Abstract. The classical Buffon problem requires a precise presentation in order to be meaningful. We reinterpret the classical problem in the planar setting with a needle whose length is equal to the grating width and find analogs of this problem in the settings of the sphere and the Poincaré disk. We show that the probability that the needle intersects the grating in these non-euclidean settings tends to the probability of the intersection in the planar setting as the length of the needle tends to zero. Finally, we calculate the Gaussian curvature of the spaces from probability deficits related to the generalized Buffon problem, obtaining a result similar to the Bertrand-Diguet-Puiseux Theorem.

1. Introduction

In his investigation of players’ chances in the game “clean tile”, Buffon introduced the following problem, its statement in his own words translated in [9] as:

E-mail address: aabel003@ucr.edu, bcarrillo@saddleback.edu, jpala019@ucr.edu,
weisbart@math.ucr.edu, adam.yassine@aucegypt.edu
“I assume that in a room, the floor of which is merely divided by parallel lines, a stick is thrown upwards and then one player bets the stick will not intersect any of the parallels on the floor, whereas on the contrary the other one bets the stick will intersect some one of these lines; it is required to find the chances of the two players. It is possible to play this game with a sewing needle or a headless pin.”

Buffon’s problem, a progenitor of geometric probability, is often simplified as it is in the present exposition to ask for the probability that a randomly dropped needle intersects a line on the floor. This simplification naturally leads to the solution of the original problem.

Buffon’s problem has attracted considerable interest and invited many generalizations and analogs following its introduction in the book [4] and in Buffon’s earlier lecture [3]. Already in 1860, Barbier studied in [1] an analog of this problem in the planar setting but where the needle is replaced by a rigid rectifiable plane curve, a “noodle”. Solomon gives an extensive treatment and review of this problem and many of its generalizations in [9]. He includes a review and discussion of an application in three dimensions. Klain and Rota give a treatment of the Buffon problem in [7]. Diaconis studies the problem in the setting of a long needle in [5], where he calculates the probability mass function for the random variable that counts the number of intersections and estimates its moments. He also discusses an applied motivation for this problem in detection deployment. Peter and Tanasi study in [8] an analog of the Buffon problem on the sphere, using a grating formed by lines of longitude. Isokawa discusses an analog of Buffon’s problem on the sphere in [6], using a grating formed by lines of latitude.

To dispense with the difficulty of dealing with the boundary of an actual floor of finite extent, we reinterpret the problem as dropping a needle on an infinite floor, modeled as the plane covered with an infinite collection of evenly spaced parallel lines. The non-existence of a uniform probability density function on all of $\mathbb{R}^2$ demands a clarification of the problem even in this classical setting. To develop some intuition, imagine that a needle is tossed high enough over an infinitely wide floor with infinitely long parallel slats of width $L$ so that the position of the center of the needle approximately has a uniform distribution on conditioning it to fall on any given bounded disk $D$ on the floor. Let $A$ be a line that is determined by a slat. Denote by $p$ the probability that a needle intersects $A$ given the following conditions: (1) the needle lands uniformly randomly on a line segment of length $L$ that is perpendicular to and bisected by $A$; and (2) the angle that the needle makes with the slat is uniformly distributed on $[0, 2\pi]$. If $D$ is sufficiently large in comparison with the width of the slats, then the probability that the needle intersects a line formed by the slats is approximately $p$.

With this physical interpretation in mind, we extend Buffon’s problem to dropping needles on two surfaces that are homogeneous but have non-zero Gaussian curvature, namely the sphere with an arbitrary given radius and the Poincaré disk. While the sphere is a compact space, making it possible to uniformly randomly select the center of the needle on this surface, the Poincaré disk, like $\mathbb{R}^2$, is non-compact and so choosing a point for the center of the needle requires further interpretation. Our interpretation of this problem in the spherical setting is different from the interpretation presented in [6] and in [8], but permits a natural and unified
treatment of the problem in three different geometries. The solution to the problem in these settings gives a probabilistic way of determining the Gaussian curvature of the sphere and the Poincaré disk through probability deficits. The relationship between probability deficits and Gaussian curvature is similar to the relationship that the Bertrand-Diguet-Puiseux Theorem establishes in [2] between area and circumference deficits and Gaussian curvature.

Acknowledgements. We thank Professor Yat Sun Poon, who as chair of the UCR Department of Mathematics has given his unwavering and enthusiastic support for undergraduate research and education abroad programs. Carrillo and Yassine wish to thank the UCR Department of Mathematics for their funding in Spring 2018 and 2019 as graduate student mentors through the Undergraduate Research Program. We thank all those involved in the Faculty Led Education Abroad Program (FLEAP), and especially Dr. Karolyn Andrews, for the programs in London in summer 2018 and 2019 that Weisbart ran that ultimately gave rise to the present paper. Abelgas and Palacios participated in this program in summer, 2018. We thank James Alcala, Christopher Kirchgraber, Frances Lam (also a FLEAP alum), and Alexander Wang for the time they spent as undergraduate researchers working on this project in its various stages.

2. A General Framework

Denote respectively by \( \mathbb{R}^2 \), \( S_r \), and \( \mathbb{H} \) the plane, the sphere of radius \( r \), and the Poincaré disk. This section develops a uniform framework for studying Buffon’s problem in these spaces and proves some general theorems that hold in all three settings. Denote by \( M \) either \( \mathbb{R}^2 \), \( S_r \), or \( \mathbb{H} \).

2.1. Isometries and Gratings. The Riemannian manifold \( M \) is homogeneous, it has an isometry group \( G \) that acts transitively.

Definition 2.1. An equator of \( M \) is a directed geodesic in \( M \).

Definition 2.2. A grating \( G(L) \) on \( M \) with equator \( E \) and spacing \( L \) is a set of geodesics in \( M \) that intersect \( E \) at right angles and whose set of intersections with \( E \) form an evenly spaced set of points \( E_L \) with smallest spacing equal to \( L \).

Select a directed geodesic \( E \) in \( M \) and a grating \( G(L) \) that is oriented by \( E \). In the setting of the sphere \( S_r \), evenness of the spacing requires \( L \) to be equal to \( \frac{\pi r}{n} \), where \( n \) is a natural number. In each of the three settings, a maximal nontrivial subgroup \( G' \) of \( G \) will preserve both \( E \) and the orientation of \( E \). There is a single element \( h_0 \) of \( G' \) that generates a subgroup \( H \) of \( G' \) that acts transitively on \( E_L \) and under which \( E_L \) is invariant, and that moves points in \( E \) in the positive direction along \( E \). Suppose that \( g \) is in \( G' \). Denote by \( \alpha_g \) the signed distance that \( g \) moves points along \( E \). For each space \( M \), the displacement function \( \alpha \) defined by

\[ \alpha : g \mapsto \alpha_g \]

gives an ordering on the elements of \( G' \), with the additional assumption in the case of \( S_r \) that the range of \( G' \) is \( \mathbb{R} \mod 2\pi r \). The function \( \alpha \) is a homomorphism. We will verify all above
assertions as well as Propositions 2.4 and 2.3 case by case when we independently discuss the three cases, but take them now for granted throughout the remainder of this section.

Further notation is useful for stating the next two propositions. Suppose that $g$ is an element of $G$ and that $x$ is an element of $M$. Denote henceforth by $gx$ the result of applying the transformation $g$ to the point $x$. If $S$ is a subset of $M$, then denote by $gS$ the set $gS = \{gs : s \in S\}$.

**Proposition 2.3.** If $M$ is any of the three spaces above, there is a unique $g$ in $G$ such that if $E$ and $E'$ are two equators in $M$, then $gE = E'$.

**Proposition 2.4.** Given any two gratings $G_1(L)$ and $G_2(L)$ with spacing $L$ and equator $E$, there is an element $g$ of $H$ such that $gG_1(L) = G_2(L)$.

