THE LOG MINIMAL MODEL PROGRAM FOR KÄHLER 3-FOLDS

OMPROKASH DAS AND CHRISTOPHER HACON

ABSTRACT. In this article we show that the Log Minimal Model Program for \(\mathbb{Q}\)-factorial dlt pairs \((X, B)\) on a compact Kähler 3-fold holds. More specifically, we show that after a finitely many divisorial contractions and flips we obtain either a (log) minimal model or a Mori fiber space. We also prove a base point free theorem Kähler 3-folds.

1. INTRODUCTION

The minimal model program or MMP is one of the most important tools in the birational classification of complex projective varieties. It was fully established in dimension 3 in the 80’s and 90’s and recently extended to many cases in arbitrary dimensions including the case of varieties of log general type [BCHM10].

There are many technical difficulties in adapting the minimal model program to compact Kähler manifolds. Some of the standard techniques used in the MMP for projective varieties fail for compact Kähler manifolds, for example, Mori’s Bend and Break technique for producing rational curves, the
base point free theorem and the contraction of negative extremal rays fail on Kähler manifolds. Campana and Peternell investigated the existence of Mori contractions in [CP97, Pet98, Pet01], using the deformation theory of rational curves on smooth 3-folds developed in [Kol91, Kol96]. In [HP16], Peternell and Höring successfully established the minimal model program for compact Kähler 3-folds $X$ with terminal singularities and $K_X$ pseudo-effective. In a subsequent paper [HP15] they also proved the existence of Mori fiber spaces when $X$ has terminal singularities and $K_X$ is not pseudo-effective. Moreover, in [CHP16], Campana, Höring, and Perternell proved the abundance theorem when $X$ has terminal singularities.

In [HP16] the authors introduced many new tools which enabled them to use several techniques from the projective MMP. Building on the work of [HP16, HP15, CHP16], in this article we show that the minimal model program on compact Kähler 3-folds works in much greater generality. More precisely, we show that this program holds for $\mathbb{Q}$-factorial dlt pairs $(X, B)$. The main results of this article are the following:

**Theorem 1.1.** Let $(X, B)$ be a dlt pair where $X$ is a $\mathbb{Q}$-factorial compact Kähler 3-fold. If $K_X + B$ is pseudo-effective, then there exists a finite sequence of flips and divisorial contractions

$$\phi : X \dasharrow X_1 \dasharrow \ldots \dasharrow X_n$$

such that $K_{X_n} + \phi_* B$ is nef.

This result is proved in [HP16] when $X$ has terminal singularities and $B = 0$.

**Theorem 1.2.** Let $(X, B)$ be a klt pair where $X$ is a $\mathbb{Q}$-factorial compact Kähler 3-fold. If $K_X + B$ is not pseudo-effective, then there exists a finite sequence of flips and divisorial contractions

$$\phi : X \dasharrow X_1 \dasharrow \ldots \dasharrow X_n$$

and a Mori fiber space $\varphi : X_n \to S$, i.e. a morphism such that $-(K_{X_n} + \phi_* B)$ is $\varphi$-ample and $\rho(X_n/S) = 1$.

This result is proved in [HP15] when $X$ has terminal singularities and $B = 0$.

We note that one of the main difficulties in proving the above theorems is proving the existence of divisorial contractions. In the pseudo-effective case, the existence of flips and divisorial contractions to a point has already been established by work of [CHP16], [HP16] and [DO19] (see Theorem 2.17), and so it remains to prove the existence of divisorial contractions to a curve. This is one of the key results of this article.
Definition 1.3. [HP16, Definition 4.3 and 7.1][CHP16, Notation 4.1] Let $X$ be a normal $\mathbb{Q}$-factorial compact Kähler 3-fold with rational singularities.

- We say that a curve $C \subset X$ is very rigid if $\dim_{mC} \text{Chow}(X) = 0$ for all $m \geq 1$.
- Let $(X, B)$ is a log canonical pair. A $(K_X + B)$-negative extremal ray $R$ of $\overline{\text{NA}}(X)$ is called small if every curve $C \subset X$ with $[C] \in R$ is very rigid.
- An extremal ray $R$ as above is called divisorial type if it is not small.

Notation 1.4. Let $(X, B)$ be a dlt pair, where $X$ is a $\mathbb{Q}$-factorial compact Kähler 3-fold. Let $R$ be a $(K_X + B)$-negative extremal ray of $\overline{\text{NA}}(X)$ of divisorial type. Let $S$ be the surface which is covered by and contains all the curves $C \subset X$ such that $[C] \in R$ (cf. [HP16, Lemma 7.5]). Let $\nu : \tilde{S} \to S$ be the normalization morphism. Consider the nef reduction $f : \tilde{S} \to T$ of the $(1, 1)$ nef class $\nu^*(\alpha|_S)$ (see [HP15, Theorem 3.19]). Note that since $S$ is covered by a family of $\alpha$-trivial curves, the lift of these curves on $\tilde{S}$ gives a family of $\nu^*(\alpha|_S)$-trivial curves. Thus from the definition of nef dimension it follows that $\dim T \leq 1$. We define the notation $n(\alpha)$ as the nef dimension of $\nu^*(\alpha|_S)$, i.e.,

$$n(\alpha) := \text{nef dim}(\nu^*(\alpha|_S)) = \dim T \in \{0, 1\}.$$  

Note that when $n(\alpha) = 1$, it follows from [BCE+02, 2.4.4] that the nef reduction map $f : \tilde{S} \to T$ is a morphism.

Theorem 1.5. Let $(X, B)$ be a $\mathbb{Q}$-factorial dlt pair, where $X$ is a compact Kähler 3-fold, and $K_X + B$ is pseudo-effective. Let $R$ be a $(K_X + B)$-negative extremal ray of divisorial type supported by a $(1, 1)$ nef class $\nu^*(\alpha|_S)$ such that the nef dimension is $n(\alpha) = 1$. Then the contraction $c_R : X \to Y$ of $R$ exists.

For an analogous contraction theorem, which applies when $K_X + B$ is not pseudo-effective, see Theorem 4.14.

One of the main difficulties in proving a contraction theorem in the Kähler category is the lack of a base-point free theorem analogous to that of [KM98, Theorem 3.3] in the projective case. Note that, an exact analogue of [KM98, Theorem 3.3] is impossible on a compact Kähler variety which is not projective, since the existence of a big divisor on a compact Kähler variety with rational singularities implies that it is projective by [Nam02, Theorem 1.6]. However, there is a base-point free conjecture in the Kähler category involving nef and big cohomology classes which can be thought of as an analogue of [KM98, Theorem 3.3]. This conjecture is stated in [Hör18, Conjecture 1.1] for manifolds.
Conjecture 1.6 (Base point freeness). Let \((X, B)\) be a klt pair, where \(X\) is a normal \(\mathbb{Q}\)-factorial compact Kähler variety. Let \(\alpha \in H^{1,1}_{BC}(X)\) be a nef class on \(X\). If \(\alpha - (K_X + B)\) is nef and big, then there exists a proper surjective morphism with connected fibers \(f : X \rightarrow Y\) to a normal compact Kähler variety \(Y\) with rational singularities and a Kähler class \(\alpha_Y \in H^{1,1}_{BC}(Y)\) such that \(\alpha = f^*\alpha_Y\).

As an application of Theorem 1.1 and 1.2 and other related results we prove this conjecture when \(X\) has dimension 3.

Theorem 1.7. Let \((X, B \geq 0)\) be a log pair, where \(X\) is a normal \(\mathbb{Q}\)-factorial compact Kähler 3-fold. Let \(\alpha \in H^{1,1}_{BC}(X)\) be a nef class. Assume that one of the following conditions is satisfied:

(i) \((X, B)\) is klt and \(\alpha - (K_X + B)\) is nef and big, or
(ii) \((X, B)\) is dlt and \(\alpha - (K_X + B)\) is a Kähler class.

Then there exists a proper surjective morphism with connected fibers \(\psi : X \rightarrow Z\) to a normal Kähler variety \(Z\) with rational singularities and a Kähler class \(\alpha_Z \in H^{1,1}_{BC}(Z)\) on \(Z\) such that \(\alpha = \psi^*\alpha_Z\). Moreover, in case (ii) we can choose \(\psi\) to be a projective morphism.

When \(X\) has terminal singularities, \(B = 0\) and \(\alpha - K_X\) is a Kähler class, this theorem is proved in [Hör18, Theorem 1.3] (when \(\alpha\) is both nef and big) and in [TZ18, Theorem 2.7] (when \(\alpha\) is nef but not big). In fact our proof is a direct generalization of the techniques in [Hör18] and [TZ18] using more general MMP results such as Theorems 1.1 and 1.2.

This article is organized is the following manner: In Section 2 we collect some important technical results which are used throughout the article. In Section 3 we prove the existence of minimal model programs for pseudo-effective pairs, more specifically we prove Theorems 1.1 and 1.5. Section 4 is dedicated to developing the cone and contraction theorems for non pseudo-effective pairs. These results are then used in Section 5 to prove the existence of the minimal model program for non pseudo-effective pairs, more specifically, in this section we prove Theorem 1.2. In Section 5 we also prove some partial cases of Theorem 1.7, more specifically, the case where \(\alpha\) is nef but not big, see Theorem 5.5 and Corollary 5.6. Finally, in Section 6 we prove the other remaining cases of Theorem 1.7, more specifically, when \(\alpha\) is both nef and big, see Theorem 6.4 and Corollary 6.5

2. Preliminaries

For a normal analytic variety $X$ and a $\mathbb{Q}$-divisor $B$ such that $K_X + B$ is $\mathbb{Q}$-Cartier, we define the singularities of the pair $(X, B)$ as in [KM98]. Note that throughout this article by a pair $(X, B)$ we will always mean that $X$ is normal, $B \geq 0$ is an effective $\mathbb{Q}$-divisor such that $K_X + B$ is $\mathbb{Q}$-Cartier. If $B$ is not effective, then we will call the corresponding singularities of $(X, B)$ sub-klt, sub-dlt, etc.

**Definition 2.1.** [HP16, Definition 2.2] An analytic variety or simply a variety is an irreducible and reduced complex space. A variety $X$ is Kähler or a Kähler space if there exists a positive closed real $(1, 1)$ form $\omega \in A^{1,1}_R(X)$ such that the following holds: for every point $x \in X_{\text{sing}}$ there exists an open neighborhood $x \in U$ and a closed embedding $\iota_U : U \to V$ into an open set $V \subset \mathbb{C}^N$, and a strictly plurisubharmonic $C^\infty$ function $f : V \to \mathbb{C}$ such that $\omega|_{U \cap X_{\text{sm}}} = (i\partial \bar{\partial} f)|_{U \cap X_{\text{sm}}}$. In the following we collect some important definitions. For a more detailed discussion, we encourage the reader to look at [HP16, HP15, CHP16] and the references therein.

**Definition 2.2.**

(i) A compact analytic variety $X$ is said to belong to Fujiki’s class $\mathcal{C}$ if one of the following equivalent conditions are satisfied:

(a) $X$ is a meromorphic image of a compact Kähler variety $Y$, i.e., there exists a meromorphic map $f : Y \dashrightarrow X$ from a compact Kähler variety $Y$ (see [Fuj78, 4.3, page 34]).

(b) $X$ is a holomorphic image of compact Kähler manifold, i.e., there is a surjective morphism $f : Y \to X$ from a compact Kähler manifold $Y$ (see [Fuj78, Lemma 4.6]).

(c) $X$ is bimeromorphic to a compact Kähler manifold (see [Var89, Theorem 3.2, page 51]).

(ii) On a normal compact analytic variety $X$ we replace the use of Néron-Severi group $\text{NS}(X)_\mathbb{R}$ by $H^{1,1}_{\text{BC}}(X)$, the Bott-Chern cohomology of real closed $(1, 1)$ forms with local potentials or equivalently, the closed bi-degree $(1, 1)$ currents with local potentials. See [HP16, Definition 3.1 and 3.6] for more details. More specifically, we define

$$N^1(X) := H^{1,1}_{\text{BC}}(X).$$

(iii) If $X$ is in Fujiki’s class $\mathcal{C}$ and has rational singularities, then from [HP16, Eqn. (3)] we know that $N^1(X) = H^{1,1}_{\text{BC}}(X) \subset H^2(X, \mathbb{R})$. In particular, the intersection product can be defined in $N^1(X)$ via the cup product of $H^2(X, \mathbb{R})$. 

(iv) Let $X$ be a normal compact analytic variety contained in Fujiki’s class $\mathcal{C}$. We define $N_1(X)$ to be the vector space of real closed currents of bi-dimension $(1,1)$ modulo the following equivalence relation: $T_1 \equiv T_2$ if and only if

$$T_1(\eta) = T_2(\eta)$$

for all real closed $(1,1)$ form with local potentials.

(v) We define $\overline{NA}(X) \subset N_1(X)$ to be the closed cone generated by the classes of positive closed currents. The Mori cone $\overline{NE}(X) \subset \overline{NA}(X)$ is defined as the closure of the cone of currents of integration $T_C$, where $C \subset X$ is an irreducible curve.

(vi) Let $X$ be a normal compact analytic variety and $u \in H^{1,1}_{BC}(X)$. Then $u$ is called pseudo-effective if it can be represented by a bi-degree $(1,1)$ current $T \in D^{1,1}(X)$ which is locally of the form $\partial \bar{\partial} f$ for some psh function $f$. $u$ is called nef if it can be represented by a form $\alpha$ with local potentials such that for some positive $(1,1)$ form $\omega$ on $X$ and for every $\epsilon > 0$, there exists a $C^\infty$ function $f_\epsilon \in A^0(X)$ such that

$$\alpha + i\partial \bar{\partial} f_\epsilon \geq -\epsilon \omega$$

(vii) The nef cone $\text{Nef}(X) \subset N^1(X)$ is the cone generated by nef cohomology classes. Let $\mathcal{K}$ be the open cone in $N^1(X)$ generated by the classes of Kähler forms. By [Dem92, Proposition 6.1.(iii)] (also see [HP16, Remark 3.12]) it follows that the nef cone $\text{Nef}(X)$ is the closure of $\mathcal{K}$, i.e. $\text{Nef}(X) = \overline{\mathcal{K}}$.

(viii) We say that a variety $X$ is $\mathbb{Q}$-factorial if every Weil divisor $D \subset X$, there is a positive integer $k > 0$ such that $kD$ is a Cartier divisor, and for the canonical sheaf $\omega_X$, there is a positive integer $m > 0$ such that $(\omega_X^\otimes m)^{**}$ is a line bundle. It is well known that if $X$ is a $\mathbb{Q}$-factorial 3-fold and $X \to X'$ is a flip or divisorial contraction, then $X'$ is also $\mathbb{Q}$-factorial.

**Remark 2.3.** Note that if $D$ is a $\mathbb{Q}$-Cartier divisor on variety $X$, then in algebraic geometry we say that $D$ is nef if $D \cdot C \geq 0$ for all $C \subset X$. But the cohomology class of the current of integration of $D$ is not necessarily nef in the sense defined above. To avoid this sort of confusion, temporarily we will call a $\mathbb{Q}$-Cartier divisor $D$ algebraically nef if $D \cdot C \geq 0$ for all $C \subset X$, and $D$ is analytically nef if the cohomology class of the current of integration associated to $D$ is nef in the sense of Definition 2.2.(vii). Note that if $X$ is a compact Kähler variety, then analytically nef implies algebraically nef but the converse is not true in general, see [HP18, Page 385] for a counter example. However, the following two lemmas show that these two versions of nefness are equivalent in important cases— (i) $X$ is a Moishezon space (see Lemma 2.4), and (ii) $X$ is a Kähler 3-fold and $D$ is an adjoint divisor (see Lemma 2.6).
Lemma 2.4. [Pau98, Corollary 1, Page 418] Let $X$ be a normal compact Moishezon variety, i.e. $X$ is bimeromorphic to a projective variety. Let $D$ be a $\mathbb{Q}$-Cartier divisor on $X$. Then $D$ is analytically nef if and only if it is algebraically nef.

Remark 2.5. Note that one can prove the above lemma more generally for $\mathbb{R}$-Cartier divisors by passing to a resolution of singularities $\pi : \tilde{X} \to X$ such that $\tilde{X}$ is a projective manifold and then use [DP04, Corollary 0.2] and [Pau98, Theorem 1, Page 412].

Lemma 2.6. Let $(X, B)$ be a dlt pair, where $X$ is a $\mathbb{Q}$-factorial compact Kähler 3-fold. Assume that one of the following conditions is satisfied:

(i) $K_X + B$ is pseudo-effective, or
(ii) $K_X + B$ is not pseudo-effective and there exists a Kähler form $\omega$ on $X$ such that $K_X + B + \omega$ is pseudo-effective.

Then $K_X + B$ (resp. $K_X + B + \omega$) is analytically nef if and only if it is algebraically nef.

Proof. If $K_X + B$ is pseudo-effective, then the result follows from a similar proof as in [HP16, Corollary 4.2] and [CHP16, Corollary 4.1]. For a complete proof in this case, see [DO19, Corollary 11.5]. In the second case, first replacing $B$ by $(1-\varepsilon)B$ and $\omega$ by $\omega + \varepsilon B$ we may assume that $(X, B)$ is klt. Now if the base of the MRC(C) fibration of $X$ has dimension $\leq 1$, then from Lemma 2.40 and its proof it follows that $X$ is projective and additionally $\text{NS}(X)_{\mathbb{R}} = H^{1,1}_{BC}(X)$. Then the result follows from Lemma 2.4 and Remark 2.5. If the base of the MRC fibration of $X$ has dimension 2, then the result follows by a similar proof as in [HP15, Corollary 3.5]. Note that this proof uses [HP15, Lemma 3.4], which is replaced here by the Claim 4.7.

Remark 2.7. If $f : X \to Y$ is a proper surjective morphism between normal analytic varieties and $\dim Y > 0$, then we say that a $\mathbb{Q}$-Cartier $\mathbb{Q}$-divisor $D$ on $X$ is nef over $Y$ or $f$-nef if $D \cdot C \geq 0$ for all (compact) curves $C \subset X$ such that $f(C) = \text{pt}$. Note that to be more precise we should call $D$, algebraically nef over $X$ or algebraically $f$-nef, however, by Lemma 2.4 it is equivalent to analytically nef (over $X$) if $f$ is a Moishezon morphism (see [GPR94, Definition VIII.3.7(b), Page 334]). Since all the morphisms considered in this article are Moishezon, e.g. projective morphisms, proper bimeromorphic morphisms, etc. this will not create any confusion.

Let $X$ be a normal variety and $\omega$ a real closed $(1, 1)$ form on $X$ local potentials. Then we can define

$$\lambda_{\omega} \in N^1(X)^*,$$

via

$$\lambda_{\omega}([T]) = T(\omega).$$
This gives a well defined canonical map
\[ \Phi : N^1(X) \to N_1(X)^* \quad [\omega] \to \lambda_\omega. \]
If in addition \( X \) belongs to Fujiki’s class \( C \) and has rational singularities, then \( \Phi \) is an isomorphism by [HP16, Proposition 3.9]. Moreover, if \( \dim X = 3 \), then \( \Phi(\text{Nef}(X)) = \text{NA}(X) \) by [HP16, Proposition 3.15].

We recall the following useful result from [HP16] for future reference.

**Lemma 2.8.** [HP16, Lemma 3.3] Let \( f : X \to Y \) be a proper bimeromorphic morphism between normal compact complex spaces in Fujiki’s class \( C \) with at most rational singularities. Then we have an injection
\[ f^* : H^{1,1}_{\text{BC}}(Y) = H^1(Y, \mathcal{H}_Y) \hookrightarrow H^1(X, \mathcal{H}_X) = H^{1,1}_{\text{BC}}(X) \]
whose image is given by
\[ \text{Im}(f^*) = \{ \alpha \in H^1(X, \mathcal{H}_X) \mid \alpha \cdot C = 0 \ \forall \ C \subset X \text{ curve s. t. } f_* C = 0 \}. \]
Furthermore, let \( \alpha \in H^1(X, \mathcal{H}_X) \subset H^2(X, \mathbb{R}) \) be a class such that \( \alpha = f^* \beta \) with \( \beta \in H^2(X, \mathbb{R}) \). Then there exists a smooth real closed \((1,1)\)-form with local potentials \( \omega_Y \) on \( Y \) such that \( \alpha = f^*[\omega_Y] \).

The push-forward of a cohomology class \([T]\) of a bi-degree \((1,1)\) current \( T \) with local potentials on \( X \) is not necessarily a cohomology class in \( H^{1,1}_{\text{BC}}(Y) \), since the current \( f_* T \) may not have local potentials on \( Y \). The following corollary gives a sufficient condition for when \( f_* [T] \) is a cohomology class on \( Y \).

