Abstract

We consider a system of two spins with degenerate Larmor frequencies under a STM bias and derive the dissipative Lindblad equations. We find that the tunneling elements to the environments (tip and substrate) generate an exchange interaction between the spins, as well as a Dzyaloshinskii-Moriya interaction in presence of spin-orbit coupling. We show that when the spins have equal tunneling amplitudes (without spin-orbit) there is a dark state with vanishing decay rate. We also show that the resulting STM spectrum has additional transitions relative to those of conventional spin resonance experiments. The presence of dipole interaction is also considered, with similar conclusions.
An intense ongoing effort is devoted to the study of two qubits coupled via a common environment, motivated by quantum information science. In particular it has been realized that dissipative dynamics due to qubit coupling to the environment can be tuned to yield entangled states both in theory and experiment. In parallel there has been considerable effort in developing techniques of scanning tunneling microscope (STM) for probing electron spin resonance (ESR) features. These ESR-STM studies are of two types, either monitoring the current power spectrum in a DC bias employing a non-magnetic tip, or monitoring the DC current with a magnetic tip when an additional AC voltage is tuned to resonance conditions.

In the present work we show that STM methods provide a novel scenario for generating a common environment between two spins, representing two qubits. The presence of two non-degenerate spins has been proposed to account for the 1st type of ESR-STM phenomena. Here we study the case of degenerate spins which necessitates a new derivation of the appropriate Lindblad equation. We find a number of novel phenomena: (i) The tunneling elements to the environments (tip and substrate) generate in general dissipation but also an exchange coupling between the two spins; in presence of spin-orbit coupling a Dzyaloshinskii-Moriya interaction is also generated. (ii) When the tunneling elements of the two spins are equal we identify a dark state, i.e. an entangled state with infinite lifetime. (iii) The spin correlation functions as measured by an STM, in presence of either exchange or dipolar interactions, show additional resonances relative to those seen in conventional ESR.

In the following we use the Lindblad formalism where a system-environment interaction, in the interaction picture, is a product of operators $A_j(t), B_j(t)$ in the system and environment spaces, respectively, $j = -J, \ldots, J$ and $A_j^\dagger = A_{-j}, B_j^\dagger = B_{-j}$ with eigenfrequency $\nu_j$ with $\nu_{-j} = -\nu_j$ i.e.

$$\mathcal{H}_{SE} = \sum_{j=-J,\ldots,J} B_j(t)A_j e^{-i\nu_j t}$$

where the sum may contain a $j = 0$ term with $\nu_0 = 0$. The master equation for the reduced density matrix, within the Markov approximation (environment correlations are short ranged) and to 2nd order in $\mathcal{H}_{SE}$ is

$$\frac{d}{dt} \rho_S(t) = \sum_{j,k} \tilde{\Gamma}_{jk}(\nu_k) e^{i(\nu_k + \nu_j)t} [A_k \rho_S(t) A_j - A_j A_j \rho_S(t)] + \text{h.c.}$$

$$\tilde{\Gamma}_{jk}(\omega) = \int_0^\infty d\tau \langle B_j(\tau) B_k(0) \rangle \mathcal{E} e^{i\omega \tau}$$
where \( \langle \ldots \rangle_E \) denotes average on the environment. In the following we use a secular assumption, i.e. only terms \( k, j \) for which \( \nu_k + \nu_j = 0 \) are kept. The neglect of terms with finite frequency difference is justified when the latter is much larger than the linewidth. It is important to note that we do include off-diagonal terms in view of degeneracies in our system.

![FIG. 1. Sketch of the system: the spins may be thought as being located in two channels where electrons tunnel from a tip (parabola) to the substrate (below the flat line).](image)

We proceed to our system with two degenerate spins described each by Pauli matrices \( \tau \) and a common Larmor frequency \( \nu \) coupled by tunneling in parallel to the two environments \( L, R \). The latter have spin independent energies \( \epsilon_L, \epsilon_R \) and Hamiltonian \( \mathcal{H}_L = \epsilon_L c_L^\dagger c_L \), same with \( L \to R \), and \( c^\dagger, c \) the corresponding electron creation and annihilation operators in spinor notation. The Hamiltonian has the form (direct products describe matrices of spin 1 times those of spin 2),

\[
\mathcal{H} = \frac{1}{2} \nu \tau_z \otimes 1 + \frac{1}{2} \nu 1 \otimes \tau_z + \left[ J_1 c_R^\dagger \sigma L \cdot \tau \otimes 1 + J_2 c_R^\dagger \sigma L c_L \cdot 1 \otimes \tau + \text{h.c.} \right] + \mathcal{H}_L + \mathcal{H}_R \tag{3}
\]

where here we allow also \( \hat{u} = e^{i\sigma_z \phi} e^{i\sigma_y \theta} \) representing spin-orbit interaction for the 2nd spin; this interaction is important for the coupling of an STM current to the spins. The exchange tunneling terms in Eq. \( (32) \) are derived from tunneling via a localized state that has strong on-site Coulomb repulsion, which eliminates electron doubly occupied or zero occupied situations, a derivation known as Schrieffer-Wolff transformation. There are additional terms that tunnel electrons from one lead and back to the same lead, however the terms in \( (32) \) dominate at large voltage, i.e. \( eV \gg \nu, k_B T \) (\( T \) is temperature), the typical case in STM experiments. The interaction picture is achieved with the unitary transformation
leading to $H_{SE}$ of the form (21) with

$$U_e = e^{-i\frac{1}{2}\nu_2 \tau_z \otimes \mathbf{1} + i\frac{1}{2}\nu_2 \otimes \tau_z + \epsilon_L c_L^\dagger c_L + \epsilon_R c_R^\dagger c_R}t$$

$$A_1 = \tau_- \otimes \mathbf{1} \quad \nu_1 = \nu \quad B_1 = 2J_1(c_R^\dagger \sigma_+ c_L \epsilon_{RL}^t + c_L^\dagger \sigma_+ c_R \epsilon_{RL}^t)$$

$$A_{-1} = \tau_+ \otimes \mathbf{1} \quad \nu_{-1} = -\nu \quad B_{-1} = B_1^\dagger$$

$$A_z = \tau_z \otimes \mathbf{1} \quad \nu_z = 0 \quad B_z = J_1 c_R^\dagger \sigma_z c_L \epsilon_{RL}^t + \text{h.c.}$$

$$A_2 = 1 \otimes \tau_- \quad \nu_2 = \nu \quad B_2 = 2J_2(c_R^\dagger \sigma_+ \hat{u} c_L \epsilon_{RL}^t + c_L^\dagger \hat{u}^\dagger \sigma_+ c_R \epsilon_{RL}^t)$$

$$A_{-2} = 1 \otimes \tau_+ \quad \nu_{-2} = -\nu \quad B_{-2} = B_2^\dagger$$

$$A_{z'} = 1 \otimes \tau_z \quad \nu_{z'} = 0 \quad B_{z'} = J_2 c_R^\dagger \sigma_z \hat{u} c_L \epsilon_{RL}^t + \text{h.c.} \quad (4)$$

The terms $A_z, A_{z'}$ are degenerate and produce off diagonal terms, as well as $A_1, A_{-2}$ or $A_{-1}, A_2$. Plugging these forms in Eq. (2) is straightforward and is detailed in the supplementary material. Here we outline the form of one particular term

$$\frac{d\rho}{dt} = \ldots + \tilde{\Gamma}_{2-1}(-\nu)e^{i(\nu_1 - \nu_2)t}[\tau_+ \otimes \mathbf{1}\rho_S 1 \otimes \tau_- - \tau_+ \otimes \tau_- \rho_S] + \text{h.c.}$$

$$\tilde{\Gamma}_{2-1}(-\nu) = 4J_1J_2N^2(0) \cos \frac{1}{2}\theta e^{-i\phi} \int_{\epsilon_L,\epsilon_R} i\{f_R(\epsilon_R)(1 - f_L(\epsilon_L)) - f_L(\epsilon_L)(1 - f_R(\epsilon_R))\epsilon_{RL} - \nu + i\eta\} \approx \frac{1}{2}$$

$$\delta_2 = \text{P.P.} \int_{\epsilon_L,\epsilon_R} \frac{f_L(\epsilon_L) - f_R(\epsilon_R)}{\epsilon_{RL}} \approx \Lambda \ln \left| \frac{16\Lambda^2}{|\Lambda^2 - V^2|} - V \ln \left| \frac{V + \Lambda}{\Lambda - V} \right| \right| \quad (5)$$

The P.P. term assumes a constant density of states $N(0)$, so that the expression for $\delta_2$ is taken just as an approximate indication that this term increases linearly with $\Lambda$ and therefore can be large.

Adding up all the degenerate terms that couple the two spins, i.e. $\tilde{\Gamma}(\pm \nu)_{i,j}$ with $i, j = 2, -1; -2, 1; 1, -2; -1, 2; z, z'; z', z$ the imaginary terms combine into $-i[H_{int}, \rho_S]$, i.e. identifying a shift of the Hamiltonian where

$$\mathcal{H}_{int} = -J_{ex} \mathbf{t}_1 \cdot \mathbf{t}_2 + J_{DM} \mathbf{t}_1 \times \mathbf{t}_2$$

$$J_{ex} = 4J_1J_2N^2(0) \delta_2 \cos \frac{1}{2}\theta \cos \phi, \quad J_{DM} = 4J_1J_2N^2(0) \delta_2 \cos \frac{1}{2}\theta \sin \phi \quad (7)$$
Hence an exchange term as well as a Dzyaloshinskii-Moriya interaction, the latter is allowed in presence of spin-orbit coupling ($\phi \neq 0$) on one of the spins, which also breaks the symmetry between the two spins. We note that these generated interactions are similar in spirit to the well known RKKY interaction\textsuperscript{17} that generates an exchange interaction between two separated spins in a metal, the metal being a common reservoir. The RKKY coupling is also sensitive to the cutoff as well as to the dimensionality of the metal\textsuperscript{17}.