2.2. **Dropping the Needle.** Take $X$ to be a random variable that is uniformly distributed on $[-\ell, \ell]$. The orientation of $E$ determines a notion of signed distance between points on $E$. Let $z$ be a real number. In the case when $M$ is the sphere, $z$ will be in $\mathbb{R}$ mod $2\pi r$. Denote by $p_x(z)$ the unique point on $E$ that lies on $E$ a signed distance of $z$ from $x$. View a needle in each of the three geometries as a directed segment of length $L$ of a geodesic whose midpoint is $p_x(X)$. The tip of the needle with center $p_x(z)$ is a marked endpoint of the needle and its position is uniformly randomly distributed on the geodesic circle $C_x(z)$ of diameter $L$ centered at $p_x(z)$. Denote by $I_x(z)$ the random variable that is 1 if the needle with midpoint $p_x(z)$ intersects $G(L)$ and 0 otherwise. The geodesic circle $C_x(z)$ will intersect either one grating line at two distinct points or two distinct grating lines at one point each. In the case when $C_x(z)$ intersects a geodesic in $G(L)$ at two points, the intersection defines two arcs of $C_x(z)$. Denote by $A_x(z)$ the arc length of the smaller of the two arcs. If the geodesic circle $C_x(z)$ intersects two grating lines at exactly one point each, then define $A_x(z)$ to be 0. If $C_x(z)$ intersects a grating line in such a way that the intersection divides $C_x(z)$ into two arcs of equal length, then take $A_x(z)$ to be half the circumference of $C_x(z)$.

![Figure 1](image-url)
Denote by $C(\ell)$ the circumference of a geodesic circle of radius $\ell$. Take the probability $P(I_x(X) = 1|X = z)$, the probability that the needle intersects $G(L)$ given that the center of the needle is a signed distance of $z$ from the point $x$, to be uniform in the angle that the needle makes with the equator. A needle that intersects a grating line will still intersect the same grating line at the same point when the needle is rotated by half a circle, hence

$$P(I_x(X) = 1|X = z) = \frac{2A_x(z)}{C(\ell)}.$$ \hfill (2.1)

The Law of Total Probability implies that for each $x$ in $\mathcal{E}$, the probability $P(I_x(X) = 1)$ is given by

$$P(I_x(X) = 1) = \int_{-\ell}^{\ell} P(I_x(X) = 1|X = z) \cdot \frac{1}{2\ell} \, dz.$$ \hfill (2.2)

### 2.3. Consequences of Homogeneity.

Suppose that $L$ is an element of $G(L)$ and that $L$ intersects $\mathcal{E}$ at a point $x$. The present section will explicitly verify that the homogeneity of the spaces ensures that the choices of $\mathcal{E}$, $G(L)$, and $x$ do not change the probability of intersection.

**Lemma 2.5.** If $g$ is in $H$, then

$$P(I_{gx}(X) = 1) = P(I_x(X) = 1).$$

**Proof.** Suppose that $g$ is in $H$ and that $C_x(z)$ intersects at two points a grating line that intersects $x$. In this case, the group element $g$ maps the intersections of $C_x(z)$ with a grating line that passes through $x$ to the intersections of $C_{gx}(z)$ with a grating line that passes through $gx$. Since $g$ is an isometry, it preserves the lengths of arcs and so

$$P(I_{gx}(X) = 1|X = z) = \frac{2A_{gx}(z)}{C(\ell)} = \frac{2A_x(z)}{C(\ell)} = P(I_x(X) = 1|X = z).$$ \hfill (2.3)

The Law of Total Probability implies that for each $x$ in $\mathbb{R}$, the probability $P(I_x(X) = 1)$ is given by

$$P(I_x(X) = 1) = \int_{-\ell}^{\ell} P(I_x(X) = 1|X = z) \cdot \frac{1}{2\ell} \, dz.$$ \hfill (2.4)

The equalities (2.3) and (2.4) together imply that

$$P(I_{gx}(X) = 1) = \int_{-\ell}^{\ell} P(I_{gx}(X) = 1|X = z) \cdot \frac{1}{2\ell} \, dz$$

$$= \int_{-\ell}^{\ell} P(I_x(X) = 1|X = z) \cdot \frac{1}{2\ell} \, dz = P(I_x(X) = 1).$$ \hfill (2.5)

\[\square\]

**Theorem 2.6.** If $g'$ is in $G'$, then

$$P(I_{g'x}(X) = 1) = P(I_x(X) = 1).$$
Proof. There is an element \( h \) of \( \mathcal{H} \) and an element of \( g \) of \( \mathcal{G}' \) such that \( \alpha_g \) is in \([0, L]\) and \( hg \) is equal to \( g' \). Given Lemma 2.5, to prove the theorem it suffices to show that

\[
P(I_{gx}(X) = 1) = P(I_x(X) = 1).
\]

The Law of Total Probability implies that for each \( x \) in \( \mathbb{R} \), the probability \( P(I_{gx}(X) = 1) \) is given by

\[
P(I_{gx}(X) = 1) = \frac{1}{2\ell} \int_{-\ell}^{\ell} P(I_{gx}(X) = 1 | X = z) \, dz
\]

(2.6)

\[
= \frac{1}{\ell} \int_{-\ell}^{\ell} \frac{A_{gx}(z)}{C(\ell)} \, dz = \frac{1}{\ell} \int_{-\ell}^{\ell} \frac{A_x(z)}{C(\ell)} \, dz
\]

since

(2.7)

\[
A_{gx}(z) = A_x(z + \alpha_g).
\]

Split the rightmost integral in (2.6) into an integral over two regions and use the equality (2.7) but with the element \( h_0^{-1} \) replacing \( g \) to obtain

\[
P(I_{gx}(X) = 1) = \frac{1}{\ell} \int_{-\ell}^{\ell} \frac{A_x(z)}{C(\ell)} \, dz + \frac{1}{\ell} \int_{\ell}^{\ell + \alpha_g} \frac{A_x(z)}{C(\ell)} \, dz
\]

(2.8)

\[
= \frac{1}{\ell} \int_{-\ell}^{\ell} \frac{A_x(z)}{C(\ell)} \, dz + \frac{1}{\ell} \int_{\ell}^{\ell + \alpha_g} \frac{A_x(z)}{C(\ell)} \, dz
\]

where Lemma 2.5 implies (2.8).

\[
\square
\]

Theorem 2.7. Suppose that \( G_1(L) \) and \( G_2(L) \) are two different gratings with common equator \( \mathcal{E} \). Denote respectively by \( P_1(I_x(X) = 1) \) and \( P_2(I_x(X) = 1) \) the probability that a needle of length \( L \) intersects \( G_1(L) \) and \( G_2(L) \), where the center of the needle is dropped uniformly randomly with respect to arc length on the segment of \( \mathcal{E} \) with midpoint equal to \( x \) and length equal to \( L \). The probability \( P_1(I_x(X) = 1) \) is equal to \( P_2(I_x(X) = 1) \).

