DIRAC SERIES FOR COMPLEX CLASSICAL LIE GROUPS: A
MULTIPLICITY-ONE THEOREM

DAN BARBASCH, CHAO-PING DONG, AND KAYUE DANIEL WONG

Abstract. This paper computes the Dirac cohomology $H_D(\pi)$ of irreducible unitary
Harish-Chandra modules $\pi$ of complex classical groups viewed as real reductive groups.
More precisely, unitary representations with nonzero Dirac cohomology are shown to be
unitarily induced from unipotent representations. When nonzero, there is a unique, mul-
tiplicity free $K$-type in $\pi$ contributing to $H_D(\pi)$. This confirms conjectures formulated
by the first named author and Pandžić in [BP].

1. Introduction

The Dirac operator was first introduced in the representation theory of real reductive
groups by Parthasarathy [P1, P2] and Schmid in order to give geometric realization of
the discrete series. A byproduct, the Dirac inequality, has proved very useful to provide
necessary conditions for unitarity. In the case of real rank one groups, the work of [BSi]
and [BB], shows that this necessary condition is also sufficient. The Dirac inequality plays a
crucial role in the determination of representations with $(g, K)$–cohomology in the work of
[E] and [VZ] for complex and real groups, subsequently expanded by [Sa] to find necessary
and sufficient conditions for the unitarity of irreducible representations with regular integral
infinitesimal character.

In order to find sharper estimates for the spectral gap in the case of locally symmetric
spaces, Vogan in [V2] introduced the notion of Dirac cohomology for irreducible repre-
sentations. He formulated a conjecture on its relationship with the infinitesimal character
of the representation.

We recall the construction of Dirac operator and Dirac cohomology. Let $G$ be a connected
real reductive Lie group. Fix a Cartan involution $\theta$, and write $K := G^\theta$ for the maximal
compact subgroup. Denote by $g_0 = \mathfrak{k}_0 \oplus \mathfrak{p}_0$ the corresponding Cartan decomposition of the
Lie algebra $g_0$, and $g = \mathfrak{k} + \mathfrak{p}$ the corresponding decomposition of the complexification. Let
$\langle , , \rangle$ be an invariant nondegenerate form such that $\langle , , \rangle|_{\mathfrak{p}_0}$ is positive definite, and $\langle , , \rangle|_{\mathfrak{k}_0}$
is negative definite. Fix $Z_1, \ldots, Z_n$ an orthonormal basis of $\mathfrak{p}_0$. Let $U(g)$ be the universal
enveloping algebra of $\mathfrak{g}$, and let $C(\mathfrak{p})$ be the Clifford algebra of $\mathfrak{p}$ with respect to $\langle , , \rangle$. The
Dirac operator $D \in U(\mathfrak{g}) \otimes C(\mathfrak{p})$ is defined as

$$D = \sum_{i=1}^{n} Z_i \otimes Z_i.$$
The operator $D$ does not depend on the choice of the orthonormal basis $Z_i$ and is $K$-invariant for the diagonal action of $K$ induced by the adjoint actions on both factors.

Define $\Delta : \mathfrak{k} \rightarrow U(\mathfrak{g}) \otimes C(\mathfrak{p})$ by $\Delta(X) = X \otimes 1 + 1 \otimes \alpha(X)$, where $\alpha : \mathfrak{k} \rightarrow C(\mathfrak{p})$ is the composition of $\text{ad} : \mathfrak{k} \rightarrow \mathfrak{so}(\mathfrak{p})$ with the embedding $\mathfrak{so}(\mathfrak{p}) \cong \wedge^2(\mathfrak{p}) \hookrightarrow C(\mathfrak{p})$. Write $\mathfrak{t}_\Delta := \alpha(\mathfrak{k})$, and denote by $\Omega_\mathfrak{g}$ (resp. $\Omega_\mathfrak{k}$) the Casimir operator of $\mathfrak{g}$ (resp. $\mathfrak{k}$). Let $\Omega_{\mathfrak{t}_\Delta}$ be the image of $\Omega_\mathfrak{k}$ under $\Delta$. Then ([P1])

$$D^2 = -\Omega_\mathfrak{g} \otimes 1 + \Omega_{\mathfrak{t}_\Delta} + (\|\rho_\mathfrak{g}\|^2 - \|\rho_\mathfrak{c}\|^2)1 \otimes 1,$$

where $\rho_\mathfrak{g}$ and $\rho_\mathfrak{c}$ are the corresponding half sums of positive roots of $\mathfrak{g}$ and $\mathfrak{k}$.