**Corollary 2.9.** Let \( f : X \to Y \) be a proper bimeromorphic morphism between normal compact analytic varieties in Fujiki’s class \( C \) with at most rational singularities. Let \( T \) be a real closed bi-degree \((1,1)\) current with local potentials on \( X \) such that \([T] = f^* \alpha \in H^{1,1}_{\text{BC}}(X)\) for some \((1,1)\) class \( \alpha \in H^{1,1}_{\text{BC}}(Y) \). Then \([f_* T] = \alpha \) in \( H^{1,1}_{\text{BC}}(Y) \).

**Proof.** Let \( \eta \in A^{n-1,n-1}(Y) \) be a \( C^\infty \) form on \( Y \). Then by the projection formula \( \alpha \cdot \eta = f^* \alpha \cdot f^* \eta = [T] \cdot f^* \eta = T \wedge f^* \eta = f_* T \wedge \eta = [f_* T] \cdot \eta. \) \( \square \)

**Remark 2.10.** Note that if \( X \) is a compact Kähler space and \( \pi : X' \to X \) a projective morphism, then \( X' \) is again Kähler (see [Var89, Prop. 1.3.1.(vi), page 24]). In particular, \( X \) has a Kähler desingularisation. A subvariety of a Kähler space is also Kähler, see [Var89, Prop. 1.3.1.(i), page 24].

### 2.1. Resolution of Singularities.

The existence of resolutions of singularities for analytic varieties and embedded resolutions is proved in [AHV77] and [BM97]. Unlike the case of algebraic varieties (of finite type over a field), for analytic varieties the resolution of singularities is not obtained via global blow ups of smooth centers, unless the variety is compact. So for simplicity
we will only state the resolution theorems here for compact analytic varieties. For non-compact analytic varieties we encourage the reader to look into the original papers.

**Theorem 2.11** (Resolution of Singularities). [BM97, Theorem 13.4] Let \( X \) be a compact analytic variety. Then there exists a projective bimeromorphic morphism \( \mu : \tilde{X} \to X \) from a smooth compact analytic variety \( \tilde{X} \) satisfying the following properties:

(i) \( \mu \) is given by successive blow-ups of smooth centers of \( X \) contained in the singular locus of \( X \),
(ii) \( \mu^{-1}(X \setminus X_{\text{sing}}) \cong X \setminus X_{\text{sing}} \), and
(iii) the exceptional locus \( \text{Ex}(\mu) \) is a simple normal crossing divisor on \( \tilde{X} \).

Now let \( X \) be a normal analytic variety and \( D = \sum_{i=1}^{n} D_i \) is a reduced Weil divisor on \( X \). Then there exists a unique largest Zariski open subset \( U \) of \( X \) contained in its smooth locus such that \( D|_U \) is a simple normal crossing divisor and \( \text{codim}_X(X \setminus U) \geq 2 \). The open set \( U \) is called the simple normal crossing locus of the pair \( (X, D) \) and we denote it by \( \text{SNC}(X, D) \).

**Theorem 2.12** (Log Resolution). [BM97, Theorem 10.7] Let \( X \) be a normal compact analytic variety and \( D = \sum_{i=1}^{n} D_i \) a Weil divisor on \( X \). Then there exists a projective bimeromorphic morphism \( \mu : \tilde{X} \to X \) from a smooth compact analytic variety \( \tilde{X} \) satisfying the following properties:

(i) \( \mu \) is a sequence of blow-ups of smooth centers contained in \( X \setminus \text{SNC}(X, D) \),
(ii) \( \mu^{-1}(\text{SNC}(X, D)) \cong \text{SNC}(X, D) \), and
(iii) \( \text{Ex}(\mu) \) is a pure codimension 1 subset of \( \tilde{X} \) such that \( \text{Ex}(\mu) + \mu_*^{-1}D \) is a simple normal crossing divisor.

Next we will state Chow’s lemma for analytic varieties due to Hironaka [Hir75]. Note that unlike Chow’s lemma for algebraic varieties (finite type over a field), in the analytic category it does not hold for arbitrary proper morphism between analytic varieties, it only holds for proper bimeromorphic morphisms. Before stating the theorem first recall that a locally compact topological space \( X \) is called countable at infinity if it can be written as a countable union of compact subsets. Clearly, any compact space \( X \) is countable at infinity.

**Theorem 2.13** (Chow’s Lemma). [Hir75, Corollary 2] Let \( f : X \to Y \) be a proper bimeromorphic morphism between two complex spaces such that \( Y \) is reduced and countable at infinity. Then there exists a bimeromorphic morphism \( \nu : X' \to X \) such that the composition \( f' = f \circ \nu : X' \to Y \) is projective.

2.2. MMP for Kähler 3-folds. The following results are improvements of the important results from [CHP16] and [HP16].
Theorem 2.14. Let $(X, B)$ be a log canonical pair, where $X$ is a compact Kähler 3-fold, and $K_X + B$ is nef. Then $K_X + B$ is semi-ample, i.e. $\mathcal{O}_X(m(K_X + B))$ is generated by global sections for some $m > 0$.

Proof. See [DO19, Theorem 1.1]. □

Theorem 2.15. Let $(X, B)$ be a dlt pair, where $X$ is a $\mathbb{Q}$-factorial compact Kähler 3-fold. Then $K_X + B$ is pseudo-effective if and only if $\kappa(K_X + B) \geq 0$.

Proof. See [DO19, Theorem 10.3]. □

Theorem 2.16. Let $(X, B)$ be a dlt pair, where $X$ is a $\mathbb{Q}$-factorial compact Kähler 3-fold. If $K_X + B$ is pseudo-effective, then there is a rational number $d > 0$ and at most a countable set of curves $\{\Gamma_i\}_{i \in I}$ such that

$$0 < -(K_X + B) \cdot \Gamma_i \leq d$$

and that

$$\overline{\text{NA}}(X) = \overline{\text{NA}}(X)_{K_X + B \geq 0} + \sum_{i \in I} \mathbb{R}^{+}[\Gamma_i].$$

Proof. See [DO19, Theorem 11.12]. □

Theorem 2.17. Let $(X, B)$ be a dlt pair, where $X$ is a $\mathbb{Q}$-factorial compact Kähler 3-fold, and $K_X + B$ is pseudo-effective. Let $R$ be a $(K_X + B)$-negative extremal ray supported by a nef and big class $\alpha$. Then

1. If $R$ is small, then the contraction $c_R : X \to Y$ of $R$ exists and $Y$ is a compact Kähler space.
2. If $R$ is divisorial and $n(\alpha) = 0$, then the contraction $c_R : X \to Y$ of $R$ exists and $Y$ is a compact Kähler space with $\mathbb{Q}$-factorial singularities.
3. If $R$ is divisorial and $n(\alpha) = 1$ and if one of the following conditions is satisfied:
   a. $X$ has terminal singularities and $K_X \cdot C < 0$, where $R = \mathbb{R}^{+} \cdot [C]$ for some curve $C \subset X$, or
   b. $S$ has semi-log canonical singularities, where $S$ is the unique surface covered by curves with class in $R$.

Then the contraction $c_R : X \to Y$ of $R$ exists and $Y$ is a compact Kähler space with $\mathbb{Q}$-factorial singularities.

Proof. (1) follows from [DO19, Theorem 11.13].
(2) follows from [DO19, Theorem 11.15].
(3) follows from [DO19, Proposition 11.16]. □

Theorem 2.18. Let $(X, B)$ be a dlt pair, where $X$ is a $\mathbb{Q}$-factorial compact Kähler 3-fold. Let $X \to Y$ be a $K_X + B$ flipping contraction, then the flip $X^+ \to Y$ exists so that $X^+$ is a $\mathbb{Q}$-factorial compact Kähler 3-fold and $(X^+, B^+)$ is dlt, where $B^+ := \phi^* B$, and $\phi : X \to X^+$. 
\textbf{Proof.} \cite[Theorem 4.3]{CHP16}. \hfill \Box

\textbf{Theorem 2.19.} Let \((X, B)\) be a dlt pair, where \(X\) is a \(\mathbb{Q}\)-factorial compact Kähler 3-fold. Then any sequence of \(K_X + B\) flips is finite.

\textbf{Proof.} See \cite[Theorem 5.1]{DO19}. \hfill \Box

\textbf{Proposition 2.20.} Let \((X, B)\) be a klt pair and \(f : X \to Y\) a projective surjective morphism between two normal compact analytic varieties. If \(\dim X \leq 3\), then we can run a relative \((K_X + B)\)-MMP over \(Y\) which terminates with either a minimal model or a Mori fiber space, according to whether \(K_X + B\) is pseudo-effective over \(Y\) or not. Moreover, if \(Y\) is a Kähler variety and \(X = X_0 \to X_1 \to \cdots \to X_n \to \cdots\) are the steps of a \((K_X + B)\)-MMP over \(Y\), then every \(X_i\) is a Kähler variety for \(i \geq 0\); additionally, if \(\psi : X_n \to Y'\) is a Mori fiber space over \(Y\), then \(Y'\) is also Kähler.

\textbf{Proof.} Since \(f\) is projective, the (relative) cone and contraction theorems are known due to \cite[Theorem 4.12]{Nak87}. Since \(\dim X \leq 3\), the existence of flips (over \(Y\)) follows from \cite{Sho92}. The termination of flips (over \(Y\)) follow from \cite[Theorem 6.11.(4.2)]{Kol92}. The proof of the fact that a \((K_X + B)\)-MMP over \(Y\) terminates either with a minimal model or a Mori fiber space according to whether \(K_X + B\) is pseudo-effective over \(Y\) or not, works exactly as in the algebraic case, since \(f : X \to Y\) is a projective morphism. Now if \(Y\) is Kähler, then by \cite[Proposition 1.3.1, page 24]{Var89}, \(X = X_0\) is Kähler. If \(g_i : X_i \to Z_i\) is a contraction of a \((K_{X_i} + B_i)\)-negative extremal ray of \(\overline{\text{NE}}(X_i/Y)\), then from the relative base-point free theorem \cite[Theorem 4.10]{Nak87} it follows that the induced morphism \(h_i : Z_i \to Y\) is projective. Then again from \cite[Proposition 1.3.1, page 24]{Var89} it follows that \(Z_i\) is Kähler. If \(g_i\) is a flipping contraction and \(g_i^+ : X_{i+1} \to Z_i\) is the flip, then again \(X_{i+1}\) is Kähler by the same argument. In the Mori fiber space case again by a similar argument it follows that \(Y'\) is Kähler. \hfill \Box

\textbf{Lemma 2.21.} Let \((X, B)\) be a klt pair, where \(X\) is a compact Kähler 3-fold. Then the following morphisms exist:

1. a small projective morphism \(\nu : X' \to X\) such that \(X'\) is \(\mathbb{Q}\)-factorial, and
2. a birational projective morphism \(\nu : X' \to X\) such that \(X'\) is \(\mathbb{Q}\)-factorial and \((X', B_{X'})\) is a terminal pair such that \(K_{X'} + B_{X'} = \nu^*(K_X + B)\).

\textbf{Proof.} (1) Let \(\nu : X' \to X\) be a log resolution of the pair \((X, B)\). We may assume that \(\nu\) is a projective morphism. Write \(\nu^*(K_X + B) = K_{X'} + B' - E'\),
where $B', E' \geq 0$, $\nu, B' = B$ and $B'$ and $E'$ have no common components. Choose $\varepsilon \in \mathbb{Q}^+$ sufficiently small so that $K_{X'} + B' + \varepsilon \operatorname{Ex}(\nu)$ is klt. Next we run a $(K_{X'} + B' + \varepsilon \operatorname{Ex}(\nu))$-MMP over $X$ using Proposition 2.20. Replacing $X'$ by the output of this MMP, we may assume that $E' + \varepsilon \operatorname{Ex}(\nu)$ is nef over $X$. Then by the negativity lemma, we have $E' + \varepsilon \operatorname{Ex}(\nu) = 0$ and hence $\nu$ is small. Since $X$ is $\mathbb{Q}$-factorial and $X'$ is the output of a MMP, then $X'$ is $\mathbb{Q}$-factorial.

For a proof of (2) first replace $\nu$ by a higher log resolution if necessary so that $X'$ contains all exceptional divisors $E$ over $X$ such that the discrepancy $a(E, X, B) \leq 0$. Then we run a $(K_{X'} + B')$-MMP over $X$. Replacing $X'$ by the output of this MMP and applying the negativity lemma we obtain the required result.

\[ \square \]

**Lemma 2.22** (DLT Modification). Let $X$ be $\mathbb{Q}$-factorial compact Kähler $3$-fold and $(X, B)$ a log canonical pair. Then there exists a projective birational morphism $f : (X', B') \to (X, B)$ such that

(i) $X'$ has $\mathbb{Q}$-factorial terminal singularities,

(ii) $(X', B')$ is a dlt pair, and

(iii) $K_{X'} + B' = f^*(K_X + B)$.

**Proof.** By [CHP16, Theorem 2.4], there is a dlt model $g : (\hat{X}, \hat{B}) \to (X, B)$ such that $K_{\hat{X}} + \hat{B} = g^*(K_X + B)$. So replacing $(X, B)$ by $(\hat{X}, \hat{B})$, we may assume that $(X, B)$ is dlt. Let $U \subset X$ be the largest open set such that $(U, B|_U)$ is a simple normal crossing pair. Then $\operatorname{codim}_X(X\setminus U) \geq 2$. Let $f : (X', \Theta' \geq 0) \to (X, 0)$ be the terminalization of $(X, 0)$ as in Lemma 2.21.(2) such that $K_{X'} + \Theta' = f^*K_X$. Then $f$ is an isomorphism over the smooth locus of $X$; in particular $f$ is an isomorphism over $U$. Set $Z = X\setminus U$. Now there is an effective divisor $B' := \Theta' + f^*B$ on $X'$ such that

$K_{X'} + B' = f^*(K_X + B),$

and $(X', B')$ is lc.

It remains to show that $(X', B')$ is a dlt pair. Let $U' = f^{-1}(U)$ and $Z' = X'\setminus U'$. Then $(U', B'|_{U'})$ is a simple normal crossing pair. If $E$ is an exceptional divisor over $X'$ with center in $Z'$, then its center in $X$ is contained in $Z$. Hence $a(E; X', B') = a(E; X, B) > -1$. Therefore by definition $(X', B')$ is a dlt pair, this completes the proof. \[ \square \]

**Proposition 2.23.** Let $X$ be a $\mathbb{Q}$-factorial compact Kähler $3$-fold with klt singularities and $\mu : X' \to X$ a proper birational morphism. Then every fiber of $\mu$ is rationally chain connected.

**Proof.** Let $\nu : \tilde{X} \to X$ be a log resolution dominating $X'$. Then it suffices to show that every fiber of $\nu$ is rationally chain connected. Thus replacing $X'$ by
\(\tilde{X}\) and \(\mu\) by \(\nu\) we may assume that \(X'\) is smooth. We run a \((K_{X'} + \text{Ex}(\mu))\)-MMP over \(X\) via Proposition 2.20:

\[
X' = X_0' \dasharrow X_1' \dasharrow \cdots \dasharrow X_n'.
\]

Since \(X\) is \(\mathbb{Q}\)-factorial and has klt singularities, we have \(X_n' = X\). Let \(\phi_i : X' \dasharrow X_i'\) and \(E_i\) be the push-forward of \(\text{Ex}(\mu)\) by \(\phi_i\).

If \(f_i : X_i' \to X_{i+1}'\) is a \((K_{X_i'} + E_i)\)-divisorial contraction of a divisor \(E\) in the above MMP (2.1), then by construction \(E\) is contained in the support of \(E_i\). In this case \(f_i\) is also a \((K_{X_i'} + E)\)-divisorial contraction. Now by adjunction \(K_E + B_E = (K_{X_i'} + E)|_E\) and \((E, B_E)\) is a klt surface. Note that \(-(K_E + B_E)\) is relatively ample with respect to the morphism \(f_i|_E : E \to f_i(E)\). It is well known that \(E\) is relatively rationally connected, for example, see [HM07, Corollary 1.3].

If instead we have \(f_i : X_i' \dasharrow X_{i+1}'\) a \((K_{X_i'} + E_i)\)-flip, then the flipping locus is contained in a component \(E\) of \(\text{Ex}(\mu)\). Let \(F = E + (1 - \epsilon)(E_i - E)\) for some \(0 < \epsilon \ll 1\). Then \(f_i\) is also a \((K_{X_i'} + F)\)-flip. Now by adjunction \((K_{X_i'} + F)|_E = K_E + B_E\) such that \((E, B_E)\) has klt singularities, and in particular, the surface \(E\) is \(\mathbb{Q}\)-factorial. Note that if \(g : X_i' \to Z\) is the \((K_{X_i'} + F)\)-flipping contraction associated to the flip \(f_i\), then \(-(K_E + B_E)\) is relatively ample with respect to the morphism \(g|_E : E \to g(E) = \tilde{E}\). Let \(C\) be any flipping curve, then \((K_E + B_E) \cdot C < 0\) and \(C^2 < 0\) (since it is an exceptional curve contained in the surface \(E\)). It follows that \((K_E + C) \cdot C < 0\) and hence that \(C\) is rational.

Finally, we argue that every flipped curve \(C^+\) is rational. Note that \(C^+\) is exceptional over \(X\) and hence must be contained in a component \(E^+\) of \(E_{i+1}^+ := f_{i+1}^*(E_i)\) (since \(E_{i+1}^+\) is the exceptional locus of \(X_{i+1}' \to X\)). Let \(g^+ : X_{i+1}' \to Z\) be the flipped contraction and \(E^+_Z = g^+_*(E^+)\). Let \(E^- = (f_{i+1}^{-1})_*E^+\) be its strict transform on \(X_i\) and \(K_{E^-} + B_{E^-} = (K_{X_i'} + E_i)|_{E^-}\). Since \((E^-, B_{E^-})\) is dlt and \(-(K_{E^-} + B_{E^-})\) is \(g|_{E^-}\) ample, it follows that \((E_Z, (g|_{E^-})_*B_{E^-})\) is dlt, where \(E_Z := g_*E^-\), and in particular \(E_Z\) has rational \(\mathbb{Q}\)-factorial singularities. Thus \(C^+\) is a rational curve.

From what we have seen above, it follows easily that the fibers of \(X_i' \to X\) are rationally chain connected if and only if the fibers of \(X_{i+1}' \to X\) are rationally chain connected. Since \(X_n' = X\), this concludes the proof.

2.3. **Technical lemmas.** In this subsection we will prove some technical results which will be used in the rest of the article. Note that some of the results here are obvious for projective varieties but not necessarily so for analytic varieties. We will use these results throughout the article without further reference.
**Lemma 2.24.** Let $f : X \to Y$ be a proper surjective morphism from a projective scheme $X$ over $\mathbb{C}$ to a complex space $Y$. Then for every point $y \in Y$, there is a (compact) curve $C_y \subset Y$ passing through $y$.

**Proof.** Set $\dim X = n$. Choose a point $y \in Y$ and fix a point $x_0 \in f^{-1}(y)$. Let $H_1, H_2, \ldots, H_{n-1}$ be $(n-1)$ general hyperplanes on $X$ containing the point $x_0$. Then $H_1 \cap H_2 \cap \cdots \cap H_{n-1}$ is a 1-dimensional subscheme of $X$ containing the point $x_0$. Let $C$ be an irreducible component of $H_1 \cap H_2 \cap \cdots \cap H_{n-1}$ containing the point $x_0$. We may pick $C$ so that $f(C) \neq \text{pt}$, i.e., $f(C)$ is a curve in $Y$ passing through the point $y \in Y$.

**Lemma 2.25.** Let $f : X \to Y$ be a proper bimeromorphic morphism between analytic varieties. Then for every $y \in f(\text{Ex}(f))$, $f^{-1}(y)$ is covered by (compact) curves.

**Proof.** Since $f$ is bimeromorphic, by [Hir75, Corollary 2] there is a bimeromorphic morphism $g : X' \to X$ such that $f' = g \circ f : X' \to Y$ is a projective bimeromorphic morphism. Choose a point $y \in f(\text{Ex}(f))$. Then $f'^{-1}(y) = g^{-1}(f^{-1}(y))$ is a projective scheme, and hence by Lemma 2.24, $f^{-1}(y)$ is covered by curves.

**Lemma 2.26.** Let $f : X \to Y$ be a projective morphism between two analytic varieties. If $C \subset Y$ is a (compact) irreducible curve, then there is a compact irreducible curve $\Gamma \subset X$ such that $f(\Gamma) = C$.

**Proof.** Set $Z = f^{-1}(C)$. Since any compact curve $C$ is projective, and $f|_Z : Z \to C$ is a projective morphism, $Z$ is projective. In particular, there is an irreducible curve $\Gamma \subset Z$ such that $f(\Gamma) = C$.

**Lemma 2.27.** Let $X$ be a normal $\mathbb{Q}$-factorial Kähler space. If $(X, B)$ is dlt, then $X$ has rational singularities.