Proof. Suppose that \( G_1(L) \) and \( G_2(L) \) are gratings for \( \mathcal{E} \). There is an element \( g \) of \( \mathcal{G}' \) such that \( G_2(L) \) is equal to \( gG_1(L) \). Since isometries do not change the lengths of arcs,

\[
P_1(I_x(X) = 1) = P_2(I_{gx}(X) = 1) = P_2(I_x(X) = 1)
\]

where Theorem 2.6 implies the rightmost equality. The probability \( P(I_x(X) = 1) \) is, therefore, independent of \( x \) and independent of the choice of grating.
Fix an equator $\mathcal{E}'$ that is different from $\mathcal{E}$ or has a different orientation. In each of the three possibilities for $M$, there is an element $g \in \mathcal{G}$ mapping $\mathcal{E}$ to $\mathcal{E}'$. The probabilities are dependent only on the lengths of arcs associated to intersections of arcs with geodesics and these lengths are invariant under isometries, implying that the probability of intersection is independent of the chosen equator. \qed

3. Probabilities for the Plane and the Sphere

3.1. The Needle in the Plane. Rotations about the origin, reflection across the $y$-axis, and the translations generate $\mathcal{G}$, the isometry group of the plane. The geodesics are the straight lines and every circle of radius $\ell$ will have circumference equal to $2\pi\ell$. Choose the equator $\mathcal{E}$ to be the positively oriented $x$-axis. Denote by $\mathcal{G}'$ the set of all translations that fix the $x$-axis and let $\mathcal{H}$ the subgroup of $\mathcal{G}'$ generated by the vector $(L,0)$, where vectors act on points by componentwise addition. Choose the grating $G(L)$ to be the set of lines that are the translates of the $y$-axis by the group $\mathcal{H}$. Defining $G(L)$ in this way automatically verifies Proposition 2.4 in the planar setting. A straightforward exercise shows that any directed line can be mapped by an isometry to any other line, verifying Proposition 2.3 in the planar setting. It is convenient to calculate the probability $P(I_x(X) = 1)$ by taking $x$ to be the origin, $(0,0)$.

Denote by $A(z)$ the length of the arc $A_{(0,0)}(z)$ and by $I(x)$ the random variable $I_{(0,0)}(X)$. Since reflection across the $y$-axis is an isometry, $A(z)$ is equal to $A(-z)$ and so

\begin{equation}
P(I(X) = 1) = \frac{1}{\ell} \int_0^\ell \frac{2A(z)}{\pi\ell} \, dz.
\end{equation}

Take $\gamma$ to be a parameterization of the arc $\Gamma$ of $C(z)$, where $\Gamma$ has arc length equal to $A(z)$ and the endpoints of $\Gamma$ are the points of intersection of $C(z)$ with the $y$-axis. The curve $\gamma$ is given by

$$
\gamma(t) = (z + \ell \cos(t), \ell \sin(t)) \quad \text{with} \quad \pi - \cos^{-1}\left(\frac{z}{\ell}\right) \leq t \leq \pi + \cos^{-1}\left(\frac{z}{\ell}\right),
$$

so that

\begin{equation}
A(z) = \int_{\pi - \cos^{-1}\left(\frac{z}{\ell}\right)}^{\pi + \cos^{-1}\left(\frac{z}{\ell}\right)} \ell \, dt = 2\ell \cos^{-1}\left(\frac{z}{\ell}\right).
\end{equation}

Combine (3.1) and (3.2) to obtain the equality

$$
P(I_x(X) = 1) = \frac{1}{\ell} \int_0^\ell \frac{A(z)}{\pi\ell} \, dz
= \frac{2}{\pi\ell} \int_0^\ell \cos^{-1}\left(\frac{z}{\ell}\right) \, dz
= \frac{2}{\pi} \int_0^1 \cos^{-1}(z) \, dz = \frac{2}{\pi}.
$$

7
3.2. The Needle in the Sphere. View $S_r$ as the subset
\[ S_r = \{(x, y, z) : x^2 + y^2 + z^2 = r^2\} \]
of $\mathbb{R}^3$. The metric is induced by the standard euclidean metric on $\mathbb{R}^3$. The distance between points $p$ and $q$ on $S_r$ is the geodesic distance. Fix a length $L$ equal to $\frac{\pi}{m}$ for some natural number $n$ that is greater than 1. The isometry group, $G$, of $S_r$ is the orthogonal group $O(3)$. The geodesics are the great circles. Choose $\mathcal{E}$, an equator for $S_r$, to be the subset of all points of $S_r$ lying on the $x$-$y$ plane endowed with a counterclockwise orientation when viewed from above. Denote by $G(L)$ the set of all great circles in $S_r$ that intersect the equator at right angles at two points in the set of points $S$ where
\[ S = \left\{ \left( r \cos \left( \frac{mL}{\ell} \right), r \sin \left( \frac{mL}{\ell} \right), 0 \right) : m \in \{0, \ldots, 2n - 1\} \right\}. \]
Denote by $G'$ the set of rotations with a common axis $\mathcal{A}$, where $\mathcal{A}$ is the line that passes through $(0, 0, r)$ and $(0, 0, -r)$. Denote by $\mathcal{H}$ the subgroup of $G'$ generated by the rotation $g$ that fixes $\mathcal{A}$, where
\[ g(r, 0, 0) = \left( r \cos \left( \frac{r}{\ell} \right), r \sin \left( \frac{r}{\ell} \right), 0 \right). \]
Defining $G(L)$ as we have automatically verifies Proposition 2.4 in the $S_r$ setting. A straightforward exercise shows that any directed geodesic can be mapped by an isometry to any other geodesic, verifying Proposition 2.3 in the $S_r$ setting. It is convenient to calculate the probability $P(I_x(X) = 1)$ by taking $x$ to be the point $(r, 0, 0)$. Take $w$ to be in $[-\ell, \ell]$. Denote by $A(w)$ the length of the arc $A_{w,0}(w)$ and by $I(X)$ the random variable $I_{(r,0,0)}(X)$. Recall that every geodesic circle of radius $\ell$ on $S_r$ has circumference equal to $2\pi r \sin \left( \frac{r}{\ell} \right)$.

**Proposition 3.1.** If $P(I(X) = 1)$ is the probability of intersection, then
\[ P(I(X) = 1) = 1 - \frac{2}{\pi \ell} \int_0^\ell \sin^{-1} \left( \tan \left( \frac{w}{r} \right) \cot \left( \frac{r}{\ell} \right) \right) \, dw. \]

**Proof.** Denote by $C_\ell$ the circle
\[ C_\ell = \left\{ \left( r \cos \left( \frac{\theta}{\ell} \right), r \sin \left( \frac{\theta}{\ell} \right), r \cos \left( \frac{\theta}{\ell} \right) \right) : 0 \leq \theta \leq 2\pi \right\}. \]
The circle $C_\ell$ is a geodesic circle of radius $\ell$ centered at $(0, 0, r)$. The rotation $f_w$, given in the standard basis by the matrix
\[ f_w = \begin{pmatrix} 0 & -\sin \left( \frac{w}{r} \right) & \cos \left( \frac{w}{r} \right) \\ 0 & \cos \left( \frac{w}{r} \right) & \sin \left( \frac{w}{r} \right) \\ -1 & 0 & 0 \end{pmatrix}, \]
rotates $C_\ell$ to the circle of radius $\ell$ centered at $\left( r \cos \left( \frac{w}{r} \right), r \sin \left( \frac{w}{r} \right), 0 \right)$, the set
\[ f_w(C_\ell) = \left\{ \left( -r \sin \left( \frac{w}{r} \right) \sin \left( \frac{\theta}{\ell} \right) + r \cos \left( \frac{w}{r} \right) \cos \left( \frac{\theta}{\ell} \right), -r \cos \left( \frac{w}{r} \right) \sin \left( \frac{\theta}{\ell} \right) + r \sin \left( \frac{w}{r} \right) \cos \left( \frac{\theta}{\ell} \right) \right) : 0 \leq \theta \leq 2\pi \right\}. \]
The probability \( P(I(X) = 1|X = w) \) is given by

\[
P(I(X) = 1|X = w) = \frac{A(w)}{\pi r \sin \left( \frac{\ell}{r} \right)}.
\]  

(3.6)

The Law of Total Probability implies that

\[
P(I(X) = 1) = \int_{-\ell}^{\ell} P(I(X) = 1|X = w) \cdot \frac{1}{2\ell} \, dw.
\]  

(3.7)

Since the reflection across the \( x-z \) plane is an isometry, \( A(w) \) is equal to \( A(-w) \) and so the integrand in the right hand side of (3.7) is an even function, implying that

\[
P(I(X) = 1) = \int_{0}^{\ell} \frac{A(w)}{\pi r \sin \left( \frac{\ell}{r} \right)} \cdot \frac{1}{\ell} \, dw.
\]  

