A P_{K+2} POLYNOMIAL LIFTING OPERATOR ON POLYGONS AND POLYHEDRONS

XIU YE* AND SHANGYOU ZHANG[†]

Abstract. A P_{k+2} polynomial lifting operator is defined on polygons and polyhedrons. It lifts discontinuous polynomials inside the polygon/polyhedron and on the faces to a one-piece P_{k+2} polynomial. With this lifting operator, we prove that the weak Galerkin finite element solution, after this lifting, converges at two orders higher than the optimal order, in both L^2 and H^1 norms. The theory is confirmed by numerical solutions of 2D and 3D Poisson equations.

Key words. weak Galerkin, finite element methods, Poisson, polytopal meshes

1. Introduction. In weak Galerkin finite element methods [12, 13], discontinuous polynomials, u_0 defined inside each element and u_b defined on each face of element, are employed to form an approximation space. In particular, on triangular/tetrahedral grids, the P_k - P_{k+1} (P_k inside a triangle, P_{k+1} on an edge) weak Galerkin finite element solution is two-order superconvergent in both L^2 and H^1 -like norms [2]. Further, with a careful construction of weak gradient, such P_k - P_{k+1} weak Galerkin finite element is also two-order superconvergent on general polygonal and polyhedral meshes [14]. Here the super-convergence is defined for the difference between finite element solution u_0 and the local L^2 projection $Q_h u$ of the exact solution.

In this paper, we construct a P_{k+2} polynomial lifting operator. It lifts an (n+1)piece polynomial, $\{u_0, u_b\}$, on a *n*-polygon/polyhedron T to a one-piece P_{k+2} polynomial on T. After such a lifting/post-processing, the weak Galerkin finite element solution is two-order super-convergent to the exact solution, i.e.,

$$||u - u_h||_0 + h|u - u_h|_{1,h} \le Ch^{k+1}|u|_{k+1},$$

$$||u - L_h u_h||_0 + h|u - L_h u_h|_{1,h} \le Ch^{k+3}|u|_{k+3},$$

where u_h and u are the finite element solution and the exact solution, respectively, and h is the mesh size.

This polynomial lifting operator is different from traditional polynomial lifting operators [1, 3, 4, 5, 10]. These operators only lift a polynomial trace on the boundary of an element to a polynomial inside the element, stably, i.e., subject to the minimum or a small energy. But here we lift both trace data and interior data to a polynomial, subject to the P_{k+2} accuracy. Additionally, even the trace (of boundary polynomials) is discontinuous here. Well, such a discontinuous-trace polynomial lifting is studied in [7, 8, 9], but for H(curl) and H(div) polynomial lifting.

2. Weak Galerkin finite element. For solving a model Poisson equation,

(2.1)
$$-\Delta u = f \quad \text{in } \Omega,$$

(2.2)
$$u = 0 \text{ on } \partial\Omega,$$

 $^{^\}dagger \text{Department}$ of Mathematical Sciences, University of Delaware, Newark, DE 19716 (szhang@udel.edu).

where Ω is a polytopal domain in \mathbb{R}^2 or \mathbb{R}^3 , we subdivide the domain into shaperegular polygons/polyhedrons of size h, \mathcal{T}_h . For polynomial degree $k \geq 1$, we define the weak Galerkin finite element spaces by

(2.3)
$$V_h = \{v_h = \{v_0, v_b\}: v_0|_T \in P_k(T), v_b|_e \in P_{k+1}(e), e \subset \partial T, T \in \mathcal{T}_h\}$$

and

(2.4)
$$V_h^0 = \{ v_h : v_h \in V_h, v_b = 0 \text{ on } e \subset \partial \Omega \}.$$

The weak Galerkin finite element function assumes one d-dimensional P_k polynomial inside each element T, and one (d-1)-dimensional P_{k+1} polynomial on each face edge/polygon e.

