Abstract

The recent outbreak of the novel coronavirus (COVID-19) has infected millions of citizens worldwide and claimed many lives. This paper examines its impact on the Chinese e-commerce market by analyzing behavioral changes seen from a large online shopping platform. We first conduct a time series analysis to identify product categories that faced the most extensive disruptions. The time-lagged analysis shows that behavioral patterns seen in shopping actions are highly responsive to epidemic development. Based on these findings, we present a consumer demand prediction method by encompassing the epidemic statistics and behavioral features for COVID-19 related products. Experiment results demonstrate that our predictions outperform existing baselines and further extend to the long-term and province-level forecasts. We discuss how our market analysis and prediction can help better prepare for future pandemics by gaining an extra time to launch preventive steps.

Introduction

The coronavirus disease 2019 (COVID-19) had a massive breakout in Wuhan during the Spring Festival in 2020 and later followed by a planetary health emergency. The novel virus had significantly influenced people's daily lives. Governments and the World Health Organization (WHO) have recommended people to stay at home and avoid crowded places. The disease dynamic was particularly rapid in China; it spread from Wuhan to all other regions and became nearly contained over the span of only two months.

According to the McKinsey report (Arora et al. 2020), global citizens increased their reliance on online shopping and delivery of essential goods, compared to the pre-pandemic time. Under this circumstance, epidemic-related products such as face masks and disinfectants were short in supply, failing to meet people's demand. Such a disruption in the supply-and-demand could reshape online shopping patterns, not only for COVID-19 related products but also for ordinary products. Understanding disruption in e-commerce could benefit all stakeholders (i.e., retailers, consumers, suppliers, delivery systems, and local governments) better prepare for the next pandemic. However, due to the lack of data or scenarios of a time-concentrated outbreak, little is known about consumer demand in the context of epidemics.

This paper conducts an extensive analysis of online shopping trends before and during the COVID-19 epidemic from the view of a popular e-commerce platform in China, Beid-

ian¹ (Cao et al. 2020). We characterize the pandemic's impact on the market from changes in product-level demand and supply. First, our analysis reveals which products increased or decreased in sales (after discounting seasonal variation), helping understand how households are coping with the pandemic. Second, it also compares the differences in browsing, searching, and purchasing activities towards pandemic-related goods such as face masks, disinfectants, and thermometers, which reveals the intricate relationship between supply and demand. We also identify which products decreased the largest in sales to infer the causes of such a drop. We also use time-lagged cross-correlation to quantify how shopping actions respond to the pandemic, interrogating product supply shortage. To the best of our knowledge, no other research has examined the disruptions in e-commerce at such a fine-grained level.

Based on these observations, we propose an **Encoder-decoder** model that leverages the online shopping behaviors and the **COVID-19** epidemic statistics to predict changes in **demand** of critical goods, **EnCod** for short. Experiments show that both shopping and epidemic features gathered from the past weeks are important for predicting pandemic-relevant goods in the upcoming days. Our model achieves higher prediction performance than baselines, and it could be fine-tuned at the province level; each province or city may adopt our model to understand the needs of their citizens during a pandemic. In summary, our main contributions are as follows:

1. We operationalize and release a dataset² of people's online shopping behaviors during the COVID-19 epidemic, and its multiple features characterize the marketing change during this period.
2. We investigate the changes of different online shopping behaviors, including purchasing, browsing, and searching on the platform, and examine the interplay between the COVID-19 epidemic and consumers' behaviors.
3. We conduct a time-lagged cross-correlation analysis could reveal which products exhibit a demand pattern that coaligns well with the epidemic dynamics.
4. We propose a model to forecast consumer demand on essential product categories, and demonstrate our model's effectiveness with regional and long-term forecast.

Related Work

Various studies have appeared since the outbreak of COVID-19 due to its unprecedented challenges for industry and society. Researchers have studied the impact of epidemics from multiple aspects, including transportation (Huang et al. 2020), gender equality (Alon et al. 2020), global poverty (Sumner et al. 2020), and stock market (Baker et al. 2020). Among those related to businesses, one study examines the online shopping food services during the government’s stay-at-home order (Chang and Meyerhoefer 2020). Others have looked at the economic impacts of a large epidemic (Schoenbaum 1987; Meltzer, Cox, and Fukuda 1999). However, little is known about consumer actions under a health risk, due to the lack of data encompassing such a time-concentrated outbreak (WTO 2020). This paper investigates the impact of the epidemic on online shopping behaviors and demand forecasting.

Several classical regression models exist in demand forecasting, such as the autoregressive integrated moving average (ARIMA) (Contreras et al. 2003). However, these models produce accurate forecasting results only when the sequence patterns are linearly correlated and stationary over time (Mills 1991; Omar, Hoang, and Liu 2016). New approaches adopt machine learning and deep learning algorithms for prediction, such as XG-Boost (Chen and Guestrin 2016) and sequence-to-sequence (seq2seq) (Sutskever, Vinyals, and Le 2014) models. Despite the potential, most models require mass data for training, and how they perform under a sudden disruption is yet to be investigated. This paper presents an encoder-decoder model in the prediction of near-future demands towards epidemic-related products.