(3.8)

Compute the arc length \( A(w) \) for any \( w \) in \([0, \ell]\) in order to calculate the probabilities given by (III.5). The great circle of \( G(L) \) that intersects \((r,0,0)\) is the longitude \( G_0 \), where

\[
G_0 = \{ (r \sin(\phi), 0, r \cos(\phi)) : 0 \leq \phi \leq 2\pi \}.
\]

The circle of radius \( \ell \) centered at the point \( p(w) \) is the circle \( f_w(C_\ell) \), which intersects \( G_0 \) when

\[
\begin{align*}
-r \sin \left( \frac{\phi}{r} \right) \sin(\theta) \sin \left( \frac{\ell}{r} \right) + r \cos \left( \frac{\phi}{r} \right) \cos \left( \frac{\ell}{r} \right) &= r \sin(\phi) \\
r \cos \left( \frac{\phi}{r} \right) \sin(\theta) \sin \left( \frac{\ell}{r} \right) + r \sin \left( \frac{\phi}{r} \right) \cos \left( \frac{\ell}{r} \right) &= 0 \\
-r \cos(\theta) \sin \left( \frac{\ell}{r} \right) &= r \cos(\phi).
\end{align*}
\]

The points of intersection are therefore given by,

\[
\sin(\theta) = -\frac{\sin \left( \frac{\phi}{r} \right) \cos \left( \frac{\ell}{r} \right)}{\cos \left( \frac{\phi}{r} \right) \sin \left( \frac{\ell}{r} \right)} = -\tan \left( \frac{\phi}{r} \right) \cot \left( \frac{\ell}{r} \right).
\]

Solve for \( \theta \) to obtain the equality

\[
\theta = -\sin^{-1} \left( \frac{\tan \left( \frac{\phi}{r} \right) \cot \left( \frac{\ell}{r} \right)}{\cos \left( \frac{\phi}{r} \right) \sin \left( \frac{\ell}{r} \right)} \right)
\]

and so

\[
A(w) = \pi r \sin \left( \frac{\ell}{r} \right) - 2r \sin \left( \frac{\ell}{r} \right) \sin^{-1} \left( \frac{\tan \left( \frac{\phi}{r} \right) \cot \left( \frac{\ell}{r} \right)}{\cos \left( \frac{\phi}{r} \right) \sin \left( \frac{\ell}{r} \right)} \right).
\]  

(3.9)

Equations (3.8) and (3.9) together imply that

\[
P(I(X) = 1) = \frac{1}{\ell} \int_{0}^{\ell} \frac{A(w)}{\pi r \sin \left( \frac{\ell}{r} \right)} \, dw = \frac{1}{\pi r \ell \sin \left( \frac{\ell}{r} \right)} \int_{0}^{\ell} A(w) \, dw
\]

\[
= \frac{1}{\pi r \ell \sin \left( \frac{\ell}{r} \right)} \int_{0}^{\ell} \left( \pi r \sin \left( \frac{\ell}{r} \right) - 2r \sin \left( \frac{\ell}{r} \right) \sin^{-1} \left( \frac{\tan \left( \frac{\phi}{r} \right) \cot \left( \frac{\ell}{r} \right)}{\cos \left( \frac{\phi}{r} \right) \sin \left( \frac{\ell}{r} \right)} \right) \right) \, dw
\]

and so

\[
P(I(X) = 1) = 1 - \frac{2}{\pi \ell} \int_{0}^{\ell} \sin^{-1} \left( \frac{\tan \left( \frac{\phi}{r} \right) \cot \left( \frac{\ell}{r} \right)}{\cos \left( \frac{\phi}{r} \right) \sin \left( \frac{\ell}{r} \right)} \right) \, dw.
\]

\[\square\]
4. The Needle in the Poincaré Disk

4.1. The Geometry of the Poincaré Disk. View $\mathbb{H}$, the Poincaré disk, as the open unit disk in $\mathbb{R}^2$ endowed with the Riemannian metric $d\sigma^2$, where

$$d\sigma^2 = \frac{4}{(1 - (x^2 + y^2))^2}(dx \otimes dx + dy \otimes dy).$$

The distance between points in $\mathbb{H}$ is the geodesic distance. Choose $\mathcal{E}$, an equator for $\mathbb{H}$, to be the set

$$\mathcal{E} = \{(t, 0): -1 < t < 1\}$$

with a left to right orientation. For any point $(x, 0)$ on $\mathcal{E}$, if $h$ is the signed hyperbolic distance from $(0, 0)$ to $(x, 0)$, meaning that $h$ is negative if $x$ is negative and positive if $x$ is positive, then $x$ is given by

$$x = \tanh\left(\frac{h}{2}\right).$$

The geodesic circles of $\mathbb{H}$ are also circles of $\mathbb{R}^2$, but their euclidean radii and euclidean centers may be different. In particular, a geodesic circle in $\mathbb{H}$ whose center is on $\mathcal{E}$ a signed hyperbolic distance of $h$ from the origin and that has a hyperbolic radius equal to $\lambda$ has a euclidean center $(x, 0)$ and euclidean radius $r$, where

$$x = \frac{1}{2}\left(\tanh\left(\frac{h+\lambda}{2}\right) + \tanh\left(\frac{h-\lambda}{2}\right)\right) \quad \text{and} \quad r = \frac{1}{2}\left(\tanh\left(\frac{h+\lambda}{2}\right) - \tanh\left(\frac{h-\lambda}{2}\right)\right).$$

The signed hyperbolic distance from $(0, 0)$ to $(x, 0)$ is $h$, where

$$h = 2\tanh^{-1}(x).$$

The geodesics of $\mathbb{H}$ are arcs of generalized circles of the euclidean plane that intersect the unit circle at right angles.

4.2. Symmetries and a Grating on the Poincaré Disk. Identify the open unit disk in $\mathbb{R}$ with the open unit disk in the complex plane. The group of Möbius transformations are the transformations of $\mathbb{C}$ of the form

$$z \mapsto \frac{az + b}{cz + d} \quad \text{where} \quad a, b, c, d \in \mathbb{R} \quad \text{and} \quad ad - bc \neq 0.$$

Denote by $\mathcal{G}$ the isometry group of $\mathbb{H}$, the subgroup of Möbius transformations that map the open unit ball to itself and consist of the transformations of the form

$$z \mapsto e^{i\phi} \frac{z + b}{bz + 1} \quad \text{with} \quad (\phi, b) \in \mathbb{R} \times (-1, 1).$$

The group $\mathcal{G}$ acts transitively on $\mathbb{H}$. The subgroup $\mathcal{G}'$ of $\mathcal{G}$ that maps $\mathcal{E}$ to itself and preserves the orientation of $\mathcal{E}$ is the group of transformations of the form $g_\tau$ where

$$g_\tau(z) = \frac{z + \tau}{\tau z + 1} \quad \text{with} \quad \tau \in (-1, 1).$$

This group is the analog in the hyperbolic setting of the group of translations along the $x$-axis in $\mathbb{R}^2$ and of the rotations around the $z$-axis in the $S_\tau$ setting. View $\mathbb{H}$ once again and
henceforth as a subset of \( \mathbb{R}^2 \) and view the elements of \( G \) as acting on \( \mathbb{R}^2 \). The function \( g_\tau \) acts on an arbitrary point \((x, y)\) in \( \mathbb{H} \) by

\[
g_\tau(x, y) = \left( \frac{\tau(x^2 + y^2) + (\tau^2 + 1)x + \tau}{(\tau x + 1)^2 + \tau^2 y^2}, \frac{(1 - \tau^2)y}{(\tau x + 1)^2 + \tau^2 y^2} \right),
\]

and so it acts on a point \((\tanh(\frac{\sigma}{2}), 0)\) of \( \mathcal{E} \) by

\[
g_\tau(\tanh(\frac{\sigma}{2}), 0) = \left( \tanh\left(\frac{h + 2\tanh^{-1}(\tau)}{2}\right), 0 \right).
\]

Define for each \( \sigma \) in \( \mathbb{R} \) the function \( F_\sigma \) by

\[
F_\sigma(x, y) = g_{\tanh(\frac{\sigma}{2})}(x, y)
\]

so that \( F_\sigma \) is a function that maps \( \mathcal{E} \) to \( \mathcal{E} \), preserves the orientation of \( \mathcal{E} \), and moves points on \( \mathcal{E} \) a signed hyperbolic distance of \( \sigma \) along \( \mathcal{E} \).