**Proof.** See [KM98, Theorem 5.22] and [CHP16, §4].

**Lemma 2.28.** Let $f : X' \to X$ be a projective bimeromorphic morphism between $\mathbb{Q}$-factorial normal compact Kähler 3-folds. Assume that $X$ has klt singularities. Then $N^1(X'/X) := N^1(X')/f^*N^1(X)$ is generated by the $f$-exceptional divisors.

**Proof.** Let $\nu : X'' \to X'$ be a resolution of singularities of $X$. We will show that $N^1(X''/X) := N^1(X'')/(f \circ \nu)^*N^1(X)$ is generated by the $f$-exceptional divisors. To this end, let $f' = f \circ \nu$ and $E$ the reduced $f'$-exceptional divisor so that $\text{Supp} E = \text{Ex}(f')$. We run the $(K_{X''} + E)$-MMP over $X$ using Proposition 2.20. Note that since $X$ has klt singularities, this MMP contracts all
f'-exceptional divisors. Let \( X'' = X_0 \rightarrow X_1 \rightarrow \ldots \rightarrow X_n \) be the corresponding MMP over \( X \). Since \( X \) is \( \mathbb{Q} \)-factorial, it follows that \( X_n = X \). By [CHP16, Proposition 3.1.(a), Eqn. (5)] it follows that if \( X_i \rightarrow X_{i+1} \) is a flip, then \( N^1(X_i) \iso N^1(X_{i+1}) \) and if \( X_i \rightarrow X_{i+1} \) is a divisorial contraction, then \( N^1(X_i/X_{i+1}) \) is one dimensional and generated by the corresponding exceptional divisor. Thus \( N^1(X''/X) \) has a basis given by the \( f' \)-exceptional divisors. Similarly one sees that \( N^1(X''/X') \) has a basis given by the \( \nu \)-exceptional divisors. The lemma now follows easily.

\[ \square \]

**Corollary 2.29.** Let \( X \) be a normal compact Kähler 3-fold with rational singularities. Let \( T_1 \) and \( T_2 \) be two closed bi-degree \((1,1)\) currents with local potentials on \( X \) such that \([T_1] = [T_2] \) in \( H^{1,1}_{BC}(X) \). Let \( \phi : X \rightarrow X' \) be a proper bimeromorphic morphism to a \( \mathbb{Q} \)-factorial compact Kähler 3-fold with klt singularities. Then \( \phi_*[T_1], \phi_*[T_2] \in H^{1,1}_{BC}(X') \) and \( \phi_*[T_1] = \phi_*[T_2] \).

**Proof.** Let \( W \) be the resolution of the graph of \( \phi, p : W \rightarrow X \) and \( q : W \rightarrow X' \) the induced morphisms. Replacing \( W \) by a higher resolution if necessary we may assume that \( q \) is a projective morphism (see Theorem 2.13). Now by Lemma 2.28 there exists a \( q \)-exceptional divisor \( E \) on \( W \) such that \( p^*[T_1] + [E] = 0 \) in \( H^{1,1}_{BC}(W/X') \). Then by Lemma 2.8 there is a \((1,1)\) class \( \alpha \in H^{1,1}_{BC}(X') \) such that \( p^*[T_1] + [E] = q^*\alpha \). Thus by Corollary 2.9 we have \( q_*p^*[T_1] = \alpha \), i.e. \( \phi_*[T_1] \) is a class in \( H^{1,1}_{BC}(X') \). Similarly, \( \phi_*[T_2] \) is a class in \( H^{1,1}_{BC}(X') \), and since \( p^*[T_1] = p^*[T_2] \), we finally have \( \phi_*[T_1] = \phi_*[T_2] \) in \( H^{1,1}_{BC}(X') \).

\[ \square \]

**Lemma 2.30.** Let \( f : X' \rightarrow X \) be a projective bimeromorphic morphism between normal compact Kähler 3-folds with rational singularities and \( X \) is \( \mathbb{Q} \)-factorial. Let \( \omega \) be a Kähler form on \( X \), then for every \( 0 < \varepsilon \ll 1 \) there is a Kähler form \( \omega_\varepsilon \) on \( X' \) and an effective \( f \)-exceptional divisor \( F_\varepsilon \) (with small coefficients) such that \( [f^*\omega] = [\omega_\varepsilon + F_\varepsilon] \).

**Proof.** Let \( H \) be a relatively ample divisor and set \( F = f^*f_*H - H \), then \( F \geq 0 \) is an exceptional divisor such that \(-F\) is \( f\)-ample. Let \( \omega'_\varepsilon = f^*\omega - \epsilon F \) for any \( \varepsilon > 0 \). By [Var89, Prop. 1.3.1], \( \omega'_\varepsilon \) is a Kähler form for any \( 0 < \varepsilon \ll 1 \).

\[ \square \]

**Lemma 2.31.** Let \( S \) be a smooth projective surface such that \( H^2(S, \mathcal{O}_S) = 0 \). Let \( \alpha \) be a nef \((1,1)\)-class such that \( \alpha^2 = 0 \) and \( K_S \cdot \alpha < 0 \). Then \( S \) is covered by \( \alpha \)-trivial curves.

**Proof.** Since \( H^2(S, \mathcal{O}_S) = 0 \), from the exponential sequence and [HP16, Eqn. (2) and (3), page 223] it follows that \( \text{NS}(S)_{\mathbb{R}} = H^{1,1}_{BC}(S) \). In particular, \( \alpha \) is a nef \( \mathbb{R} \)-divisor, i.e., \( \alpha \) is a nef curve on \( S \). Now recall that on a projective variety the cone \( \overline{\text{NE}}(S) \) of numerical classes of nef curves is equal to the cone of numerical classes of movables curves \( \overline{\text{NM}}(S) \). Thus by Araujo’s decomposition
of the cone of movable curves $\overline{\mathcal{N}}M(S)$ [Ara10] (also see [Leh12] and [Das18] for the dlt case), there is a family of curves $\{C_t\}_{t \in T}$ covering $S$ such that $α \cdot C_t = 0$. □

**Definition 2.32.** [Bou04, Def. 2.2] Let $X$ be a normal compact Kähler variety.

(i) A closed positive bi-degree $(1, 1)$ current $T$ with local potentials is called a *Kähler current*, if $T \geq \omega$ for some Kähler form $\omega$ on $X$.

(ii) A class $α \in H^{1,1}_{BC}(X)$ is called *big* if it contains a Kähler current $T$.

(iii) A big class $α \in H^{1,1}_{BC}(X)$ is called a *modified Kähler class* if it contains a Kähler current $T$ such that the Lelong number $ν(T, D) = 0$ for all prime Weil divisors $D$ on $X$.

**Lemma 2.33.** [Bou04, Proposition 2.3] Let $X$ be a normal compact Kähler variety and $α \in H^{1,1}_{BC}(X)$. Then $α$ is a modified Kähler class if and only if there is a projective bimeromorphic morphism $μ : X' \to X$ from a Kähler manifold $X'$ and a Kähler class $α'$ such that $μ_*α' = α$.

Proof. See [Bou04, Proposition 2.3] and [CHP16, Page 990, Footnote 5]. □

**Lemma 2.34.** Let $X$ be a Q-factorial compact Kähler 3-fold with klt singularities. Let $ω \in H^{1,1}_{BC}(X)$ be a modified Kähler class. If $f : Y \to X$ is a projective bimeromorphic morphism from a Kähler manifold $Y$ and if there is a Kähler class $ω_Y \in H^{1,1}_{BC}(Y)$ such that $f_*ω_Y = ω$, then there exists an effective $f$-exceptional $\mathbb{R}$-divisor $E \geq 0$ such that $-E$ is $f$-ample, $\text{Supp} E = \text{Ex}(f)$ and $f^*ω = ω_Y + [E]$.

Proof. Since $X$ has Q-factorial klt singularities and $f$ is projective, by Lemma 2.28 there exists an $f$-exceptional divisor $E$ such that $[ω_Y + E] = 0$ in $N^1(Y/X)$. Then by Lemma 2.8, there exists a class $β \in H^{1,1}_{BC}(X)$ such that $[ω_Y + E] = f^*β$. But then by Corollary 2.9 we have $f^*ω_Y = β$, and hence $ω_Y + [E] = f^*ω$. In particular, $-E$ is $f$-ample and thus by the negativity lemma we have that $E$ is effective and $\text{Supp} E = \text{Ex}(f)$. □

**Corollary 2.35.** [Bou04, Proposition 2.4] Let $X$ be a Q-factorial compact Kähler 3-fold with klt singularities, and $α \in H^{1,1}_{BC}(X)$ a modified Kähler class. If $S \subset X$ is an irreducible surface, then $α|_S$ is big.

Proof. By Lemma 2.33 there is a projective bimeromorphic morphism $μ : X' \to X$ from a Kähler manifold $X'$ and a Kähler class $α'$ such that $μ_*α' = α$. Then by Lemma 2.34, $μ^*α = α' + [E]$, where $E$ is an effective and $μ$-exceptional divisor. Let $S' = μ^{-1}|S$ and $ν : S' \to S$. We may assume that $S'$ is smooth. Since $S'$ is not contained in the support of $E$, then

$$ν^*α|_S = (μ^*α)|_{S'} = (α' + [E])|_{S'}$$
is big and so $\alpha|_S$ is also big.

\[ \square \]

**Lemma 2.36.** Let $\phi : X \rightarrow X'$ be either a divisorial contraction or a flip between two compact Kähler 3-folds with $\mathbb{Q}$-factorial klt singularities. If $\omega$ is a modified Kähler class on $X$, then $\omega' := \phi_*\omega$ is a modified Kähler class on $X'$.

**Proof.** Since $\omega$ is a modified Kähler class, by Lemma 2.33 there exists a projective bimeromorphic morphism $\mu : \tilde{X} \rightarrow X$ from a Kähler manifold $\tilde{X}$ and a Kähler form $\tilde{\omega}$ such that $\mu_*[\tilde{\omega}] = \omega \in H^{1,1}_{BC}(X)$. Let $p : \overline{X} \rightarrow \tilde{X}$ and $q : X \rightarrow X'$ be a projective resolution of the graph of the bimeromorphic map $X \rightarrow \tilde{X}$. Then by Lemma 2.30 there exists a Kähler form $\omega$ and an effective $p$-exceptional divisor $E \geq 0$ such that $[\omega + E] = [p^*\tilde{\omega}]$. From Corollary 2.9 it follows that $[p_*\omega] = [\omega] \in H^{1,1}_{BC}(\overline{X})$. But from the definition of current it also follows that $[p_*\omega] = p_*[\tilde{\omega}]$, so we have $(\mu \circ p)_*[\tilde{\omega}] = \mu_*[\tilde{\omega}] = \omega$. Now by Lemma 2.28, there is a $q$-exceptional divisor $F$ such that $[\tilde{\omega} + F] = 0 \in N^1(X/X')$. Thus from Lemma 2.8 and its Corollary 2.9 it follows that $q_*[\tilde{\omega}]$ is a $(1,1)$ cohomology class in $X'$. Finally, from the commutative diagram we have $\phi_*\omega = q_*[\tilde{\omega}]$.

\[ \square \]

**Lemma 2.37.** Let $(X, B)$ be a klt pair, where $X$ is a $\mathbb{Q}$-factorial compact Kähler 3-fold. Let $\alpha$ be a nef and big $(1,1)$ class on $X$. Then there exist a modified Kähler class $\Theta$ and an effective $\mathbb{Q}$-divisor $F \geq 0$ such that $\alpha = \Theta + F$ and $(X, B + F)$ is klt.

**Proof.** Since $\alpha$ is a big class, by [Bou02, Theorem 1.4] there exists a projective bimeromorphic morphism $f : X' \rightarrow X$ from a Kähler manifold $X'$, a Kähler form $\omega'$ and an effective $\mathbb{R}$-divisor $E \geq 0$ such that $f^*\alpha = \omega' + E$. Then we can rewrite $\alpha$ as

\[ \alpha = f_*((\varepsilon \omega' + (1 - \varepsilon)f^*\alpha) + \varepsilon f_*E) \quad \text{for } 0 < \varepsilon < 1. \]

Note that $\varepsilon \omega' + (1 - \varepsilon)f^*\alpha$ is a Kähler class on $X'$, since $\alpha$ is nef, and therefore $\Theta' := f_*(\varepsilon \omega' + (1 - \varepsilon)f^*\alpha)$ is a modified Kähler class on $X$. Observe that $(X, B + \varepsilon f_*E)$ is klt for $0 < \varepsilon \ll 1$. Unfortunately $\varepsilon E$ is an $\mathbb{R}$-divisor. To remedy this we proceed as follows.

Let $E_m = \frac{1}{m}[m\epsilon E]$, then $E_m$ are $\mathbb{Q}$-divisors with the same support as $E$ such that $\lim_{m \rightarrow \infty} E_m = \epsilon E$. Since the modified Kähler cone $\mathcal{MK}(X)$ is an open cone (see [Bou04, §2.7]) and the klt condition is open, it follows easily that for $m \gg 0$ we have that $(X, B + f_*E_m)$ is klt and $\Theta' + f_*(\epsilon E - E_m)$ is also a modified Kähler class and hence replacing $E$ by $E_m$ and $\Theta'$ by $\Theta' + f_*(\epsilon E - E_m)$, we may assume that $E$ is a $\mathbb{Q}$-divisor.

\[ \square \]
Lemma 2.38 (Hodge Index Theorem). [BHPVdV04, Theorems IV.2.14 and IV.3.1] Let \( S \) be a smooth compact Kähler surface and \( \omega \in H^{1,1}(S) \) a \((1,1)\) class such that \( \omega^2 > 0 \). Let \( \alpha \in H^{1,1}(S) \) be a \((1,1)\)-class on \( S \). If \( \omega \cdot \alpha = 0 \), then \( \alpha^2 \leq 0 \); moreover, if \( \alpha \neq 0 \), then \( \alpha^2 < 0 \).

Lemma 2.39. Let \( X \) be a normal \( \mathbb{Q} \)-factorial Kähler 3-fold and \( S \) a prime divisor with normalization \( \tilde{S} \to S \) and minimal resolution \( \nu : S' \to S \). Then there is an effective \( \mathbb{Q} \)-divisor \( E \) on \( S' \) such that
\[
\nu^*((K_X + S)|_S) = K_{S'} + E.
\]

Proof. By adjunction, we have \( K_{\tilde{S}} + B_{\tilde{S}} = (K_X + S)|_{\tilde{S}} \), where \( B_{\tilde{S}} \geq 0 \) is the different. Since \( \nu \) is a resolution of singularities of \( S \) and \( \tilde{S} \to S \) is the normalization, \( \nu \) factors through \( \tilde{S} \); let \( \pi : S' \to \tilde{S} \) be the induced morphism. Then, as \( \pi \) is the minimal resolution of \( \tilde{S} \), we have \( K_{S'} = \pi^*K_{\tilde{S}} - E' \), where \( E' \geq 0 \). Finally, we have
\[
\nu^*((K_X + S)|_S) = \pi^*(K_{\tilde{S}} + B_{\tilde{S}}) = K_{S'} + E' + \pi^*B_{\tilde{S}} = K_{S'} + E,
\]
where \( E = E' + \pi^*B_{\tilde{S}} \geq 0 \). \( \square \)

Lemma 2.40. Let \( X \) be a uniruled normal \( \mathbb{Q} \)-factorial compact Kähler 3-fold with klt singularities and \( \phi : X \to X' \) a bimeromorphic contraction to a \( \mathbb{Q} \)-factorial compact Kähler 3-fold \( X' \) with klt singularities such that \( \phi \) does not extract any divisor, i.e. \( \phi^{-1} : X' \to X \) does not contract any divisor. If the base of the MRC(C) fibration of \( X \) has dimension less than 2, then \( X' \) is a projective variety.

Proof. Let \( \pi : X \to Z \) be the MRC(C) fibration (see [CH20, Remark 6.10]). By assumption \( \dim Z = 0 \) or 1. First note that, since \( X \) has rational singularities, by [Nam02, Theorem 1.6], \( X \) is projective if and only if any resolution \( \tilde{X} \) of the singularities of \( X \) is projective. Note also that by Proposition 2.23, the fibers of \( \nu : \tilde{X} \to X \) are rationally chain connected, thus it follows that \( \tilde{X} \to Z \) is also a MRC(C) fibration. Note that as \( \tilde{X} \) is smooth, then its MRC and MRCC fibrations coincide. Thus replacing \( X \) by a resolution of singularities we may assume that \( X \) is a compact Kähler manifold and \( \phi : X \to X' \) is a morphism. Possibly replacing \( X \) further by a higher resolution we may assume that \( \pi \) and \( \phi \) are both morphisms. Since the general fibers of \( \pi \) are rationally connected, by [Deb01, Corollary 4.18] \( H^0(F, \Omega_F) = 0 \) for all \( i \geq 1 \) where \( F \) is a general fiber. We claim that \( H^0(X, \Omega_X^2) = 0 \). If \( \dim Z = 0 \), then this is clear, so assume that \( \dim Z = 1 \). Then observe that the following exact sequence
\[
\pi^*\Omega_Z \longrightarrow \Omega_X \longrightarrow \Omega_{X/Z} \longrightarrow 0
\]
is left exact over Zariski open dense subset of $Z$. This follows from the generic smoothness of $\pi$ and the fact that the MRC fibration is an almost holomorphic map. Restricting this sequence to a general fiber $F$ of $\pi$ we get the following short exact sequence

$$0 \rightarrow \mathcal{O}_F \rightarrow \Omega_X|_F \rightarrow \Omega_F \rightarrow 0.$$ 
Thus we have a short exact sequence

$$0 \rightarrow \Omega_F \rightarrow \Omega^2_X|_F \rightarrow \Omega^2_F \rightarrow 0.$$ 
Since, as observed above, $H^0(\Omega^i_F) = 0$ for $i = 1, 2$, we have $H^0(F, \Omega^2_X|_F) = 0$. In particular, $s|_F = 0$ for any section $s \in H^0(X, \Omega^2_X)$. Since $\Omega^2_X$ is torsion free, it follows that $H^0(X, \Omega^2_X) = 0$. Then $H^2(X, \mathcal{O}_X) = H^0(X, \Omega^2_X) = 0$ and by Kodaira’s projectivity criterion we have that $X$ is projective.

Finally, since $X'$ has $\mathbb{Q}$-factorial klt singularities, running a $(K_X + \text{Ex}(\phi))$-MMP over $X'$ will recover $X'$, and hence $X'$ is also projective.

□

**Lemma 2.41.** Let $S$ be a smooth compact Kähler surface. If $K_S$ is not pseudo-effective, then $S$ is projective.

**Proof.** Contracting the $(-1)$-curves by repeated application of Castelnuovo’s contraction theorem we may assume that $S$ is a minimal surface. Now since $S$ is a Kähler surface, by [BHPVdV04, Theorem IV.3.1] the first Betti number $b_1(S)$ is even. Since $K_S$ is not pseudo-effective, the Kodaira dimension is negative $\kappa(K_S) = -\infty$. Thus from [BHPVdV04, Table 10, Chap. VI, page 244] we see that $S$ is either a compact minimal rational surface or a compact ruled surface over a curve of genus $g \geq 1$. Now by [BHPVdV04, Corollary IV.6.5] a compact complex surface $S$ is projective if and only if its algebraic dimension $a(S) = 2$. From [BHPVdV04, Table 10, Chap. VI, page 244] we again see that the $a(S) = 2$ in each of the above two cases, and hence $S$ is projective.

□

**Lemma 2.42.** Let $(X, B \geq 0)$ be a log pair, where $X$ is a normal $\mathbb{Q}$-factorial compact analytic variety. Let $f : X \rightarrow Y$ be a proper surjective morphism to a normal compact analytic variety $Y$. Assume that one of the following conditions is satisfied:

1. $(X, B)$ is dlt and $-(K_X + B)$ is $f$-ample, or
2. $(X, B)$ is klt and $-(K_X + B)$ is $f$-nef and $f$-big.

Then $Y$ has rational singularities.

**Proof.** Since $X$ is klt, by Lemma 2.27, $X$ has rational singularities. Now since $X$ is $\mathbb{Q}$-factorial, perturbing the coefficients of $B$ in the dlt case we may assume
that \((X, B)\) is klt and \(-(K_X + B)\) is still \(f\)-ample. Therefore by the relative Kawamata-Viehweg vanishing theorem as in [DO19, Theorem 5.3], in both of the cases above we have \(R^i f_* \mathcal{O}_X = 0\) for all \(i > 0\). Then by [Kov00, Theorem 1] \(Y\) has rational singularities. Note that the proof of [Kov00, Theorem 1] uses Grothendieck duality and the Grauert-Riemenschneider vanishing theorem, both of which are known in the analytic category due to [RR74, RRV71] and [Tak85, Corollary II], respectively.

\[\square\]

3. Minimal model program for dlt pseudo-effective pairs

In this section we will prove Theorems 1.5 and 1.1. Throughout this section \((X, B)\) will be a dlt pair such that \(X\) is a \(\mathbb{Q}\)-factorial compact Kähler 3-fold and \(K_X + B\) is pseudo-effective. By [Bou04, Thm. 3.12 and Pro. 3.8] there exist positive real numbers \(\lambda_j > 0\) and irreducible surfaces \(S_j \subset X\) such that

\[K_X + B \equiv \sum \lambda_j S_j + N(K_X + B),\]

where \(N = N(K_X + B)\) is a pseudo-effective class which is nef in codimension 1, i.e. \(N|_{S'}\) is pseudo-effective for any surface \(S' \subset X\).