During the outbreak of COVID-19, efforts are being paid to understand COVID-19 from the perspectives of structural biology (Wrapp et al. 2020), genetics (Hoffmann et al. 2020), economics (Cornwall 2020), policy (Tian et al. 2020; Maier and Brockmann 2020) and trend prediction (Cohen 2020). In addition to these efforts, the current study aims to provide a picture of the COVID-19 impact seen on Chinese e-commerce and leverages both the epidemic-related and behavior-related information to forecast the demand for essential goods.

Data

We use two data sources. The first is from a mobile-based shopping platform, Beidian. The platform is one of the largest in China and has a monthly user base of 3.44 million and an aggregate 187 million app downloads. It is a one-stop-shop and offers products ranging to nearly two thousand categories. We received anonymized session logs that span from January 1, 2019, to April 30, 2020. Each session information contained, for every instance, the action type (e.g., browsing, purchasing, searching), product ID, product category, and time. At the user-level, we were also given information about the cities they reside in. In the current analysis, logs originating from Hubei province were removed since the delivery of goods was prohibited during this area’s lockdown. Table 1 displays the summary of data statistics.

The pre-pandemic period data in (2019 and early 2020) are used to adjust for any seasonality pattern in post-pandemic period data analysis.

Table 1: Summary of the Beidian e-commerce dataset.

Statistics	Users	Products	Purchase	Browse	Search
Value	18M	550K	190M	8,285M	1,318M

The next data source is the daily epidemic statistics describing the newly confirmed cases within China. We combine two data sources: (1) the official reports from the Nation Health Commission of China³ are used for all data up to January 22, 2020, and (2) the COVID-19 dashboard data by the Center for Systems Science and Engineering at Johns Hopkins University⁴ are used for January 22, 2020, and onward.

Modeling Market Disruptions

Demands on specific health-related products such as face masks and hand sanitizers are bound to increase a health crisis, leading to a temporary surge in shopping actions. To quantify the degree of a rank change in purchase popularity of a product category c over a given period of t , we define the Relative Popularity (RP) as follows:

$$RP(c, t) = \log_{10} \frac{\text{ranking}(c, t_0)}{\text{ranking}(c, t)}, \quad (1)$$

where t_0 is the reference time to which a target period’s popularity is compared to. We consider the first week of 2020 as a reference point and repeatedly compute the RP value every week in 2020. This metric measures the change of popularity at the product-level and address potential confounders such as the number of active users. The trajectory of this value represents disruptions on the purchase before and after COVID-19.

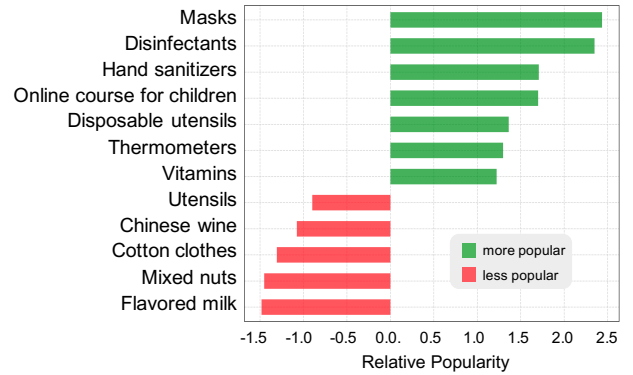

Figure 1: Products with the largest purchase rank change.

Popularity change by products

The most affected products. Figure 1 presents the signature categories that mark the highest and the lowest RP