Take \( G_0 \) to be the bounded open line segment in \( \mathbb{R}^2 \) given by

\[
G_0 = \{ (0, y) : -1 < y < 1 \}.
\]

The set \( G_0 \) is an unbounded clopen geodesic in \( \mathbb{H} \). Define for each \( \sigma \) in \( \mathbb{R} \) the geodesic \( G_\sigma \) by

\[
G_\sigma = F_\sigma(G_0).
\]

The geodesic \( G_\sigma \) is an arc of a (generalized if \( \sigma = 0 \)) circle in \( \mathbb{R}^2 \) that intersects \( \mathcal{E} \) at a right angle at \((2\tanh^{-1}(\sigma), 0)\), a point that is a signed distance of \( \sigma \) from \((0, 0)\). Suppose that \( \sigma \) is positive. Viewed as a subset of \( \mathbb{R}^2 \) with the euclidean metric, the center of \( G_\sigma \) lies on the \( x \)-axis. A straightforward calculation reveals that the closure of \( G_\sigma \) intersects the unit disk at right angles at the points \((a(\sigma), \pm \sqrt{1 - (a(\sigma))^2})\) and that the center of \( G_\sigma \) is \((b(\sigma), 0)\), where

\[
a(\sigma) = \frac{\sigma}{\sigma^2 + 1} \quad \text{and} \quad b(\sigma) = \sigma + \frac{1}{\sigma}.
\]

With \( a(\sigma) \) and \( b(\sigma) \) given above and \( r(\sigma) \) defined by

\[
r(\sigma) = b(\sigma) - \sigma = \frac{1}{\sigma},
\]

the arc \( G_\sigma \) has the parameterization

\[
G_\sigma = \left\{ (b(\sigma) + r(\sigma) \cos(t), r(\sigma) \sin(t)) : \pi - \tan^{-1}\left(\frac{\sqrt{1 - (a(\sigma))^2}}{b(\sigma) - a(\sigma)}\right) < t < \pi + \tan^{-1}\left(\frac{\sqrt{1 - (a(\sigma))^2}}{b(\sigma) - a(\sigma)}\right) \right\}.
\]

If \( \sigma \) is negative, then \( G_\sigma \) is the reflection of \( G_{-\sigma} \) across the \( y \)-axis. Figure 2 displays a geodesic \( G_\sigma \) in \( \mathbb{H} \) as well as the circle in \( \mathbb{R}^2 \) that gives rise to the arc that is the geodesic \( G_\sigma \), when viewed as a subset of \( \mathbb{R}^2 \). Take \( x(\sigma) \) in Figure 2 to be equal to \( \tanh\left(\frac{\sigma}{2}\right) \), so that the point \((x(\sigma), 0)\) is a distance of \( \sigma \) from \((0, 0)\).
Fix a positive length $L$ and denote by $G(L)$ the grating
\[ G(L) = \{ G_{nL} : n \in \mathbb{Z} \}. \]

Defining $G(L)$ as we have automatically verifies Proposition 2.4 in the $\mathbb{H}$ setting. A straightforward exercise shows that any directed geodesic can be mapped by an isometry to any other geodesic, verifying Proposition 2.3 in the $\mathbb{H}$ setting.

4.3. The Probability of Intersection. To simplify notation, denote for each $z$ in $\mathbb{R}$ by $A(z)$ the length of the arc $A_{(0,0)}(z)$ and by $I(X)$ the random variable $I_{(0,0)}(X)$.

**Theorem 4.1.** For any $(x,0)$ in $\mathcal{E}$,

\[
(4.2) \quad P(I_{(x,0)}(X) = 1) = 2 \left( 1 - \frac{1}{\pi \ell \sinh(\ell)} \right) \int_{0}^{\ell} \frac{2 \left( \tanh \left( \frac{z+\ell}{2} \right) - \tanh \left( \frac{z-\ell}{2} \right) \right)}{\sqrt{\left( 1 - \tanh^{2} \left( \frac{z+\ell}{2} \right) \right) \left( 1 - \tanh^{2} \left( \frac{z-\ell}{2} \right) \right)}} \cdot \tan^{-1} \left( \sqrt{\frac{1 - \tanh^{2} \left( \frac{z-\ell}{2} \right)}{1 - \tanh^{2} \left( \frac{z+\ell}{2} \right)}} \cdot \sqrt{\frac{\tanh \left( \frac{\ell+z}{2} \right)}{\tanh \left( \frac{\ell-z}{2} \right)}} \right) \, dz.
\]

**Proof.** Theorem 2.6 implies that for any $x$ in $(-1,1)$, the probability $P(I_{(x,0)}(X) = 1)$ is independent of $x$. It is convenient to calculate this probability by taking $x$ to be zero. Recall that every geodesic of radius $\ell$ on $\mathbb{H}$ has circumference equal to $2\pi r \sinh(\ell)$. The probability $P(I(X) = 1|X = z)$ that the needle with hyperbolic center $p(z)$ on $\mathcal{E}$ intersects $G_0$ is given by

\[
(4.3) \quad P(I(X) = 1|X = z) = \frac{A(z)}{\pi \sinh(\ell)},
\]

and so the Law of Total Probability implies

\[
P(I(X) = 1) = \int_{-\ell}^{\ell} P(I(X) = 1|X = z) \cdot \frac{1}{2\ell} \, dz
\]
(4.4) \[ A(z) = \int_{-\ell}^{\ell} \frac{A(z)}{\pi \sinh(\ell)} \cdot \frac{1}{2\ell} \, dz. \]

Since reflection across the y-axis is an isometry, \( A(z) \) is equal to \( A(-z) \) and so the integrand in (4.4) is an even function, implying that

\[ P(I(X) = 1) = \int_{0}^{\ell} \frac{A(z)}{\pi \sinh(\ell)} \cdot \frac{1}{\ell} \, dz. \]

Denote by \( x(z) \) and \( r(z) \) the real values with the property that the euclidean center of \( C(z) \) is \((x(z), 0)\) and the euclidean radius of \( C(z) \) is \( r(z) \). The circle \( C(z) \) intersects \( G_0 \) at the points \((0, \pm y)\), where

\[ y = \sqrt{r(z)^2 - x(z)^2}. \]

Let \( R(z) \) be the ray from \((x(z), 0)\) to the point of intersection of \( C(z) \) and \( G_0 \) in the upper half real plane. Define by \( \theta(z) \) the angle formed by \( R(z) \) and the ray lying along the \( x \)-axis with its tail (or origin) at \((x(z), 0)\). Equation (4.1) and the fact that reflection across the \( x \)-axis is an isometry of \( \mathbb{H} \) together imply that the hyperbolic arc length \( A(z) \) is given by

\[
A(z) = \int_{A(x,0)(z)} ds \\
= 2 \int_{\theta(z)}^{\pi} \frac{2\|(-r(z)\sin(t), r(z)\cos(t))\|}{(1 - (x(z) + r(z)\cos(t)))^2 - (r(z)\sin(t))^2} \, dt \\
= 4r(z) \int_{\theta(z)}^{\pi} \frac{d\theta}{(1 - (x(z) + r(z)\cos(t)))^2 - (r(z)\sin(t))^2}.
\]