Proof of Theorem 1.5. Recall that \(\alpha\) is a \((1, 1)\) nef class such that \(\alpha \cdot C = 0\) if and only if \([C] \in R\). Let \(S\) be the unique surface which is covered by and contains all the curves \(C \subset X\) such that \([C] \in R\). Let \(\nu : \tilde{S} \to S\) be the normalization morphism and \(\tilde{f} : \tilde{S} \to T\) the nef reduction of \(\nu^*(\alpha|_S)\) (see [HP15, Theorem 3.19]). Since \(n(\alpha) = 1\), \(T\) is a smooth projective curve. Moreover, we have \(F \cdot \nu^*(\alpha|_S) = 0\) for any fiber \(F\) of \(\tilde{f}\). We also have that \(\alpha \cdot C > 0\) if \(C \subset X\) is not contained in \(S\) or if \(C\) is contained in \(S\) but dominates \(T\). Scaling \(\alpha\) if necessary and then using Theorem 2.16 we may assume that \(\omega = \alpha - (K_X + B)\) is a Kähler class. Next replacing \(B\) by \((1 - \varepsilon)B\) and \(\omega\) by \(\omega + \varepsilon B\) for sufficiently small \(\varepsilon \in \mathbb{Q}^+\), we may assume that \((X, B)\) is klt.

Let \(b = \text{mult}_SB\). For two divisors \(D\) and \(D'\) we say \(D \equiv_\alpha D'\) if and only if \((D - D') \cdot C = 0\) for any curve \(C \subset X\) such that \(\alpha \cdot C = 0\). Since \(S \cdot R < 0\) (cf. [HP16, Lemma 7.5]) and \(\alpha\) supports the extremal ray \(R\), we have \(K_X + B \equiv_\alpha aS\) for some \(a > 0\).

Let \(\mu : X' \to X\) be a log resolution of \((X, B)\) and set \(\Delta' = \mu^{-1}(B + (1 - b)S) + \text{Ex}(\mu)\) and \(S' = \mu^{-1}S\). Since \(\mu\) is a projective morphism, after running a \((K_X + \Delta')\)-MMP over \(X\) via Proposition 2.20, we may assume that \(\mu\) is an isomorphism over the complement of \(S\) (since \((X, B)\) is \(\mathbb{Q}\)-factorial and klt). Then we have

\[K_{X'} + \Delta' = \mu^*(K_X + B) + \sum c_j E_j + (1 - b)S' \equiv_\alpha \sum d_j E_j + dS',\]
where \( d_j \geq c_j > 0 \) and \( d > 1 - b > 0 \).

Now we run the \( \alpha' := \mu^*\alpha \)-trivial \((K_X + \Delta')\)-MMP, say
\[
\phi_i : X' = X'_0 \rightarrow X'_1 \rightarrow X'_2 \rightarrow \cdots \rightarrow X'_i.
\]

We claim that this MMP exists and each step preserves the above relation
\[
K_{X'_i} + \Delta'_i \equiv_{\alpha'_i} \phi_{i,*} \left( \sum d_j E_j + dS' \right),
\]
where \( \alpha'_i = \phi_{i,*} \alpha' \) is a nef (1,1) class. We proceed by induction. Let \( R_i \) be an \( \alpha'_i \)-trivial, \((K_{X'_i} + \Delta'_i)\)-negative extremal ray. From the above relation, it follows that \( R_i \cdot \phi_{i,*} \left( \sum d_j E_j + dS' \right) < 0 \) and hence the contracted locus is contained in the support of \( [\Delta'_i] \). Since \((X', \Delta')\) is dlt, so is \((X_i, \Delta'_i)\) and so by Theorem 2.17 and Theorem 2.18, we may flip/contract \( R_i \) via \( X'_i \rightarrow X'_{i+1} \). Let \( g : X'_i \rightarrow Z \) be the contraction of \( R_i \) (\( Z = X'_{i+1} \) if \( R_i \) is divisorial). By [CHP16, Proposition 3.1(5)], \( \alpha'_i = g^*\alpha_Z \), where \( \alpha_Z \) is a nef (1,1) class on \( Z \) and \( g_*(K_{X'_i} + \Delta'_i - \phi_{i,*} \left( \sum d_j E_j + dS' \right)) \) is a \( \mathbb{Q} \)-Cartier divisor such that
\[
g_*(K_{X'_i} + \Delta'_i - \phi_{i,*} \left( \sum d_j E_j + dS' \right)) \equiv_{\alpha_Z} 0.
\]

Pulling back to \( X'_{i+1} \) we have \( K_{X'_{i+1}} + \Delta'_{i+1} \equiv_{\alpha'_{i+1}} \phi_{i+1,*} \left( \sum d_j E_j + dS' \right) \). By Theorem 2.19, after finitely many steps, we may assume that there are no \( \alpha'_n \)-trivial, \((K_{X'_n} + \Delta'_n)\)-negative extremal rays.

Recall that \( \mu \) is an isomorphism over the complement of \( S \), and hence the support of \( S' + \sum E_j \) is equal to the support of \( \mu^{-1}(S) \). Since each component of \( S' + \sum E_j \) is normal (being a dlt center), there is a unique induced morphism from each component of \( S' + \sum E_j \) to the normalization \( \tilde{S} \) and hence to \( T \). Since the above MMP only contracts curves and divisors contained in the support of \( S' + \sum E_j \), it follows that there is a meromorphic map \( \phi_{i,*}(S' + \sum E_j) \rightarrow T \) for all \( i \geq 0 \).

**Claim 3.1.** \( \phi_{n,*}(\sum E_j + S') \) does not dominate \( T \), i.e., \( S' \) and every \( E_j \) that dominates \( T \) are contracted by \( \phi_n \).

Let \( K_{X'} + B' = \mu^*(K_X + B) \). After perturbing \( B' \) by a small effective \( \mu \)-exceptional \( \mathbb{Q} \)-divisor, we may write \( \alpha' = \mu^*\alpha = K_{X'} + B' + \omega' \), where by Lemma 2.30, \( \omega' \) is a Kähler class on \( X' \). Then \( K_{X'} + \Delta' = K_{X'} + B' + \mathcal{E}' \), where \( \mathcal{E}' \geq 0 \) is a \( \mathbb{Q} \)-divisor such that \( \text{Supp}(\mathcal{E}') = S' + \sum E_j \). Thus on \( X'_n \) we have
\[
\alpha'_n + \mathcal{E}'_n = K_{X'_n} + \Delta'_n + \omega'_n,
\]
where \( \omega'_n \in H^1_{BC}(X_n) \) is a modified Kähler class (see Lemma 2.36).

Let \( F \) be an effective \( \mu \)-exceptional \( \mathbb{Q} \)-divisor such that \(-F\) is \( \mu \)-ample. Then for a sufficiently small positive rational number \( \epsilon \in \mathbb{Q}^+ \), set \( \mathcal{F}' := \mu^*S + \epsilon F \) so that for any \( m > 0 \) sufficiently divisible, the line bundles \( \mathcal{O}_{X'}(-m\mathcal{F}')|_{S'} \) and \( \mathcal{O}_{X'}(-m\mathcal{F})|_{E_j} \) are ample over \( T \) for all \( j \).
Let \( F'_i := \phi_i^* F' \). We make the following claim.

**Claim 3.2.** If \( E_i \) is a component of \( F' \) dominating \( T \), then for every \( 0 \leq i \leq n \) we have that
\[
\text{mult}_{E_i}(F') \geq \text{mult}_{E_i}(\phi_i^* F'_i),
\]
and the above inequality is strict if and only if \( \phi_i^* E_i = 0 \).

**Proof of Claim.** We will show that \((3.4)_i\) holds for \( 0 \leq i \leq n \) by induction on \( i \). It is clear that this inequality holds for \( i = 0 \), so assuming that it holds for some \( i \geq 0 \), we must show that it also holds when \( i \) is replaced by \( i + 1 \). If \( X_i \rightarrow X_{i+1} \) is a flip, then it is an isomorphism over a neighborhood of the generic point of \( T \) and hence the inequality \((3.4)_{i+1}\) holds. Thus we may assume that \( h_i : X'_i \rightarrow X'_{i+1} \) is a divisorial contraction that contracts \( E_i \), a component of \( F' \) dominating \( T \) as otherwise \( h_i \) is an isomorphism over a neighborhood of the generic point of \( T \) and the statement is clear. It suffices to show that \( F'_i \geq h_i^* F'_{i+1} \) over a neighborhood of the generic point of \( T \) and the inequality is strict along \( E_{i,i} := \phi_i^* E_i \). Let \( C_{i,t} \) be a general fiber of \( E_i \rightarrow T \). Notice that since the flipping loci do not dominate \( T \), then \( \phi_i \) is a morphism on a neighborhood of \( C_{i,t} \). Let \( C_{i,i,t} = \phi_i^* C_{i,t} \) then \( C_{i,i,t} \) is contained in \( E_{i,i} \) and does not dominate \( T \). It is then easy to see that \( C_{i,i,t} \) generates the extremal ray corresponding to the contraction \( h_i \). We have
\[
C_{i,i,t} \cdot F'_i = C_{i,t} \cdot \phi_i^* F'_i \leq C_{i,t} \cdot F' < 0,
\]
where the first inequality follows from the induction hypothesis and the fact that \( \text{mult}_{E_i} F' = \text{mult}_{E_i} \phi_i^* F'_i \), since \( E_i \) is not contracted by \( \phi_i \); the second inequality follows from \( \mathcal{O}_{E_i}(-mF') \) being ample over \( T \).

It then follows that \( h_i \) is \( F'_i \)-negative and so from negativity lemma it follows that \( h_i^* F'_{i+1} = F'_i + tE_{i,i} \) for some \( t > 0 \). This implies that \((3.4)_{i+1}\) holds and we are done by induction. \( \square \)

Assume by contradiction that \( \phi_{n,*}(\sum E_j + S') \) dominates \( T \). Let \( \lambda \) be the smallest positive rational number such that \( \Gamma_n = \phi_{n,*}(\mathcal{E}' - \lambda F') \leq 0 \) over \( \eta_T \) the generic point of \( T \). Renaming \( S' \) by \( E_0 \) we observe that there is a component \( E^n_k \) of \( \phi_{n,*}(\sum E_j + S') \) dominating \( T \) such that \( \text{mult}_{E^n_k}(\phi_{n,*}(\mathcal{E}' - \lambda F')) = 0 \). Let \( \{C_{k,n,t}\}_{t \in \mathbb{T}} \) as above be an \( \alpha'_n \)-trivial family of curves covering \( E^n_k \). Then
\[
C_{k,n,t} \cdot (\alpha'_n + \mathcal{E}_n' - \lambda F') = C_{k,n,t} \cdot \Gamma_n \leq 0.
\]

Since \( \omega'_n \) is a modified Kähler class, by Corollary 2.35, \( \omega'_n|_{E^n_k} \) is big. In particular, \( \omega'_n \cdot C_{k,n,t} > 0 \) for a covering family of curves on \( E^n_k \). Thus, as \( (K_{X^n_k} + \Delta_n') \cdot C_{k,n,t} \geq 0 \), it follows from \((3.5)\) and \((3.3)\) that
\[
0 \geq C_{k,n,t} \cdot (K_{X^n_k} + \Delta_n' + \omega'_n - \lambda F'_n) > -\lambda C_{k,n,t} \cdot F'_n.
\]
Now since the component $E_k$ of $\mathcal{F}'$ is not contracted by $\phi_n$ (since $E^n_k = \phi_n^* E_k \neq 0$), it follows from Claim 3.2 and its proof that $\text{mult}_{E_k} \mathcal{F}' = \text{mult}_{E_k} \phi^* \mathcal{F}'$. Set $\Lambda = \{ i \geq 0 : E_i$ is a component of $\mathcal{F}'$ dominating $T \}$. Then again from Claim 3.2 it follows that we can write

$$\mathcal{F}' - \phi^*_n \mathcal{F}'_n = \sum_{i \in \Lambda, i \neq k} a_i E_i + F,$$

where $a_i \geq 0$ for all $i \in \Lambda \setminus \{ k \}$, and $F$ is a $\mu$-exceptional divisor on $X'$ which does not dominate $T$. Note that $F$ is not necessarily an effective divisor.

Then $E_i \cdot C_{k,t} \geq 0$ for all $i \in \Lambda \setminus \{ k \}$ and $F \cdot C_{k,t} = 0$. Moreover, since $\mathcal{O}_{E_k}(-m \mathcal{F}')$ is ample over $T$ we have

$$-C_{k,n,t} \cdot \mathcal{F}' = -C_{k,n,t} \cdot \phi^* \mathcal{F}'_n \geq -C_{k,t} \cdot \mathcal{F}' > 0.$$

This is a contradiction to (3.6), and thus $\phi_n^*(\sum E_j + S')$ does not dominate $T$.

**Claim 3.3.** $\phi_n^*(\sum E_j + S') = 0$.

**Proof.** Let $W$ be the normalization of the graph of the induced bimeromorphic map $\psi_n : X \dashrightarrow X'_n$, and $p : W \to X$ and $q : W \to X'_n$ are the projections. Let $I$ and $I'$ be the set of all indices of the $\mu$-exceptional divisors which are contracted and respectively, not contracted by $\phi_n$. Then $\phi_n$ contracts $S'$ and the divisor $\sum_{i \in I} E_i \subset \text{Ex}(\mu)$, and $\psi_n$ contracts $S$ and extracts $\sum_{i \in I'} E_i \subset \text{Ex}(\mu)$. Set $\mathcal{G} = q^* \phi^*_n(\sum d_j E_j + dS') \geq 0$. We claim that $\mathcal{G}$ is $p$-exceptional. Indeed, if $F$ is a component of $\mathcal{G}$, then it does not dominate $T$, since $q(F)$ is contained in the support of $\phi_n^*(\sum d_j E_j + dS')$ and the latter one does not dominate $T$ by Claim 3.2. But if $p_* F \neq 0$, then $p_* F = S$, since the only divisor contracted by $\psi_n$ is $S$. Since $S$ dominates $T$, this is a contradiction.

Now we will show that $\mathcal{G}$ is nef over $X$. To this end assume by contradiction that $\mathcal{G} \cdot C < 0$ for some curve $C \subset W$ such that $p(C) = pt$. Then $C$ is contained in the support of $\mathcal{G}$, since $\mathcal{G}$ is effective. Now set $Z := p^{-1}(S) \subset W$. Then from the construction above it is clear that the support of $\mathcal{G}$ is contained in $Z$. In particular, $C$ is contained in $Z$. Since no component of $\mathcal{G}$ dominates $T$, $C$ is vertical over $T$ and hence either $q_* C = 0$ or $q_* C$ is an $\alpha_n$-trivial curve on $X'_n$. Since $\phi_n^*(\sum d_j E_j + dS') \equiv_{\alpha_n} K_{X'_n} + \Delta'_n$, it follows that $\mathcal{G} \cdot C = (K_{X'_n} + \Delta'_n) \cdot q_* C \geq 0$, which is a contradiction. Thus $\mathcal{G}$ is nef over $X$.

Then by the negativity lemma we have $\mathcal{G} = 0$, and hence $\phi_n^*(\sum E_j + S') = 0$. \hfill \qed

**Claim 3.4.** $\psi_n : X \dashrightarrow X'_n$ is a morphism.

**Proof.** By contradiction assume that $\psi_n$ is not a morphism. Let $W$ be a resolution of the graph of $\psi_n$ and $p : W \to X$ and $q : W \to X'_n$ are the induced morphisms. By Theorem 2.13, possibly replacing $W$ by a higher resolution we
may assume that a \( p \) is projective. If \( \psi_n \) is not a morphism, then there is a curve \( C \) in \( W \) such that \( p_* C = 0 \) but \( q_* C = C' \neq 0 \). Let \( \omega'_n \) be a Kähler form on \( X'_n \). Then \( \omega'_n \cdot C' > 0 \). Note that since \( X \) is \( \mathbb{Q} \)-factorial with klt singularities and \( p \) is projective, by Lemma 2.28, \( N^1(W/X) \) is generated by the \( p \)-exceptional divisors, say \( E_1, \ldots, E_r \). Then there exist real numbers \( e_1, \ldots, e_r \in \mathbb{R} \) such that \( \left[q^* \omega'_n + \sum e_i E_i\right] = 0 \) in \( N^1(W/X) \). By Lemma 2.8 there exists a \((1,1)\) form \( \omega \) with local potentials on \( X \) such that \( [p^* \omega] = \left[q^* \omega'_n + \sum e_i E_i\right] \). Now since \( S \cdot R < 0 \), there is a real number \( r \in \mathbb{R} \) such that \( (\omega + r S) \cdot R = 0 \).

Since \( \psi_{n,*} S = 0 \), it follows that \( \sum e_i E_i + r p^* S \) is a \( q \)-exceptional divisor and \( [p^*(\omega + r S) - q^* \omega'_n] \equiv_{X'_n} 0 \). Indeed, if \( \gamma \) is a curve contracted by \( q \) but not by \( p \), then \( \alpha \cdot p_* \gamma = 0 \), since \( \psi_{n,*} (p_* \gamma) = 0 \) and \( \psi_n \) only contracts \( \alpha \)-trivial curves. In particular, \( p_* \gamma \) is a curve contained in the extremal ray \( R \), and hence \( [\omega + r S] \cdot p_* \gamma = 0 \) and the claim follows. Then applying the negativity lemma we get \( \sum e_i E_i + r p^* S = 0 \), and hence we have \( [p^*(\omega + r S)] = [q^* \omega'_n] \). Therefore

\[
0 < \omega'_n \cdot C' = q^* \omega'_n \cdot C = (\omega + r S) \cdot p_* C = 0,
\]

and this is a contradiction. \( \square \)

**Proof of Theorem 1.1.** By Theorem 2.16 the cone theorem holds for \((X, B)\). By Theorem 2.17, Theorem 2.18 and Theorem 1.5 flips and divisorial contractions exist and hence we may run a MMP which terminates by Theorem 2.19. \( \square \)

4. The minimal model program for uniruled pairs

In this section we will consider the minimal model program for non-pseudo-effective dlt compact Kähler 3-fold pairs \((X, B)\). Since \( K_X + B \) is not pseudo-effective, neither is \( K_X \) and hence the MRC fibration \( X \dashrightarrow Z \) is non-trivial (see e.g. [HP15, Introduction]). Let \( \nu : X' \to X \) be any resolution, then since \((X, B)\) is dlt, the fibers of \( \nu \) are rationally connected (see Proposition 2.23) and hence \( X' \dashrightarrow Z \) is the MRC fibration of \( X' \). Recall that if \( \dim Z \leq 1 \), then \( X \) is projective by Lemma 2.40. Since the projective case is well understood, we will focus on the case where \( \dim Z = 2 \). Note that by [HP15, Remark 3.2], \( Z \) is not uniruled and hence \( K_Z \) is pseudo-effective. Moreover, from Definition 2.22(i) it follows that \( Z \) is in Fujiki’s class \( \mathcal{C} \). Then replacing \( Z \) by a resolution of singularities we may assume that \( Z \) is a smooth compact complex surface in Fujiki’s class \( \mathcal{C} \), and hence by [Fuj83, Proposition 2, page 104], \( Z \) is Kähler.

**Definition 4.1.** Let \((X, B \geq 0)\) be a log pair, where \( X \) is a \( \mathbb{Q} \)-factorial compact Kähler 3-fold. Suppose that the base of the MRC fibration \( f : X \dashrightarrow Z \) has dimension 2. Let \( X_2 \cong \mathbb{P}^1 \) be a general fiber of \( f \). Then a modified
Kähler class $\omega$ on $X$ is called $(K_X + B)$-normalized if $(K_X + B + \omega) \cdot X_z = 0$. Note that as $\omega$ is a modified Kähler class, it is positive on general fibers $X_z$, and hence $(K_X + B) \cdot X_z < 0$.

**Lemma 4.2.** With the same notations and hypothesis as in the definition above assume that $(X, B)$ is dlt and $\omega$ is a $(K_X + B)$-normalized modified Kähler class. Then $K_X + B + \omega$ is pseudo-effective.