Let

$$\tilde{K} := \{(k, s) \in K \times \text{Spin}(\mathfrak{p}_0) : \text{Ad}(k) = p(s)\},$$

where $p : \text{Spin}(\mathfrak{p}_0) \rightarrow \text{SO}(\mathfrak{p}_0)$ is the spin double covering map. If $\pi$ is a $(\mathfrak{g}, K)$-module, and if $S_G$ denotes a spin module for $C(\mathfrak{p})$, then $\pi \otimes S_G$ is a $(U(\mathfrak{g}) \otimes C(\mathfrak{p}), \tilde{K})$ module.

The action of $U(\mathfrak{g}) \otimes C(\mathfrak{p})$ is the obvious one, and $\tilde{K}$ acts on both factors; on $\pi$ through $K$ and on $S_G$ through the spin group $\text{Spin}\mathfrak{p}_0$. The Dirac operator acts on $\pi \otimes S_G$. The Dirac cohomology of $\pi$ is defined as the $K$-module

$$H_D(\pi) = \text{Ker } D / (\text{Im } D \cap \text{Ker } D).$$

The following foundational result on Dirac cohomology, conjectured by Vogan, was proven by Huang and Pandžić in 2002. Let $\mathfrak{h}$ be a $\theta$–stable Cartan subalgebra with Cartan decomposition $\mathfrak{h} = \mathfrak{t} + \mathfrak{a}$ and $\mathfrak{t}$ a Cartan subalgebra of $\mathfrak{k}$.

**Theorem 1.1 ([HP1] Theorem 2.3).** Let $\pi$ be an irreducible $(\mathfrak{g}, K)$-module. Assume that the Dirac cohomology of $\pi$ is nonzero, and that it contains the $\tilde{K}$-type with highest weight $\gamma \in \mathfrak{k}^* \subset \mathfrak{h}^*$. Then the infinitesimal character of $\pi$ is conjugate to $\gamma + \rho_\mathfrak{c}$ under $W(\mathfrak{g}, \mathfrak{h})$.

1.1. **Dirac Series.** Denote by $\hat{G}$ the set of equivalence classes of irreducible unitary $(\mathfrak{g}, K)$-modules. If $\pi \in \hat{G}$, then $\pi \otimes S_G$ acquires a natural inner product, and $D$ is self-adjoint. As a result, Dirac cohomology simplifies to

$$H_D(\pi) = \text{Ker } D = \text{Ker } D^2.$$

For a unitary irreducible representation, ([1]) is a nonnegative scalar on any $\tilde{K}$–type. If $\chi_\pi$ is the infinitesimal character of $\pi$, and $\tau$ is the highest weight of a $K$–type in $\pi \otimes S_G$, then

$$||\chi_\pi||^2 \leq ||\tau + \rho_\mathfrak{c}||^2$$

This is Parthasarathy’s Dirac operator inequality. Moreover, by Theorem 3.5.2 of [HP2], the equality holds precisely when $\tau$ is the highest weight of a $\tilde{K}$-type in $H_D(\pi)$ (see Section 2.3).

Let $\hat{G}^d$ be the representations with nonzero Dirac cohomology. This subset forms an interesting part of $\hat{G}$. For convenience, we call these representations Dirac series of $G$ (terminology suggested by J.-S. Huang).

When $G$ is a complex Lie group viewed as a real Lie group, the following conjecture on $\hat{G}^d$ was formulated in [BP].
Conjecture 1.2 ([BP] Conjecture 1.1). Let $G$ be a connected complex simple Lie group and $\pi \in \hat{G}$ whose infinitesimal character is regular and half-integral. Then $\pi \in \hat{G}^d$ if and only if $\pi$ is parabolically induced from a unipotent representation with nonzero Dirac cohomology, tensored with a unitary character.

Remark 1.3. A necessary condition for $\pi \in \hat{G}^d$ is that twice the infinitesimal character of $\pi$ must be regular integral. We call this case half-integral regular. The first step in [BP], reviewed in Section 2.3, is to make this more precise. Therefore, the above conjecture gives a complete classification of $\hat{G}^d$.