The density matrix is expanded in the a general form $\rho_S(t) = \sum_{\alpha,\beta} \rho_{\alpha,\beta}(t) \tau_\alpha \otimes \tau_\beta$, with $\alpha,\beta = 0, z, +, -$ so that $\tau_\alpha = 1, \tau_z, \tau_+, \tau_-$ and $\rho_{00} = \frac{1}{4}$. We exhibit now the dark state, inspired by works on two qubit systems coupled by either a plasmonic waveguide\textsuperscript{18} or by cavity electrodynamics\textsuperscript{4}. We consider the case where the spins are equally coupled to the environments $J_1 = J_2$ and $\theta = \phi = 0$ so that spin-orbit does not distinguish between the spins. The proposed dark state is $|↑↓⟩ - |↓↑⟩/\sqrt{2}$. The corresponding density matrix operator is $\hat{d}$, whose expectation is

$$\rho_{\text{dark}} = \frac{1}{2} \text{Tr}[\rho \hat{d}] = \frac{1}{4} - \rho_{zz} - \frac{1}{2} \rho_{+-} - \frac{1}{2} \rho_{--} \quad (8)$$

From the full Lindblad equation (see supplementary material) we find

$$\frac{d\rho_{\text{dark}}}{dt} = - \frac{d\rho_{zz}}{dt} - \frac{1}{2} \frac{d\rho_{+-}}{dt} - \frac{1}{2} \frac{d\rho_{--}}{dt} = 0 \quad (9)$$

i.e. it is indeed a dark state and the decaying rates precisely cancel.

To derive correlation functions we consider $\rho_{\alpha,\beta}$ as a vector of 16 entries so that the Lindblad equation has the form $\frac{d\rho}{dt} = R \rho$ with $R$ a $16 \times 16$ matrix. Following the quantum regression formula\textsuperscript{6}, the Fourier transform of a correlation function can be written as $\langle A(t)B(0)\rangle_\omega = -2\text{Re} \text{Tr}[A \frac{1}{R+i\omega} B \rho_\infty]$, where $\rho_\infty$ is the steady state density matrix, i.e. the solution of $R \rho_\infty = 0$. We present in Fig. 1 the correlation function for the dark state, i.e. $\langle \hat{d}(t)\hat{d}(0)\rangle_0$, ($\hat{d} \rightarrow \hat{d} - \frac{1}{4} 1 \otimes 1$ here) for couplings close to the degenerate case $\frac{J_2}{J_1} = 0.9$. The huge peak at $\omega = 0$ diverges as $J_1 \rightarrow J_2$, signifying a dark state. The dark state persists even with exchange interaction and Fig. 1 is unchanged. However spin-orbit and DM interaction eliminate the dark state.

Consider next correlation functions that are measured by either ESR or an STM probe. To identify the various lines, diagonalize the system Hamiltonian, i.e. the Larmor term with
Correlation of the dark state operator for frequency $\frac{\nu}{eV} = 0.1$ and electrode couplings $\lambda_1 = 0.01$, $\lambda_2 = 0.009$ where $\lambda_i = 16\pi N^2(0) J_i^2 (i = 1, 2)$ and $\theta = \phi = 0$. The figure is the same for either vanishing exchange interaction or with $\frac{J_{ex}}{eV} = 0.2$.

\[ H_{\text{int}}, \]

\[
\begin{align*}
|\uparrow\uparrow\rangle : & \quad E_1 = \nu - J_{ex} \\
\frac{1}{\sqrt{2}} [ |\uparrow\downarrow\rangle + e^{i\psi} |\downarrow\uparrow\rangle] : & \quad E_2 = J_{ex} + 2\sqrt{J_{ex}^2 + J_{DM}^2} \\
\frac{1}{\sqrt{2}} [ |\uparrow\downarrow\rangle - e^{i\psi} |\downarrow\uparrow\rangle] : & \quad E_3 = J_{ex} - 2\sqrt{J_{ex}^2 + J_{DM}^2} \\
|\downarrow\downarrow\rangle : & \quad E_4 = -\nu - J_{ex}
\end{align*}
\]

where $\tan \psi = \frac{J_{DM}}{J_{ex}}$. If both interactions are strictly within our model Eq. (7), then remarkably, $\psi = \phi$, the spin-orbit phase.

Consider first the exchange only case ($J_{DM} = 0$); an ESR experiment allows only transitions within the triplet states at frequency $\nu$. There are no transitions between the singlet and triplet states, the reason is the opposite permutation symmetry of these states, while the probing field is uniform in space. In contrast, we note that an STM experiment allows the probing current to tunnel via only one spin, hence permutation symmetry does not hold. The experiment would then show also singlet to triplet transition, i.e. total of 3 lines at $\nu$, $4J_{ex} + \nu$, $|4J_{ex} - \nu|$. This remarkable effect is shown in Fig. 2 with the correlations

\[
\begin{align*}
C_1(\omega) = & \langle (\tau_- \otimes \tau_z + \tau_z \otimes \tau_-) (\tau_+ \otimes \tau_z + \tau_z \otimes \tau_+)(0) \rangle_{\omega} + (\omega \rightarrow -\omega) \\
C_2(\omega) = & \langle (\tau_- \otimes \tau_z)(\tau_+ \otimes \tau_z)(0) \rangle_{\omega} + (\omega \rightarrow -\omega)
\end{align*}
\]

Hence $C_1(\omega)$ probes both spins equally, as in macroscopic ESR, while $C_2(\omega)$ probes only one spin, as allowed with STM. Fig. 2 shows that the single line allowed in ESR becomes
FIG. 3. Correlations of Eq. (11) with the same parameters as Fig. 1 and exchange interaction $J_{ex}$ = 0.2 for the correlation $C_1(\omega)$ (left), and $C_2(\omega)$ (right).

FIG. 4. Correlations of Eq. (11) with the same parameters as Fig. 1 and exchange interaction $J_{ex}$ = 0.2 as well as DM interaction $J_{DM}$ = 0.2 (i.e. $\phi = \pi/4$) for the correlation $C_1(\omega)$ (left), and $C_2(\omega)$ (right).

3 lines in the STM type measurement. Thus ESR-STM is capable of probing the spectra of the dimer, i.e. the two-qubit system, in more detail.

The case with spin-orbit coupling where both $J_{ex}$, $J_{DM}$ are finite, is asymmetric within the dimer (only the 2nd spin has spin-orbit), hence both ESR and STM yield 4 lines: $\nu \pm [2\sqrt{J_{ex}^2 + J_{DM}^2} - 2J_{ex}]$ (i.e. the previous single line at $\nu$ is split), and $[2\sqrt{J_{ex}^2 + J_{DM}^2} - 2J_{ex}] \pm \nu$. Note also that there is no dark state in this case. This case is shown in Fig. 3, for the chosen case with $J_{ex} = J_{DM}$ $C_1(\omega)$ shows indeed 4 lines, however the additional two are rather weak. The STM case represented by $C_2(\omega)$ has four lines of comparable intensity.

We note that if there is an additional external interaction between the two spins $H_{ext}$ one can proceed in two ways:\[10] (i) Local method, where dissipative terms are evaluated for the original system $H_S$ and then $-i[H_{ext}, \rho_S]$ is added to the master equation, or (ii) Global
method where the total $\mathcal{H}_S + \mathcal{H}_\text{ext}$ is diagonalized and then dissipative terms evaluated. If $D$ is a measure of the strength of $\mathcal{H}_\text{ext}$ then the global method fails when $D \to 0$ since its secular assumption ignores degeneracies that are present only at $D = 0$. If, however, $D$ is large then the local method fails with incorrect dissipative terms. The crossover of validity between the two methods is estimated\cite{19} as $D$ of order of the level spacing in $\mathcal{H}_S$. We note that our previous $\mathcal{H}_\text{int}$ is formally treated as in the local method, yet this is valid even for strong $J_{\text{ex}}$ or $J_{\text{DM}}$ since these particular interactions originate directly from the system-environment coupling.

We consider as an example dipole-dipole interaction with the simplest symmetry that has rotation invariance around the magnetic field axis\cite{20}. This has a single parameter $D$ such that the interaction is

$$
\mathcal{H}_{\text{dipole}} = \frac{D}{3} [\tau_z \otimes \tau_z - \tau_+ \otimes \tau_- - \tau_- \otimes \tau_+]
$$

(12)

We study this coupling by adding $-i[\mathcal{H}_{\text{dipole}}, \rho]$ to the master equation (no exchange or DM interactions), i.e. the "local" method. This is essential for treating properly the Larmor degeneracy as well as keeping the presence of a dark state. The practical validity of this approach is expected\cite{19} to be $D/3 \lesssim \nu$. The system energies are triplet states at $\frac{1}{3}D \pm \nu$, $-\frac{2}{3}D$ and a singlet state at energy 0. The allowed ESR transitions are within the triplet states at $|D \pm \nu|$, while an STM experiment would show also the singlet-triplet transitions, i.e. additional lines at $|\frac{1}{3}D \pm \nu|$. This phenomena is shown in Fig. 4 with $\frac{D}{eV} = 0.9$ which is beyond the validity range, yet this is chosen for illustration purpose, i.e. to separate the additional two lines of the STM method.

FIG. 5. Correlations of Eq. (11) with the same parameters as Fig. 1 and dipole interaction $\frac{D}{eV} = 0.9$ for (a) the correlation $C_1(\omega)$ (left), and (b) the correlation $C_2(\omega)$ (right).
In conclusion, we have shown a number of novel resonance phenomena that can be achieved by probing dimers with an STM based experiment. These phenomena include generating exchange and DM interactions between the spins, the presence of a dark state (in some cases) that is highly significant for quantum information applications, and finally the observation of additional lines in the STM setup, providing more information on the dimer state.

We present in this supplementary details of our derivation of the master equation for various spin configurations, as well as matrix notations in section D needed for the evaluation of correlation functions.