**Proof.** Since $\omega$ is modified Kähler class, there is a bimeromorphic morphism from a compact Kähler manifold $\mu : X' \rightarrow X$ and a Kähler class $\omega' \in H^{1,1}_{\mathbb{R}}(X')$ represented by Kähler form on $X'$ such that $\mu_{*} \omega' = \omega$. We may write $K_{X'} + B' = \mu^{*}(K_X + B) + E$ where $E \geq 0, B' \geq 0, \mu_{*}B' = B$ and $E$ and $B'$ do not share any common component. Since $\dim Z = 2$, we may assume that $X' \rightarrow X$ is an isomorphism on a neighborhood of a general fiber $X_z$ of $X \rightarrow Z$. Therefore $\omega'$ is $(K_{X'} + B')$-normalized. Note that if $K_{X'} + B' + \omega'$ is pseudo-effective, then so is $K_X + B + \omega = \mu_{*}(K_{X'} + B' + \omega')$. Replacing $(X, B)$ by $(X', B')$ we may therefore assume that $\omega$ is a Kähler class.

Since the pseudo-effective cone is closed, it is enough to show that $K_X + (1 - \delta)B + (1 + \varepsilon)\omega$ is pseudo-effective for all $1 \gg \varepsilon \gg \delta > 0$. Let $Z' \rightarrow Z$ be a resolution of singularities of $Z$ and $\mu : X' \rightarrow X$ a log resolution of $(X, B)$ such that the induced meromorphic map $\varphi' : X' \rightarrow Z'$ is a morphism. We may assume that $X_z = X'_z$ for general $z \in Z$. Let $F$ be an effective and $\mu$-exceptional $\mathbb{Q}$-divisor such that $\omega' = [\mu^{*}\omega - F]$ is a Kähler class on $X'$ (see Lemma 2.30). Set

$$K_{X'} + B'_{\delta,\varepsilon} := \mu^{*}(K_X + (1 - \delta)B) + \varepsilon F.$$  

Then we have

$$\mu^{*}(K_X + (1 - \delta)B + (1 + \varepsilon)\omega) = K_{X'} + B'_{\delta,\varepsilon} + \omega'_{\varepsilon},$$

where $\omega'_{\varepsilon} = \mu^{*}\omega + \varepsilon\omega'$ is Kähler class, since $\omega$ is a Kähler class on $X$.

Therefore it is enough to show that $K_{X'} + (B'_{\delta,\varepsilon})^{\geq 0} + \omega'_{\varepsilon}$ is pseudo-effective. Let $X'_t$ be a general fiber of $\varphi' : X' \rightarrow Z'$. Then $X'_t \cong \mathbb{P}^1$ and $c_1(K_{X'} + (B'_{\delta,\varepsilon})^{\geq 0} + \omega'_{\varepsilon})|_{X'_t}$ is a Kähler class. Thus by [Gue20, Theorem], $K_{X'/Z'} + (B'_{\delta,\varepsilon})^{\geq 0} + \omega'_{\varepsilon}$ is pseudo-effective. Now since $Z'$ is not uniruled, $K_{Z'}$ is pseudo-effective. Therefore $K_{X'} + (B'_{\delta,\varepsilon})^{\geq 0} + \omega'_{\varepsilon}$ is pseudo-effective as required.

**Corollary 4.3.** Let $(X, B)$ be a klt pair, where $X$ is a $\mathbb{Q}$-factorial compact Kähler 3-fold. Assume that $X$ is uniruled and the dimension of the base of the MRC fibration $X \rightarrow Z$ is 2. Let $\omega$ be a nef and big class on $X$ such that $(K_X + B + \omega) \cdot F = 0$ for general fibers $F$ of $X \rightarrow Z$. Then $K_X + B + \omega$ is pseudo-effective.
Proof. Since $(X, B)$ is klt and $\omega$ is nef and big, by Lemma 2.37 we can write $\omega = \Theta + F$, where $\Theta$ is a modified Kähler class and $F$ is an effective $\mathbb{Q}$-divisor such that $(X, B + F)$ klt. Thus replacing $B$ by $B + F$ and $\omega$ by $\Theta$ we may assume that $\omega$ is a modified Kähler class. Then the result follows from Lemma 4.2.

Lemma 4.4. Let $(X, B)$ be a dlt pair, where $X$ is a $\mathbb{Q}$-factorial compact Kähler 3-fold. Suppose that $X$ is uniruled and the base of the MRC fibration $f : X \to Z$ has dimension 2. Let $F(\cong \mathbb{P}^1)$ be a general fiber of $f$. If $(K_X + B) \cdot F \geq 0$, then $K_X + B$ is pseudo-effective.

Proof. First, replacing $Z$ by a resolution, we may assume that $Z$ is a smooth compact Kähler non-uniruled surface. Let $\mu : X' \to X$ be a log resolution of $(X, B)$ which resolves the map $f : X \to Z$ and

$$K_{X'} + B' = \mu^*(K_X + B) + E,$$

where $B' \geq 0, E \geq 0, \mu_* B' = B$ and $B'$ and $E$ do not share any common component.

Observe that $X'_z \cong X_z \cong \mathbb{P}^1$ for a general $z \in Z$. In particular, $(K_{X'}) \cdot F = (K_X + B) \cdot F \geq 0$ for general fibers $F$ of $X' \to Z$. Moreover, if $K_{X'} + B'$ is pseudo-effective, then $K_X + B$ is also pseudo-effective. Therefore replacing $(X, B)$ by $(X', B')$ we may assume that $(X, B)$ is a simple normal crossing dlt pair and the MRC fibration $f : X \to Z$ is a morphism. Now since the pseudo-effective cone is closed, it is enough to show that $K_X + B + \omega$ is pseudo-effective for all Kähler classes $\omega$. Note that $(K_X + B + \omega) \cdot F > 0$ for a general fiber $F$ of $f$. So $(K_X + (1 - \delta)B + \omega) \cdot F > 0$ for $0 < \delta \ll 1$, and it is enough to prove that $K_X + (1 - \delta)B + \omega$ is pseudo-effective. In particular, replacing $B$ by $(1 - \delta)B$ we may assume that $(X, B)$ is a simple normal crossing klt pair and $(K_X + B + \omega) \cdot F > 0$. Since $F \cong \mathbb{P}^1$, it follows from [Gue20, Theorem] that $K_{X/Z} + B + \omega$ is pseudo-effective. Since $Z$ is a non-uniruled smooth compact Kähler surface, from classification it follows that $K_Z$ is pseudo-effective, and hence $K_X + B + \omega$ is pseudo-effective. This completes the proof.

We will also need the following result.

Lemma 4.5. Let $(X, B)$ a dlt pair, where $X$ is a $\mathbb{Q}$-factorial compact Kähler 3-fold. Let $\omega$ be a modified Kähler class on $X$ such that $\alpha = K_X + B + \omega$ is a $(1, 1)$ nef and big class. Let $S \subset X$ be an irreducible surface such that $S \subset \text{Null}(\alpha)$, i.e., $\alpha^2 \cdot S = 0$. Then $S$ is a Moishezon space and it is covered by $\alpha$-trivial curves.
Proof. Let \( \pi : S' \to S \) be the minimal resolution of \( S \) dominating the normalization \( \tilde{S} \to S \). By Lemma 2.39 we have

\[
(4.1) \quad K_{S'} + E = \pi^*((K_X + S)|_S),
\]

where \( E \geq 0 \) is an effective \( \mathbb{Q} \)-divisor.

Note that \( S' \) is a Kähler surface, since so is \( S \). We separate two cases based on the numerical dimension of \( \pi^*(\alpha|_S) \).

**Case I:** \( \pi^*(\alpha|_S) \equiv 0 \). In this case \( -\pi^*((K_X + B)|_S) = \pi^*(\omega|_S) \). Since \( \omega \) is a modified Kähler class, \( \omega|_S \) is a big \((1,1)\)-class by Corollary 2.35. Therefore \( -\pi^*(K_X + B) \) is a big divisor on \( S' \); in particular, \( S' \) is a Moishezon space. Furthermore, \( S' \) is then projective by [Nam02, Theorem 1.6], since \( S' \) is smooth and Kähler. Consequently, \( S' \) can be covered by a family of \( \pi^*(\alpha|_S) \)-trivial curves \( \{C_t\}_{t \in T} \). Pushing forward these curves give a covering family of \( \alpha|_S \)-trivial curves on \( S \).

**Case II:** \( \pi^*(\alpha|_S) \not\equiv 0 \). Since \( \omega \) is modified Kähler, \( \omega|_S \) is big. Since \( \alpha \) is nef,

\[
(4.2) \quad \omega \cdot \alpha \cdot S = (\omega|_S \cdot \alpha|_S) \geq 0.
\]

Note also that since \( \alpha \) is big, \( K_X + B + (1 - \epsilon)\omega \) is also big for \( 0 < \epsilon \ll 1 \) (recall in fact that the big cone \( B \) is open cf. [Bou04, §2.3]). We may write

\[
K_X + B + (1 - \epsilon)\omega \equiv \sum_{j=1}^r \lambda_j S_j + P,
\]

where \( \lambda_j > 0 \) for all \( j \) and \( P \) is nef in codimension 1.

Since \( \alpha^2 \cdot S = 0 \), it follows that

\[
\left( \sum_{j=1}^r \lambda_j S_j + P \right) \cdot \alpha \cdot S = (K_X + B + (1 - \epsilon)\omega) \cdot \alpha \cdot S = -\epsilon \omega \cdot S \cdot \alpha < 0.
\]

Since \( \alpha \) is nef and \( P|_S \) is pseudo-effective, we must have \( S = S_j \) for some \( 1 \leq j \leq r \) and \( \alpha \cdot S^2 < 0 \).

Let \( B = aS + B' \) such that \( 0 \leq a \leq 1 \) and \( S \) is not contained in the support of \( B' \). Then we have

\[
(4.3) \quad K_{S'} \cdot \pi^*(\alpha|_S) \leq (K_{S'} + E) \cdot \pi^*(\alpha|_S) = \pi^*((K_X + S)|_S) \cdot \pi^*(\alpha|_S)
\]

\[
= (K_X + S)|_S \cdot \alpha|_S
\]

\[
= (\alpha - aS - B' - \omega + S) \cdot \alpha \cdot S
\]

\[
= \alpha^2 \cdot S + (1 - a)\alpha \cdot S^2 - B'|_S \cdot \alpha|_S - \omega \cdot \alpha \cdot S < 0.
\]
Since $\pi^*(\alpha|_S)$ is nef, this shows that $K_S'$ is not pseudo-effective. Thus by Lemma 2.41, $S'$ is projective, and hence $S$ is a Moishezon space. Furthermore, by Lemma 2.31, $S'$ is covered by $\pi^*(\alpha|_S)$-trivial curves. Pushing forward these curves on $S$ we see that $S$ is also covered $\alpha|_S$-trivial curves. □

4.1. Cone Theorem. The purpose of this section is to prove the following cone theorem which is a direct generalization of the results of Horing and Peternell [HP15], [HP16], [CHP16] and [DO19]. The techniques that we use are all inspired by these papers.

**Theorem 4.6.** Let be a $(X, B)$ is dlt pair, where $X$ is a $\mathbb{Q}$-factorial compact Kähler 3-fold. Suppose that $X$ is uniruled and the base of the MRC fibration $X \to Z$ is a surface. Let $\omega$ be a modified Kähler class such that $(K_X + B + \omega)|_{X_z} \equiv 0$ for general $z \in Z$. Then there exists a countable family of curves $\Gamma_i$ on $X$ and a positive number $d$ such that

$$0 < -(K_X + B + \omega) \cdot \Gamma_i \leq d$$

and

$$\text{NA}(X) = \text{NA}(X)_{(K_X + B + \omega) \geq 0} + \sum_{i \in I} \mathbb{R}^+ [\Gamma_i].$$

**Proof.** By Lemma 4.2, $K_X + B + \omega$ is pseudo-effective and so by [Bou04] (applied to a resolution of $X$ and then pushing forward) we have a divisorial Zariski decomposition

$$(4.4) \quad K_X + B + \omega \equiv \sum_{j=1}^r \lambda_j S_j + P,$$

where the $S_j$’s are surfaces, $\lambda_j \in \mathbb{R}^+$ for all $j$ and $P$ is a pseudo-effective class which is nef in codimension 1.

**Claim 4.7.** Let $S \subset X$ be a surface such that $(K_X + B + \omega)|_S$ is not pseudo-effective, then $S = S_j$ for some $1 \leq j \leq r$, $S$ is Moishezon and any desingularization $\tilde{S} \to S$ is a uniruled projective surface.

**Proof.** Since $P$ is nef in codimension 1, then $P|_S$ is pseudo-effective. If $S \neq S_j$ for all $1 \leq j \leq r$, then $(\sum_{j=1}^r \lambda_j S_j)|_S \geq 0$ and hence $(K_X + B + \omega)|_S$ is pseudo-effective, contradicting our assumptions. Thus, possibly reindexing, we may assume that $S = S_1$. Let $b = \text{mult}_S(B)$, then $0 < b < 1$. We then have

$$(4.5) \quad K_X + S + B - bS + \omega + \frac{1 - b}{\lambda_1} \left( \sum_{j=2}^r \lambda_j S_j + P \right) \equiv \left( 1 + \frac{1 - b}{\lambda_1} \right) (K_X + B + \omega).$$

Since $(K_X + B + \omega)|_S$ is not pseudo-effective and $(B - bS + \omega + \frac{1 - b}{\lambda_1} (\sum_{j=2}^r \lambda_j S_j + P))|_S$ is pseudo-effective, from the above equality it follows that $(K_X + S)|_S$ is not pseudo-effective. Let $\pi : \hat{S} \to S$ be the minimal resolution of $S$ dominating its normalization $\tilde{S}$, then by Lemma 2.39, there exists an effective divisor
$E \geq 0$ on $\hat{S}$ such that $K_{\hat{S}} = \pi^*((K_S + S)|_S) - E$. But then it follows that $K_{\hat{S}}$ is not pseudo-effective, and hence $\hat{S}$ is projective by Lemma 2.41 and also uniruled. In particular, $S$ is Moishezon. Finally, observe that if $S'$ is any resolution of singularities of $S$, then it factors through the minimal resolution $\hat{S}$, and hence $S'$ is projective and uniruled. □

Next we establish a form of bend and break.

Claim 4.8. There exists a number $d > 0$ such that if $C \subset X$ is a curve with $-(K_X + B + \omega) \cdot C > d$, then $[C] = [C_1] + [C_2]$, where $C_1$ and $C_2$ are two non-zero integral effective 1-cycles.

Proof. First using the arguments of [CHP16, Lemma 4.2] and passing to a dlt model as in Lemma 2.22, we may assume that $(X, B)$ is dlt and $X$ has terminal singularities. The proof of this claim involves two main steps, in the first step we will construct four sets $A, B, C$ and $D$ of finitely many curves of $X$. These sets will determine the number $d > 0$. Next we will show that if $C$ is curve in $X$ such that $-(K_X + B + \omega) \cdot C > d$, then $\dim_C Chow(X) > 0$. We proceed with the constructions of the sets.

Let $A$ be the set of all curves $C \subset X$ satisfying the following properties:

1. $(K_X + B) \cdot C < 0$,
2. $B \cdot C < 0$ and
3. $C$ is contained in a horizontal (over $Z$) component $T$ of $B$.

We claim that $A$ is a finite set. Indeed, if $C$ is curve in $A$ contained in a horizontal component $T$ of $B$, then $T$ is not uniruled, since the induced morphism $T \to Z$ is generically finite and $Z$ is not uniruled. Let $\pi : \hat{T} \to T$ be the minimal resolution of $T$. Then $\hat{T}$ is not uniruled, and hence $K_{\hat{T}}$ pseudo-effective. Moreover, by MMP and abundance for compact Kähler surfaces, there exists an effective $\mathbb{Q}$-divisor $D \geq 0$ on $\hat{T}$ such that $K_{\hat{T}} \sim_{\mathbb{Q}} D$. Now since the coefficients of $B$ are contained in the interval $(0, 1]$, there is a non-negative rational number $\lambda \geq 0$ such that $\text{mult}_T(1 + \lambda)B = 1$. Then from our hypothesis it follows that $(K_X + (1 + \lambda)B) \cdot C < 0$. Then by Lemma 2.39 there is an effective $\mathbb{Q}$-divisor $E \geq 0$ on $\hat{T}$ such that

$$\pi^*((K_X + (1 + \lambda)B)|_T) = K_{\hat{T}} + E \sim_{\mathbb{Q}} D + E.$$ 

Therefore, from the projection formula, it follows that $\pi_*(D + E) \cdot C < 0$, i.e. $C$ is contained in the support of $\pi_*(D + E)$. In particular, the set $A$ is finite.

Now let $S$ be a component of $B$ which is vertical over $\hat{Z}$ and write

$$K_S + E \sim_{\mathbb{Q}} \pi^*((K_X + S)|_S),$$

where $\pi : \hat{S} \to S$ is the minimal resolution of $S$. 

Next we establish a form of bend and break.
If \( \kappa(\hat{S}) \geq 0 \), set \( F := B(K_{\hat{S}}) \), where \( B(\cdot) \) denotes the stable base locus. If \( \kappa(\hat{S}) = -\infty \), the we set \( F := 0 \). Let \( B \) be the union of the curves \( \pi_*(E + F) \) as \( S \) varies over all components of \( B \) that do not dominate \( Z \).

Let \( C \) be the finite set of curves \( C \subset X \) which are contained in the singular locus of the support of \( B + \sum S_j \).

Let \( D \) be the set of all curves \( C \subset X \) such that \( \omega \cdot C \leq 0 \). We claim that \( D \) is a finite set. Indeed, since \( \omega \) is a modified Kähler class, there exists a projective bimeromorphic morphism \( f : Y \to X \) from a compact Kähler manifold \( Y \) and a Kähler class \( \omega_Y \in H^{1,1}_{BC}(Y) \) such that \( f_*\omega_Y = \omega \). Now since \( X \) has \( \mathbb{Q} \)-factorial klt singularities and \( f \) is projective, by Lemma 2.34 there exists an effective \( f \)-exceptional \( \mathbb{R} \)-divisor \( E \geq 0 \) such that \( -E \) is \( f \)-ample and \( \omega_Y + [E] = f^*\omega \). Now if \( C \) is a curve from the set \( D \) and \( C' \subset Y \) is a curve in \( Y \) such that \( f(C') = C \), then \( 0 \geq \omega \cdot C = f^*\omega \cdot C' = (\omega_Y + E) \cdot C' \). This implies that \( E \cdot C' < 0 \), since \( \omega_Y \cdot C' > 0 \), as \( \omega_Y \) is a Kähler class. In particular, \( C' \) is contained in the support of \( E \), since \( E \) is effective. Therefore \( C = f(C') \) is contained in \( f(SuppE) \). Since \( E \) is \( f \)-exceptional and \( \dim X = 3 \), it follows that \( D \) is a finite set.

Now we define

\[
d := \max\{4, - (K_X + B + \omega) \cdot C \mid C \subset X \text{ is a curve, and } C \in \mathcal{A} \cup \mathcal{B} \cup \mathcal{C} \cup \mathcal{D}\}.
\]

Claim 4.9. For any curve \( C \subset X \) such that \( - (K_X + B + \omega) \cdot C > d \), we have \( \dim_{\text{Chow}}(X) > 0 \).

**Proof.** By assumption \( \omega \cdot C > 0 \) and so \( - (K_X + B) \cdot C > d \). We will separate two cases depending on whether \( B \cdot C < 0 \) or \( B \cdot C \geq 0 \).

**Case I:** Suppose that \( B \cdot C < 0 \). In this case there is a component \( S \) of \( B \) containing \( C \). Moreover, we see that \( C \) is not contained in any other component of \( B \) or \( \sum S_j \), since \( C \not\in \mathcal{C} \), and also that \( S \) is not horizontal over \( Z \), since \( C \not\in \mathcal{A} \). In particular, \( S \) is vertical over \( Z \). Now since \( C \not\in \mathcal{B} \), \( C \) is not contained in \( \pi(E) \), where \( E \) and \( \pi : \hat{S} \to S \) as in (4.6). Let \( \hat{C} \subset \hat{S} \) be the strict transform of \( C \) and \( \text{mult}_SB = b \). Then as \( S \cdot C < 0 \), \( (B - bS) \cdot C \geq 0 \) and \( \omega \cdot C > 0 \), we have

\[
K_{\hat{S}} \cdot \hat{C} \leq (K_{\hat{S}} + E) \cdot \hat{C}
= (K_X + S) \cdot C
= (K_X + B + (1 - b)S - (B - bS)) \cdot C
\leq (K_X + B) \cdot C
< (K_X + B + \omega) \cdot C
< -d.
\]
Case II: Suppose now that $C \subset S$ from Claim 4.7 that $\hat{S}$ is pseudo-effective. We also know that the curve $C$ is a unique surface since $\hat{S}$ is smooth and projective surface and $-K_{\hat{S}} \cdot \hat{C} > d \geq 4$, by [Kol96, Theorem II.1.15] we have $\dim \text{Chow}(\hat{S}) > 0$, i.e. $\hat{C}$ deforms in $\hat{S}$, in particular its push-forward $C$ deforms in $S \subset X$, and hence $\dim \text{Chow}_C(X) > 0$.