³<http://www.nhc.gov.cn/>

⁴<https://github.com/CSSEGISandData/COVID-19>

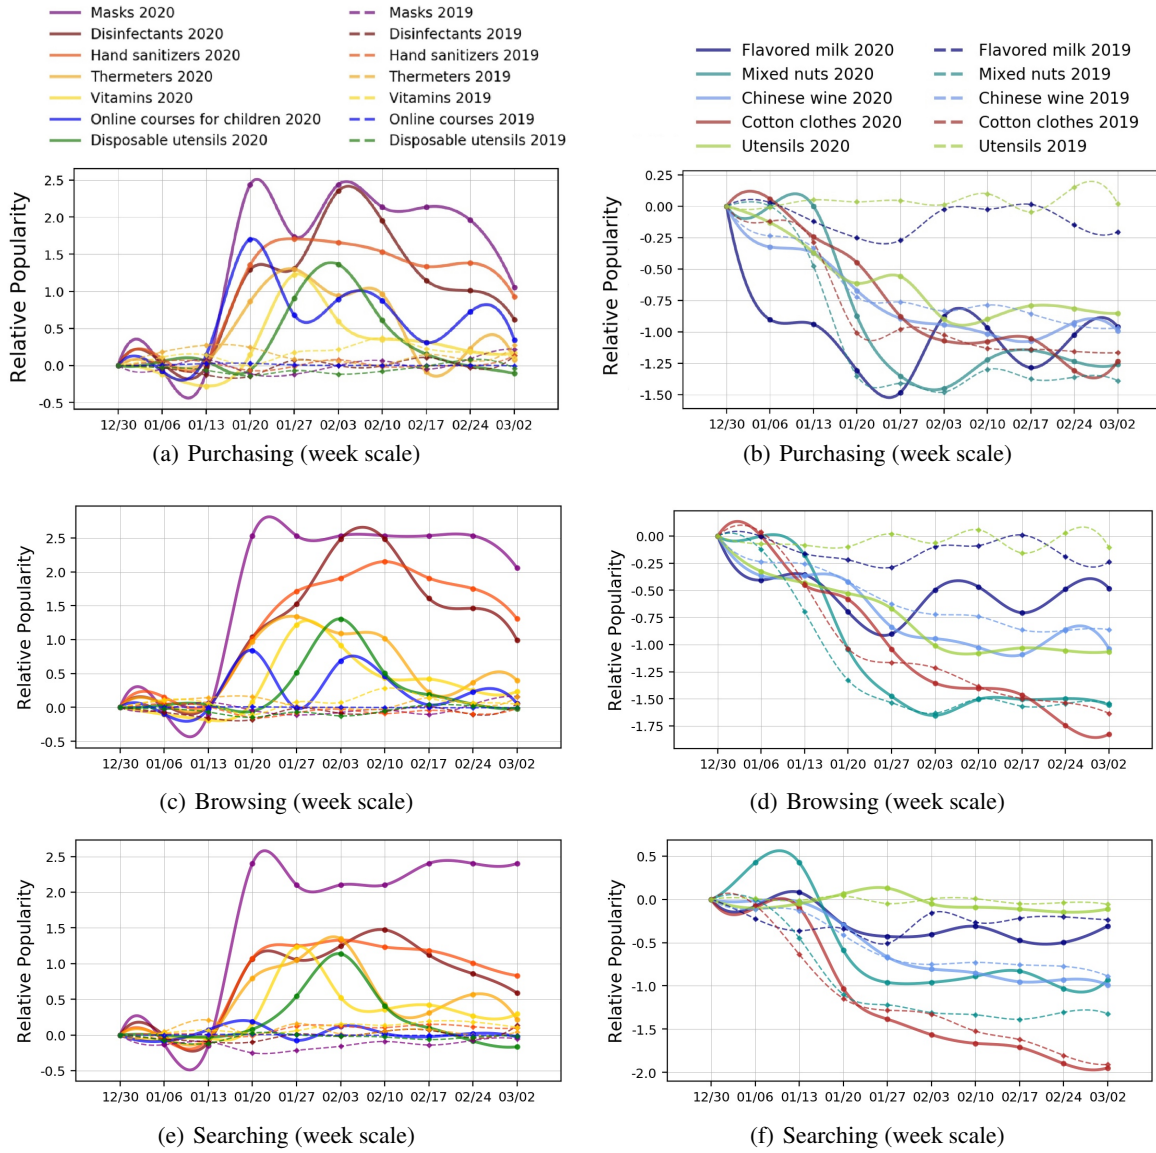

Figure 2: Weekly popularity dynamics during the COVID-19 period. Most products in panels (a), (c) are increasing in their relative popularity ranking, whereas most products in panels (b), (d) show decreasing popularity ranks.

values. The top seven items, from masks to vitamins, are within the top-20 to increase purchase rank change; their sales have surged compared to the final week of 2019. In contrast, the bottom five items from utensils to flavored milk, within the bottom-20, mark the largest decrease in purchase rank change; their sales decrease the largest during the pandemic.

The top list includes epidemic-related products such as face masks, disinfectants, hand sanitizers, and thermometers. The list also includes online course programs for children, disposable utensils, and vitamins, which could be assumed relevant during the pandemic given homeschooling, hygiene, and immunity have become either mandatory or important. We see (non-disposable) utensils, Chinese wine, cotton clothes, mixed nuts, and flavored milk moving on to the bottom list. These items are mostly within the top 100

before the pandemic. However, their purchase ranks drop by more than ten times during the pandemic. We list the full list of top-20 and bottom-20 product categories in the Appendix.

Weekly fluctuations. Figure 2 shows the week-by-week RP values of the 12 prominent goods along with their fitted lines. Here t_0 is again set to the first week of 2020. Product rank is shown for all three shopping actions: browsing, searching, and purchasing. The figure also shows the popularity trajectory of the same items in the year of 2019. We shift the timeline for 2019 and sync the new year's holiday week to appear as the fourth data point, to discount seasonal effect. Note that the studied popularity measure RP is stable and applicable to all popularity levels since it looks at the relative rank changes in the logarithmic scale.