A. Single spin

As a preliminary, consider the Hamiltonian for a single spin. The strong Coulomb interaction on the spin site allows virtual tunneling that involves the spins of the tunneling electrons (Pauli operators $\sigma$) and the local spin (Pauli operators $\tau$), derived via the Schrieffer-Wolff transformation

\begin{equation}
\mathcal{H} = \frac{1}{2} \nu \tau_z + \left[ J c_R^\dagger \sigma c_L \cdot \tau + \text{h.c.} \right] + \mathcal{H}_L + \mathcal{H}_R
\end{equation}

Here $\nu$ is the Larmor frequency ($\hbar = 1$), and $\mathcal{H}_L = \sum_k \epsilon_{kL} c_{kL}^\dagger c_{kL}$, $\mathcal{H}_R = \sum_k \epsilon_{kR} c_{kR}^\dagger c_{kR}$ are the environment (electrode) Hamiltonians with $c^\dagger$, $c$ spinors (between which $\sigma$ is acting); the energy levels $\epsilon_{kL}, \epsilon_{kR}$ include a relative voltage $V$. The tunneling is dominated by a single site so that $c_L = \sum_k c_{kL}$, $c_R = \sum_k c_{kR}$. In general there are additional exchange terms of the form $c_R^\dagger \sigma c_R \cdot \tau$, $c_L^\dagger \sigma c_L \cdot \tau$, however these lead to relaxation rates $\sim 1/\beta$ (the temperature) while the term in (13) leads to $\sim eV$, hence for the interesting case $eV \gg 1/\beta$ the latter dominates.

The interaction picture is obtained by the evolution operator ($k$ is implicit in the spectra and operators)

\begin{align*}
U_e &= e^{-i(\frac{1}{2} \nu \tau_z + \epsilon_{RL} c_{RL}^\dagger c_{RL} + \epsilon_{R} c_{R}^\dagger c_{R}) t} \\
U_e^\dagger c_R^\dagger c_L U_e &= c_R^\dagger c_L e^{i\epsilon_{RL} t} \quad \epsilon_{RL} = \epsilon_R - \epsilon_L, \quad U_e^\dagger \tau c_e U_e = \tau_e^{-i\nu_t} \quad (14)
\end{align*}
Using $\sigma \cdot \tau = 2\sigma_+\tau_- + 2\sigma_-\tau_+ + \sigma_z\tau_z$ the system-environment (SE) coupling (2nd term of (13)) in the interaction picture becomes

$$\mathcal{H}_{SE} = 2J_c^R\sigma_c + c_L\sigma_L e^{i\omega_{RL}t - i\nu t} + 2J_c^R\sigma_c + c_L\sigma_L e^{i\omega_{RL}t + i\nu t} + J_c^R\sigma_+c_L\sigma_- e^{i\omega_{RL}t} + \text{h.c.} \quad (15)$$

Hence the form of Eq. (1) in the main text with

$$A_1 = \tau_-, \quad \nu_1 = \nu \quad B_1 = 2J(c_R^\dagger\sigma_+c_L e^{i\omega_{RL}t} + c_L^\dagger\sigma_-c_R e^{-i\omega_{RL}t})$$
$$A_{-1} = \tau_+ \quad \nu_{-1} = -\nu \quad B_{-1} = B_1^\dagger$$
$$A_z = \tau_z \quad \nu_z = 0 \quad B_z = Jc_R^\dagger\sigma_+c_L e^{i\omega_{RL}t} + \text{h.c.} \quad (16)$$

Consider the correlation (implicit integration on $\epsilon_R, \epsilon_L$)

$$\Gamma_{1,-1}(s) = 4J^2 \text{Tr}[c_R^\dagger\sigma_+c_L e^{i\omega_{RL}s} + c_L^\dagger\sigma_-c_R e^{-i\omega_{RL}s})(c_R^\dagger\sigma_-c_R + c_L^\dagger\sigma_+c_L)\rho_E]$$
$$= 4J^2 \{f_R(\epsilon_R)(1 - f_L(\epsilon_L)) \text{Tr}[\sigma_+\sigma_- e^{i\omega_{RL}s} + f_L(\epsilon_L)(1 - f_R(\epsilon_R)) \text{Tr}[\sigma_-\sigma_+ e^{-i\omega_{RL}s}] \}$$
$$\Gamma_{-1,1}(s) = 4J^2 \text{Tr}[c_R^\dagger\sigma_-c_R e^{-i\omega_{RL}s} + c_L^\dagger\sigma_+c_L e^{i\omega_{RL}s})(c_R^\dagger\sigma_+c_R + c_L^\dagger\sigma_-c_L)\rho_E] = \Gamma_{1,-1}(s) \quad (17)$$

since $\text{Tr}[\sigma_+\sigma_-] = \text{Tr}[\sigma_-\sigma_+] = 1$. With a convergence factor $\eta \int_0^\infty e^{i\omega_{RL}s + i\omega - i\eta} ds = \frac{1}{i(\omega_{RL} + \omega + i\eta)}$

$$\tilde{\Gamma}_{1,-1}(\omega) = 4J^2N^2(0) \int_{\epsilon_R<\epsilon_L} \frac{-f_L(\epsilon_L)(1 - f_R(\epsilon_R))}{i(-\epsilon_{RL} + \omega + i\eta)} + \frac{-f_R(\epsilon_R)(1 - f_L(\epsilon_L))}{i(\epsilon_{RL} + \omega + i\eta)} \} \Rightarrow$$
$$\frac{1}{2} \gamma_1(\omega) = \text{Re}\tilde{\Gamma}_{1,-1}(\omega) = 4\pi J^2N^2(0) \int_{\epsilon_L} \frac{[f_L(\epsilon_L)(1 - f_R(\epsilon_L + \omega)) + f_R(\epsilon_L - \omega)(1 - f_L(\epsilon_L))]}{\epsilon_L}$$
$$= 4\pi J^2N^2(0) \{(eV + \omega) e^{\beta(eV + \omega)} e^{\beta(-eV + \omega)} - 1 + (-eV + \omega) e^{\beta(-eV + \omega)} e^{\beta(-eV + \omega)} - 1 \} \quad (18)$$

where $N(0)$ is the density of states of either environment (we assume that $N(\epsilon)$ is constant, valid for $eV \ll \text{bandwidth}$). For $V = 0$ FDT is obeyed with the bath temperature, however, not for $V \neq 0$,

$$V = 0 : \quad \gamma_1(\omega) = 16\pi J^2N^2(0)(\omega) e^{\beta\omega} e^{\beta\omega} - 1 \Rightarrow \gamma_1(-\omega) = e^{-\beta\omega}\gamma_1(\omega) \quad e^{-\beta(eV \pm \omega)} \ll 1 : \quad \gamma_1(\omega) = 8\pi J^2N^2(0)(eV + \omega) + O(e^{-\beta(eV \pm \omega)}) \Rightarrow$$
$$e^{-\beta\omega} \equiv \frac{eV - \omega}{eV + \omega} \Rightarrow \gamma_1(-\omega) = e^{-\beta\omega}\gamma_1(\omega) \quad (19)$$

$1/\beta^*$ defines an effective temperature for the spin population, which in general depends on the frequency $\omega = \nu$; if $eV \gg 1/\beta, \omega$ then $\beta^* \rightarrow 2/eV$. The condition $e^{-\beta(eV \pm \omega)} \ll 1$ simplifies the following calculation, though it is not essential. Furthermore, it justifies the Markoff assumption since for $\omega \lesssim eV$ $\gamma_1(\omega)$ is weakly $\omega$ dependent and $\Gamma_1(s)$ is short ranged.
The imaginary part generates in general a term $\sim -i[H', \rho_S]$ so that $H'$ is a shift of the Hamiltonian. We have,

$$\text{Im} \tilde{\Gamma}_{1,-1}(\omega) = -4J^2N^2(0)P.P. \int_{\epsilon_{R,L}} f_{L}(\epsilon_{L})(1-f_{R}(\epsilon_{R}))(\epsilon_{RL} + \omega) - f_{R}(\epsilon_{R})(1-f_{L}(\epsilon_{L}))(\epsilon_{RL} - \omega)$$

$$= -4J^2N^2(0)P.P. \int_{\epsilon_{R,L}} \{\omega f_{L}(\epsilon_{L})(1-f_{R}(\epsilon_{R})) + f_{R}(\epsilon_{R})(1-f_{L}(\epsilon_{L})) + \epsilon_{RL} f_{L}(\epsilon_{L}) - f_{R}(\epsilon_{R})\}$$

$$\approx -4J^2N^2(0)\{\omega \ln \frac{eV}{\Lambda} + P.P. \int_{\epsilon_{R,L}} \frac{f_{L}(\epsilon_{L}) - f_{R}(\epsilon_{R})}{\epsilon_{RL}}\}$$

(20)

where a cutoff $\Lambda \gtrsim eV$ is needed. The 1st term of $\text{Im} \tilde{\Gamma}_{1,-1}(\omega)$ is smaller than the resonance linewidth (see below), yet we keep it, neglecting only $e^{-\beta(eV \pm \omega)}$ terms. The 2nd term of $\text{Im} \tilde{\Gamma}_{1,-1}(\omega)$ strongly depends on cutoffs so that the $\omega$ dependence can be neglected, this term is

$$\approx -4J^2N^2(0)P.P. \sum_{\Lambda} \int_{-\Lambda}^{\Lambda} d\epsilon_{R} f_{R}(\epsilon_{R}) \int_{-\Lambda'}^{\Lambda'} d\epsilon_{L} f_{L}(\epsilon_{L}) \int_{-\Lambda}^{\Lambda} d\epsilon_{R} f_{R}(\epsilon_{R})$$

$$= -4J^2N^2(0)\{2\Lambda' \ln \frac{\Lambda + \Lambda'}{\Lambda'} + \Lambda \ln \frac{(\Lambda + \Lambda')^2}{\Lambda^2 - V^2} - V \ln \frac{V + \Lambda}{\Lambda - \Lambda'}\} \equiv -4J^2N^2(0)\delta_2$$

$$\Rightarrow \text{Im} \tilde{\Gamma}_{1,-1}(\omega) = -4J^2N^2(0)(\omega \ln \frac{eV}{\Lambda} + \delta_2)$$

(21)

where $\Lambda, \Lambda'$ are the cutoffs (bandwidths) of the R,L electrodes, respectively, and temperature is neglected, being relatively small. When $\Lambda, \Lambda' \gg V$ then $\delta_2 = 2\Lambda \ln \frac{\Lambda + \Lambda'}{\Lambda'} + 2\Lambda \ln \frac{\Lambda + \Lambda'}{\Lambda}$, i.e. it diverges logarithmically when one of the cutoffs is large and linearly when both are large.

In the case of 2-spins (see below) this term leads to an RKKY type exchange interaction between the spins.