Now if $\kappa(\hat{S}) \geq 0$, then as $\hat{C}$ is not contained in $F = B(K_{\hat{S}})$, it follows that $K_{\hat{S}} \cdot \hat{C} \geq 0$, which is a contradiction to the above inequality. Thus $\kappa(\hat{S}) < 0$ and then from MMP and abundance for smooth compact Kähler surfaces it follows that $K_{\hat{S}}$ is not pseudo-effective. Hence $\hat{S}$ is projective by Lemma 2.41. Now since $\hat{S}$ is smooth and projective surface and $-K_{\hat{S}} \cdot \hat{C} > d \geq 4$, by [Kol96, Theorem II.1.15] we have $\dim \text{Chow}(\hat{S}) > 0$, i.e. $\hat{C}$ deforms in $\hat{S}$, in particular its push-forward $C$ deforms in $S \subset X$, and hence $\dim \text{Chow}_C(X) > 0$.

**Case II:** Suppose now that $B \cdot C \geq 0$. Since $C \notin D$, $\omega \cdot C > 0$ and hence $K_X \cdot C < (K_X + B + \omega) \cdot C < -d \leq -4$. Since $X$ has $\mathbb{Q}$-factorial terminal singularities, it follows from [HP16, Theorem 4.5] that $C$ is not very rigid (see [HP16, Definition 4.3]). Let $m$ be the smallest positive integer such that $\dim \text{Chow}(X) > 0$. Let $C \to T$ be the corresponding family. Replacing $C$ by an irreducible component which contains $C \subset X$ we may assume that $\hat{C}$ is irreducible, and hence so is the locus covered by the family $(C_t)_{t \in T}$. Consequently, $C_t$ is irreducible for $t \in T$ very general. Then from the minimality of $m$ it also follows that this family has no fixed component. Now by (4.4) there is a unique surface $S_j$ covered by the $\{C_t\}_{t \in T}$. Note that $(K_X + B + \omega)|_{S_j}$ is not pseudo-effective, since $(K_X + B + \omega)|_{S_j} \cdot C_t = m(K_X + B + \omega) \cdot C < 0$. By Claim 4.7, the minimal resolution $\hat{S}$ of $S = S_j$ is projective and uniruled. Since $C \notin C$, we have that $C$ is not contained in $S_j$ for $l \neq j$ and hence $S_l \cdot C \geq 0$ for $l \neq j$. Since $P|_{S_j}$ is pseudo-effective,

$$P \cdot mC = P|_{S_j} \cdot mC = P|_{S_j} \cdot C_t \geq 0.$$  

Using the same notation as in Claim 4.7 and its proof we see that $E \cdot m\hat{C} \geq 0$ and $\omega \cdot mC > 0$, where $\hat{C}$ is the strict transform of $C$ under $\pi: \hat{S} \to S = S_j$. We also know that $S_j \cdot C < 0$. Therefore from (4.5) we have

$$K_{S_j} \cdot \hat{C} \leq (K_{S_j} + E_j) \cdot \hat{C} = (K_X + S_j) \cdot C \leq \left(1 + \frac{1 - b}{\lambda_1}\right)(K_X + B + \omega) \cdot C < -d \leq -4.$$  

By [Kol96, Theorem II.1.15], we have $\dim \text{Chow}(\hat{S}_j) > 0$, i.e. $\hat{C}$ deforms in $\hat{S}$. Thus by pushing forward $\hat{C}$ we have that $C$ deforms, i.e., $\dim \text{Chow}_C(X) > 0$. 

We will now prove the bend and break property, i.e. the Claim 4.8. If $C \subset X$ is a curve satisfying $-(K_X + B + \omega) \cdot C > d$, then from Claim 4.9 and its proof it follows that, the curve $C$ deforms in a family $\{C_t\}_{t \in T}$ covering a unique uniruled surface $S = S_j$ in (4.4) such that $(K_X + B + \omega)|_{S}$ is not pseudo-effective. We also know that the curve $C$ is contained in $S$ but not in $S_{\text{sing}}$. Moreover, if $\pi: \hat{S} \to S$ is the minimal resolution of $S$, then we know from Claim 4.7 that $\hat{S}$ is a projective uniruled surface. Now from the proof of
Claim 4.9 we have $K_S \cdot C < -d \leq -4$. Thus by [HP16, Lemma 5.5(b)] there is an effective 1-cycle $\sum_{k=1}^{m} C_k$ with $m \geq 2$ such that $[C] = [\sum_{k=1}^{m} C_k]$ and $K_S \cdot C_i < 0$ for $i = 1, 2$. Since $\pi : \hat{S} \rightarrow S$ is the minimal resolution, $K_S$ is $\pi$-nef and hence $\pi_* C_j \neq 0$ for $j = 1, 2$. In particular, we also have a decomposition $[C] = [\sum_{k=1}^{m} \pi_* C_k]$ with at least two non-zero terms. This concludes the proof of Claim 4.8.

□

The theorem now follows from Claim 4.8 and the arguments in the proof of [CHP16, Theorem 4.2].

□

Corollary 4.10. Let $(X, B)$ be a dlt pair, where $X$ is a $\mathbb{Q}$-factorial compact Kähler 3-fold. Suppose that $X$ is uniruled and the base of the MRC fibration $X \rightarrow Z$ is a surface. Let $\omega$ be a modified Kähler class such that $(K_X + B + \omega) \cdot X_z > 0$ for general $z \in Z$, then there exist finitely many curves $\{\Gamma_i\}_{i=1}^{N}$ such that

$$\NA(X) = \NA(X)_{(K_X+B+\omega)\geq 0} + \sum_{i=1}^{N} \mathbb{R}^{+}[\Gamma_i].$$

Proof. Pick $t = -(K_X+B) \cdot X_z/\omega \cdot X_z$, then $0 < t < 1$ and $(K_X+B+t\omega) \cdot X_z = 0$. By Theorem 4.6, there exists a countable family of rational curves $\Gamma_i$ with $0 < -(K_X+B+t\omega) \cdot \Gamma_i \leq d$ and

$$\NA(X) = \NA(X)_{(K_X+B+\omega)\geq 0} + \sum_{i=1}^{N} \mathbb{R}^{+}[\Gamma_i].$$

Claim 4.11. $\omega \cdot \Gamma_i > d/(1-t)$ for all but finitely many $i$’s.

Assuming the claim for the time being we will complete the proof first. Using the claim we have

$$(K_X + B + \omega) \cdot \Gamma_i = (K_X + B + t\omega) \cdot \Gamma_i + (1-t)\omega \cdot \Gamma_i > 0$$

for all but finitely many $i$’s. This concludes the proof.

Proof of Claim 4.11. Since $\omega$ is a modified Kähler class, there exists a projective bimeromorphic morphism $\nu : X' \rightarrow X$ from a Kähler manifold $X'$ and Kähler class $\omega' \in H^{1,1}_{BC}(X')$ such that $\nu_* \omega' = \omega$. Then by Lemma 2.34 there exists an effective $\nu$-exceptional divisor $F \geq 0$ such that $-F$ is $\nu$-ample, $\text{Supp} F = \text{Ex}(\nu)$ and $\nu^* \omega = \omega' + [F]$. Now let $\Gamma_i'$ be the strict transform of the curve $\Gamma_i$ which is not contained in $\nu(F)$. Note that since $\dim \nu(F) \leq 1$, there are only finitely many $\Gamma_i$’s contained in $\nu(F)$.

We will assume by contradiction that the claim is false, i.e. $\omega \cdot \Gamma_i \leq d/(1-t)$ for infinitely many indices $i$. Let $\Lambda$ be the set of indices for all such curves $\Gamma_i$. Without loss of generality we may assume that $\Gamma_i$ is not contained in
Supp(ν(F)) for any \( i \in \Lambda \). Observe that the \( \Gamma_i \)’s for \( i \in \Lambda \) belong to distinct equivalence classes in \( \overline{\text{NA}}(X) \); in particular, the strict transforms \( \Gamma_i' \) also belong to distinct equivalence classes in \( \overline{\text{NA}}(X') \) for all \( i \in \Lambda \). Now by the projection formula we have
\[
\omega' \cdot \Gamma_i' = (\nu^* \omega - F) \cdot \Gamma_i' \leq \omega \cdot \Gamma_i \leq \frac{d}{1-t} \quad \text{for all} \quad i \in \Lambda.
\]

Since \( \omega' \) is a Kähler class, by [Tom16, Lemma 4.4] the curves \( \Gamma_i' \) belong to a bounded family for all \( i \in \Lambda \). In particular, the \( \Gamma_i' \)’s belong to a finitely many distinct equivalence classes in \( \overline{\text{NA}}(X') \), this is a contradiction. □ □

Next we prove a technical result which will be used in the existence of small contractions (see Theorem 4.14) and also in Section 6.

**Proposition 4.12.** Let \((X, B)\) be a dlt pair, where \( X \) is a \( \mathbb{Q} \)-factorial compact Kähler 3-fold. Assume that \( X \) is uniruled, \( K_X + B \) is not pseudo-effective, and the base of the MRC fibration \( X \to Z \) has dimension 2. Let \( R = \mathbb{R}^+[\Gamma_i] \) be an extremal ray of \( \overline{\text{NA}}(X) \) with a nef supporting class \( \alpha \). Assume that there is a nef and big class \( \eta \) such that \( K_X + B + \eta \) is pseudo-effective and \( (K_X + B + \eta) \cdot R < 0 \). If \( R \) is small and \( S \subset X \) is an irreducible surface, then the following holds:
\[
\alpha^2 : S > 0.
\]

**Proof.** First note that by a standard technique using Theorem 4.6 and Corollary 4.10 we can write \( \alpha - (K_X + B + \eta) = \omega \), for some Kähler class \( \omega \), i.e. \( \alpha = K_X + B + \eta + \omega \). By contradiction assume that \( \alpha^2 : S = (\alpha|_S)^2 = 0 \).

First assume that \( \alpha|_S = 0 \). Then we have \( -(K_X + B)|_S = (\eta + \omega)|_S \). Thus \( -(K_X + B)|_S \) is an ample divisor on \( S \), in particular, \( S \) is projective. So we can cover \( S \) by a family of curves. But since \( \alpha|_S = 0 \), all these curves are contained in \( R \), this is a contradiction, since \( R \) is small.

Next assume that \( \alpha|_S \neq 0 \) but \( (\alpha|_S)^2 = 0 \). Then we have
\[
0 = \alpha^2 : S = (K_X + B) : \alpha : S + (\eta + \omega) : \alpha : S
\]
and
\[
(\eta + \omega) : \alpha : S = (\eta + \omega)|_S : \alpha|_S > 0, \quad \text{since} \quad \alpha|_S \text{ is a non-zero nef class.}
\]

Therefore we have
\[
(4.7) \quad (K_X + B) : \alpha : S < 0.
\]

By a similar computation we also have
\[
(4.8) \quad (K_X + B + \eta) : \alpha : S < 0.
\]

In particular, \((K_X + B)|_S\) (resp. \((K_X + B + \eta)|_S\)) is not pseudo-effective, since \( \alpha|_S \) is a nef class.
Let $\pi: \hat{S} \to S$ be the minimal resolution of $S$ dominating the normalization of $S$. We make the following claim.

Claim 4.13. There is an effective $\mathbb{Q}$-divisor $E \geq 0$ in $\hat{S}$ such that

$$(K_{\hat{S}} + E) \cdot \pi^*(\alpha|_S) < 0.$$  

Note that once we have this claim, the rest of the proof works exactly as in the proof of [CHP16, Proposition 4.4], since the only thing used there is this property of the nef class $\pi^*(\alpha|_S)$, and it does not depend on whether $K_X + B$ is pseudo-effective or not. In the following we will prove our claim.

Proof of Claim 4.13. We will split the proof into two cases.

Case I: Assume that $B \cdot \alpha \cdot S = B|_S \cdot \alpha|_S < 0$. Then $S$ is contained in the support of $B$, since $\alpha|_S$ is nef. Then there exists a real number $\lambda \geq 0$ such that the coefficient of $S$ in $(1 + \lambda)B$ is 1. Then using (4.7) we have

$$(K_X + (1 + \lambda)B) \cdot \alpha \cdot S \leq (K_X + B) \cdot \alpha \cdot S < 0.$$  

Thus by adjunction (see Lemma 2.39), there exists an effective $\mathbb{Q}$-divisor $E$ on $\hat{S}$ such that

$$(K_{\hat{S}} + E) \cdot \pi^*(\alpha|_S) = \pi^*((K_X + (1 + \lambda)B)|_S) \cdot \pi^*(\alpha|_S) = (K_X + (1 + \lambda)B) \cdot \alpha \cdot S < 0.$$  

This proves our claim in this case.

Case II: Assume that $B \cdot \alpha \cdot S \geq 0$. Then we have

(4.9)  

$$K_X \cdot \alpha \cdot S \leq (K_X + B) \cdot \alpha \cdot S < 0.$$  

Now consider the Zariski decomposition of $K_X + B + \eta$:

$$K_X + B + \eta \equiv \sum_{j=1}^r \lambda_j S_j + P,$$

where $\lambda_j \geq 0$ for all $j$ and $P$ is nef in codimension 1.

We claim that $S = S_j$ for some $j$. If not, then $\sum \lambda_j S_j|_S + P|_S$ is pseudo-effective. But then from (4.8) we have

$$0 > (K_X + B + \eta) \cdot \alpha \cdot S = \left( \sum \lambda_j S_j|_S \right) \cdot \alpha|_S + P|_S \cdot \alpha|_S \geq 0,$$  

a contradiction.

Next we claim that $\alpha \cdot S^2 < 0$. To see this first assume that $S = S_1$. Then we have

$$0 > (K_X + B + \eta) \cdot \alpha \cdot S = \left( \sum_{j=2}^r \lambda_j S_j|_S \cdot \alpha|_S \right) + \lambda_1 \alpha \cdot S^2 + P|_S \cdot \alpha|_S.$$
Since the first and the last term in the right hand side are non-negative, it follows that $\alpha \cdot S^2 < 0$. Combining this with (4.9) we have $(K_X + S) \cdot \alpha \cdot S < 0$. Then by adjunction (see Lemma 2.39) there exists an effective $\mathbb{Q}$-divisor $E$ on $\hat{S}$ such that

$$(K_{\hat{S}} + E) \cdot \pi^*(\alpha|_S) = \pi^*((K_X + S)|_S) \cdot \pi^*(\alpha|_S) = (K_X + S) \cdot \alpha \cdot S < 0.$$ 

This completes the proof of the claim.

□

4.2. Existence of divisorial contractions and flips.

**Theorem 4.14.** Let $(X, B)$ be a dlt pair, where $X$ is a $\mathbb{Q}$-factorial compact Kähler 3-fold. Suppose that $X$ is uniruled and the dimension of the base of the MRC fibration $X \dashrightarrow Z$ is 2, and $(K_X + B) \cdot F < 0$ for a general fiber $F$ of $X \dashrightarrow Z$. Let $\omega$ be a Kähler class (or more generally a nef and big class) such that $K_X + B + \omega$ is pseudo-effective, and $R$ is a $(K_X + B + \omega)$-negative extremal ray. Then the contraction $c_R : X \rightarrow Y$ of the ray $R$ exists. Moreover, if $c_R$ is a small contraction, then the flip of $c_R$ exists.

**Proof.** By a similar proof as in [CHP16, Proposition 4.3] we may assume that the extremal ray $R$ is cut out by a $(1, 1)$ nef class $\alpha$. Rescaling $\alpha$ if necessarily, we see that $\eta = \alpha - (K_X + B + \omega)$ is positive on $\text{NA}(X) \setminus \{0\}$, and hence $\eta$ is a Kähler class by [HP16, Corollary 3.16]. Thus it follows that $\alpha$ is a nef and big class, since $K_X + B + \omega$ is pseudo-effective.

Suppose that $R$ is small, then the contraction $c_R$ exists by [CHP16, Theorem 4.2]. Note that this proof works in our case if we replace [CHP16, Proposition 4.4] by Proposition 4.12. Since $\omega \cdot R \geq 0$ (as $\omega$ is nef), we have $(K_X + B) \cdot R < 0$ and so this is also a $K_X + B$ flipping contraction. The existence of the flip then follows from Theorem 2.18.

If $R$ is of divisorial type, then the corresponding irreducible divisor $S$ is covered by and contains all the curves $C \subset X$ such that $[C] \in R$. Recall from Notation 1.4 that there is a desingularization $\nu : \tilde{S} \rightarrow S$ and an $\alpha$-trivial fibration $\tilde{f} : \tilde{S} \rightarrow T$ with $\dim T = n(\alpha) \in \{0, 1\}$.

If $n(\alpha) = 0$, then the existence of $c_R$ follows by the same arguments as in [HP16, Corollary 7.7]. Note in fact that in this case it suffices to show that if $mS$ is Cartier, then $(-mS)|_S$ is ample. This in turn is a consequence of the fact that $-mS \cdot R > 0$.

If $n(\alpha) = 1$, and $(S, 0)$ has semi-log canonical singularities, then the existence of $c_R$ follows from [CHP16, Proposition 4.5].

The general case follows from the proof of Theorem 1.5. For the convenience of the reader we indicate all necessary adjustments to this proof. We may

□
assume that \((X, B)\) is klt, \(\eta = \alpha - (K_X + B + \omega)\) is Kähler and \(\alpha\) is nef and big. Note that as \(\omega\) is nef, \(R \cdot (K_X + B) < 0\). In particular, there is an \(a > 0\) such that \(K_X + B \equiv_a aS\). Let \(\mu : X' \to X\) be a log resolution of \((X, B)\) and set \(\Delta' = \mu_*^{-1}(B + (1 - b)S) + \text{Ex}(\mu)\) and \(S' = \mu_*^{-1}S\). Since \(\mu\) is a projective morphism, after running a \((K_X + \Delta')\)-MMP over \(X\) via Proposition 2.20, we may assume that \(\mu\) is an isomorphism over the complement of \(S\) (since \((X, B)\) is \(\mathbb{Q}\)-factorial and klt). Then we have

\[
K_{X'} + \Delta' = \mu^*(K_X + B) + \sum c_j E_j + (1 - b)S' \equiv \mu^*\alpha \sum d_j E_j + dS',
\]

where \(d_j \geq c_j > 0\) and \(d > 1 - b > 0\).

We now run the \(\alpha' = \mu^*\alpha\)-trivial \((K_{X'} + \Delta')\)-MMP. We must show by induction that all flips and divisorial contractions exist. Suppose that we have already constructed the first \(i\) steps

\[
\phi_i : X' \dashrightarrow X_1' \dashrightarrow \ldots \dashrightarrow X_i'.
\]

Note however that in our situation \(\alpha_i := \phi_i^*\alpha'\) is nef and big, and hence \(K_{X_i'} + \Delta_i' + t_i\alpha_i'\) is pseudo-effective for some \(t_i > 0\). Now if there is an \(\alpha_i\)-trivial and \((K_{X_i'} + \Delta_i' + t_i\alpha_i')\)-negative curve, then by Lemma 2.37 combined with Theorem 4.6 and Corollary 4.10 it follows that there is an extremal ray \(R_i'\) of \(\overline{\text{NA}}(X_i')\) which is \(\alpha_i\)-trivial and \((K_{X_i'} + \Delta_i')\)-negative. If \(R_i'\) is small, then its contraction and the flip both exist by the discussion above. If \(R_i'\) is divisorial, say the corresponding unique divisor is \(S_i'\), then \(S_i'\) is a component of \([\Delta_i']\).

Since \((X_i', \Delta_i')\) is dlt, it follows that \((S_i', 0)\) has log canonical singularities, and hence the contraction of \(S_i'\) exists by the discussion above. Finally, by Theorem 2.19 this MMP terminates after a finitely many steps.

The rest of the proof is identical to that of Theorem 1.5, since in the corresponding part of the proof of Theorem 1.5 we never used the fact that \(K_X + B\) is pseudo-effective.

\[\square\]

5. Existence of Mori fiber spaces

In this section we will prove Theorem 1.2. But first we need some preparation. The following result is a log-version of [HP15, Theorem 1.3].

**Theorem 5.1.** Let \((X, B)\) be a dlt pair, where \(X\) is a \(\mathbb{Q}\)-factorial compact Kähler 3-fold. Suppose that \(X\) is uniruled and the base of the MRC fibration \(f : X \dashrightarrow Z\) has dimension 2 and \((K_X + B) \cdot F < 0\), where \(F\) is a general fiber of \(f\). Then there is a bimeromorphic map \(\phi : X \dashrightarrow X'\) given by a sequence of \(K_X + B\) flips and divisorial contractions such that for any \((K_{X'} + B')\)-normalized Kähler class \(\omega'\) on \(X'\), the adjoint class \(K_{X'} + B' + \omega'\) is nef, where \(B' = \phi_* B\).
Proof. Suppose that there is a \((K + B)\)-normalized Kähler class \(\omega\) on \(X\), such that the adjoint class \(K + B + \omega\) is not nef. Replacing \(B\) by \((1 - \epsilon)B\) and \(\omega\) by \(\omega + \epsilon B\) for \(0 < \epsilon \ll 1\), we may assume that \((X, B)\) is klt. By Theorem 4.6, there is a \(K + B + \omega\) negative extremal ray \(R\). By Theorem 4.14, we may flip or contract \(R\). Repeating this procedure, since every step is \((K + B)\)-negative, by Theorem 2.19 we obtain the required bimeromorphic map \(\phi : X \to X'\).