On taking \( \alpha(z) = 1 - x(z)^2 - r(z)^2 \) and \( \beta(z) = 2r(z)x(z) \),

the equality

\[
\int \frac{dt}{\alpha(z) - \beta(z)\cos(t)} = \frac{2}{\sqrt{\alpha(z)^2 - \beta(z)^2}} \tan^{-1} \left( \sqrt{\frac{\alpha(z) + \beta(z)}{\alpha(z) - \beta(z)}} \cdot \tan \left( \frac{t}{2} \right) \right) + C
\]

implies that

\[
A(z) = \frac{8r(z)}{\sqrt{\alpha(z)^2 - \beta(z)^2}} \tan^{-1} \left( \sqrt{\frac{\alpha(z) + \beta(z)}{\alpha(z) - \beta(z)}} \cdot \tan \left( \frac{t}{2} \right) \right) \bigg|_{\theta(z)}^{\pi}.
\]

Since the integral describing the arc length gives the arc length of the top half of a geodesic circle when the lower bound is zero,

\[
A(z) = 2 \left( \pi \sinh(\ell) - \frac{4r(z)}{\sqrt{\alpha(z)^2 - \beta(z)^2}} \tan^{-1} \left( \sqrt{\frac{\alpha(z) + \beta(z)}{\alpha(z) - \beta(z)}} \cdot \tan \left( \frac{t}{2} \right) \right) \bigg|_{\theta(z)}^{\pi} \right).
\]
\[ A(z) = 2 \left( \pi \sinh(\ell) - \frac{4r(z)}{\sqrt{\alpha(z)^2 - \beta(z)^2}} \tan^{-1} \left( \frac{\sqrt{\alpha(z) + \beta(z)}}{\sqrt{\alpha(z) - \beta(z)}} \tan \left( \frac{\theta(z)}{2} \right) \right) \right). \]

The equalities
\[ \alpha(z) - \beta(z) = 1 - (x(z) + r(z))^2, \quad \alpha(z) + \beta(z) = 1 - (x(z) - r(z))^2 \]
and
\[ \alpha(z)^2 - \beta(z)^2 = (\alpha(z) + \beta(z))(\alpha(z) - \beta(z)) = (1 - (x(z) + r(z))^2)(1 - (x(z) - r(z))^2) \]
together with the equalities
\[ x(z) - r(z) = \tanh \left( \frac{z - \ell}{2} \right) \quad \text{and} \quad x(z) + r(z) = \tanh \left( \frac{z + \ell}{2} \right) \]
imply that
\[ (4.6) \quad A(z) = 2 \left( \pi \sinh(\ell) - \frac{2 \left( \tanh \left( \frac{z + \ell}{2} \right) - \tanh \left( \frac{z - \ell}{2} \right) \right)}{\sqrt{1 - \tanh^2 \left( \frac{z + \ell}{2} \right)} \left( 1 - \tanh^2 \left( \frac{z - \ell}{2} \right) \right)} \right. \]
\[ \left. \quad \cdot \tan^{-1} \left( \frac{\sqrt{1 - \tanh^2 \left( \frac{z - \ell}{2} \right)}}{1 - \tanh^2 \left( \frac{z + \ell}{2} \right)} \cdot \tan \left( \frac{\theta(z)}{2} \right) \right) \right). \]

Use the equality
\[ \tan \left( \frac{\theta(z)}{2} \right) = \frac{1 - \cos(\theta(z))}{\sin(\theta(z))} \]
to show after some simplification that
\[ A(z) = 2 \left( \pi \sinh(\ell) - \frac{2 \left( \tanh \left( \frac{z + \ell}{2} \right) - \tanh \left( \frac{z - \ell}{2} \right) \right)}{\sqrt{1 - \tanh^2 \left( \frac{z + \ell}{2} \right)} \left( 1 - \tanh^2 \left( \frac{z - \ell}{2} \right) \right)} \right. \]
\[ \left. \quad \cdot \tan^{-1} \left( \frac{\sqrt{1 - \tanh^2 \left( \frac{z - \ell}{2} \right)}}{1 - \tanh^2 \left( \frac{z + \ell}{2} \right)} \cdot \tan \left( \frac{\ell + z}{2} \right) \right) \right). \]

Since
\[ P(I | X = z) = \frac{A(z)}{\pi \sinh(\ell)} \]
\[ = 2 \left( 1 - \frac{1}{\pi \sinh(\ell)} \left( \frac{2 \left( \tanh \left( \frac{z + \ell}{2} \right) - \tanh \left( \frac{z - \ell}{2} \right) \right)}{\sqrt{1 - \tanh^2 \left( \frac{z + \ell}{2} \right)} \left( 1 - \tanh^2 \left( \frac{z - \ell}{2} \right) \right)} \right. \]
\[ \left. \quad \cdot \tan^{-1} \left( \frac{\sqrt{1 - \tanh^2 \left( \frac{z - \ell}{2} \right)}}{1 - \tanh^2 \left( \frac{z + \ell}{2} \right)} \cdot \tan \left( \frac{\ell + z}{2} \right) \right) \right), \]
the equalities

\[ P(I(X) = 1) = \int_{-\ell}^{\ell} P(I(X) = 1 \mid X = z) \cdot \frac{1}{2\ell} \, dz = \int_{0}^{\ell} P(I(X) = 1 \mid X = z) \cdot \frac{1}{\ell} \, dz. \]

imply the equality given in the statement of the theorem. □

5. LIMITING BEHAVIOR AND PROBABILITY DEFICITS

This section computes series expansions for the probabilities given by (3.4) and (4.2) that describe the probabilities up to zeroth, first, and second order in the parameter \( \ell \). Zeroth order terms give the probability in the planar case, first order terms vanish, and second order terms depend on the Gaussian curvature of the space. Probability deficits determine the Gaussian curvature of the space in a way that is very similar to the way in which the length and area deficits of the Bertrand-Diguet-Puiseux Theorem determine Gaussian curvature. The following subsections utilize the standard “little-o” notation to simplify expressions. Let \( M \) be either \( \mathbb{R}^2 \), \( S_r \), or \( \mathbb{H} \) and in each case denote by \( I(X) \) the probability of intersection first defined by (2.2) in Section 2. Note that (3.3) already implies that if \( M = \mathbb{R}^2 \), then

\[ I(X) = \frac{2}{\pi} \]

and there is no dependency on \( \ell \).

5.1. ORDER ESTIMATES FOR SPHERES.

**Proposition 5.1.** If \( M = S_r \), then

\[ P(I(X) = 1) = \frac{2}{\pi} + \frac{4}{9\pi r^2} \ell^2 + o(\ell^2). \]

**Proof.** Change variables to rewrite (3.4) as

\[ P(I(X) = 1) = 1 - \frac{2}{\pi} \int_{0}^{1} \sin^{-1} \left( \tan \left( \frac{\ell z}{r} \right) \cot \left( \frac{z}{r} \right) \right) \, dz. \]

The series expansions

\[ \tan(x) = x + \frac{x^3}{3} + o(x^4) \quad \text{and} \quad \cot(x) = \frac{1}{x} - \frac{x}{3} - \frac{x^3}{45} + o(x^4) \]

imply that

\[ P(I(X) = 1) = 1 - \frac{2}{\pi} \int_{0}^{1} \sin^{-1}(z + \ell^2 \left( \frac{x^3}{3r^2} - \frac{z}{3r^2} \right) + o(\ell^3)) \, dz. \]

Define \( F \) by

\[ F(\ell) = \int_{0}^{1} \sin^{-1} \left( z + \ell^2 \left( \frac{x^3}{3r^2} - \frac{z}{3r^2} \right) + o(\ell^3) \right) \, dz \]
so that
\[(5.4) \quad F'(\ell) = \int_0^1 \frac{2\ell(z^3 - \ell^2)}{\sqrt{1 - (z + \ell^2(z^3 - \ell^3 + o(\ell^3))}} \, dz + o(\ell)\]
and
\[(5.5) \quad F''(\ell) = \int_0^1 \frac{2(z^3 - \ell^2)}{\sqrt{1 - (z + \ell^2(z^3 - \ell^3 + o(\ell^3))}} \, dz + o(\ell)\].