For the $z$ correlation, the integral is the same as for $\Gamma_{1,-1}$ except that $\omega = 0$, hence

$$\Gamma_{zz}(s) = J^2 \text{Tr}[(c_R^\dagger \sigma_z c_L^e \kappa^{\text{RL}} + \text{h.c.})(c_R^\dagger \sigma_z c_L^e + \text{h.c.})\rho_E] =$$

$$J^2 f_{L}(\epsilon_{L})(1-f_{R}(\epsilon_{R})) \text{Tr}[\sigma_z^2] e^{-i\kappa^{\text{RL}}} + J^2 f_{R}(\epsilon_{R})(1-f_{L}(\epsilon_{L})) \text{Tr}[\sigma_z^2] e^{+i\kappa^{\text{RL}}}$$

$$\text{Im} \tilde{\Gamma}_{zz}(0) = 2J^2N^2(0) \int_{\epsilon_{R,L}} \{-f_{L}(\epsilon_{L})(1-f_{R}(\epsilon_{R})) - f_{R}(\epsilon_{R})(1-f_{L}(\epsilon_{L}))\}$$

$$= 2\pi J^2N^2(0)eV - 2iJ^2N^2(0)\delta_2$$

(22)

The master equation (Eq. (2) in the main text) becomes

$$\frac{d\rho_S}{dt} = \Gamma_{1,-1}(-\nu)[\tau_+ \rho_S \tau_- - \tau_- \tau_+ \rho_S] + \Gamma_{1,-1}(\nu)[\tau_- \rho_S \tau_+ - \tau_+ \tau_- \rho_S] + \Gamma_{zz}(0)[\tau_z \rho_S \tau_z - \tau_z^2 \rho_S] + \text{h.c.}$$

(23)
Consider first only imaginary terms, defining \( \delta_1 = \nu \ln \frac{V}{\chi} \),

\[
-4iJ^2N^2(0)\{(-\delta_1 + \delta_2)[\tau_+\rho_\tau - \tau_-\rho_\tau] - (-\delta_1 + \delta_2)[\tau_+\rho_\tau - \rho_\tau\tau_+] + (\delta_1 + \delta_2)[\tau_-\rho_\tau - \tau_+\rho_\tau]
\]

\[
- (\delta_1 + \delta_2)[\tau_-\rho_\tau + \rho_\tau\tau_-] + \frac{1}{2}\delta_2[\tau_+\rho_\tau - \rho_\tau] - \frac{1}{2}\delta_2[\tau_-\rho_\tau - \rho_\tau] \} = -i[H', \rho_\tau]
\]

\[
H' = -4J^2N^2(0)[(-\delta_1 + \delta_2)\tau_-\tau_+ + (\delta_1 + \delta_2)\tau_+\tau_-] = -4J^2N^2(0)[\delta_1\tau_z + \delta_2 \cdot 1]
\]

Hence \( \delta_1 \) can be included as a shift of the Larmor frequency (which is actually smaller than the linewidth) while \( \delta_2 \) is a mere constant in the effective Hamiltonian.

Denoting \( \gamma_1 = \gamma_{\pm 1}(\nu) \), \( \gamma_{-1} = \gamma_{\pm 1}(\nu) \), the master equation for \( \rho_S = \frac{1}{2} \cdot 1 + \rho_z(t)\tau_z + \rho_+(t)\tau_+ + \rho_-(t)\tau_- \) becomes (without the imaginary terms)

\[
\frac{d}{dt}[\rho_z(t)\tau_z + \rho_+(t)\tau_+ + \rho_-(t)\tau_-]
\]

\[
= \gamma_0[\tau_+\rho_\tau - \rho_\tau] + \frac{1}{2}\gamma_1[\tau_+\rho_\tau - \tau_-\rho_\tau + \rho_\tau + \rho_\tau] + \frac{1}{2}\gamma_{-1}[\tau_-\rho_\tau + \tau_+ - \rho_\tau + \rho_\tau]
\]

\[
= \gamma_0[\rho_+(\tau_+\tau_+ - \tau_-) + \rho_-\tau_-] + \frac{1}{2}\gamma_1[\tau_+\tau_+ - \tau_-\tau_- + \rho_\tau + \rho_\tau] + \frac{1}{2}\gamma_{-1}[\tau_-\tau_- - \tau_+\tau_+ + \rho_\tau + \rho_\tau]
\]

\[
= -2\gamma_0(\rho_+ + \rho_-) - \frac{1}{2}\gamma_1(\tau_+ + 2\rho_+\tau_- + \rho_-\tau_- + \rho_+\tau_+) - \frac{1}{2}\gamma_{-1}(\tau_- + 2\rho_-\tau_+ + \rho_-\tau_- + \rho_+\tau_-)
\]

using \( \tau_+\tau_+ = \pm\tau_+ \), \( \tau_+\tau_- = \tau_+ - \tau_- \), \( \tau_-\tau_+ = \tau_+ - \tau_- \), \( \tau_+\tau_+ = \tau_+ + \tau_- \), \( \tau_-\tau_- = \tau_+ - \tau_- \). Comparing coefficients yields the standard form of a Bloch equation,

\[
\frac{d\rho_z}{dt} = -(\gamma_1 + \gamma_-)\rho_z + \frac{1}{2}(\gamma_1 - \gamma_-) = -\frac{1}{T_1}(\rho_z - \rho_z^0)
\]

\[
\frac{d\rho_+}{dt} = -2\gamma_0\rho_+ - \frac{1}{2}(\gamma_1 + \gamma_-)\rho_+ = -\frac{1}{T_2}\rho_+
\]

\[
\frac{1}{T_1} = 16\pi J^2eVN^2(0), \quad \frac{1}{T_2} = \frac{1}{2T_1} + 2\gamma_0 = 16\pi J^2eVN^2(0)
\]

Since \( \rho_z^0 = \frac{1}{2}\langle \sigma_z \rangle_0 = -\frac{1}{2} \tanh \frac{1}{2} \beta \nu \) \( |\langle \sigma_z \rangle_0| < 0 \) for \( \nu > 0 \), as expected. From [18], with full dependence on parameters

\[
\rho_z^0 = \frac{eV - \nu}{\tanh \frac{1}{2} \beta (eV + \nu)} + \frac{eV - \nu}{\tanh \frac{1}{2} \beta (eV + \nu)}
\]

a result known from studies of the Kondo model [2].

**B. Two spins \( \nu_1 \neq \nu_2 \)**

Consider two spins with Pauli operators \( \tau_1, \tau_2 \) and Larmor frequencies \( \nu_1, \nu_2 \) so that \( |\nu_1 - \nu_2| \ll \Gamma \), where \( \Gamma \) is a typical linewidth or \( 1/T_2 \). The secular treatment is valid in this
case, i.e. time dependent term $\sim e^{i(\nu_1-\nu_2)t}$ are neglected. The latter terms become significant when $\nu_1 = \nu_2$, treated in the next subsection. Both spins are coupled by tunneling in parallel to the two environments, $L, R$. The Hamiltonian has the form

$$ \mathcal{H} = \frac{1}{2} \nu_1 \tau_z \otimes 1 + \frac{1}{2} \nu_2 1 \otimes \tau_z + [J_1 c_R^\dagger \sigma_L \cdot \tau \otimes 1 + J_2 e^{i R L \sigma R L t} u_c 1 \otimes \tau + \text{h.c.}] + \mathcal{H}_{R, L} \quad (27) $$

where here we allow also $\hat{u} = e^{i \sigma_2 \phi} e^{i \sigma_y \theta}$ representing spin-orbit on the 2nd spin tunneling.

The interaction picture yields

$$ U_e = e^{-i [\frac{1}{2} \nu_1 \tau_z \otimes 1 + \frac{1}{2} \nu_2 1 \otimes \tau_z + \epsilon_L c_1^\dagger c_L + \epsilon_R c_R^\dagger c_R] t} \quad (28) $$

$$ \mathcal{H}_{SE} = 2 J_1 c_R^\dagger \sigma c_L \tau \otimes 1 e^{i R L \tau_L t - i \nu_1 t} + 2 J_1 c_R^\dagger \sigma - c_L \tau_+ \otimes 1 e^{i R L \tau_L t + i \nu_1 t} + J_1 c_R^\dagger \sigma_L \tau_+ \otimes 1 e^{i R L t} + J_2 [2 c_R^\dagger \sigma_R \hat{u} c_L \otimes \tau_+ e^{i R L \tau_L t - i \nu_2 t} + 2 c_R^\dagger \sigma_R \hat{u} c_L \otimes \tau_+ e^{i R L \tau_L t + i \nu_2 t} + c_R^\dagger \sigma_R \hat{u} c_L \otimes \tau_+ e^{i R L t}] + \text{h.c.} $$

Hence $\mathcal{H}_{SE}$ has the form of Eq. (1) in the main text with

$$ A_1 = \tau_+ \otimes 1 \quad \nu_1 \quad B_1 = 2 J_1 (c_R^\dagger \sigma_R \hat{u} c_L e^{i R L t} + c_L^\dagger \sigma_R \hat{u} c_R) $$

$$ A_{-1} = \tau_- \otimes 1 \quad \nu_{-1} = -\nu_1 \quad B_{-1} = B_1^\dagger $$

$$ A_{z} = \tau_z \otimes 1 \quad \nu_2 = 0 \quad B_{z} = J_1 c_R^\dagger \sigma_R \hat{u} c_L e^{i R L t} + \text{h.c.} $$

$$ A_{-2} = 1 \otimes \tau_- \quad \nu_{-2} = -\nu_2 \quad B_{-2} = B_2^\dagger $$

$$ A_{z'} = 1 \otimes \tau_+ \quad \nu_{z'} = 0 \quad B_{z'} = J_2 c_R^\dagger \sigma_R \hat{u} c_L e^{i R L t} + \text{h.c.} $$