Products in panels (a) and (c) such as face masks, disin-

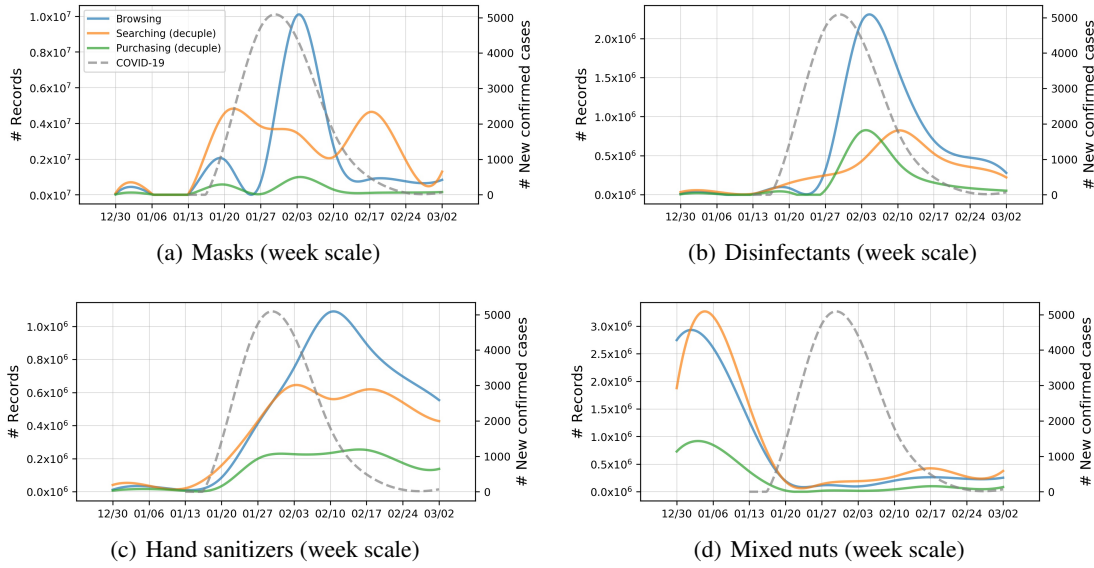

Figure 3: Weekly records of browsing, searching and purchasing on different kinds of products. Those of searching and purchasing are multiplied by ten (i.e., 1×10^5 in these figures actually represents 1×10^4 of searching and purchasing).

fectants, hand sanitizers, and thermometers show a surge in all shopping actions from the week of January 20th.⁵ This is when the lockdown of Hubei province was enforced. Face masks, in particular, continue to remain the top-ranked item throughout the pandemic period. The rank difference is substantially high and above 2.0 for the search action. Note that the RP value of 2.0 indicates several hundreds of rank increases. The dashed lines, representing the identical item’s rank changes in 2019, do not show any notable increase. This confirms that the surges are not seasonal but unique to 2020 (i.e., epidemic-related).

The sudden rank change for children’s online courses is also noticeable during the pandemic’s first week. The search action of this product, nonetheless, is not as high as other top products. We also pay attention to the products like thermometers, vitamins, and disposable utensils whose peaks in demand come a week or two after the disease outbreak. The times at which each product shows the highest rank change in demand could be used to understand what popular health practices households adopt during the pandemic and how much they are concerned about the disease.

In contrast, products in panels (b) and (d) show decreased ranks in all shopping actions. Some changes, however, are seasonal and can also be observed in 2019. For instance, the rank order of cotton clothes and Chinese wine gradually decreases in 2019 and 2020, indicating a seasonal effect (e.g., warmer weather, wine demands decreasing after the new year’s celebration). However, products like flavored milk and utensils show decreased popularity only in 2020, indicating households consume certain items less during the pandemic. It is interesting to contrast the decreasing demand for utensils against disposable utensils that shows a rise in demand during the pandemic. This contrast likely arises due

to increased efforts for hygiene.

Session counts by action type. To examine the dynamics across the shopping actions, Figure 3 compares the session counts for four representative products. The data shows that shoppers engage the most frequently in browsing actions, up to ten times more than the searching and purchasing actions. Also shown in the figure is the number of weekly confirmed epidemic statistics in China.

For mixed nuts, a non-epidemic product, the relative session counts across the three action types remain similar over time. In contrast, for the other three epidemic-related goods, searching and purchasing action rates may differ because products may be sold out. Interestingly, browsing and purchasing actions show similar fluctuations. These distinctive patterns are the most obvious for face masks in Figure 3(a), where the searching action demonstrates that it continues to be in high demand. Plots of disinfectants show a similar trend. The plot of hand sanitizers, however, show less difference across the three shopping actions. This may be because hand sanitizers were accessible more widely than the other two items.