Equations (5.3), (5.4), and (5.5) respectively imply that
\[(5.6) \quad F(0) = \int_0^1 \sin^{-1}(z) \, dz = \frac{\pi}{2} - 1,
(5.7) \quad F'(0) = 0,
and
(5.8) \quad F''(0) = -2 \frac{2}{3r^2} \int_0^1 \frac{z - z^3}{\sqrt{1 - z^2}} \, dz = -2 \frac{2}{3r^2} \int_0^1 z\sqrt{1 - z^2} \, dz = -\frac{2}{9r^2}.

Equalities (5.6), (5.7), and (5.8) together imply that
\[(5.9) \quad F(\ell) = \frac{\pi}{2} - \frac{2\ell^2}{9r^2} + o(\ell^2).\]

Combine (5.2), (5.6), and (5.9) to obtain the equality
\[(5.10) \quad P(I(X) = 1) = \frac{2}{\pi} + \frac{4}{9\pi r^2} \ell^2 + o(\ell^2).\]

5.2. Order Estimates for the Poincaré Disk.

Proposition 5.2. If \(M\) is \(H\), then
\[
P(I(X) = 1) = 2 \left( 1 - \frac{\ell}{\pi \sinh(\ell)} \left( (\pi - 1) + \frac{\ell^2}{6} \left( \pi + \frac{1}{3} \right) + o(\ell^2) \right) \right).
\]

Proof. Change variables to rewrite (4.2) as
\[
(5.11) \quad P(I(X) = 1) = 2 \left( 1 - \frac{1}{\pi \sinh(\ell)} \int_0^1 \frac{2 \left( \tanh \left( \ell \cdot \frac{z+1}{2} \right) - \tanh \left( \ell \cdot \frac{z-1}{2} \right) \right)}{\sqrt{(1 - \tanh^2 \left( \ell \cdot \frac{z+1}{2} \right))(1 - \tanh^2 \left( \ell \cdot \frac{z-1}{2} \right))}} \cdot \tan^{-1} \left( \frac{1 - \tanh^2 \left( \ell \cdot \frac{z-1}{2} \right)}{1 - \tanh^2 \left( \ell \cdot \frac{z+1}{2} \right)} \cdot \frac{\tanh \left( \ell \cdot \frac{1+z}{2} \right)}{\tanh \left( \ell \cdot \frac{1-z}{2} \right)} \right) \, dz.
\]
Use the series expansions for \( \tan(x) \), \( \sqrt{1 - x} \), and \( \frac{1}{1-x} \) to obtain the equalities

\[
(5.12) \quad \tanh \left( \ell \cdot \frac{z + 1}{2} \right) - \tanh \left( \ell \cdot \frac{z - 1}{2} \right) = \ell \left( 1 - \frac{\ell^2}{12}(3z^2 + 1) \right) + o(\ell^4),
\]

\[
(5.13) \quad \frac{1}{\sqrt{(1 - \tanh^2 \left( \ell \cdot \frac{z+1}{2} \right)) \left( 1 - \tanh^2 \left( \ell \cdot \frac{z-1}{2} \right) \right)}} = 1 + \frac{\ell^2}{4}(z^2 + 1) + o(\ell^3),
\]

\[
(5.14) \quad \sqrt{1 - \tanh^2 \left( \ell \cdot \frac{z+1}{2} \right)} \cdot \sqrt{\frac{1 - \tanh^2 \left( \ell \cdot \frac{z+1}{2} \right)}{1 - \tanh^2 \left( \ell \cdot \frac{z-1}{2} \right)}} = 1 + \frac{\ell^2}{2}z + o(\ell^3),
\]

and

\[
(5.15) \quad \frac{\tanh \left( \ell \cdot \frac{1+z}{2} \right)}{\tanh \left( \ell \cdot \frac{1-z}{2} \right)} = \frac{z + 1}{1 - z} \left( 1 - \frac{\ell^2}{3}z + o(\ell^3) \right).
\]

Equations (5.12) and (5.13) together imply that

\[
(5.16) \quad \tanh \left( \ell \cdot \frac{z + 1}{2} \right) - \tanh \left( \ell \cdot \frac{z - 1}{2} \right) = \ell \left( 1 + \frac{\ell^2}{6} \right) + o(\ell^4).
\]

Equations (5.14) and (5.15) together imply that

\[
(5.17) \quad \sqrt{1 - \tanh^2 \left( \ell \cdot \frac{z+1}{2} \right)} \cdot \frac{\tanh \left( \ell \cdot \frac{1+z}{2} \right)}{\tanh \left( \ell \cdot \frac{1-z}{2} \right)} = \left( 1 + \frac{\ell^2}{2}z + o(\ell^3) \right) \sqrt{\frac{z + 1}{1 - z} \left( 1 - \frac{\ell^2}{3}z + o(\ell^4) \right)}.
\]

Define the function \( H \) by

\[
(5.18) \quad H(\ell) = \frac{1}{\ell} \int_0^1 \frac{\tanh \left( \ell \cdot \frac{z + 1}{2} \right) - \tanh \left( \ell \cdot \frac{z - 1}{2} \right)}{\sqrt{(1 - \tanh^2 \left( \ell \cdot \frac{z+1}{2} \right)) \left( 1 - \tanh^2 \left( \ell \cdot \frac{z-1}{2} \right) \right)}} \cdot \tan^{-1} \left( \sqrt{\frac{1 - \tanh^2 \left( \ell \cdot \frac{z+1}{2} \right)}{1 - \tanh^2 \left( \ell \cdot \frac{z+1}{2} \right)}} \cdot \sqrt{\frac{\tanh \left( \ell \cdot \frac{1+z}{2} \right)}{\tanh \left( \ell \cdot \frac{1-z}{2} \right)}} \right) \, dz.
\]

Combine (5.16) and (5.17) to obtain the equality

\[
(5.19) \quad H(\ell) = \int_0^1 \left( 1 + \frac{\ell^2}{6} + o(\ell^3) \right) \cdot \tan^{-1} \left( \left( 1 + \frac{\ell^2}{2}z + o(\ell^3) \right) \sqrt{\frac{z + 1}{1 - z} \left( 1 - \frac{\ell^2}{3}z + o(\ell^4) \right)} \right) \, dz.
\]
Simplify (5.11) using the expression for $H(\ell)$ to obtain the equality

$$P(I(X) = 1) = 2 \left( 1 - \frac{\ell}{\pi \sinh(\ell)} H(\ell) \right).$$

Define by $F$ the function

$$F(\ell) = \int_0^1 \tan^{-1} \left( \left( 1 + \frac{\ell^2 z}{2} + o(\ell^3) \right) \sqrt{\frac{z + 1}{1 - z} \left( 1 - \frac{\ell^2 z}{3} + o(\ell^4) \right)} \right) dz.$$

Since

$$\sqrt{\frac{z + 1}{1 - z} \left( 1 - \frac{\ell^2 z}{3} + o(\ell^4) \right)} = \left( 1 - \frac{\ell^2 z}{6} + o(\ell^3) \right) \sqrt{\frac{z + 1}{1 - z}},$$

we have

$$F(\ell) = \int_0^1 \tan^{-1} \left( \left( 1 + \frac{\ell^2 z}{3} + o(\ell^3) \right) \sqrt{\frac{z + 1}{1 - z}} \right) dz.$$