The terms $B_z, B_{z'}$ are degenerate and produce off diagonal terms, while correlations like $B_1 B_{-2}$ are neglected since $|\nu_1 - \nu_2| \ll \Gamma$. Therefore all correlations except $B_z B_{z'}$ follow their diagonal form Eq.[18] with $J_1, J_2$, respectively and the corresponding imaginary terms produce a small shift $\approx -4 J_i^2 N^2(0) \nu_i \ln \frac{W}{\Delta}$ in $\nu_i$, $i = 1, 2$ (note that in $\Gamma_{-2}(s) \hat{u} \hat{u}^\dagger = 1$). Hence for $e^{-\beta (eV \pm \nu_i)} \ll 1$ the real parts are

$$ \tilde{\Gamma}_{1-1}(-\nu_1) = 4 \pi J_1^2 N^2(0)(eV - \nu_1), \quad \tilde{\Gamma}_{2-2}(-\nu_2) = 4 \pi J_2^2 N^2(0)(eV - \nu_2) $$

$$ \tilde{\Gamma}_{11}(\nu_1) = 4 \pi J_1^2 N^2(0)(eV + \nu_1), \quad \tilde{\Gamma}_{22}(\nu_2) = 4 \pi J_2^2 N^2(0)(eV + \nu_2) $$

$$ \tilde{\Gamma}_{zz}(0) = \frac{1}{2} \gamma_{01} = 2 \pi J_1^2 N^2(0) eV, \quad \tilde{\Gamma}_{zz'}(0) = \frac{1}{2} \gamma_{02} = 2 \pi J_2^2 N^2(0) eV $$

The real parts define $\frac{1}{2} \gamma_{\pm i} = 4 \pi J_i^2 N^2(0)(eV \mp \nu_i)$. 
The off diagonal term is

\[
\Gamma_{zz'} = \text{Tr}[B_z(s)B_{z'}(0)\rho_E] = J_1J_2\left((c_R^\dagger\sigma_zc_L e^{i\mathcal{E}_{RL}^z} + c_L^\dagger\sigma_zc_R e^{-i\mathcal{E}_{RL}^z})(c_R^\dagger\sigma_z\hat{u}c_L + c_L^\dagger\hat{u}^\dagger\sigma_zc_R)\right)
\]

\[
= J_1J_2\{f_R(\epsilon_R)(1 - f_L(\epsilon_L))e^{i\mathcal{E}_{RL}^z}\text{Tr}[\sigma_z^2\hat{u}] + f_L(\epsilon_L)(1 - f_R(\epsilon_R))e^{-i\mathcal{E}_{RL}^z}\text{Tr}[\sigma_z^2\hat{u}]\}
\]

\[
\Gamma_{zz'}(\omega) = 2J_1J_2N^2(0)\cos \frac{1}{2}\theta \cos \phi \int_{\epsilon_L,\epsilon_R} \left\{-f_L(\epsilon_L)(1 - f_R(\epsilon_R)) + f_R(\epsilon_R)(1 - f_L(\epsilon_L))\right\}
\]

\[
\text{Re}\Gamma_{zz'}(0) = \gamma_z = 2\pi J_1J_2N^2(0)eV \cos \frac{1}{2}\theta \cos \phi, \quad \text{Im}\Gamma_{zz'}(0) = -2J_1J_2N^2(0)\cos \frac{1}{2}\theta \cos \phi \cdot \delta_2
\]

using \(\text{Tr}[\hat{u}] = \text{Tr}[\hat{u}^\dagger] = 2\cos \frac{1}{2}\theta \cos \phi\) and neglecting in the real part the \(f_R(\epsilon_L)(1 - f_L(\epsilon_L))\) term when \(eV > 0\) on the L lead. Note also \(\Gamma_{zz'}(s) = \Gamma_{zz'}(\tau)\).

The imaginary term \(\sim \delta_2\) produces in the master equation

\[
i\text{Im}\Gamma_{zz'}(0)[1 \otimes \tau_z\rho_S\tau_z \otimes 1 - \tau_z \otimes \tau_z\rho_S - \tau_z \otimes \rho_S\tau_z \otimes \tau_z] +
\]

\[
i\text{Im}\Gamma_{zz'}(0)[\tau_z \otimes 1\rho_S 1 \otimes \tau_z - \tau_z \otimes \rho_S\tau_z 1 \otimes 1 + \rho_S\tau_z \otimes \tau_z] = -i[H_1, \rho_S]
\]

\[
H_1 = -J_{ex}\tau_z \otimes \tau_z, \quad J_{ex} = 4J_1J_2N^2(0)\cos \frac{1}{2}\theta \cos \phi \cdot \delta_2
\]

This anisotropic exchange term may have a noticeable shift on the observed resonance frequencies.

Consider a general form \(\rho_S(t) = \sum_{\alpha,\beta} \rho_{\alpha,\beta}(t)\tau_\alpha \otimes \tau_\beta\), with \(\alpha, \beta = 0, z, +, -\) so that \(\tau_\alpha = 1, \tau_z, \tau_+, \tau_-\) and \(\rho_{00} = \frac{1}{4}\). The diagonal terms produce the same terms as in \((26)\) except that the \(\rho_{00} = \frac{1}{4}\) replaces the \(\rho_{00} = \frac{1}{2}\) of the single spin case, changing the equilibrium definitions. Apart from \(\rho_{z,\pm}\) (see below) we have

\[
\frac{d\rho_{z0}}{dt} = -\frac{1}{T_1^{(1)}}(\rho_{z0} - \rho_{0z}), \quad \frac{d\rho_{0z}}{dt} = -\frac{1}{T_1^{(2)}}(\rho_{0z} - \rho_{z0}), \quad \rho_{20} = \frac{1}{4}\gamma_1 - \gamma_{-1}, \quad \rho_{0z} = \frac{1}{4}\gamma_2 - \gamma_{-2}
\]

\[
\frac{d\rho_{z+}}{dt} = -\frac{1}{T_2^{(1)}}\rho_{z+}, \quad \frac{d\rho_{0+}}{dt} = -\frac{1}{T_2^{(2)}}\rho_{0+}, \quad \frac{1}{T_1^{(1)}} = \gamma_{i} + \gamma_{-i}, \quad \frac{1}{T_2^{(1)}} = \frac{1}{2}(\gamma_i + \gamma_{-i}) + 2\gamma_{0i}
\]

\[
\frac{d\rho_{zz}}{dt} = -\gamma_{i} + \gamma_{-i})\rho_{zz} + (\gamma_i - \gamma_{-i})\rho_{0z} - (\gamma_2 + \gamma_{-2})\rho_{zz} + (\gamma_2 - \gamma_{-2})\rho_{z0}
\]

\[
\frac{d\rho_{z+}}{dt} = -\gamma_{i} + \gamma_{-i})\rho_{z+} + (\gamma_i - \gamma_{-i})\rho_{0+} - \frac{1}{T_2^{(2)}}\rho_{z+}
\]

\[
\frac{d\rho_{+z}}{dt} = -\frac{1}{T_2^{(1)}}\rho_{+z} - (\gamma_2 + \gamma_{-2})\rho_{+z} + (\gamma_2 - \gamma_{-2})\rho_{+0}
\]

where \(T_2^{(1),(2)}\) are the corresponding \(T_2\) relaxation times. Equations with \(+ \rightarrow -\) are related
by c.c. ($\rho_S$ is hermitian), e.g. $\rho_{z-} = \rho_{z+}^*$. In equilibrium (note $\beta_i^*$ depends on $\nu_i$, $i = 1, 2$)

\[
S_{z1} = \frac{1}{2} \tau_z \otimes 1, \quad \langle S_{z1} \rangle_0 = 2 \rho_{0z}^0 = -\frac{1}{2} \tanh(\frac{1}{2} \beta_1^* \nu_1) \approx -\frac{\nu_1}{2eV}
\]

\[
S_{z2} = \frac{1}{2} 1 \otimes \tau_z, \quad \langle S_{z2} \rangle_0 = 2 \rho_{0z}^0 = -\frac{1}{2} \tanh(\frac{1}{2} \beta_2^* \nu_2)
\]

\[
S_{z1}S_{z2} = \frac{1}{4} \tau_z \otimes \tau_z, \quad \langle S_{z1}S_{z2} \rangle_0 = \rho_{zz}^0 = \frac{(\gamma_1 - \gamma_{-1})\rho_{0z}^0 + (\gamma_2 - \gamma_{-2})\rho_{20}^0}{\gamma_1 + \gamma_{-1} + \gamma_2 + \gamma_{-2}}
\]

\[
= \frac{1}{4} \tanh(\frac{1}{2} \beta_1^* \nu_1) \tanh(\frac{1}{2} \beta_2^* \nu_2) = \langle S_{z1} \rangle_0 \langle S_{z2} \rangle_0 .
\]

Consider next the $\text{Re} \tilde{\Gamma}_{z'z}(0) = \gamma_z$ term in the master equation

\[
\text{Re} \tilde{\Gamma}_{z'z}(0) [A_{z'} \rho_S A_z - A_z A_{z'} \rho_S] + \text{h.c.} = \gamma_z \sum_{\alpha, \beta} \rho_{\alpha \beta} [1 \otimes \tau_z \cdot \tau_\alpha \otimes \tau_\beta \cdot \tau_z \otimes 1
\]

\[- \tau_z \otimes 1 \cdot 1 \otimes \tau_\alpha \otimes \tau_\beta + \text{h.c.} = \gamma_z \sum_{\alpha, \beta} \rho_{\alpha \beta} [\tau_\alpha \tau_z \otimes \tau_\beta \tau_z - \tau_z \tau_\alpha \otimes \tau_\beta \tau_z] + \text{h.c.}
\]

\[
= \gamma_z \sum_{\pm, \beta} 2 \rho_{\pm \beta}(\mp) \tau_\pm \otimes \tau_\beta \tau_z + \text{h.c.} = \gamma_z \sum_{\pm, \beta = 0, \pm'} 2 [\rho_{\pm \beta}(\mp) \tau_\pm \otimes \tau_\beta + \rho_{\mp \beta}(\mp) \tau_\beta \otimes \tau_\tau] +
\]

\[
\gamma_z \sum_{\pm, \pm} 2 [\rho_{\pm \pm}(\mp) \tau_\pm \otimes (\pm) \tau_\pm + \rho_{\mp \pm}(\mp) \tau_\pm \otimes (\mp) \tau_\pm] = 4 \gamma_z \sum_{\pm, \pm} \rho_{\pm \pm}(\mp) \tau_\pm \otimes (\pm) \tau_\pm
\]