On an element $T \in \mathcal{T}_h$, we define the weak gradient $\nabla_w v_h$ of a weak function $v_h = \{v_0, v_b\} \in V_h$ by the solution of polynomial equation on T:

(2.5)
$$\int_{T} \nabla_{w} v_{h} \mathbf{q} d\mathbf{x} = \int_{\partial T} v_{b} \mathbf{q} \cdot \mathbf{n} dS - \int_{T} v_{0} \nabla \cdot \mathbf{q} d\mathbf{x} \quad \forall \mathbf{q} \in \Lambda_{k}(T),$$

where $\Lambda_k(T)$ is a piece-wise polynomial space, but with one piece polynomial divergence and one piece polynomial trace on each face, on a sub-triangular/tetrahedral subdivision of $T = \{T_i, i = 1, ..., n\}$,

$$\Lambda_k(T) = \{ \mathbf{q} \in H(\operatorname{div}, T) : \mathbf{q} |_{T_i} \in P_{k+1}^d(T_i), T_i \subset T, \\ \nabla \cdot \mathbf{q} \in P_k(T), \ \mathbf{q} \cdot \mathbf{n} |_e \in P_{k+1}(e) \}.$$

Here **n** is a fixed normal vector on edge/polygon e. To get a simplicial subdivision on T, some face edges/polygons have to be subdivided. That is, in addition to $T = \bigcup_i \overline{T}_i$, $e = \bigcup_j \overline{e}_j$, where $\{e_j\}$ is the set of face edges/triangles of $\{T_i\}$.

A weak Galerkin finite element approximation for (2.1)-(2.2) is defined by the unique solution $u_h = \{u_0, u_b\} \in V_h^0$ satisfying

(2.6)
$$(\nabla_w u_h, \nabla_w v_h) = (f, v_0) \quad \forall v_h = \{v_0, v_b\} \in V_h^0.$$

In [14], both (2.5) and (2.6) are proved to have a unique solution.

THEOREM 2.1. ([14]) Let u and u_h be the solutions of (2.1) and (2.6), respectively. The following two-order superconvergence holds

(2.7)
$$\|Q_h u - u_h\|_0 + h\| \|Q_h u - u_h\| \le Ch^{k+3} |u|_{k+3},$$

where $Q_h u = \{Q_0 u, Q_b u\} \in V_h^0$ (Q_0 and Q_b are local L^2 -projection on T and e respectively), and $||v_h||| = (\nabla_w v_h, \nabla_w v_h)^{1/2}$.

3. A P_{k+2} polynomial lifting operator. On an *m*-face polygon/polyhedron T we have (m+1) pieces of polynomials from a weak Galerkin finite element function. We need to lift these polynomials to a one-piece P_{k+2} polynomial, preserving P_{k+2} polynomials in the sense that $L_hQ_hu = u$ if u is a P_{k+2} polynomial.

THEOREM 3.1. The local L^2 projection $Q_h : u \in P_{k+2}(T) \to u_h = \{Q_0 u, Q_b u\} \in V_h$ is an injection, i.e.,

$$Q_h u = 0$$
 if and only if $u = 0$.

Proof. Let $u \in P_{k+2}(T)$ and $Q_h u = 0$. For any vector polynomial $\mathbf{q}_{k+1} \in [P_{k+1}(T)]^2$, we have

$$\int_{T} \nabla u \cdot \mathbf{q}_{k+1} d\mathbf{x} = \sum_{e \subset \partial T} \int_{e} u \mathbf{q}_{k+1} \cdot \mathbf{n} dS - \int_{T} u \nabla \cdot \mathbf{q}_{k+1} d\mathbf{x}$$
$$= \sum_{e \subset \partial T} \int_{e} Q_{b} u \mathbf{q}_{k+1} \cdot \mathbf{n} dS - \int_{T} Q_{0} u \nabla \cdot \mathbf{q}_{k+1} d\mathbf{x}$$
$$= 0.$$

Thus $\nabla u = \mathbf{0}$ everywhere and u = C. Since $Q_0 u = 0$, C = 0 and u = 0. \Box

THEOREM 3.2. The P_{k+2} polynomial lifting operator L_h , defined in (3.3) below, is P_{k+2} polynomial preserving in the sense that

(3.1)
$$L_h Q_h u = u, \quad \text{if } u \in P_{k+2}(T).$$

Consequently we have

(3.2)
$$\|u - L_h Q_h u\|_0 + h |u - L_h Q_h u|_{1,h} \le C h^{k+3} |u|_{k+3}.$$

Proof. Let $P_h : u_h = \{u_0, u_b\} \in V_h \to \{(P_h u_h)_0, (P_h u_h)_b\} \in V_h$ be the local, discrete $L^2(T)$ projection on to the image space $Q_h P_{k+2}(T)$, i.e.,

$$\int_{T} (P_h u_h)_0 Q_0 p_{k+2} d\mathbf{x} + \sum_{e \subset \partial T} \int_e (P_h u_h)_b Q_b p_{k+2} dS$$
$$= \int_{T} u_0 Q_0 p_{k+2} d\mathbf{x} + \sum_{e \subset \partial T} \int_e u_b Q_b p_{k+2} dS \quad \forall p_{k+2}(T).$$