A similar conjecture is made for all real reductive Lie groups; replace unitary induction by the more general cohomological induction in a range where unitarity is preserved. The special case of the conjecture (for all real groups) when the infinitesimal character is regular integral is essentially the case of representations with nontrivial $(g, K)$-cohomology. In that case, treated in [E] and [VZ] as already mentioned, the only unipotent representations that play a role are the Trivial representation tensored with unitary characters. In the complex case, Parthasarathy’s Dirac inequality ([1]) implies that all $\pi \in \hat{G}$ with regular integral infinitesimal character are unitarily induced from unitary characters of parabolic subgroups, and hence the conjecture follows immediately.

However, this is not the case in the more general setting. A good a priori understanding of $\hat{G}$ for half-integral regular infinitesimal character is essential. If $G$ is complex classical, the following unitarity result is proved in [V1] and [B].

Theorem 1.4 (Theorem 3.1). Let $G$ be a classical complex Lie group. Any $\pi \in \hat{G}$ with regular, half-integral infinitesimal character is of the form

$$\pi := \text{Ind}_{MN}^G((C_\xi \otimes \pi_u) \otimes 1),$$

where $P = MN$ is a parabolic subgroup of $G$ with Levi factor $M$, and $C_\mu$ is a unitary character on $M$. Moreover, $\pi_u$ is the trivial representation for Type A, or a unipotent representation of $M$ listed in Sections 5.4–5.6 of [BP] for other classical types.

A self-contained proof of Theorem 1.4 for classical groups is in Sections 3 to 6. The techniques involved apply to exceptional Lie groups and some real reductive groups. Using this, we will prove the following:

Theorem 1.5. Conjecture 1.2 holds for complex connected classical Lie groups.

1.2. Spin-lowest $K$–type. Following [D1], we are interested in studying spin-lowest $K$–type (spin-LKT) of an admissible $(g, K)$–module. See Definition 2.8 for the precise meaning of spin-lowest $K$–type in the setting of complex Lie groups. If $\pi \in \hat{G}^d$, then the spin-lowest $K$–types are precisely those contributing to $H_D(\pi)$. More explicitly, let $\tau$ be the highest weight of the $\tilde{K}$–type occurring $H_D(\pi)$. Then

$$[V_\ell(\tau) : H_D(\pi)] = \sum_{\eta \text{ spin–LKT}} [V_\ell(\eta) : \pi] \cdot [V_\ell(\eta) \otimes S_G : V_\ell(\tau)],$$
where $V_a(\eta)$ is the irreducible, finite-dimensional $a$-module with highest weight $\eta$. In view of this, the following conjecture, formulated in [BP], makes $\widehat{G}^d$ and $H_D(\pi)$ precise.

**Conjecture 1.6** ([BP] Conjecture 4.1 and J.-S. Huang). *Let $G$ be a connected complex simple Lie group, and $\pi \in \widehat{G}^d$. Then $\pi$ has a unique spin-lowest $K$-type $V_k(\eta)$ which occurs with multiplicity one.*

Based on the results in [DD, D2, DW], the above conjecture holds for complex $G_2$, $F_4$, $E_6$ and $E_7$. Here is the second main result of this paper:

**Theorem 1.7.** Conjecture 1.6 holds for complex connected classical Lie groups.

Note that the techniques in this manuscript can also be applied to simple groups of exceptional type. This is carried out in [DW] for complex $E_8$, and the conjecture is also shown to be true in that case. We will study the case of complex $E_8$ in a forthcoming work.

The manuscript is organized as follows. Section 2 includes some preliminary results on complex simple Lie groups, Dirac cohomology and spin-lowest $K$-types. Sections 3–6 state the classification of the unitary dual for complex classical Lie groups with half integral regular infinitesimal character (c.f. [B], [V1]) and give complete proofs. Section 7, proves a stronger version of Conjecture 1.6 which is essential for the determination of $H_D(\pi)$ in Section 8. In the Appendix, we present some calculations on atlas ([ALTV], [A1]) for the modules appearing in Sections 4–6, offering examples for the results in these sections.

### 2. Preliminaries

Let $G$ be a connected complex simple Lie group viewed as a real Lie group. Fix a maximal compact subgroup $K$ and a Borel subgroup $B$. Then $T := K \cap B$ is a maximal torus in $K$.

Denote by $t_0$ the Lie algebra of $T$. Then $a_0 := \sqrt{-1}t_0$ is a maximally split Cartan subalgebra of $g_0$. Let $A := \exp(a_0)$. Then $H = TA$ is a Cartan subgroup of $G$ with Lie algebra $h_0 = t_0 + a_0$.