(35)

the indices $\pm$ for $\alpha, \beta$ are uncorrelated; on the 3rd line above only $\alpha = \pm$ contributes, using $\tau_z \tau_\pm = \pm \tau_\pm$, $\tau_\pm \tau_\pm = \mp \tau_\pm$ and $\gamma_z$ is real. Similarly, for $\tilde{\Gamma}_{z'z}$ only $\beta = \pm$ contributes, hence

\[
\gamma_z [A_{z'} \rho_S A_z - A_z A_{z'} \rho_S] + \text{h.c.} = \gamma_z \sum_{\alpha, \beta} \rho_{\alpha \beta} [\tau_z \otimes 1 \cdot \tau_\alpha \otimes \tau_\beta \cdot 1 \otimes \tau_z
\]

\[- 1 \otimes \tau_\beta \cdot \tau_z \otimes 1 \cdot \tau_\alpha \otimes \tau_\beta + \text{h.c.} = \gamma_z \sum_{\alpha, \beta} \rho_{\alpha \beta} [\tau_\alpha \tau_z \otimes \tau_\beta \tau_z - \tau_z \tau_\alpha \otimes \tau_\beta \tau_z] + \text{h.c.}
\]

\[
= \gamma_z \sum_{\alpha, \pm} 2 \rho_{\alpha \pm}(\mp) \tau_\pm \otimes (\mp) \tau_\pm + \text{h.c.} = \gamma_z \sum_{\alpha = 0, \pm, \beta = \pm} 2 [\rho_{\alpha \pm}(\mp) \tau_\pm \otimes (\mp) \tau_\pm + \rho_{\alpha \pm}(\mp) \tau_\pm \otimes (\mp) \tau_\pm] +
\]

\[
+ \gamma_z \sum_{\pm, \pm} 2 [\rho_{\pm \pm}(\mp) \tau_\pm \otimes (\pm) \tau_\pm + \rho_{\mp \pm}(\mp) \tau_\pm \otimes (\mp) \tau_\pm] = 4 \gamma_z \sum_{\pm, \pm} \rho_{\pm \pm}(\mp) \tau_\pm \otimes (\pm) \tau_\pm
\]

(36)

Hence the equation that completes (33) is

\[
\frac{d \rho_{\alpha, \pm \alpha}}{dt} = -\left( \frac{1}{T_2^{(1)}} + \frac{1}{T_2^{(2)}} \right) \pm 8 \gamma_z \rho_{\alpha, \pm \alpha} = -16 \pi eVN^2(0) [J_1^2 + J_2^2 \pm J_1J_2 \cos \frac{1}{2} \theta \cos \phi] \rho_{\alpha, \pm \alpha}
\]

(37)
C. Two resonant spins $\nu_1 = \nu_2 \equiv \nu$

The case $\nu_1 = \nu_2 \equiv \nu$ allows for new time-independent terms in the master equation (Eq. (2) in the main text)

\[
\frac{dp}{dt} = \ldots + \tilde{\Gamma}_{2-1}(-\nu_1)[\tau_+ \otimes 1 \rho_S 1 \otimes \tau_- - \tau_+ \otimes \tau_- \rho_S] + \text{h.c.} \\
+ \tilde{\Gamma}_{-21}(\nu_1)[\tau_- \otimes 1 \rho_S 1 \otimes \tau_- \otimes \tau_+ \rho_S] + \text{h.c.} \\
+ \tilde{\Gamma}_{1-2}(-\nu_2)[1 \otimes \tau_+ \rho_S \tau_- \otimes 1 - \tau_- \otimes \tau_+ \rho_S] + \text{h.c.} \\
+ \tilde{\Gamma}_{-12}(\nu_2)[1 \otimes \tau_- \rho_S \tau_+ \otimes 1 - \tau_+ \otimes \tau_- \rho_S] + \text{h.c.}
\] (38)

The correlations are

\[
\tilde{\Gamma}_{2-1}(-\nu_1) = \int_0^\infty \text{Tr}[B_2(s)B_{-1}(0)\rho_E]e^{-i\nu_1 s} ds \\
= 4J_1J_2 \int_0^\infty \text{Tr}[(c_R^d \sigma_c L e^{i\nu_1 L s} + c_L^d \sigma_c R e^{-i\nu_1 L s})(c_R^d \sigma_c L + c_L^d \sigma_c R)\rho_E]e^{-i\nu_1 s} ds = 4J_1J_2 \times \int_0^\infty \{f_R(\nu_1)(1 - f_L(\nu_1)) \text{Tr}[\sigma_+ \sigma_-]e^{i\nu_1 L s} + f_L(\nu_1)(1 - f_R(\nu_1)) \text{Tr}[\sigma_+ \sigma_-]e^{-i\nu_1 L s}\}e^{i\nu_1 s} ds \\
= \eta(eV - \nu)e^{-i\phi} - i\frac{\eta}{\pi}(-\delta_1 + \delta_2)e^{-i\phi} + O(e^{-\beta(eV \pm \nu)})
\] (39)

where $\text{Tr}[\sigma_+ \sigma_-] = \text{Tr}[\hat{u}^\dagger \sigma_+ \sigma_-] = \cos \frac{1}{2} \theta e^{-i\phi}$, $\eta = 4\pi J_1J_2N^2(0) \cos \frac{1}{2} \theta$, $\delta_1 = \nu \ln \frac{eV}{A}$, $\delta_2$ is defined in Eq. (21). The integral above is identical to that of Eq. (18), so that the last line is obtained from (18)21 with $J^2 \rightarrow J_1J_2 \cos \frac{1}{2} \theta e^{-i\phi}$.

The other correlations are then

\[
\tilde{\Gamma}_{-21}(\nu_1) = \int_0^\infty \text{Tr}[B_{-2}(s)B_1(0)\rho_E]e^{i\nu_1 s} ds \\
= 4J_1J_2 \int_0^\infty \text{Tr}[(c_L^d \hat{u}^\dagger \sigma_- c_R e^{-i\nu_1 L s} + c_R^d \sigma_- \hat{u} c_L e^{i\nu_1 L s})(c_R^d \sigma_+ c_L + c_L^d \sigma_+ c_R)\rho_E]e^{i\nu_1 s} ds = 4J_1J_2 \times \int_0^\infty \{f_R(\nu_1)(1 - f_L(\nu_1)) \text{Tr}[\sigma_+ \sigma_-]e^{i\nu_1 L s} + f_L(\nu_1)(1 - f_R(\nu_1)) \text{Tr}[\sigma_+ \sigma_-]e^{-i\nu_1 L s}\}e^{i\nu_1 s} ds \\
= \eta(eV + \nu)e^{i\phi} - i\frac{\eta}{\pi}(\delta_1 + \delta_2)e^{i\phi} + O(e^{-\beta(eV \pm \nu)})
\] (40)

\[
\tilde{\Gamma}_{1-2}(-\nu_2) = 4J_1J_2 \int_0^\infty \text{Tr}[(c_R^d \sigma_- c_L e^{i\nu_2 L s} + c_L^d \sigma_- \hat{u} c_R e^{-i\nu_2 L s})(c_R^d \hat{u}^\dagger \sigma_- c_L + c_L^d \hat{u} c_R)\rho_E]e^{-i\nu_2 s} ds \\
= 4J_1J_2 \int_0^\infty \{f_R(\nu_2)(1 - f_L(\nu_1)) \text{Tr}[\sigma_+ \sigma_-]e^{i\nu_2 L s} + f_L(\nu_1)(1 - f_R(\nu_2)) \text{Tr}[\sigma_+ \sigma_-]e^{-i\nu_2 L s}\}e^{-i\nu_2 s} ds \\
= \eta(eV - \nu)e^{i\phi} - i\frac{\eta}{\pi}(-\delta_1 + \delta_2)e^{i\phi} + O(e^{-\beta(eV \pm \nu)})
\] (41)
\[ \tilde{\Gamma}_{-12}(\nu_2) = 4J_1J_2 \int_0^\infty \text{Tr}\left[ (c_L^\dagger \sigma_+ c_R e^{-i\epsilon R L} + c_R^\dagger \sigma_- c_L e^{i\epsilon R L})(c_R^\dagger \sigma_+ \hat{u} c_L + c_L^\dagger \hat{u}^\dagger \sigma_+ c_R)\rho_E\right] e^{i\nu_2 s} ds \]
\[ = 4J_1J_2 \int_0^\infty \left\{ f_R(\epsilon_R)(1 - f_L(\epsilon_L)) \text{Tr}[\sigma_- \hat{u}^\dagger \sigma_+ e^{i\epsilon R L} + f_L(\epsilon_L)(1 - f_R(\epsilon_R)) \text{Tr}[\sigma_- \hat{u}^\dagger \sigma_+] e^{-i\epsilon R L}\right\} e^{i\nu_2 s} ds \]
\[ = \eta(eV + \nu) e^{-i\phi} - i\frac{\eta}{\pi}(\delta_1 + \delta_2)e^{-i\phi} + O(e^{-\beta(eV + \nu)}) \quad (42) \]

Consider next all imaginary terms
\[ -i\frac{\eta}{\pi}(\delta_1 + \delta_2)e^{-i\phi}[\tau_+ \otimes \tau_- + \tau_- \otimes \tau_+] + i\frac{\eta}{\pi}(\delta_1 + \delta_2)e^{-i\phi}[\tau_+ \otimes \tau_- + \tau_- \otimes \tau_+] \]
\[ -i\frac{\eta}{\pi}(\delta_1 + \delta_2)e^{-i\phi}[\tau_- \otimes \tau_+ - \tau_- \otimes \tau_+] + i\frac{\eta}{\pi}(\delta_1 + \delta_2)e^{-i\phi}[\tau_- \otimes \tau_+ - \tau_- \otimes \tau_+] \]
\[ -i\frac{\eta}{\pi}(\delta_1 + \delta_2)e^{-i\phi}[\tau_- \otimes \tau_+ - \tau_- \otimes \tau_+ + \tau_- \otimes \tau_-] + i\frac{\eta}{\pi}(\delta_1 + \delta_2)e^{-i\phi}[\tau_- \otimes \tau_+ - \tau_- \otimes \tau_+] = \]
\[ 2i\frac{\eta}{\pi}(\delta_1 + \delta_2)e^{-i\phi}[\tau_- \otimes \tau_+ - \tau_- \otimes \tau_-] + \text{h.c.} = -\frac{\eta}{\pi}\delta_2 \cos \phi[\tau_x \otimes \tau_x + \tau_y \otimes \tau_y] - \frac{\eta}{\pi}\delta_2 \sin \phi[\tau_x \otimes \tau_y - \tau_y \otimes \tau_x] \]

Note that \( \delta_1 \) cancels, as it changes sign with \( \nu \). The \( zz' \) correlation is the same as for the \( \nu_1 \neq \nu_2 \) case, Eq. (32), so that the total induced Hamiltonian for the two spin operators becomes

\[ \mathcal{H}_3 = \mathcal{H}_1 + \mathcal{H}_2 = -J_{ex} \tau_1 \cdot \tau_2 + J_{DM}[\tau_1 \times \tau_2] \]
\[ J_{ex} = 4J_1J_2N^2(0)\delta_2 \cos \frac{\theta}{2} \sin \phi, \quad J_{DM} = 4J_1J_2N^2(0)\delta_2 \cos \frac{\theta}{2} \cos \phi \quad (44) \]

where \( J_{DM} \) is a Dzyaloshinskii-Moriya coupling.