Following the same ideas as in [HP15] we prove a log version of [HP15, Theorem 1.4] below.

**Theorem 5.2.** Let \((X, B)\) be a terminal pair, where \(X\) is a \(\mathbb{Q}\)-factorial compact Kähler 3-fold. Suppose that \(X\) is uniruled and the base of the MRC-fibration \(f : X \to Z\) has dimension 2 and \((K + B) \cdot F < 0\), where \(F\) is a general fiber of \(f\). Let \(\omega\) be a nef and big class on \(X\) such that \(K + B + \omega\) is nef and \((K + B + \omega) \cdot F = 0\). Then there exists a proper surjective morphism with connected fibers \(\varphi : X \to S\) onto a normal compact Kähler surface \(S\) such that \(K + B + \omega\) is \(\varphi\)-trivial, i.e., \((K + B + \omega)|_{X_s} = 0\) for all \(s \in S\).

*Proof.* We will closely follow the proof of [HP15, Theorem 1.4] here. We will consider the nef dimension \(n(K + B + \omega)\). First note that, since a dense open subset of \(X\) is covered by \((K + B + \omega)\)-trivial curves, the nef dimension \(n(K + B + \omega) \leq 2\). We claim that \(n(K + B + \omega) = 2\). Indeed, if the nef dimension is 0, then \(-(K + B) \equiv \omega\), and thus \(-(K + B)\) is nef and big. In particular, \(X\) is a Moishezon space. Since \(X\) is also Kähler and has rational singularities, by [Nam02, Theorem 1.6] \(X\) is projective. Then by [Zha06, Theorem 1] \(X\) is rationally connected. This contradicts the fact that the base of the MRC fibration of \(X\) has dimension 2. If the nef dimension is 1, then there is a proper surjective morphism \(f : X \to C\) to a smooth projective curve \(C\) such that \((K + B + \omega)|_{C} = 0\) for all general fibers \(F\) of \(f\) (see [BCE+02, 2.4.4]). Now since \(X\) has terminal singularities, a general fiber \(F\) is smooth, and thus by adjunction we have \((K + B)|_{F} = K_{F} + B|_{F}\) such that \((F, B|_{F} \geq 0)\) has klt singularities. Moreover, from Lemma 5.3 we see that \(-(K_{F} + B|_{F}) \equiv \omega|_{F}\) is nef and big. Therefore by [Zha06, Theorem 1] the general fiber of \(f\) is rationally connected. This contradicts the fact that the base of the MRC fibration of \(X\) has dimension 2. Thus \(n(K + B + \omega) = 2\) as claimed.

There is an induced rational map \(Z \to \text{Chow}(X)\) sending the general points of \(Z\) to the point corresponding to the general fibers of the MRC fibration \(X \to Z\). Replace \(Z\) by an appropriate resolution so that \(Z \to \text{Chow}(X)\) is a morphism, and let \(\Gamma \to Z\) be the normalization of the pull-back of the universal family over \(\text{Chow}(X)\). Then \(\Gamma\) is a normal compact complex 3-fold with equi-dimensional fibers of dimension 1 over \(Z\). Let \(p : \Gamma \to X\) and
\( q : \Gamma \to Z \) be the projection maps. Note that as observed in the proof of [HP15, Theorem 1.4], \( \Gamma \) is in Fujiki’s class \( \mathcal{C} \) and hence by [Var86, Theorem 3], \( Z \) is in Fujiki’s class \( \mathcal{C} \). Moreover, since \( Z \) is a smooth compact surface, by [Fuj83, Proposition 2, page 104] \( Z \) is Kähler.

We claim that there is a nef and big \((1,1)\)-class \( \alpha \) on \( Z \) such that
\[
(5.1) \quad p^*(K_X + B + \omega) = q^*\alpha.
\]

We split our proof into 4 steps below as in the proof of [HP15, Theorem 1.4].

**Step 1:** This step shows the existence of a \((1,1)\) nef class \( \alpha \) on \( Z \) satisfying (5.1). The proof of this step is exactly the same as the proof of Step 1 of [HP15, Theorem 1.4]. However, for the convenience of the reader, we include the details here. Since the general fiber of \( q \) is a rational curve, by [Kol96, II, 2.8.6.2], it follows that \( R_1 q^* \mathcal{O}_\Gamma = 0 \). Consider the exponential sequence
\[
0 \to \mathcal{O} \to q^* \mathcal{O}_\Gamma \to q^* \mathcal{O}_\Gamma^* \to 0.
\]
Since \( \mathcal{O}_Z = q^* \mathcal{O}_\Gamma \to q^* \mathcal{O}_\Gamma^* = \mathcal{O}_Z^* \) is surjective, we have \( R_1 q_* Z = 0 \). By the universal coefficient theorem \( R^1 q_* \mathbb{R} = 0 \). We now consider the Leray spectral sequence \( E_2^{i,j} = H^i(Z, R^j q_* \mathbb{R}) \) degenerating to \( H^*(\Gamma, \mathbb{R}) \). Since \( E_2^{1,1} = 0 \) for all \( i \), it follows that there is an exact sequence
\[
0 \to H^2(Z, \mathbb{R}) \to H^2(\Gamma, \mathbb{R}) \to H^0(Z, R^2 q_* \mathbb{R}).
\]
To show that \([p^*(K_X + B + \omega)] = [q^* \alpha]\) it then suffices to show that if \( s \in E_2^{0,2} = H^0(Z, R^2 q_* \mathbb{R}) \) is the section defined by \( s(z) = [p^*(K_X + B + \omega)](z) \in H^2(\Gamma, \mathbb{R}), \) then \( s = 0 \). Since \( R^2 q_* \mathbb{R} \) is constructible (see [EZS10, Proposition 3.5]), then the section \( s \) vanishes if and only if it vanishes point wise. Note that since \( \omega \) is a \((K_X + B)\)-normalized Kähler class, the claim clearly holds for general \( z \in Z \). Since \( \Gamma \to Z \) is equi-dimensional and \( p^*(K_X + B + \omega) \) is nef, it follows that \( p^*(K_X + B + \omega) \equiv 0 \) on every irreducible component of every fiber. Note that since \( q^* \alpha \) is nef, \( \alpha \) is also nef by [Pau98, Theorem 1].

**Step 2:** Since \( X \) has \( \mathbb{Q} \)-factorial terminal singularities, the proof of this step is also the same the proof of Step 2 of [HP15, Theorem 1.4], so we skip the details here. With the notation as in the Step 2 of the proof of [HP15, Theorem 1.4] let \( \mu : \hat{X} \to \Gamma \) be a resolution of singularities of \( \Gamma \) such that the exceptional locus of \( \hat{\rho} = p \circ \mu : \hat{X} \to X \) has pure codimension 1. Set \( \hat{q} = q \circ \mu \). Then we have
\[
(5.2) \quad \hat{q}^* \alpha \cdot \hat{D} = 0 \quad \text{in} \ N_1(X)
\]
for every irreducible component \( \hat{D} \) of the exceptional locus of \( \hat{\rho} \).

Next we claim that \( \alpha \) is a big class on \( Z \), i.e., \( \alpha^2 > 0 \). This is Step 3 below.
Step 3: The proof of this step is almost identical to the proof of Step 3 of [HP15, Theorem 1.4]. We include the details here for the convenience of the reader. Note that using Lemma 2.37 from now on we may assume that \( \omega \) is a modified Kähler class; observe that we loose the nefness of \( \omega \) here, but it is not needed in the rest of the proof. Then by Lemmas 2.33 and 2.34, replacing \( X \) by a higher resolution of \( \Gamma \) if necessary, we may assume that there is an effective \( \hat{p} \)-exceptional \( \mathbb{R} \)-divisor \( F \geq 0 \) on \( \hat{X} \) such that \( \hat{p}^* \omega - F \) is a Kähler class. Since the Kähler cone is open, there is a Kähler class \( \eta_Z \) on \( Z \) such that \( \hat{p}^* \omega - F - \hat{q}^* \eta_Z \) is a Kähler class on \( \hat{X} \). Then by a similar argument as in the proof of Lemma 4.2 it follows that

\[
K_{\hat{X}/Z} + \hat{B} + \hat{p}^* \omega - F - \hat{q}^* \eta_Z \quad \text{is pseudo-effective},
\]

where \( K_{\hat{X}} + \hat{B} = \hat{p}^*(K_X + B) + E, \hat{B} \geq 0, E \geq 0, \hat{p}_* \hat{B} = B, \) and \( \hat{B} \) and \( E \) do not share any common component.

Now we have

\[
\hat{p}^*(K_X + B + \omega) = (K_{\hat{X}/Z} + \hat{B} + \hat{p}^* \omega - F - \hat{q}^* \eta_Z) - E + F + \hat{q}^* K_Z + \tilde{q}^* \eta_Z.
\]

We will show that \( \hat{q}^* \alpha^2 = \hat{q}^* \alpha \cdot \hat{p}^*(K_X + B + \omega) \) is a non-zero class in \( \overline{\mathcal{N}A}(\hat{X}) \).

To that end first observe that, since \( \alpha \) is nef and \( K_{\hat{X}/Z} + \hat{B} + \hat{p}^* \omega - F - \hat{q}^* \eta_Z \) is pseudo-effective, the intersection product \( \hat{q}^* \alpha \cdot (K_{\hat{X}/Z} + \hat{B} + \hat{p}^* \omega - F - \hat{q}^* \eta_Z) \) is an element of \( \overline{\mathcal{N}A}(\hat{X}) \). Since \( E \) and \( F \) are both \( \hat{p} \)-exceptional, from (5.2) it follows that \( \hat{q}^* \alpha \cdot (-E + F) = 0 \) in \( \overline{\mathcal{N}A}(\hat{X}) \). Now since the surface \( Z \) is not uniruled, by classification \( K_Z \) is pseudo-effective; in particular, \( \hat{q}^* \alpha \cdot \hat{q}^* K_Z \) is an element of \( \overline{\mathcal{N}A}(\hat{X}) \). Now recall that \( \alpha \neq 0 \), since \( K_X + B + \omega \neq 0 \). Since \( \eta_Z \) is a Kähler class and \( \alpha \) is a non-zero nef class, the Hodge index theorem yields \( \eta_Z \cdot \alpha > 0 \) (see Lemma 2.38). In particular, \( \hat{q}^* \alpha \cdot \hat{q}^* \eta_Z \) is a non-zero element of \( \overline{\mathcal{N}A}(\hat{X}) \). Therefore \( \hat{q}^* \alpha^2 = \hat{q}^* \alpha \cdot \hat{p}^*(K_X + B + \omega) \) is a non-zero element of \( \overline{\mathcal{N}A}(\hat{X}) \), and thus \( \alpha^2 \neq 0 \) in \( N^1(Z) \).

Step 4: Finally, Step 4 of the proof of [HP18, Theorem 1.4] shows the existence of a fibration \( \varphi : X \to S \) such that \( (K_X + B + \omega)|_{X_s} \equiv 0 \) for \( s \in S \). This step works here without any change, and completes our proof.

\[
\square
\]

**Lemma 5.3.** Let \( X \) be a normal compact Kähler variety and \( f : X \to C \) a proper surjective morphism to a smooth projective curve \( C \). Let \( \omega \in H^{1,1}_{BC}(X) \) be a nef and big class. Then the restriction \( \omega|_F \) is nef and big for general fibers \( F \) of \( f \).

**Proof.** Let \( g : X' \to X \) be a resolution of singularities of \( X \). Then by [CT15, Theorem 1.1], the non-Kahler locus \( \text{EnK}(g^* \omega) = \text{Null}(g^* \omega) \) (see Def. 6.1 for
the definition of \( \text{Null} (\cdot) \). Since by [CT15, Theorem 2.2] \( \text{EnK}(g^*\omega) \) is a closed analytic subset of \( X' \), if \( F' \) is the strict transform of a general fiber \( F \) of \( f \), then \( F' \not\subset \text{EnK}(g^*\omega) \). In particular, by the projection formula we have

\[
0 < (g^*\omega)^{n-1} \cdot F' = \omega^{n-1} \cdot F = (\omega|_F)^{n-1}
\]

where \( n = \dim X \). Therefore \( \omega|_F \) is a nef and big class for general fibers \( F \) of \( f \). This completes the proof.

\[\square\]

**Corollary 5.4.** Let \((Y, B_Y)\) be a klt pair, where \( Y \) is a \( \mathbb{Q} \)-factorial compact Kähler 3-fold. Suppose that \( Y \) is uniruled and the base of the MRC-fibration \( g : Y \to Z' \) has dimension 2. Let \( \omega_Y \) be a nef and big class on \( Y \) such that \( K_Y + B_Y + \omega_Y \) is \( g \)-trivial, \( i.e., (K_Y + B_Y + \omega_Y)|_{Y_s} \equiv 0 \) for all \( s \in S \).

**Proof.** Let \( h : X \to Y \) be a terminalization of the pair \((Y, B_Y)\) (cf. Lemma 2.21). Set \( K_X + B := h^*(K_Y + B_Y) \) and \( \omega = h^*\omega_Y \). Then we have

\[
K_X + B + \omega = h^*(K_Y + B_Y + \omega_Y).
\]

Note that since \( \dim Z' = 2 \), then general fibers of \( g : Y \to Z' \) and \( g \circ h : X \to Z' \) are isomorphic. In particular, if \( F \) is a general fiber of \( g \circ h : X \to Z' \), then \( (K_X + B + \omega) \cdot F = (K_Y + B_Y + \omega_Y) \cdot F = 0 \). Thus by Theorem 5.2 there is a proper surjective morphism with connected fibers \( \varphi : X \to S \) to a Kähler surface \( S \) such that \( K_X + B + \omega \) is \( \varphi \)-trivial. With the notations as in the proof of Theorem 5.2 we get the following commutative diagram.

\[\text{(5.5)}\]

Using the rigidity lemma now we will show that the fibration \( \varphi : X \to S \) factors through \( h : X \to Y \). Note that the fibers of \( h \) are covered by curves by Lemma 2.25, so it is enough to work with the curves contained in the fibers of \( h \). Let \( C \) be a curve in \( X \) contracted by \( h \). Then \( (K_X + B + \omega) \cdot C = \)
\(h^*(K_Y + B_Y + \omega_Y) \cdot C = 0\). Let \(\hat{C}\) be a curve in \(\hat{X}\) such that \(\hat{p}(\hat{C}) = C\). Recall from the proof of Theorem 5.2 that \(\hat{p}^*(K_X + B + \omega) = \hat{q}^*\alpha\) for some nef and big class \(\alpha\) on \(Z\). Thus we have

\[\hat{q}^*\alpha \cdot \hat{C} = \hat{p}^*(K_X + B + \omega) \cdot \hat{C} = (K_X + B + \omega) \cdot C = 0.\]

Therefore \(\alpha \cdot \hat{q}_*(\hat{C}) = 0\). Now recall from the construction of \(\nu : Z \to S\) in Step 4 of the proof of [HP15, Theorem 1.4] that the morphism \(\nu : Z \to S\) contracts exactly the \(\alpha\)-trivial curves. Therefore, either \(\hat{C}\) is contracted \(\hat{q}\), or its image is contracted by \(\nu\). In particular, from the diagram (5.5) it follows that the curve \(C \subset X\) is contracted by \(\phi : X \to S\). Therefore, by the rigidity lemma (see [BS95, Lemma 4.1.13]), there is a proper surjective morphism with connected fibers \(\psi : Y \to S\) such that \(K_Y + B_Y + \omega_Y\) is \(\psi\)-trivial.

The following theorem is an application of Corollary 5.4 and also a generalization of [TZ18, Theorem 2.7].

**Theorem 5.5.** Let \((X, B)\) be a klt pair, where \(X\) is a \(\mathbb{Q}\)-factorial compact Kähler 3-fold. Let \(\omega\) be a nef and big class on \(X\) such that \(\alpha := K_X + B + \omega\) is nef but not big. Then there exists a proper surjective morphism with connected fibers \(\psi : X \to Y\) onto a normal compact Kähler surface \(Y\) with rational singularities and a Kähler class \(\alpha_Y \in H^{1,1}_{BC}(Y)\) such that \(\alpha = \psi^*\alpha_Y\).

**Proof.** We will closely follow the arguments in [TZ18, Theorem 2.7]. First observe that, since \(\omega\) is a big class and \(\alpha\) is not big, \(K_X + B\) is not pseudo-effective; in particular \(K_X\) is not pseudo-effective. Therefore \(X\) is uniruled. Let \(X \to T\) be the MRC fibration of \(X\). If \(\dim T \leq 1\), then from Lemma 2.40 and its proof it follows that \(X\) is projective and \(H^2(X, \mathcal{O}_X) = 0\). In particular, \(\alpha\) is an \(\mathbb{R}\)-divisor in this case, and our result follows from the well known base-point free theorem. So from now on we assume that \(\dim T = 2\). Now we claim that \(\omega\) is a \((K_X + B)\)-normalized nef and big class, i.e. \((K_X + B + \omega) \cdot F = 0\) for general fibers \(F\) of \(X \to T\). If not, then by Lemma 4.4 there exists a \(0 < \mu < 1\) such that \((K_X + B + \mu\omega) \cdot F = 0\), where \(F \cong \mathbb{P}^1\) is a general fiber of the MRC fibration \(X \to T\). Then by Corollary 4.3, \(K_X + B + \mu\omega\) is pseudo-effective. Thus we have \(\alpha = (K_X + B + \mu\omega) + (1 - \mu)\omega\) is a big class, a contradiction.

Now by Corollary 5.4 there exists a proper surjective morphism \(f : X \to Y\) to a normal compact Kähler surface \(Y\) such that \((K_X + B + \omega)|_{X_y} \equiv 0\) for all \(y \in Y\). Also, as in the proof of Theorem 5.2 (see diagram (5.5)) for the dlt...
case) we get the following commutative diagram:

$$\begin{array}{c}
\Gamma \\ \downarrow^p \\
X \rightarrow Y
\end{array} \quad \begin{array}{c}
\rightarrow \\
Z \\
\downarrow^\nu
\end{array} \quad \begin{array}{c}
\rightarrow \\
\rightarrow
\end{array} \quad \begin{array}{c}
\rightarrow \\
\rightarrow
\end{array}$$

where $Z$ is a smooth compact Kähler surface, $\Gamma$ is a normal 3-fold in Fujiki’s class $\mathcal{C}$, and $p$ and $\nu$ are bimeromorphic.

Replacing $\Gamma$ by a resolution we may further assume that $\Gamma$ is a compact Kähler 3-fold (see Definition 2.2.(i)). As in the proof of Corollary 5.4 and Theorem 5.2 we have $p^*\alpha = q^*\beta$ for some nef and big $(1,1)$ class $\beta$ on $Z$.

We claim that $\beta$ is pullback of a Kähler class from $Y$. To see this, first recall that from the Step 4 of the proof of [HP15, Theorem 1.4] it follows that $\text{Ex}(\nu) = \text{Null}(\beta)$ (see Definition 6.1 for $\text{Null}(\beta)$). Moreover, by Lemma 2.42, $Y$ has rational singularities. Thus by Lemma 2.8 there is a $(1,1)$ class $\gamma \in H^{1,1}_{\text{BC}}(Y)$ such that $\beta = \nu^*\gamma$. Then $\gamma$ is nef and big (see [Pau98, Theorem 1]), and by the projection formula we have $\gamma^2 = (\nu^*\gamma)^2 = \beta^2 > 0$. Moreover, if $C \subset Y$ is a curve and $C' \subset Z$ its strict transform, then $\beta \cdot C' > 0$, since $\text{Null}(\beta) = \text{Ex}(\nu)$ and $C'$ is not contained $\text{Ex}(\nu)$. Then again by the projection formula we have $\gamma \cdot C = \nu^*\gamma \cdot C' = \beta \cdot C' > 0$. Finally, since $Y$ is a normal surface, it has only finitely many (rational) singular points. Therefore by [Hör18, Lemma 2.1], $\gamma$ is a Kähler class on $Y$. This proves the claim.