The realization of the complexification of $g_0$ in (2.1.3) – (2.1.7) of [B] gives

(5) $g \cong g_0 \oplus g_0$, $h \cong h_0 \oplus h_0$, $t \cong \{(x, -x) : x \in h_0\}$, $a \cong \{(x, x) : x \in h_0\}$

(we drop the subscripts of the Lie algebras to denote their complexifications).

Let $\rho$ be the half sum of positive roots in $\Delta^+_G$. A choice of positive roots of $g$ is

$$\Delta^+(g, h) = \{\alpha \times 0\} \cup \{0 \times (-\alpha)\}_{\alpha \in \Delta^+_G}.$$  

Denote by $W$ the Weyl group $W(g_0, h_0)$, which has identity element $e$ and longest element $w_0$. Then $W(g, h) \simeq W \times W$. 
2.1. **Classification of irreducible modules.** The classification of irreducible \((\mathfrak{g}, K)\)-modules for complex Lie groups was first obtained by Parthasarathy-Rao-Varadarajan [PRV] and Zhelobenko [Zh]. Let \((\lambda_L, \lambda_R) \in \mathfrak{h}_0^* \times \mathfrak{h}_0^*\) be such that \(\lambda_L - \lambda_R\) is a weight of a finite dimensional holomorphic representation of \(G\). Using (5), we can view \((\lambda_L, \lambda_R)\) as a real-linear functional on \(\mathfrak{h}\) (we will also sometimes denote it as \(\left(\frac{\lambda_L}{\lambda_R}\right)\)), and write \(\mathbb{C}(\lambda_L, \lambda_R)\) as the character of \(H\) with differential \((\lambda_L, \lambda_R)\) (which exists) with

\[
\mathbb{C}(\lambda_L, \lambda_R)|_T = \mathbb{C}_\mu := \mathbb{C}_{\lambda_L - \lambda_R}, \quad \mathbb{C}(\lambda_L, \lambda_R)|_A = \mathbb{C}_\nu := \mathbb{C}_{\lambda_L + \lambda_R}.
\]

Put \(X(\lambda_L, \lambda_R) := K\)-finite part of \(\text{Ind}_H^G(\mathbb{C}(\lambda_L, \lambda_R) \otimes 1)\).

**Theorem 2.1.** ([PRV], [Zh]) The \(K\)-type with extremal weight \(\mu := \lambda_L - \lambda_R\) occurs with multiplicity one in \(X(\lambda_L, \lambda_R)\). Let \(J(\lambda_L, \lambda_R)\) be the unique subquotient of \(X(\lambda_L, \lambda_R)\) containing this \(K\)-type.

a) Every irreducible admissible \((\mathfrak{g}, K)\)-module is of the form \(J(\lambda_L, \lambda_R)\).

b) Two such modules \(J(\lambda_L, \lambda_R)\) and \(J(\lambda'_L, \lambda'_R)\) are equivalent if and only if there exists \(w \in W\) such that \(w\lambda_L = \lambda'_L\) and \(w\lambda_R = \lambda'_R\).

c) \(J(\lambda_L, \lambda_R)\) admits a nondegenerate Hermitian form if and only if there exists \(w \in W\) such that \(w(\lambda_L - \lambda_R) = \lambda_L - \lambda_R, w(\lambda_L + \lambda_R) = - (\lambda_L + \lambda_R)\).

The \(W \times W\)-orbit of \((\lambda_L, \lambda_R)\) is the infinitesimal character of \(J(\lambda_L, \lambda_R)\).

2.2. **PRV-component.** In this subsection, we summarize Corollaries 1 and 2 to Theorem 2.1 of [PRV] on the decomposition of the tensor product \(V_\ell(\sigma_1) \otimes V_\ell(\sigma_2)\) for highest weights \(\sigma_1\) and \(\sigma_2\).

**Theorem 2.2.** ([PRV]) The component \(V_\ell(\{\sigma_1 + w_0\sigma_2\})\) occurs exactly once in \(V_\ell(\sigma_1) \otimes V_\ell(\sigma_2)\), where \(\{\sigma_1 + w_0\sigma_2\}\) is the unique dominant element to which \(\sigma_1 + w_0\sigma_2\) is conjugate under the action of \(W\). Moreover, any other component \(V_\ell(\eta')\) occurring in \(V_\ell(\sigma_1) \otimes V_\ell(\sigma_2)\) must be of the form

\[
\eta' = \{\sigma_1 + w_0\sigma_2\} + \sum_{i=1}^l n_i \alpha_i, \text{ where } n_i \in \mathbb{N}.
\]

In particular,

\[
\|\{\sigma_1 + w_0\sigma_2\} + \rho\| < \|\eta' + \rho\|.
\]

The factor \(V_\ell(\{\sigma_1 + w_0\sigma_2\})\) is usually called the **PRV-component** of \(V_\ell(\sigma_1) \otimes V_\ell(\sigma_2)\).