Time-lagged analysis

The temporal analysis so far has revealed the dependency of online shopping actions to COVID-19; demand for some products is immediate upon a health risk, but other products stagger in their rank change. This subsection examines the time difference in detail via computing the lagged correlation between the two sequences. We compute the time-lagged cross-correlation (TLCC) (Shen 2015). The method shifts two sequences relatively in time (time-lagged) and calculates the correlation between them (cross-correlation). Therefore, it can analyze non-stationary time series and quantify how the three shopping actions appear upon a pandemic. We use a rolling window to analyze different peri-

⁵The surge appears on the fourth data points; the fitted lines are for visual aid and do not represent a gradual increase in popularity.

Figure 4: Time-lagged cross-correlation results of different products with a rolling time window. The color denotes the Pearson correlation coefficient between the two time series of corresponding behavior and newly confirmed cases.

ods and set each window to be a size of 21 days, and the lagged time is set from 0 to 6 days between the two series. Figure 4 presents the results of the time-lagged cross-correlation (TLCC) for selected products based on the purchase log. The y-axis represents the time-difference offset denoting the number of days that behavioral response falls behind the epidemic spreading, and the color represents the Pearson correlation coefficient from negative (blue) to positive (red).

The correlations are not uniform across products. Figure 4(a) demonstrates that the strong correlation between mask purchases and epidemic development does not last long due to falling mask supplies. This trend is shown by dark red blocks on Jan 14, followed by blue shaded regions in the figure. Figure 4(b) in contrast, shows that disinfectant purchases closely follow the epidemic development throughout the whole period, resulting in high correlation (i.e., red shaded areas). We can deduce that there is no shortage of disinfectant supplies on the platform.

On the other hand, the demands of hand sanitizers (Figure 4(c)) and vitamins (Figure 4(d)) remain high until the end of February. For example, as shown in Figure 3(c) and 4(c), sales of hand sanitizer skyrocket by following the epidemic development at the early stages of COVID-19. It shows a week’s lagged response to epidemic development. However, the lagged effect decreases over time, implying that shopping demands become neutral to epidemic development. Furthermore, a positive relationship becomes weak and turns to a negative. This can be interpreted as hand sanitizers are still high in demand, even after the number of new confirmed cases decreased. Toward the end of the time frames, the lagged positive correlation appears again, which means that consumers have stocked enough hand sanitizers, thus no longer purchase them.

Our data shows that correlations are found across shopping actions. Mask is a representative product that faced supply shortage during the epidemics in China. The searching actions in Figure 5(a) show a negative correlation in the later period of epidemics, indicating that people are still searching for masks although the COVID-19 confirmed cases is decreasing, identified as blue shaded regions. Positive correlation appearing on the later part of Figure 5(b) can be understood in the same context that only when the number of confirmed patients decreased, the number of sales and the number of confirmed cases show positive correlation.

In summary, our analysis shows that dynamic correlations exist between online shopping behaviors and epidemic de-

Figure 5: Even when the epidemic subsided, consumer interest in searching masks remained. For preparing future epidemic, demand forecasting and inventory planning are vital to avoid supply shortage.

velopment. We find that behaviors respond to the epidemic in a lagged manner, but the correlation can be reversed when there is a shortage or continued caution. These patterns and observations inspire us to design an accurate and explainable predictor for forecasting consumer demand on key product categories.

Demand Forecasting and Evaluations

The analysis so far has demonstrated how COVID-19 impacted product popularity and behavioral patterns. The distinctive patterns of the purchasing and searching for critical items like facial masks suggest that the pandemic disrupts the supply of essential goods and leads to an imbalance of demand and supply. The analysis also confirmed a significant correlation between shopping actions and epidemic sequences. Together, these findings suggest that many products’ purchase intent is directly affected by the epidemic development during a health crisis.

Based on the insights above, we present a Gated Recurrent Unit (GRU)-based encoder-decoder model named **EnCod** that leverages the epidemic information along with historical shopping behaviors to predict the demand for critical goods. We use the data of daily confirmed cases and searching behaviors in the past two weeks to predict the number of searches in the following n days. Figure 6 shows the detail of the prediction model. The EnCod model is based on the GRU network (Bahdanau, Cho, and Bengio 2014). The model takes in the concatenation of sequences of daily confirmed cases and searches as input. The encoder module extracts the historical sequence features and outputs the last hidden states that serve as the decoder’s input. Then the decoder model generates the prediction results in the future.

Table 2: The NRMSE performance of our method compared to baselines. The results represent the prediction performance in China except for Hubei province.