Now from the commutativity of the diagram (5.6) we have $p^*(f^*\gamma - \alpha) = 0$. Since $p^* : H^{1,1}_{\text{BC}}(X) \rightarrow H^{1,1}_{\text{BC}}(\Gamma)$ is injective, we have $f^*\gamma - \alpha = 0$, i.e. $K_X + B + \omega = f^*\gamma$, where $\gamma$ is a Kähler class on $Y$. This completes the proof.

\begin{corollary}
Let $(X, B)$ be a dlt pair, where $X$ is a $\mathbb{Q}$-factorial compact Kähler 3-fold. Let $\omega$ be a Kähler class on $X$ such that $\alpha := K_X + B + \omega$ is nef but not big. Then there exists a projective surjective morphism with connected fibers $\psi : X \rightarrow Y$ onto a normal compact Kähler surface $Y$ with rational singularities and a Kähler class $\alpha_Y \in H^{1,1}_{\text{BC}}(Y)$ such that $\alpha = \psi^*\alpha_Y$.
\end{corollary}

\begin{proof}
Replacing $B$ by $(1-\varepsilon)B$ and $\omega$ by $\omega+\varepsilon B$ for $\varepsilon \in \mathbb{Q}^+$ sufficiently small, we may assume that $(X, B)$ is klt. Then the result follows from Theorem 5.5. Note that the projectivity of $\psi$ in this case follows from the fact that $-(K_X+B)$ is $\psi$-ample, since $-(K_X+B)|_{X_y} \equiv \omega|_{X_y}$ for all $y \in Y$ and $\omega$ is a Kähler class.
\end{proof}

As a last result of this section we prove Theorem 1.2.

\begin{proof}[Proof of Theorem 1.2]
Since $K_X + B$ is not pseudo-effective, $K_X$ is not pseudo-effective. Thus by [Bru06, Corollary 1.2] applied to a resolution of $X$ it follows

$$
\square
$$
that $X$ is uniruled. By Lemma 2.40, we may assume that the dimension of the base of the MRC fibration $f: X \rightarrow Z$ is 2. Let $F$ be a general fiber of the MRC fibration $f: X \rightarrow Z$. By Lemma 4.4, if $(K_X + B) \cdot F \geq 0$, then $K_X + B$ is pseudo-effective, contradicting our assumption. Therefore $(K_X + B) \cdot F < 0$.

By Theorem 5.1, there is a $(K_X + B)$-MMP, $\phi: X \rightarrow X'$ such that for every $(K_{X'} + B')$-normalized Kähler class $\omega'$, the class $K_{X'} + B' + \omega'$ is nef, where $B' = \phi_* B$. Since $X'$ is Kähler and $(K_{X'} + B') \cdot F' < 0$, where $F' \sim F$ is a general fiber of the induced MRC fibration $X' \rightarrow Z$, we may pick a $(K_{X'} + B')$-normalized Kähler class, say $\omega'$. By Corollary 5.4, there exists a holomorphic fibration $\psi: X' \rightarrow S'$ on to a normal compact Kähler surface $S'$ such that $K_{X'} + B' + \omega'$ is $\psi$-trivial, i.e., $(K_{X'} + B' + \omega')|_{X'} \equiv 0$ for all $s' \in S'$.

In particular, $\psi$ is a projective morphism and so the theorem now follows from the usual relative minimal model program for projective morphisms as in Proposition 2.20.

6. Applications

In this section we prove a log version of the base-point free Theorem 1.7 for Kähler 3-folds. But first we need some preparation.

Definition 6.1. Let $X$ be a normal compact Kähler variety and $\alpha \in H^{1,1}_{BC}(X)$ is a nef and big class. Then we define the null locus of $\alpha$ as follows:

$$\text{Null}(\alpha) = \bigcup_{Z \subset X, \dim Z > 0, \alpha^{\dim Z} Z = 0} Z.$$ 

A priori we do not know whether $\text{Null}(\alpha)$ is a closed subvariety of $X$ or not.

Proposition 6.2. Let $X$ be a normal $\mathbb{Q}$-factorial compact Kähler 3-fold with klt singularities. Let $\alpha$ be a nef and big $(1,1)$ class on $X$. Assume that $\text{Null}(\alpha)$ consists only finitely many curves of $X$. Then there exists a proper bimeromorphic morphism $\mu: X \rightarrow Z$ onto a normal analytic variety $Z$ such that every connected component of $\text{Null}(\alpha)$ is contracted to a point and $Y \setminus \text{Null}(\alpha) \cong Z \setminus \mu(\text{Null}(\alpha))$.

Proof. The proof of [CHP16, Theorem 4.2] holds here without any change. Note that the proof of Theorem 4.2 of [CHP16] uses [CHP16, Proposition 4.4], however, this proposition is only used to prove that $\text{Null}(\alpha)$ consists of finitely many curves, which is part of our hypothesis here.

Lemma 6.3. Let $X$ be a normal compact analytic variety of dimension 3. Let $\alpha \in H^{1,1}_{BC}(X)$ be a nef and big class such that $\alpha^{\dim V} \cdot V > 0$ for every positive dimensional subvariety $V \subset X$. Then $\alpha$ is a Kähler class.
Proof. Let \( f : Y \to X \) be a resolution of singularities of \( X \). Then \( f^* \alpha \) is a nef and big class on \( Y \), and by the projection formula and [CT15, Theorem 1.1] it follows that \( \text{EnK}(f^* \alpha) = \text{Null}(f^* \alpha) = \text{Ex}(f) \). Next, by Demailly’s regularization theorem [Dem92] and [Bou04, Theorem 3.17(ii)], there exists a Kähler current \( T \) with analytic singularities contained in the class \( f^* \alpha \) such that \( T \) is singular (i.e., not a smooth form) precisely along the exceptional locus of \( f \). Therefore the current \( f_* T \) (contained in the class \( \alpha \)) is a Kähler current which is singular along the closed set \( f(\text{Ex}(f)) \). Since \( \dim X = 3 \), we have that \( \dim f(\text{Ex}(f)) \leq 1 \). Now, since by construction \( f_* T \) is a smooth form on the open set \( X \setminus f(\text{Ex}(f)) \), the Lelong numbers \( \nu(f_* T, x) = 0 \) for all \( x \in X \setminus f(\text{Ex}(f)) \). Thus for any positive real number \( c > 0 \), the Lelong sublevel sets \( E_c(f_* T) := \{ x \in X \mid \nu(f_* T, x) \geq c \} \) are contained in \( f(\text{Ex}(f)) \). By a theorem of Siu [Su74], we know that \( E_c(T) \) is a closed analytic subset of \( X \) for all \( c > 0 \). Therefore every irreducible component of \( E_c(T) \) is either a projective curve or a point contained in \( f(\text{Ex}(f)) \) for all \( c > 0 \). Let \( C \subset f(\text{Ex}(f)) \) be an irreducible projective curve. Then first observe that if \( \nu : \tilde{C} \to \tilde{C} \) is the normalization, then \( \text{NS}_{\text{R}}(\tilde{C}) = H^{1,1}_{\text{BC}}(\tilde{C}) \), since \( H^2(\tilde{C}, \mathcal{O}_{\tilde{C}}) = 0 \). Therefore \( \alpha|_{\tilde{C}} \) is a class of an \( \mathbb{R} \)-Cartier nef divisor on \( \tilde{C} \) and in fact, it is and ample class, since \( \deg(\alpha|_{\tilde{C}}) = \alpha \cdot C > 0 \) by hypothesis. Now pushing-forward \( \alpha|_{\tilde{C}} \) by \( \nu \), we see that \( \alpha|_{\tilde{C}} \) is a class of an \( \mathbb{R} \)-Cartier divisor on \( \tilde{C} \). Since \( \nu \) is finite, \( \alpha|_{\tilde{C}} \) is an ample class on \( \tilde{C} \), hence a Kähler class. Then by [DP04, Proposition 3.3(iii)] it follows that \( \alpha \) is a Kähler class on \( X \).

\[ \square \]

**Theorem 6.4.** Let \((X, B)\) be a klt pair, where \( X \) is a normal \( \mathbb{Q} \)-factorial compact Kähler 3-fold. Let \( \omega \) be a nef and big class on \( X \) such that \( \alpha := K_X + B + \omega \) is nef and big. Then there exists a proper bimeromorphic morphism \( \psi : X \to Z \) onto a normal compact Kähler 3-fold \( Z \) with rational singularities and a Kähler class \( \alpha_Z \in H^{1,1}_{\text{BC}}(Z) \) on \( Z \) such that \( \alpha = \psi^* \alpha_Z \).

**Proof.** We closely follow the arguments of [Hör18, Theorem 1.3]. For the convenience of the reader, we reproduce these arguments here indicating the necessary changes. The main idea is to construct \( \psi \) by running an \( \alpha \)-trivial mmp and then to contract the remaining \( \alpha \)-trivial curves. First note that using Lemma 2.37 we may assume that \( \omega \) is a modified Kähler class on \( X \). Now if \( H^2(X, \mathcal{O}_X) = 0 \), then \( \alpha \) is an \( \mathbb{R} \)-divisor. Therefore \( X \) is a Moishezon space with rational singularities. Then by [Nam02, Theorem 1.6] \( X \) is projective, and the results follows from a well known base-point free theorem for projective varieties. So assume that \( X \) is not projective, and \( H^2(X, \mathcal{O}_X) \neq 0 \). Then either \( X \) is not uniruled and hence \( K_X \) is pseudo-effective, or \( X \) is uniruled
and the base of the MRC fibration $X \rightarrow Z$ has dimension 2 (see Lemma 2.40 and its proof).

We will run the $\alpha$-trivial $(K_X + B)$-MMP. We start with $(X_0, B_0) := (X, B), \omega_0 := \omega$ and $\alpha_0 := \alpha$. By induction assume that we have already constructed the first $i$ steps

$$\phi_i : X_0 \rightarrow X_1 \rightarrow X_2 \rightarrow \ldots \rightarrow X_i.$$ 

Note that $(X_i, B_i) := \phi_i, * B)$ is klt, $\omega_i = \phi_i, * \omega$ is modified Kähler and $\alpha_i = \phi_i, * \alpha$ is nef and big. Now suppose that there is an $\alpha_i$-trivial curve $C \subset X_i$ such that $(K_{X_i} + B_i) \cdot C < 0$. We will show that there is an $\alpha_i$-trivial flip or divisorial contraction $\mu_i : X_i \rightarrow X_{i+1}$. If $K_{X_i} + B_i$ is not pseudo-effective (and hence the base of the MRC fibration $X_i \rightarrow Z_i$ has dimension 2), then by Lemma 4.4 it follows that $(K_{X_i} + B_i) \cdot F_i < 0$ for general fibers $F_i$ of $X_i \rightarrow Z_i$.

The existence of $\mu_i$ follows from Theorem 4.6, Corollary 4.10 and Theorem 4.14. To see this, pick $0 < \epsilon \ll 1$ and note that $K_{X_i} + B_i + (1 - \epsilon)\omega_i$ is big and in particular $(K_{X_i} + B_i + (1 - \epsilon)\omega_i) \cdot F_i > 0$. By Corollary 4.10

$$\text{NA}(X) = \text{NA}(X)_{(K_{X_i} + B_i + (1 - \epsilon)\omega_i) \geq 0} + \sum_{j=1}^{N} \mathbb{R}^+ [\Gamma_j]$$

where $(K_{X_i} + B_i + (1 - \epsilon)\omega_i) \cdot \Gamma_j < 0$. We decompose $C = \eta + \sum_{j \in J} \lambda_j \Gamma_j$ accordingly. Since $\alpha \cdot C = 0$, we may assume that $\alpha \cdot \Gamma_j = 0$ for all $j \in J$. Since $(K_{X_i} + B_i + (1 - \epsilon)\omega_i) \cdot C < 0$, we may assume that $J \neq \emptyset$ and hence for some $j_0 \in J$, we have $\lambda_{j_0} \neq 0$ and $(K_{X_i} + B_i + (1 - \epsilon)\omega_i) \cdot \Gamma_{j_0} < 0$. Note that Theorem 4.14 does not immediately apply since $\omega_i$ is no longer nef, however the only place that we use this in the proof of Theorem 4.14 is to conclude that $(K_{X_i} + B_i) \cdot \Gamma_{j_0} < 0$. Since $\alpha_i \cdot \Gamma_{j_0} = 0$, it follows that $\omega_i \cdot \Gamma_{j_0} > 0$ and hence that $(K_{X_i} + B_i) \cdot \Gamma_{j_0} < 0$. Thus the proof of Theorem 4.14 still applies verbatim and hence we obtain the corresponding divisorial or flipping contraction. If we have a flipping contraction, the flip then exists by Theorem 2.18.

On the other hand if $K_{X_i} + B_i$ is pseudo-effective, then the existence of $\mu_i$ follows from Theorems 2.16, 2.17, 2.18 and 1.5. Note that $\alpha_{i+1} := \mu_i, * \alpha_i$ is nef and big by [CHP16, Pro. 3.1, eqn. (5)], and $\omega_{i+1} := \mu_i, * \omega_i$ is a modified Kähler class by Lemma 2.36. This MMP terminates after finitely many steps by Theorem 2.19, so assume that it terminates at $\phi : X \rightarrow X_n$. In particular, every $\alpha_n$-trivial curve on $X_n$ is $(K_{X_n} + B_n)$-non-negative, or equivalently, every $(K_{X_n} + B_n)$-negative curve is $\alpha_n$-positive.

By Lemma 4.5, if Null($\alpha_n$) contains a surface $S$, then $S$ is Moishezon and thus it is covered by a family of $\alpha_n$-trivial curves $\{C_t\}_{t \in T}$. Since $\omega_n$ is a modified Kähler class, $\omega_n|_S$ is big and hence $\omega_n \cdot C_t = \omega_n|_S \cdot C_t > 0$. But then
from $0 = \alpha_n \cdot C_t = (K_{X_n} + B_n + \omega_n) \cdot C_t$ it follows that $(K_{X_n} + B_n) \cdot C_t < 0$, this is a contradiction. Therefore $\text{Null}(\alpha_n)$ is a union of curves.

Now let $f : X' \to X_n$ be a resolution of singularities of $X_n$. Then $f^*\alpha_n$ is nef and big, and thus by [CT15, Theorem 1.1], the non-Kähler locus is $\text{EnK}(f^*\alpha_n) = \text{Null}(f^*\alpha_n)$. If $S' \subset \text{EnK}(f^*\alpha_n)$ is a divisor, then by the projection formula $0 = (f^*\alpha_n)^2 \cdot S' = \alpha_n^2 \cdot f^*S'$. Thus $S'$ is $f$-exceptional, since $\text{Null}(\alpha_n)$ does not contain any surface, as proved above. Moreover, since $\text{EnK}(f^*\alpha_n)$ is a proper closed analytic subset of $X'$ (see [CT15, Theorem 2.2]), it follows that $\text{Null}(f^*\alpha_n)$ is a finite union of curves and $f$-exceptional divisors. But since $\text{Null}(\alpha_n) \subset \text{EnK}(\alpha_n) \subset f(\text{EnK}(f^*\alpha_n))$, it follows that $\text{Null}(\alpha_n)$ is a finite union of curves. Then by Proposition 6.2 there exists a proper birational morphism $\mu : X_n \to Z$ onto a normal compact analytic variety $Z$ contracting each curve in $\text{Null}(\alpha_n)$ to a point and inducing an isomorphism on the open sets $X_n \setminus \text{Null}(\alpha_n) \cong Z \setminus \mu(\text{Null}(\alpha_n))$.

Set $\psi := \mu \circ \phi_n : X \to Z$. We claim that $\psi$ is a morphism. To see this, we will use descending induction to show that the induced map $\psi_i : X_i \to Z$ is a morphism. Note that $\psi_n$ is a morphism as constructed above. Suppose that we have already shown that $\psi_i : X_i \to Z$ is a morphism. If $X_{i-1} \to X_i$ is a divisorial contraction, then clearly $X_{i-1} \to Z$ is a morphism and we are done by induction on $i$. If on the other hand $X_{i-1} \to X_i$ is a flip, then let $X_i \to Z_{i-1}$ be the flipped contraction. If $Z_{i-1} \to Z$ is not a morphism, then by the rigidity lemma (see [BS95, Lemma 4.1.13]) there is a flipped curve $C_i \subset X_i$ such that $C = \psi_{i,*}C_i \neq 0$. Let $W$ be the normalization of the graph of the induced bimeromorphic map $\pi_i : X_i \to X_n$, and $p : W \to X_i$ and $q : W \to X_n$ are the projections. Now by construction $\alpha_i$ and $\alpha_n$ are both nef classes. Moreover, since $\pi_i : X_i \to X_n$ is a composition of a finite sequence of $\alpha_i$-trivial flips and divisorial contractions, by a repeated application of [CHP16, Proposition 3.1, eqn. (5)] it follows that $p^*\alpha_i = q^*\alpha_n$. Let $C_W \subset W$ be a curve such that $p_*C_W = dC_i$ for some $d > 0$ and $C_n = q_*C_W \subset X_n$. Since $\psi_n(C_n) = C$, then $\alpha_n \cdot C_n > 0$. Then we have

$$0 = dC_i \cdot \alpha_i = C_W \cdot p^*\alpha_i = C_W \cdot q^*\alpha_n = C_n \cdot \alpha_n > 0,$$

a contradiction.

Therefore $Z_{i-1} \to Z$ is a morphism, and since $X_{i-1} \to Z_{i-1}$ is a flipping contraction, $X_{i-1} \to Z$ is also a morphism. This concludes the proof that $\psi : X \to Z$ is a morphism.

Next we claim that $Z$ is a Kähler variety with rational singularities and there exists a Kähler class $\alpha_Z \in H^{1,1}_{\text{BC}}(X)$ such that $\alpha_n = \mu^*\alpha_Z$. To this end, first observe that $(X, B)$ has $\mathbb{Q}$-factorial klt singularities, and $\alpha = K_X + B + \omega$ and $\omega$ are both nef and big classes. Now recall that $\mu : X_n \to Z$ contracts precisely the null locus $\text{Null}(\alpha_n)$, and since this locus is 1 dimensional, $\mu$ is $\alpha_n$-trivial. Since $X \to X_n$ is a sequence of $\alpha$-trivial flips and divisorial
contractions, it follows that \( \psi : X \to Z \) is also \( \alpha \)-trivial, i.e., the restriction of \( \alpha \) to every fiber of \( \psi \) is numerically trivial, so that \( \alpha|_{X_z} \equiv 0 \) for all \( z \in Z \).

Thus \( -(K_X + B)|_{X_z} \equiv \omega|_{X_z} \) for all \( z \in Z \). In particular, \( -(K_X + B) \) is \( \psi \)-nef, since \( \omega \) is nef by hypothesis. Moreover, since \( \psi \) is a bimeromorphic morphism, \( -(K_X + B) \) is \( \psi \)-big. By Lemma 2.42, \( Z \) has rational singularities.

Now form Definition 2.2.(i) it follows that \( Z \) is in Fujiki’s class \( \mathcal{C} \). Then by Lemma 2.8 there exists a \((1,1)\) class \( \alpha_Z \in H^{1,1}_{BC}(Z) \) (represented by a real closed \((1,1)\) form with local potentials) such that \( \alpha_n = \mu^* \alpha_Z \).

Next we claim that \( \alpha_Z \) is a Kähler class on \( Z \). Indeed, let \( V \subset Z \) be subvariety of positive dimension and \( V' \) is the strict transform of \( V \) under \( \mu \). By the projection formula we have \( (\alpha_Z)^{\dim V} \cdot V = (\alpha_n)^{\dim V'} \cdot V' > 0 \), since \( V' \) is not contained in \( \text{Null}(\alpha_n) \). Then by Lemma 6.3, \( \alpha_Z \) is a Kähler class on \( Z \).

Finally notice that, since every step of the above MMP is \( \alpha \)-trivial, from the construction above it follows that \( \alpha = \psi^* \alpha_Z \). This completes the proof. \( \square \)

**Corollary 6.5.** Let \((X, B)\) be a dlt pair, where \( X \) is a normal \( \mathbb{Q} \)-factorial compact Kähler 3-fold. Let \( \omega \) be a Kähler class on \( X \) such that \( \alpha := K_X + B + \omega \) is nef and big. Then there exists a projective bimeromorphic morphism \( \psi : X \to Z \) onto a normal compact Kähler 3-fold \( Z \) with rational singularities and a Kähler class \( \alpha_Z \in H^{1,1}_{BC}(Z) \) on \( Z \) such that \( \alpha = \psi^* \alpha_Z \).

**Proof.** First replacing \( B \) by \((1 - \varepsilon)B\) and \( \omega \) by \( \omega + \varepsilon B \) for a sufficiently small \( \varepsilon \in \mathbb{Q}^+ \), we may assume that \((X, B)\) is klt. Then the existence of \( \psi \) follows from Theorem 6.4. Finally, the projectivity of the morphism \( \psi \) follows from the fact that \( -(K_X + B) \) is \( \psi \)-ample, since \( -(K_X + B)|_{X_z} \equiv \omega|_{X_z} \) for all \( z \in Z \) and \( \omega \) is a Kähler class. \( \square \)

**Proof of Theorem 1.7.** If \( \alpha \) is nef but not big, then this is Theorem 5.5 and Corollary 5.6. When \( \alpha \) is both nef and big, it is Theorem 6.4 and Corollary 6.5. \( \square \)