The above equation has a unique solution as the left hand side bilinear form is coercive. By last theorem, Q_h is one-to-one from $P_{k+2}(T)$ on to the image space P_hV_h . Its inverse defines an unique lifting operator:

(3.3)
$$L_h u_h = Q_h^{-1}(P_h u_h) \in \prod_{T \in \mathcal{T}_h} P_{k+2}(T).$$

By definition, (3.1) holds. Further, because L_hQ_h is a stable, local preserving P_{k+2} polynomial operator, by [11], it is an optimal-order interpolation operator and (3.2) holds. \Box

THEOREM 3.3. Let u and u_h be the solutions of (2.1) and (2.6), respectively. Then

$$||u - L_h u_h||_0 + h|u - L_h u_h|_{1,h} \le Ch^{k+3}|u|_{k+3},$$

where $|u|_{1,h}^2 = \sum_{T \in \mathcal{T}_h} (\nabla u, \nabla u).$

Proof. Noting the weak gradient of $u_h - P_h u_h$ is a piece-wise higher order, $\|\cdot\|$ -orthogonal polynomial over the polynomial $\nabla L_h u_h$, we have

$$\|L_h u_h\|_{1,h}^2 = \|\|P_h u_h\|\|^2 = \|\|u_h\|\|^2 - \||(I - P_h) u_h\|\|^2 \le \||u_h\|\|^2.$$
3

By the triangle inequality, (3.2) and (2.7),

$$\begin{aligned} |u - L_h u_h|_{1,h} &\leq |u - L_h Q_h u|_{1,h} + |L_h (Q_h u - u_h)|_{1,h} \\ &\leq C h^{k+3} |u|_{k+3} + ||Q_h u - u_h|| \\ &\leq C h^{k+2} |u|_{k+3}. \end{aligned}$$

By the finite dimensional norm equivalence with scaling, the trace inequality and the definition of weak gradient, we have

$$\|L_h u_h\|_0^2 \le C \sum_{T \in \mathcal{T}_h} \left(\|P_h u_0\|_T^2 + 2h \|P_h (u_0 - u_b)\|_{\partial T}^2 \right)$$

$$\le Ch \|L_h u_h\|_0 \| (I - P_h) u_h \|.$$

By the triangle inequality, (3.2) and (2.7), we get

$$\|u - L_h u_h\|_0 \le \|u - L_h Q_h u\|_0 + \|L_h (Q_h u - u_h)\|_0$$
$$\le C h^{k+3} |u|_{k+3}.$$

4. Numerical Experiments. We solve the 2D Poisson equation (2.1) on the unit square domain. The exact solution is chosen as

(4.1)
$$u = \sin(\pi x)\sin(\pi y).$$

We compute the solution (4.1) on a perturbed quadrilateral grids, shown in Figure 4.1. We have two orders of superconvergence in L^2 -norm and in H^1 -like norm, shown

TABLE 4.2 Errors and orders of convergence by the P_2 - P_3 WG finite element on quadrilateral grids shown in Figure 4.1 for (4.1).

in Tables 4.1-4.2. In particular, the error after lifting is two orders higher than that of the original error.

Next we solve again the 2D Poisson equation (2.1) on the unit square domain with exact solution (4.1). We use quadrilateral-pentagon-hexagon hybrid grids, shown in Figure 4.2. Again the error after lifting is two orders higher, shown in Table 4.3.

Finally we solve the 3D Poisson equation (2.1) on the unit cube, with exact solution

(4.2)
$$u = \sin(\pi x)\sin(\pi y)\sin(\pi z).$$

We use a wedge-type grids shown in Figure 4.3. The lifted finite element solution has two orders of superconvergence, shown in Table 4.4.

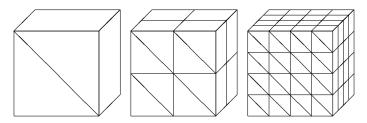

FIG. 4.3. The first three levels of wedge grids used in Table 4.4.