2.3. **Hermitian modules with Dirac cohomology.** Let \(\pi\) be an irreducible \((\mathfrak{g}, K)\)-module for a complex Lie group \(G\). By Theorem 1.1 and (5), \(\pi\) has Dirac cohomology if and only if its Zhelobenko parameter \((w_1\lambda_L, w_2\lambda_R)\) satisfies

\[
\begin{cases}
w_1\lambda_L - w_2\lambda_R = \tau + \rho \\
w_1\lambda_L + w_2\lambda_R = 0,
\end{cases}
\]

for some \(\tau, \rho \in \mathbb{R}\).
where $V_{t}(\tau)$ is a $\tilde{K}$–type in $H_{D}(\pi)$. The second equation implies $\lambda_{R} = -w_{2}^{-1}w_{1}\lambda_{L}$. Since $\tau + \rho$ is regular integral, the first equation implies that $2w_{1}\lambda_{L}$ is regular integral.

Write $\lambda = w_{1}\lambda_{L}$. The module can be written as $\pi = J(\lambda, -s\lambda)$ with $2\lambda$ regular integral, and the first equation of (5) implies that the only $\tilde{K}$–type that can appear in $H_{D}(\pi)$ is $V_{t}(2\lambda - \rho)$. Furthermore, if $J(\lambda, -s\lambda)$ is Hermitian (e.g. if $J(\lambda, -s\lambda)$ is unitary), it follows as in [BP] that $s$ is an involution.

Assume further that $\pi = J(\lambda, -s\lambda) \in \hat{G}$, i.e. it is unitary. To relate the above arguments in terms of Parthasarathy’s Dirac inequality, note that $V_{t}(\tau)$ is in $H_{D}(\pi)$ if and only if

$$2\lambda = \tau + \rho,$$

which is precisely when the equality holds in (4). Moreover, if $\pi$ contributes to $H_{D}(\pi)$, then by Theorem 2.2 it must come from the PRV component of

$$V_{t}(\eta) \otimes S_{G} = 2^{\frac{k}{2}} V_{t}(\eta) \otimes V_{t}(\rho),$$

where the equality comes from Lemma 2.2 of [BP]. This leads to the following definition given in [D1].

**Definition 2.3.** The spin norm of the $K$–type $V_{t}(\eta)$ is defined as

$$\|\eta\|_{\text{spin}} := \|\{\eta - \rho\} + \rho\|$$

For any irreducible admissible $(\mathfrak{g}, K)$–module $\pi$, we define

$$\|\pi\|_{\text{spin}} := \min \|\eta\|_{\text{spin}},$$

where $\eta$ runs over all the $K$–types occurring in $\pi$. A module $V_{t}(\eta)$ is called a spin-lowest $K$–type of $\pi$ if it occurs in $\pi$ and $\|\eta\|_{\text{spin}} = \|\pi\|_{\text{spin}}$.

Using the terminology in Definition 2.3, the results of this section can be summarized as follows.

**Proposition 2.4.** Let $\pi = J(\lambda, -s\lambda) \in \hat{G}$ with $2\lambda$ regular integral, and $s \in W$ an involution. Then $\|\pi\|_{\text{spin}} \geq \|2\lambda\|$, and the equality holds if and only if $J(\lambda, -s\lambda) \in \hat{G}^{d}$.

In such cases, if $V_{t}(\sigma_{1}), \ldots, V_{t}(\sigma_{k})$ are the spin-lowest $K$–types of $\pi$, then $H_{D}(\pi)$ consists of a single $\tilde{K}$–type $V_{t}(2\lambda - \rho)$ with multiplicity

$$[V_{t}(2\lambda - \rho) : H_{D}(\pi)] = \sum_{i} [V_{t}(\sigma_{i}) : \pi] \cdot [V_{t}(\sigma_{i}) \otimes S_{G} : V_{t}(2\lambda - \rho)]$$