Model	Products with increased purchase ranks (COVID-19 related)					Products with decreased purchase ranks (COVID-19 irrelevant)				
	Masks	Disinfectants	Hand sanitizers	Vitamins	Thermometers	Flavored milk	Daily necessities	Vegetables	Mixed nuts	Decorations
AR	0.657	0.366	0.226	0.287	0.248	0.281	0.287	0.387	0.269	0.469
ARIMA	0.461	0.633	0.865	0.258	0.232	0.292	0.298	0.405	0.267	0.447
Seq2seq	0.438	0.323	0.197	0.216	0.149	0.283	0.305	0.330	0.253	0.286
XGBoost	0.718	0.578	0.597	0.492	0.309	0.283	0.301	0.327	0.294	0.463
XGBoost-C	0.468	0.512	0.289	0.307	0.293	0.281	0.330	0.326	0.295	0.547
EnCod	0.307	0.212	0.156	0.201	0.126	0.285	0.279	0.331	0.252	0.284

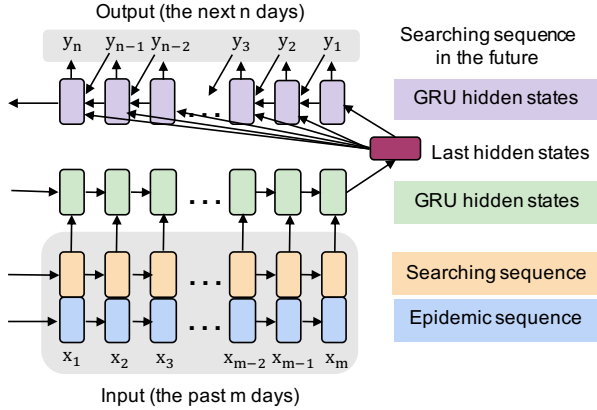

Figure 6: The overall architecture of our proposed model EnCod, which takes in the concatenation of epidemic and searching sequences in the past m days and outputs the daily number of searches in the next n days.

Performance evaluations

We compare our model with baselines of classical time series forecasting algorithms, including autoregressive (AR) model (Mills 1991), ARIMA model (Contreras et al. 2003), and a deep learning algorithm like Seq2Seq and XGBoost (Chen and Guestrin 2016). These methods only use in historical shopping behaviors and predict its future. For a fair comparison, we also use a variant of the XGBoost model that utilizes both the historical shopping history and epidemic statistics (which we call XGBoost-C).

We evaluate the prediction performance with the Normalized Root Mean Square Error (NRMSE) (Rocha, Cortez, and Neves 2007). The experimental period is from January 1 to March 31, 2020, covering the leading COVID-19 epidemic development in China. We use historical searching logs from the Beidian platform, and the daily confirmed cases over the past two weeks to predict consumer demand (i.e., product searches) in the immediate week. We split the data into the training and testing sets with a ratio of 3:1 according to time. We train the model parameters with Adam optimizer regularized by an early stop and set the mini-batch size 10. The learning rate is initialized as $1e-2$, which is gradually reduced by 0.1.

Table 2 contains the prediction performance of EnCod

along with other baselines. We choose ten categories of two groups, including both the COVID-19 related and COVID-19 unrelated product categories. Products with the highest relative popularity (RP) such as face masks appear in the COVID-19 related products, and those with low RP value appear as the irrelevant group.⁶

The COVID-19 related group results show that adding the epidemic statistics contributes to a substantial demand forecasting performance. This was consistent for both XGBoost and encoder-decoder models. (Seq2Seq is a variant of our model without the epidemic information.) Compared to the best performing baseline, EnCod could reduce the NRMSE value by an additional 6.9% to 34.3% in the prediction tasks for the COVID-19 related products. However, having the epidemic information as in XGBoost-C is not necessarily the second-best performing alternative. Sometimes it was the AR, ARIMA, or the Seq2Seq model that produced a good alternative, excluding EnCod.

Next, in the comparison of COVID-19 irrelevant products, EnCod no longer produces the best results in all prediction tasks. EnCod is only marginally better, and the XGBoost-C model produces the best result for flavored milk and vegetables. This means that obtaining additional epidemic statistics is no longer helpful for items with low RP value. Among the items, we show the results for daily necessities (e.g., toilet paper, storage bags, kitchen supplies) and home decorations. All other results can be found in the Appendix.

The comparison results between the two groups validate that our method can capture the relationship between epidemic development and the demand change of essential goods. Moreover, it verifies the usability of the metrics RP , which is defined to characterize the market. The prediction results indicate that the metrics RP can distinguish the product’s relevance to an epidemic.

Regional and long-term forecasting

We now focus on a single product category, face masks, to examine the regional and long-term forecasting capability. To examine province-level results, we choose nine representative provinces in China considering the geography, the distance from Hubei, and confirmed cases. We train each province-specific model with its own confirmed cases and

⁶We show the full results for all of the major product categories in the Appendix.

Table 3: The NRMSE performance of baseline methods and our model measured in nine representative provinces in China. Provinces nearby Hubei are marked with the * sign.