Take derivatives with respect to $\ell$ to see that

$$F'(\ell) = \frac{2\ell}{3} \int_0^1 \frac{z}{1 + (1 + \ell^2 z)^2 \left( \frac{z + 1}{1 - z} \right)} dz + o(\ell^2)$$

and

$$F''(\ell) = \frac{2}{3} \int_0^1 \frac{z}{1 + (1 + \ell^2 z)^2} \left( \frac{z + 1}{1 - z} \right) dz + \frac{2\ell}{3} \int_0^1 \frac{d}{d\ell} \left( \frac{z}{1 + (1 + \ell^2 z)^2} \left( \frac{z + 1}{1 - z} \right) \right) dz + o(\ell).$$

Equations (5.22), (5.23), and (5.24) respectively imply that

$$F(0) = \int_0^1 \tan^{-1} \left( \sqrt{\frac{z + 1}{1 - z}} \right) dz$$

$$= \lim_{c \to 1^-} \left( \frac{1}{2} \sqrt{1 - x^2} + x \tan^{-1} \left( \sqrt{\frac{z + 1}{1 - z}} \right) \right) \bigg|_0^c = -\frac{1}{2} + \frac{\pi}{2},$$

$$F'(0) = 0,$$

and

$$F''(0) = \frac{2}{3} \int_0^1 \frac{z}{1 + (\frac{z + 1}{1 - z})} dz = \frac{1}{3} \int_0^1 z \sqrt{1 - z^2} dz = \frac{1}{9}.$$

Equalities (5.25), (5.26), and (5.27) together imply that

$$F(\ell) = -\frac{1}{2} + \frac{\pi}{2} + \frac{1}{9} \ell^2 + o(\ell^2),$$

and

$$F(\ell) = -\frac{1}{2} + \frac{\pi}{2} + \frac{1}{9} \ell^2 + o(\ell^2).$$
and so

\[ H(\ell) = \left( 1 + \frac{\ell^2}{6} + o(\ell^3) \right) F(\ell) \]

\[ = \left( 1 + \frac{\ell^2}{6} + o(\ell^3) \right) \left( -\frac{1}{2} + \frac{\pi}{2} + \frac{1}{9} \ell^2 + o(\ell^2) \right) \]

\[ = \left( -\frac{1}{2} + \frac{\pi}{2} \right) + \ell^2 \left( \frac{\pi}{12} + \frac{1}{36} \right) + o(\ell^2). \]

Equations (5.20) and (5.29) together imply that

\[ P(I(X) = 1) = 2 \left( 1 - \frac{2\ell}{\pi \sinh(\ell)} \left( -\frac{1}{2} + \frac{\pi}{2} \right) + \ell^2 \left( \frac{\pi}{12} + \frac{1}{36} \right) + o(\ell^2) \right), \]

verifying the proposition. \( \Box \)

5.3. Probability Deficits and Gaussian Curvature. In the setting of the sphere, the probability of intersection given by Proposition 5.1 implies that

\[ \lim_{\ell \to 0^+} P(I(X) = 1) = \lim_{\ell \to 0^+} 2 \left( 1 - \frac{2\ell}{\pi \sinh(\ell)} \left( -\frac{1}{2} + \frac{\pi}{2} \right) + \ell^2 \left( \frac{\pi}{12} + \frac{1}{36} \right) + o(\ell^2) \right) = \frac{2}{\pi}. \]

Similarly, in the setting of the Poincaré disk, the probability of intersection given by Proposition 5.2 together with the fact that

\[ \lim_{\ell \to 0^+} \frac{\sinh(\ell)}{\ell} = 1 \]

implies that

\[ \lim_{\ell \to 0^+} P(I(X) = 1) = \lim_{\ell \to 0^+} 2 \left( 1 - \frac{2\ell}{\pi \sinh(\ell)} \left( -\frac{1}{2} + \frac{\pi}{2} \right) + \ell^2 \left( \frac{\pi}{12} + \frac{1}{36} \right) + o(\ell^2) \right) = \frac{2}{\pi}. \]

The probability of intersection in the planar case is \( \frac{2}{\pi} \). Theorem 5.3 summarize these calculations.

**Theorem 5.3.** If \( M \) is \( \mathbb{R}^2 \), \( S_r \), or \( H \), then

\[ \lim_{\ell \to 0^+} P(I(X) = 1) = \frac{2}{\pi}. \]

**Definition 5.4.** The probability deficit of \( M \) is the difference

\[ P(I(X) = 1) - \frac{2}{\pi} \]

and is a function of the parameter \( \ell \).

Denote by \( \kappa(M) \) the Gaussian curvature of \( M \). Similar to the way in which circumference and area deficits determine through a limiting procedure the Gaussian curvature of a surface, the probability deficits determine the Gaussian curvature of \( M \).
Theorem 5.5. If $M$ is $\mathbb{R}^2$, $S_r$, or $H$, then

$$\lim_{\ell \to 0^+} \frac{9\pi}{4} \frac{P(I(X) = 1) - \frac{2}{\pi}}{\ell^2} = \kappa(M).$$

Proof. In the planar setting, the result is immediate because the Gaussian curvature of the plane is 0. To prove the theorem in the setting of spheres, recall first that the Gaussian curvature of the sphere is the square reciprocal of the sphere’s radius. Use Proposition 5.1 to obtain the equalities

$$\lim_{\ell \to 0^+} \frac{9\pi}{4} \frac{P(I(X) = 1) - \frac{2}{\pi}}{\ell^2} = \lim_{\ell \to 0^+} \frac{9\pi}{4} \frac{\frac{2}{\pi} + \frac{4}{9\pi r^2} \ell^2 + o(\ell^2) - \frac{2}{\pi}}{\ell^2} = \lim_{\ell \to 0^+} \frac{9\pi}{4} \frac{\frac{4}{9\pi r^2} \ell^2 + o(\ell^2)}{\ell^2} = \frac{1}{r^2}.$$

To prove the theorem in the Poincaré disk setting, recall first that the Gaussian curvature of the Poincaré disk is $-1$. Use Proposition 5.2 to obtain the equalities

$$\lim_{\ell \to 0^+} \frac{9\pi}{4} \frac{P(I(X) = 1) - \frac{2}{\pi}}{\ell^2} = \lim_{\ell \to 0^+} \frac{9\pi}{4} \frac{\frac{2}{\pi} + \frac{4}{9\pi r^2} \ell^2 + o(\ell^2) - \frac{2}{\pi}}{\ell^2} + \frac{d}{d\ell} \left( \frac{4\ell}{9\pi r^2} \left( \frac{1}{2} + \frac{\pi}{2} \right) - \frac{2}{\pi} \right)$$

(5.33)

Use Bernoulli’s rule for indeterminate forms to obtain

$$\lim_{\ell \to 0^+} \frac{d}{d\ell} \left( \frac{4\ell}{9\pi r^2} \left( \frac{1}{2} + \frac{\pi}{2} \right) - \frac{2}{\pi} \right) = \frac{1}{3} \left( 1 - \frac{1}{\pi} \right).$$

(5.34)

Substitute (5.34) into the limit in (5.33) to obtain the limit

$$\lim_{\ell \to 0^+} \frac{9\pi}{4} \frac{P(I(X) = 1) - \frac{2}{\pi}}{\ell^2} = \frac{9\pi}{4} \left\{ -\frac{1}{3} - \frac{1}{9\pi} + \frac{1}{3} \left( 1 - \frac{1}{\pi} \right) \right\} = -1.$$
To obtain the Gaussian curvature from circumference and area deficits requires a limit of the quotient of the deficit by respectively the cube and the fourth power of the radius of the circle and these are the quotients that appear in the Bertrand-Diguet-Puiseux Theorem. The determination of the Gaussian curvature in the settings we have considered involves a quotient of the probability deficit by the square of the needle length. This indicates that the current probabilistic method for determining Gaussian curvature is different from the prior methods, although arc length determines the probability of intersection on conditioning the needle to fall at a particular location. It should be possible to extend this method to more general surfaces, although the lack of homogeneity of a more general surface complicates the calculations involved in determining the probabilities.