$$= 2^{\frac{k}{2}} \sum_{i} [V_{t}(\sigma_{i}) : \pi] \cdot [V_{t}(\sigma_{i}) \otimes V_{t}(\rho) : V_{t}(2\lambda - \rho)]$$

$$= 2^{\frac{k}{2}} \sum_{i} [V_{t}(\sigma_{i}) : \pi].$$

Conjecture 1.6 takes on the following sharper form. This is the main result of the paper in the case of groups of classical type (including spin groups).
Conjecture 2.5. If \( \pi \in \hat{G} \), then

\[
[\pi \otimes V_\ell(\rho) : V_\ell(2\lambda - \rho)] := \sum_\kappa [V_\ell(\kappa) : \pi] \cdot [V_\ell(\kappa) \otimes V_\ell(\rho) : V_\ell(2\lambda - \rho)] = \begin{cases} 1 & \text{if } \pi \in \hat{G}^d \\ 0 & \text{otherwise} \end{cases}.
\]

3. Unitary Dual

We use the notation and terminology in the previous section. We determine the unitary representations \( J(\lambda, -s\lambda) \) with \( 2\lambda \) regular and integral; as already mentioned, \( s \) must be an involution. The results were first proved in [B] and [V1], and can be summarized as follows.

Theorem 3.1 ([B], [V1]). Let \( G \) be a classical complex Lie group. Any irreducible unitary representation \( \pi := J(\lambda, -s\lambda) \) of \( G \) with \( 2\lambda \) regular and integral must be of the form

\[
\pi := \text{Ind}_{LU}^G((\mathbb{C}_\mu \otimes \pi_u) \otimes 1),
\]

where \( P = LU \) is a parabolic subgroup of \( G \) with Levi factor \( L \), \( \mathbb{C}_\mu \) is a unitary character of \( L \), and \( \pi_u \) are the unipotent representations of \( L \) listed in Sections 5.4–5.6 of [BP]. For each type of factor in the Levi component, \( \pi_u \) is given as follows:

Type \( B_n \): The spherical unipotent representations

\[
\pi_u = \begin{cases} J \left( -b + 1/2, \ldots, -1/2; -a, \ldots, -1 \right), & \text{if } 0 < a \leq b \text{ integers and } a + b = n \end{cases},
\]

It has \( K \)-spectrum

\[
V_\ell(\alpha_1, \alpha_1, \ldots, \alpha_a, 0, \ldots, 0), \quad \alpha_1 \geq \cdots \geq \alpha_a \geq 0.
\]

Type \( C_n \): The Trivial representation \( J(\rho, \rho) \), and the Oscillator representations

\[
\pi_{u_{\text{even}}} = J \left( -n + 1/2, \ldots, -1/2 \right) \quad \text{and} \quad \pi_{u_{\text{odd}}} = J \left( -n + 1/2, \ldots, 1/2 \right),
\]

Their \( K \)-spectra are given by

\[
V_\ell(2k, 0, \ldots, 0) \quad \text{and} \quad V_\ell(2k + 1, 0, \ldots, 0), \quad k \geq 0
\]

Type \( D_n \): The unipotent representations

\[
\pi_{u_{\text{even}}} = J \left( -a + 1/2, \ldots, -3/2, -1/2, -b + 1, \ldots, 0 \right) \quad \text{and} \quad \pi_{u_{\text{odd}}} = J \left( -a + 1/2, \ldots, -3/2, -1/2, -b + 1, \ldots, 0 \right)
\]

with \( 0 < a \leq b \) integers and \( a + b = n \). Their \( K \)-spectra are

\[
V_\ell(\alpha_1, \ldots, \alpha_{2a}, 0, \ldots, 0), \quad \alpha_1 \geq \cdots \geq \alpha_{2a} \geq 0, \quad \sum_i \alpha_i \text{ is even/odd}.
\]
3.1. Bottom Layer $K$–types. We use the standard realizations of the classical groups and Lie algebras. As in [32], we will use the notion of relevant $K$–types to detect non-unitarity of $\pi$.

**Definition 3.2.** The $K$–types $V_{\ell}(1, \ldots, 1, 0, \ldots, 0, -1, \ldots, -1)$ with equal number of 1 and $-1$ for type $A$, and $V_{\ell}(1, \ldots, 1, 0, \ldots, 0)$ and $V_{\ell}(2, 1, \ldots, 1, 0, \ldots, 0)$ in types $B$, $C$, $D$ will be called cx-relevant. The ones with coordinates $\pm 1$ only, will be called fundamental cx-relevant.

