30)
for \(0 < \beta \leq \frac{1}{2}\) and \(0 < \varepsilon \ll 1\), where
\[
C_0(Y_N(t)) := 1 + \|Y_N(t)\|_{C^{\frac{1}{2} - \varepsilon}} \|\Sigma_Y^2(t)\|_{C^{\frac{1}{2} - \varepsilon}} + \|T_N^2\|_{\mathcal{L}(L^2; L^2)}
\] (C.31)
for some \(c > 0\).

From (C.12), we have
\[
\pi_N \Theta(t) = \int_0^t \pi_N \hat{\Theta}(t') \, dt' = \int_0^t \pi_N \hat{Y}(t') \, dt'.
\] (C.32)

Then, from (C.32), Minkowski’s integral inequality, Sobolev’s inequality, and (3.3), we have
\[
\int_{\mathbb{T}^3} (V \ast \Theta_N^2(t)) \Theta_N^2(t) \, dx \lesssim \|\Theta_N(t)\|_{L^4_x}^4 \lesssim \|\Theta(t)\|_{L^4_x}^2 + \|\pi_N \hat{Y}\|_{L^2([0,1]; H^1_x)}^4
\lesssim \|\Theta(t)\|_{H^1_x}^{19} \|\Theta(t)\|_{W^{\frac{1}{2} - \varepsilon, 20}_x}^7 + \|\hat{Y}\|_{L^2([0,1]; H^1_x)}^4
\lesssim \|\Theta(t)\|_{H^1_x}^2 + \varepsilon \|\Theta(t)\|_{W^{\frac{1}{2} - \varepsilon, 20}_x}^{20} + \|\hat{Y}\|_{L^2([0,1]; H^1_x)}^4 + C_\varepsilon
\] (C.33)
for $\beta \geq 0$ and $0 < \varepsilon \ll 1$. Moreover, it follows from (5.35) and Young’s inequality that

$$\int_{T^3} \left( (\nabla)^{-\frac{1}{2} - \varepsilon} (Y(t) + \Theta(t)) \right)^2 \nabla \left( (\nabla)^{-\frac{1}{2} - \varepsilon} \Theta(t) \right) dx$$

$$\geq \frac{1}{2} \int_{T^3} \left( (\nabla)^{-\frac{1}{2} - \varepsilon} \Theta(t) \right)^2 dx - c \int_{T^3} \left( (\nabla)^{-\frac{1}{2} - \varepsilon} Y(t) \right) \nabla \left( (\nabla)^{-\frac{1}{2} - \varepsilon} \Theta(t) \right) dx$$

$$\geq \frac{1}{2} \left\| \Theta(t) \right\|_{W^{-\frac{1}{2} - \varepsilon, 20}}^{20} - c \left\| Y(t) \right\|_{W^{-\frac{1}{2} - \varepsilon, 20}}^{19} \left\| \Theta(t) \right\|_{W^{-\frac{1}{2} - \varepsilon, 20}}$$

$$(C.34)$$

Therefore, from (C.29) - (C.34), we obtain

$$\frac{d}{dt} \left\| \Theta(t) \right\|_{H^1}^2 \lesssim \left\| \Theta(t) \right\|_{H^1}^2 + \left\| \dot{Y}(t) \right\|_{H^1}^4 + \left\| \dot{\Theta} \right\|_{L^4([0,1]; H^1)}^{4} + C_0(Y_N(t)) + \left\| Y(t) \right\|_{L^{20}([0,1]; W^{\frac{1}{2} - \varepsilon, 20})}^{20}.$$

By Gronwall’s inequality, this implies

$$\left\| \Theta(t) \right\|_{H^1}^2 \lesssim \left\| \dot{Y} \right\|_{L^4([0,1]; H^1)}^{4} + C_0(Y_N(t)) \left\| \dot{Y} \right\|_{L^4([0,1]; H^1)} + \left\| Y(t) \right\|_{L^{20}([0,1]; W^{\frac{1}{2} - \varepsilon, 20})}^{20},$$

(C.35)

uniformly in $0 \leq t \leq 1$. The a priori bound (C.35) allows us to iterate the local well-posedness argument, guaranteeing existence of the solution $\Theta$ on $[0,1]$.

It follows from (C.31) and a small modification of the proofs of Lemmas 5.4 and 6.4 that

$$\mathbb{E} \left[ \left\| C_0(Y_N(t)) \right\|_{L^p([0,1]; L^p)}^p \right] + \mathbb{E} \left[ \left\| Y \right\|_{L^{20}([0,1]; W^{\frac{1}{2} - \varepsilon, 20})}^p \right] < \infty,$$  

(C.36)

for any $1 < p < \infty$, uniformly in $N \in \mathbb{N}$. Then, from (C.27), (C.28), (C.35), and (C.36) that

$$\left\| (1 - \Delta)^{-1} P_N(Y, \Theta) + \dot{W}_N(Y + \Theta) \right\|_{L^2([0,1]; H^1)} \lesssim \left\| \dot{Y} \right\|_{L^4([0,1]; H^1)}^{\frac{38}{19}} + C_N,$$

(C.37)

with $\mathbb{E}[\left| C_N \right|^p] < \infty$ for any $1 < p < \infty$, uniformly in $N \in \mathbb{N}$. Therefore, from (C.12) and (C.37), we obtain the bound (C.13). □