The various real contributions to the master equation are (up to their c.c.)
\[ \tilde{\Gamma}_{-1}(-\nu_1) = \eta(eV - \nu_1)e^{-i\phi} : \quad \tau_+ \otimes 1 \sum_{\alpha\beta} \rho_{\alpha\beta} \tau_\alpha \otimes \tau_\beta 1 \otimes \tau_- - \tau_+ \otimes \tau_+ \sum_{\alpha\beta} \rho_{\alpha\beta} \tau_\alpha \otimes \tau_\beta \quad (45) \]
\[ = \sum_{\alpha} \sum_{\beta = z,z_+} \rho_{\alpha\beta} [\tau_+ \tau_\alpha \otimes \tau_\beta \tau_- - \tau_+ \tau_\alpha \otimes \tau_- \tau_\beta] = \sum_{\alpha = 0,z,-} \left[ -2\rho_{\alpha z} \tau_+ \tau_\alpha \otimes \tau_- + \rho_{\alpha +} \tau_+ \tau_\alpha \otimes \tau_+ \right] \]
\[ = -2\rho_{0z} \tau_+ \otimes \tau_- + 2\rho_{zz} \tau_+ \otimes \tau_- - \rho_{-z}(1 + \tau_+) \otimes \tau_- + \rho_{0+} \tau_+ \otimes \tau_z - \rho_{+z} \tau_+ \otimes \tau_+ + \frac{1}{2} \rho_{-+}(1 + \tau_z) \otimes \tau_z \]

\[ \tilde{\Gamma}_{-1}(\nu_1) = \eta(eV + \nu_1)e^{i\phi} : \quad \tau_- \otimes 1 \sum_{\alpha\beta} \rho_{\alpha\beta} \tau_\alpha \otimes \tau_\beta 1 \otimes \tau_+ - \tau_- \otimes \tau_- \sum_{\alpha\beta} \rho_{\alpha\beta} \tau_\alpha \otimes \tau_\beta \quad (46) \]
\[ = \sum_{\alpha} \sum_{\beta = z,z_-} \rho_{\alpha\beta} [\tau_- \tau_\alpha \otimes \tau_\beta \tau_+ - \tau_- \tau_\alpha \otimes \tau_+ \tau_\beta] = \sum_{\alpha = 0,z,+} \left[ 2\rho_{\alpha z} \tau_- \tau_\alpha \otimes \tau_+ - \rho_{\alpha -} \tau_- \tau_\alpha \otimes \tau_+ \right] \]
\[ = 2\rho_{0z} \tau_- \otimes \tau_+ + 2\rho_{zz} \tau_- \otimes \tau_+ + \rho_{+z}(1 - \tau_+) \otimes \tau_+ - \rho_{0-} \tau_- \otimes \tau_- - \rho_{-z} \tau_- \otimes \tau_+ - \frac{1}{2} \rho_{-+}(1 - \tau_z) \otimes \tau_z \]
\[\tilde{\Gamma}_{1-2}(-\nu_2) = \eta(eV - \nu)e^{i\phi} : 1 \otimes \tau_+ \sum_{\alpha\beta} \rho_{\alpha\beta} \tau_\alpha \otimes \tau_\beta \tau_- \otimes 1 - \tau_- \otimes \tau_+ \sum_{\alpha\beta} \rho_{\alpha\beta} \tau_\alpha \otimes \tau_\beta \]  
(47)

\[\tilde{\Gamma}_{-12}(\nu_2) = \eta(eV + \nu)e^{-i\phi} : 1 \otimes \tau_- \sum_{\alpha\beta} \rho_{\alpha\beta} \tau_\alpha \otimes \tau_\beta \tau_+ \otimes 1 - \tau_+ \otimes \tau_- \sum_{\alpha\beta} \rho_{\alpha\beta} \tau_\alpha \otimes \tau_\beta \]  
(48)

The addition to the previous terms of Eqs. (33,37) (denoted by \(...\)) of the master’s equation, keeping \(\sim \nu\) terms, while neglecting \(O(e^{-\beta(eV+\nu)})\), are

\[
\frac{d\rho_{00}}{dt} = \ldots + \frac{1}{2}\eta(eV - \nu)e^{i\phi}\rho_{0-} - \frac{1}{2}\eta(eV + \nu)e^{-i\phi}\rho_{0+} + c.c. = -\eta\nu(e^{i\phi}\rho_{0+} + e^{-i\phi}\rho_{0-})
\]

\[
\frac{d\rho_{02}}{dt} = \ldots + \frac{1}{2}\eta(eV - \nu)e^{-i\phi}\rho_{2-} - \frac{1}{2}\eta(eV + \nu)e^{i\phi}\rho_{2+} + c.c. = -\eta\nu(e^{i\phi}\rho_{2+} + e^{-i\phi}\rho_{2-})
\]

\[
\frac{d\rho_{0+}}{dt} = -\eta(eV - \nu)e^{-i\phi}\rho_{2+} + \eta(eV + \nu)e^{i\phi}\rho_{2+} = 2\eta\nu e^{-i\phi}\rho_{2+}
\]

\[
\frac{d\rho_{0-}}{dt} = -\eta(eV - \nu)e^{i\phi}\rho_{2-} + \eta(eV + \nu)e^{-i\phi}\rho_{2-} = 2\eta\nu e^{i\phi}\rho_{2-}
\]

\[
\frac{d\rho_{2z}}{dt} = \ldots + \frac{1}{2}\eta(eV - \nu)e^{-i\phi}\rho_{2-} + \frac{1}{2}\eta(eV + \nu)e^{i\phi}\rho_{2+} + \frac{1}{2}\eta(eV - \nu)e^{i\phi}\rho_{2-} + \frac{1}{2}\eta(eV + \nu)e^{-i\phi}\rho_{2+}
\]

\[
\frac{d\rho_{2z}}{dt} = \ldots + \eta e^{i\phi}[-(eV - \nu)\rho_{2z} - (eV + \nu)\rho_{2z} + (eV - \nu)\rho_{00}]
\]

\[
\frac{d\rho_{2z}}{dt} = \ldots + \eta e^{-i\phi}[(eV - \nu)\rho_{00} - (eV - \nu)\rho_{2z} - (eV + \nu)\rho_{00}]
\]

\[
\frac{d\rho_{2z}}{dt} = \ldots + 2\eta e^{-i\phi}[-(eV - \nu)\rho_{00} - (eV - \nu)\rho_{2z} + (eV + \nu)\rho_{00} + (eV - \nu)\rho_{2z}]
\]

The final equations for density matrix in the form of a 16-vector are next ordered such that the 16x16 \(R\) matrix can be readily identified, i.e. \(\frac{d\phi}{dt} = Rp\). We also display the result.
in the Lab frame, i.e. \( \rho \to U_e \rho U_e^\dagger \), e.g. \( U_e \tau_+ \otimes 1 U_e^\dagger = \tau_+ \otimes 1 e^{-i\nu t} \). With the notation \( \lambda_1 = 16\pi N^2(0)J_1^2 \), \( \lambda_2 = 16\pi N^2(0)J_2^2 \), \( \bar{\nu} = \frac{\nu}{V} \) and time in units of \( eV \),