We will make heavy use of bottom layer $K$–types as detailed in [KnV]. The special case of complex groups is in Section 2.7 of [B]. For the classical case, the results in coordinates are as follows. Write the lowest $K$–type of $J(\lambda, -s\lambda)$ as

$$\mu = (\ldots, r_1, \ldots, r_1, 1, 1, 0, \ldots, 0) = (\ldots, r_{\mu_r}, \ldots, 1^{\mu_1}, 0^{\mu_0}).$$

Let

$$M_1 = \prod_{r \geq 1} GL(\mu_r) \times G(\mu_0) \quad J_1 = \bigotimes_{r \geq 1} J_{GL(\mu_r)}(\lambda_{L_r}^0, \lambda_{R_r}^0) \otimes J_{G(\mu_0)}(\lambda_{L_0}^0, \lambda_{R_0}^0)$$

$$M_2 = \prod_{r \geq 2} GL(\mu_r) \times G(\mu_1 + \mu_0) \quad J_2 = \bigotimes_{r \geq 2} J_{GL(\mu_r)}(\lambda_{L_r}^0, \lambda_{R_r}^0) \otimes J_{G(\mu_1 + \mu_0)}(\lambda_{L_1}^0 \cup \lambda_{L_0}^0, \lambda_{R_1}^0 \cup \lambda_{R_0}^0)$$

be Levi components of real parabolic subalgebras containing the centralizer of $\mu$, and irreducible modules. Let

$$I_1 := \text{Ind}_{M_1}^G(J_1)$$
$$I_2 := \text{Ind}_{M_2}^G(J_2)$$

be induced modules containing $J(\lambda, -s\lambda)$. We only specify the information on the Levi subgroup for parabolic induction when there is no danger of confusion. Bottom layer $K$–types are of the form $\mu_i = \mu + \mu_{M_i}$ where $\mu_{M_i}$ are $K \cap M_i$–types in $J_i$ so that $\mu_i$ is dominant. They possess the crucial property that the multiplicities and signatures of $\mu_{M_i}$ on the $J_i$ and $\mu_i$ in the induced modules in (9) and the lowest $K$–type factor $J$ coincide. By Section 2.7 of [B], bottom layer $K$–types for $I_1$ are obtained by adding $(1, \ldots, 1, 0, \ldots, 0, -1, \ldots, -1)$ (equal number of 1 and $-1$) to the coordinates equal to $r \geq 1$ in $\mu$. In addition one can add $(1, \ldots, 1, 0, \ldots, 0)$ to the coordinates of $\mu$ equal to 0; an even number in cases $C$, $D$. For $I_2$, there are extra bottom layer $K$–types obtained by replacing the coordinates $(1^{\mu_1}, 0^{\mu_0})$ with $(2^{\mu_2}1^{\mu_1}, 0^{\mu_0})$ which also denote a $K \cap M_2$–type coming from $J_{G(\mu_1 + \mu_0)}$. 

**Proposition 3.3.** Assume that $\lambda$ is half-integral regular. The parameter $(\lambda_L^r, \lambda_R^r)$ in (9) for $r \geq 1$ consists of at most two strings,

$$
\begin{pmatrix}
A, & \ldots, & \frac{r}{2} + 1, & \frac{r}{2}, & \frac{r}{2} - 1, & \ldots, & a \\
-a, & \ldots, & -\frac{r}{2} + 1, & -\frac{r}{2}, & -\frac{r}{2} - 1, & \ldots, & -A
\end{pmatrix},
$$

and/or

$$
\begin{pmatrix}
B, & \ldots, & \frac{r+1}{2}, & \frac{r-1}{2}, & \frac{r-1}{2}, & \ldots, & b \\
-b, & \ldots, & -\frac{r+1}{2}, & -\frac{r-1}{2}, & -\frac{r-1}{2}, & \ldots, & -B
\end{pmatrix}
$$

only $(a + A = r, \text{ and } B + b = r)$.