Model	Provinces								
	Beijing	Shanxi	Jilin	Zhejiang*	Shanghai	Sichuan*	Guangdong	Hunan*	Henan*
AR	0.521	0.990	0.686	0.454	0.597	0.432	0.990	0.398	0.563
ARIMA	0.442	0.491	0.536	0.346	0.439	0.340	0.589	0.350	0.345
Seq2seq	0.338	0.403	0.579	0.267	0.353	0.314	0.723	0.294	0.310
XGBoost	0.621	0.481	0.860	0.284	0.493	0.354	0.672	0.376	0.412
XGBoost-C	0.463	0.444	0.628	0.251	0.452	0.257	0.501	0.322	0.411
EnCod	0.315	0.334	0.349	0.245	0.278	0.271	0.377	0.269	0.280

Table 4: The NRMSE performance for long-term prediction.

Model	Forecasting interval (n)					
	1	3	5	7	10	14
AR	0.215	0.336	0.475	0.657	0.820	0.796
ARIMA	0.289	0.370	0.395	0.461	0.453	0.342
Seq2seq	0.393	0.436	0.430	0.438	0.438	0.316
XGBoost	0.464	0.666	0.704	0.718	0.697	0.502
XGBoost-C	0.429	0.513	0.496	0.468	0.528	0.389
EnCod	0.316	0.309	0.288	0.304	0.335	0.245

searching records to predict their citizens’ needs.

Table 3 shows the comparison of regional forecasting. Even when learning is fine-tuned over province-level data, EnCod still outperforms baselines in most cases. Compared with other provinces, the EnCod model adopted in Hunan, Henan, Sichuan and Zhejiang, which are places nearby Hubei province, delivers relatively low prediction error. It could be explained as the epidemic more influences these areas. Thus the effect of adding COVID-19 statistics is more helpful and leads to better e-commerce behavior predictions.

Next, to test how well EnCod performs for a longer period prediction, we increase the days of a forecast by changing the n value to $\{1, 3, 5, 7, 10, 14\}$. Table 4 displays the results from this long-term prediction. The immediate day prediction $n = 1$ performs better for the AR model. For $n > 1$, EnCod consistently outperforms all baselines by a substantial margin. In contrast, the AR model performs poorly for longer-term prediction, reaching an NRMSE value above 0.5 after a week or longer prediction. The ability to look beyond a week makes the proposed EnCod model practical and applicable to study future epidemics.

To summarize, all the above results verify that our method can be applied to global and local forecasts and long-term forecasts of the demand for essential goods, which is crucial and meaningful in the pandemic period. Overall, our method can effectively improve forecasting performance, no matter the historical records of time series are sparse or dense, no matter how long the future is predicted, which shows the model’s utility and robustness.

Discussion and Conclusion

The COVID-19 epidemic has exacerbated difficulties in the sufficient supply of essential products to meet the demand and, consequently, influence people’s activities on the

e-commerce platform. This paper conducts extensive data analysis to investigate how people’s online shopping behaviors respond to the epidemic and discover different behavioral patterns. We find out the disruption in the supply of essential goods in this period led to changes in shopping actions (e.g., a positive rank change of search action for face masks and other epidemic-relevant products). Therefore, we incorporate the epidemic development statistics into demand forecasting and present an EnCod model. The model is simple yet effective in forecasting the demand for COVID-19 related items during the epidemics.

The findings of this research have multiple implications. First, the product-level detailed shopping logs will be anonymized and released to the research community and serve as a critical data source to understand market disruptions during a health pandemic. Second, health professionals and e-commerce marketers can utilize the model for predicting surges in the short-term demand for particular goods under risks from an epidemic. Third, policymakers can review the most relevant product goods identified in this research to understand households’ needs. Fourth, the encoder-decoder model (EnCod) can be utilized in domains beyond e-commerce (such as trade data) to review the impact of COVID-19 in other sectors.

In China, the population’s proportion using mobile e-commerce is relatively high, and the country has gone through the leading COVID-19 epidemic development during the first quarter of 2020. However, it will be necessary to determine how this analysis can be repeated in other countries where the proportion of using mobile e-commerce may be lower, or COVID-19 is still in progress. In the post-COVID-19 era, inventory planning and pricing of goods will have to be decided based on multiple data sources, including user demands. Moreover, combining other modality of mobile e-commerce (Cao et al. 2020; Chen et al. 2020) to assist demand forecasting, in consideration of cost-effectiveness, would also be an excellent direction to extend this work. As the first to identify the impact of COVID-19 from this perspective of mobile e-commerce, we believe that this study makes an important contribution to the community.

Appendix

This is the supplementary material for the submission 4638 to AAAI-21. We share the per-product-level logs of browsing, sales, and search logs at <https://bit.ly/3kcAEN5>. This data, containing before and after e-commerce logs, will be of great value to the research community to study the impact of a health risk such as COVID-19.

List of Top-Products Affected by COVID-19

The Modeling Market Descriptions section revealed which items saw large disruptions in purchasing during COVID-19. Table 5 and Table 6 display the top-20 and bottom-20 products with their highest and lowest relative popularity. As we aggregate data by each week, the week of January 20 will contain events related to both the Chinese new year holiday as well as the COVID-19 lock impact.