\[
\frac{d\rho_{z0}}{dt} = -\lambda_1(\rho_{z0} + \frac{1}{4}\nu) - \frac{1}{4}\nu \sqrt{\lambda_1 \lambda_2} \cos \frac{1}{2}\theta (e^{i\phi} \rho_{+-} + e^{-i\phi} \rho_{-+})
\frac{d\rho_{+0}}{dt} = -(\lambda_1 + i\nu)\rho_{+0} + \frac{1}{2}\nu \sqrt{\lambda_1 \lambda_2} \cos \frac{1}{2}\theta e^{-i\phi} \rho_{-+}
\frac{d\rho_{-0}}{dt} = -(\lambda_1 - i\nu)\rho_{-0} + \frac{1}{2}\nu \sqrt{\lambda_1 \lambda_2} \cos \frac{1}{2}\theta e^{i\phi} \rho_{+-}
\frac{d\rho_{0z}}{dt} = -\lambda_2(\rho_{0z} + \frac{1}{4}\nu) - \frac{1}{4}\nu \sqrt{\lambda_1 \lambda_2} \cos \frac{1}{2}\theta (e^{i\phi} \rho_{-+} + e^{-i\phi} \rho_{+-})
\frac{d\rho_{zz}}{dt} = -(\lambda_1 + \lambda_2)\rho_{zz} - \lambda_1\nu \rho_{0z} - \lambda_2\nu \rho_{z0} + \frac{1}{2}\nu \sqrt{\lambda_1 \lambda_2} \cos \frac{1}{2}\theta (e^{i\phi} \rho_{-+} + e^{-i\phi} \rho_{+-})
\frac{d\rho_{+z}}{dt} = -(\lambda_1 + \lambda_2 + i\nu)\rho_{+z} - \lambda_2\nu \rho_{+0} - \sqrt{\lambda_1 \lambda_2} \cos \frac{1}{2}\theta e^{-i\phi} (\rho_{+z} + \frac{1}{2}\nu \rho_{0z})
\frac{d\rho_{-z}}{dt} = -(\lambda_1 + \lambda_2 - i\nu)\rho_{-z} - \lambda_2\nu \rho_{-0} - \sqrt{\lambda_1 \lambda_2} \cos \frac{1}{2}\theta e^{i\phi} (\rho_{-z} + \frac{1}{2}\nu \rho_{0-})
\frac{d\rho_{0+}}{dt} = -(\lambda_1 + i\nu)\rho_{0+} + \frac{1}{2}\nu \sqrt{\lambda_1 \lambda_2} \cos \frac{1}{2}\theta e^{i\phi} \rho_{+z}
\frac{d\rho_{+z}}{dt} = -(\lambda_1 + \lambda_2 + i\nu)\rho_{+z} - \lambda_1\nu \rho_{0+} - \sqrt{\lambda_1 \lambda_2} \cos \frac{1}{2}\theta e^{i\phi} (\rho_{+z} + \frac{1}{2}\nu \rho_{0z})
\frac{d\rho_{++}}{dt} = -[\lambda_1 + \lambda_2 + \sqrt{\lambda_1 \lambda_2} \cos \frac{1}{2}\theta \cos \phi + 2i\nu] \rho_{++}
\frac{d\rho_{++}}{dt} = -[\lambda_1 + \lambda_2 - \sqrt{\lambda_1 \lambda_2} \cos \frac{1}{2}\theta \cos \phi] \rho_{+-} + \sqrt{\lambda_1 \lambda_2} \cos \frac{1}{2}\theta e^{i\phi} (2\rho_{zz} + \nu \rho_{0z} + \bar{\nu} \rho_{z0})
\frac{d\rho_{0-}}{dt} = -(\lambda_2 - i\nu)\rho_{0-} + \frac{1}{2}\nu \sqrt{\lambda_1 \lambda_2} \cos \frac{1}{2}\theta e^{-i\phi} \rho_{-z}
\frac{d\rho_{-z}}{dt} = -(\lambda_1 + \lambda_2 - i\nu)\rho_{-z} - \lambda_1\nu \rho_{10-} - \sqrt{\lambda_1 \lambda_2} \cos \frac{1}{2}\theta e^{-i\phi} (\rho_{-z} + \frac{1}{2}\nu \rho_{0-})
\frac{d\rho_{-+}}{dt} = -[\lambda_1 + \lambda_2 - \sqrt{\lambda_1 \lambda_2} \cos \frac{1}{2}\theta \cos \phi] \rho_{+-} + \sqrt{\lambda_1 \lambda_2} \cos \frac{1}{2}\theta e^{-i\phi} (2\rho_{zz} + \nu \rho_{0z} + \bar{\nu} \rho_{z0})
\frac{d\rho_{--}}{dt} = -[\lambda_1 + \lambda_2 + \sqrt{\lambda_1 \lambda_2} \cos \frac{1}{2}\theta \cos \phi - 2i\nu] \rho_{--}
\]

(50)

One needs to add \(-i[\mathcal{H}_3, \rho_S]\), the exchange and DM interactions.

In the steady state \( \rho_{+0} = \rho_{0+} = \rho_{+z} = \rho_{-z} = \rho_{++} = 0 \) and after some algebra, remarkably \( \rho_{+-} = \rho_{-+} = 0 \), hence the only finite elements are

\[
\rho_{z0} = \rho_{0z} = -\frac{1}{4}\nu, \quad \rho_{zz} = \frac{1}{4}\nu^2
\]

(51)

The connected part is then \( \rho_{zz} - 4\rho_{z0}\rho_{0z} = 0 \) (for the factor 4 see (34)), hence no entanglement in the steady state.
D. Matrix notations

In this subsection we define our matrix notations and illustrate them for a single spin 1/2. The system Hamiltonian is $H = \frac{1}{2} \nu \sigma_z$ where $\nu$ is the Larmor frequency and $\sigma_x, \sigma_y, \sigma_z$ are Pauli matrices. The 2x2 density matrix $\tilde{\rho}_{\alpha\beta}$, $\alpha, \beta = 0, 1$ determines the magnetization $M = \text{Tr}[\sigma \tilde{\rho}]$. It is convenient to work with $\rho$ as in a 4-vector notation and redefine indices, so that

$$\rho = \begin{pmatrix} 1 & 0 & 0 & 1 \\ \frac{1}{2} & 0 & 0 & -\frac{1}{2} \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \end{pmatrix} \begin{pmatrix} \tilde{\rho}_{00} \\ \tilde{\rho}_{01} \\ \tilde{\rho}_{10} \\ \tilde{\rho}_{11} \end{pmatrix} = \begin{pmatrix} \rho_0 \\ \rho_z \\ \rho_+ \\ \rho_- \end{pmatrix}$$

(52)

with $\rho_0 = 1$. The standard Bloch’s equation, as derived in Eq. (26), identifies $R$

$$\dot{\rho}_+ = -i\nu \rho_+ - \frac{1}{T_2} \rho_+, \quad \dot{\rho}_z = -\frac{1}{T_1} (\rho_z - \rho_z^0)$$

$$R = \begin{pmatrix} 0 & 0 & 0 & 0 \\ \rho_z^0 / T_1 & -1 / T_1 & 0 & 0 \\ 0 & 0 & -i\nu - 1 / T_2 & 0 \\ 0 & 0 & 0 & i\nu - 1 / T_2 \end{pmatrix}$$

(53)

To evaluate correlation functions we need the Pauli matrices (or any other operator) as 4x4 matrices that operate on the 4-vector density matrix. The process is to identify the 2x2 product $A \cdot \tilde{\rho} = B$ with elements $B_{ij}$ as a 4-vector ($\text{Tr} = B_{00} + B_{11}, \frac{1}{2} (B_{00} - B_{11}), B_{01}, B_{10}$). Hence

$$\begin{pmatrix} A_{00} & A_{01} \\ A_{10} & A_{11} \end{pmatrix} \begin{pmatrix} \frac{1}{2} + \rho_z & \rho_+ \\ \rho_- & \frac{1}{2} - \rho_z \end{pmatrix} = \begin{pmatrix} A_{00} \left( \frac{1}{2} + \rho_z \right) + A_{01} \rho_- & A_{00} \rho_+ + A_{01} \left( \frac{1}{2} - \rho_z \right) \\ A_{10} \left( \frac{1}{2} + \rho_z \right) + A_{11} \rho_- & A_{10} \rho_+ + A_{11} \left( \frac{1}{2} - \rho_z \right) \end{pmatrix}$$

$$\Rightarrow \begin{pmatrix} A_{00} \left( \frac{1}{2} + \rho_z \right) + A_{01} \rho_- + A_{10} \rho_+ + A_{11} \left( \frac{1}{2} - \rho_z \right) \\ \frac{1}{2} \left[ A_{00} \left( \frac{1}{2} + \rho_z \right) + A_{01} \rho_- - A_{10} \rho_+ - A_{11} \left( \frac{1}{2} - \rho_z \right) \right] \end{pmatrix}$$

$$A_{00} \rho_+ + A_{01} \left( \frac{1}{2} - \rho_z \right)$$

$$A_{10} \left( \frac{1}{2} + \rho_z \right) + A_{11} \rho_-$$

$$= \begin{pmatrix} \frac{1}{2} (A_{00} + A_{11}) & A_{00} - A_{11} & A_{10} & A_{01} \\ \frac{1}{4} (A_{00} - A_{11}) & \frac{1}{2} (A_{00} + A_{11}) & -\frac{1}{2} A_{10} & \frac{1}{2} A_{01} \\ \frac{1}{2} A_{01} & -A_{01} & A_{00} & 0 \\ \frac{1}{2} A_{10} & A_{10} & 0 & A_{11} \end{pmatrix} \begin{pmatrix} 1 \\ \rho_z \\ \rho_+ \\ \rho_- \end{pmatrix}$$
The last matrix identifies the 4x4 form of the original 2x2 matrix $A$. Hence the Pauli matrices when operating from the left become

$$\sigma_z = \begin{pmatrix} 0 & 2 & 0 & 0 \\ \frac{1}{2} & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & -1 \end{pmatrix}, \quad \sigma_+ = \begin{pmatrix} 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & \frac{1}{2} \\ \frac{1}{2} & -1 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}, \quad \sigma_- = \begin{pmatrix} 0 & 0 & 1 & 0 \\ 0 & 0 & -\frac{1}{2} & 0 \\ \frac{1}{2} & 1 & 0 & 0 \end{pmatrix}$$

(54)

In the following we need also the 4x4 form when multiplying from the right. Following the process above for the product $\tilde{\rho} \cdot A$ we obtain

$$\sigma_z' = \begin{pmatrix} 0 & 2 & 0 & 0 \\ \frac{1}{2} & 0 & 0 & 0 \\ 0 & 0 & -1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}, \quad \sigma_+ = \begin{pmatrix} 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & -\frac{1}{2} \\ \frac{1}{2} & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}, \quad \sigma_- = \begin{pmatrix} 0 & 0 & 1 & 0 \\ 0 & 0 & \frac{1}{2} & 0 \\ \frac{1}{2} & -1 & 0 & 0 \end{pmatrix}$$

(55)

The regression theorem yields correlation functions. Their Fourier transform can be written as

$$\langle A(t)B(0)\rangle_\omega = -2\text{Re} \text{Tr}[A(\frac{1}{R+\omega})B\rho_\infty], \text{ where } \rho_\infty \text{ is the steady state density matrix, i.e. the solution of } R\rho_\infty = 0. \text{ Note that the Tr in the latter form is just the 1st entry of the resulting 4-vector.}$$

To illustrate this process we consider Bloch’s equation and find (using Mathematica)

$$C_{-+}^\omega = \int_t \langle \sigma_-(t)\sigma_+(0)\rangle e^{i\omega t} = \frac{(1 - 2\rho_z^0)/T_2}{(\omega - \nu)^2 + (1/T_2)^2}$$

$$A(\omega) = \omega[C_{-+}(\omega) - C_{+-}(-\omega)] = \frac{-\rho_z^0\omega/T_2}{(\omega - \nu)^2 + (1/T_2)^2}$$

(56)

where the absorption rate $A(\omega)$ is a known result for Bloch’s equations (see e.g. Eq. (2.48) of Ref. [8]).