The relative ranking $RP(c, t)$ of COVID-19 related products became very high at the end of January. Especially in the peak period, the corresponding absolute ranking of masks, disinfectants, daily necessities, and hand sanitizers were very high among thousands of items in the Beidian platform, top-1 during the week of January 20, top-2 during the week of February 3, top-1 during the week of January 27, top-8 during the week of January 27, respectively.

Evaluation Metrics

Among the evaluation metrics we employ, here we describe how we compute the Normalized Root Mean Square Error (NRMSE) (Rocha, Cortez, and Neves 2007):

$$\text{NRMSE}(y, \hat{y}) = \frac{\text{RMSE}(y, \hat{y})}{y_{\max} - y_{\min}}, \quad (2)$$

where N is the number of test samples, $y_i, i \in [1, N]$ represents the ground truth, and $\hat{y}_i, i \in [1, N]$ represents the predicted values.

Time-Lagged Cross-Correlation Results

The Modeling Market Descriptions section showed results on time-lagged cross-correlation (TLCC). The method shifts two sequences relatively in time (time-lagged) and calculates the correlation between them (cross-correlation). Therefore, it can analyze non-stationary time series and quantify how the three shopping actions appear upon a pandemic. We use a rolling window and set each window to be a size of 21 days, and the lagged time is set from 0 to 6 days between the two series.

The trends seen on browsing and searching are similar to that of purchasing for snacks in Figure 7. Because the supply has not been affected, the behavioral response during the epidemic is similar across different action types.

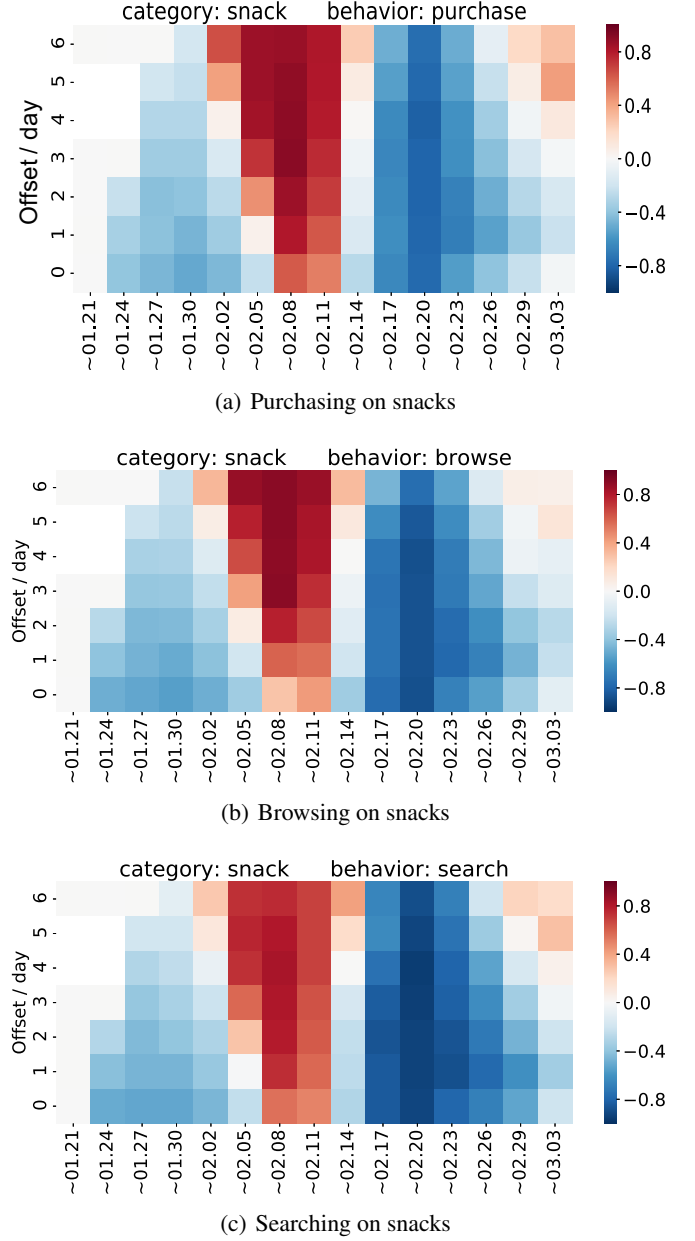

Figure 7: The TLCC results of searching and browsing behaviors on snacks.

Table 5: Top-20 products with the highest relative popularity. The Peak time column displays the first day of the examined week that reached the largest rank change (i.e. $\arg \min_t \text{rank.}(t)$). Note that some of the purchases in the week of January 20th to 26th may be related to the new year’s holiday. The city of Wuhan went through lockdown since January 23rd.