**Proof.** The irreducible module $J_{GL(\mu)}(\lambda_L^r, \lambda_R^r)$ in (9) has $1-$dimensional lowest $K-$type. The condition that $2\lambda$ be regular integral implies that $J(\lambda_L^r, \lambda_R^r)$ is unitarily induced irreducible from a finite dimensional $J_e \times J_o$ of a Levi component $GL_e \times GL_o \subset GL(\mu)$. Since finite dimensional representations have indefinite form on $K-$types $(r+1, \ldots, r, \ldots, r)$ and $(r, \ldots, r)$, the form on these $K \cap M_2-$types is indefinite unless $J_e$ and $J_o$ are unitary characters. Since these give rise to bottom layer $K-$types, $J$ is unitary only if $J(\lambda_L^r, \lambda_R^r)$ is unitary and induced from unitary characters. So $(\lambda_L^r, \lambda_R^r)$ must consist of at most two strings as in the statement of the Proposition. $\square$

**Corollary 3.4.** Assume $\mu_1 \neq 0$. Then

$$(\lambda_L^r, \lambda_R^r) = \begin{cases} 
\left( \begin{array}{c}
\frac{1}{2} \\
-\frac{1}{2}
\end{array} \right) & \text{in types } B, C \\
\left( \begin{array}{c}
\frac{1}{2} \\
-\frac{1}{2}
\end{array} \right) & \text{or } \left( \begin{array}{c}
1, 0 \\
0, -1
\end{array} \right) \text{ in type } D.
\end{cases}$$

**Proof.** The statement is a direct consequence of the fact that $2\lambda$ is assumed regular integral. $\square$

We consider $J_{G(\mu_1 + \mu_0)}(\lambda_L^1, \lambda_L^0, \lambda_R^1, \lambda_R^0)$ appearing in $J_2$ of (9). A consequence of Proposition 3.3 and Corollary 3.4 is that we can write the parameter as

$$(10) \quad (\lambda_{rel}, -s_{rel} \lambda_{rel}) := (\lambda^1, \lambda^0, -\lambda^1, \lambda^0) \quad \text{with} \quad \lambda^1 = \left( \begin{array}{c}
1, 1, 1, 1 \\
\mu_1
\end{array} \right) \quad \mu_1 = 0, 1, 2.$$

Specifically, $\lambda_{rel} = (\lambda^1, \lambda^0)$ and $s_{rel}$ is an involution so that $s_{rel}(\lambda^1, \lambda^0) = (-\lambda^1, \lambda^0)$.

**Theorem 3.5.** Assume that the parameter is half-integral regular, and $\mu_r = 0$ for $r \geq 2$ so that $\lambda = \lambda_{rel}$. Then $J(\lambda, -s_{rel} \lambda)$ is unitary if and only if it is of the form given in Theorem 3.1, i.e. unipotent tensored with a unitary character. When it is not unitary, the form is indefinite on $cx$-relevant $K-$types.
Corollary 3.6. Let $J(\lambda, -s\lambda)$ be an irreducible module with half integral regular infinitesimal character. Then Theorem 3.1 holds.

Proof. The Corollary (and therefore Theorem 3.1) follows immediately from properties of bottom layer $K$-types. Suppose $J(\lambda_{rel}, -s_{rel}\lambda_{rel})$ is not of the form given in Theorem 3.1. Then by Proposition 3.5 it must be non-unitary, which has indefinite form on cx-relevant $K$-types. Since all cx-relevant $K$-types are bottom layer in $I_2$, this implies that $J(\lambda, -s\lambda)$ is not unitary.

On the other hand, if $J(\lambda_{rel}, -s_{rel}\lambda_{rel})$ is of the form given in Theorem 3.1, then by induction in stages $I_2$ is of the form given by Theorem 3.1, with $J(\lambda, -s\lambda)$ being its lowest $K$-type subquotient. Since it is a subquotient of the unitary module $I_2$, $J$ is unitary. A sharper result holds – by Theorem 14.1 of [B], $I_2 = J(\lambda, -s\lambda)$. □

3.3. General Strategy. By the corollary above, it suffices to prove Theorem 3.5. In particular, when the parameter is not as in Theorem 3.1, the form is indefinite on a cx-relevant $K$-type. These give rise to bottom layer $K$-type in the general case.

To treat the case $J((\lambda^1, \lambda^0), (-\lambda^1, \lambda^0))$ given in Theorem 3.3, the spherical case $J(\lambda^0, \lambda^0)$ plays an important role. Write $\lambda = \lambda^0$ from now on. We define a parabolic subgroup $P(\lambda)$ and a representation $\pi_{L(\lambda)}$ on its Levi component so that the induced module $I_{P(\lambda)} := \text{Ind}^G_{P(\lambda)}(\pi_{L(\lambda)})$ is Hermitian, and the cx-relevant $K$-types occur with full multiplicity in the spherical subquotient $J(\lambda, \lambda)$. The induction step proceeds as follows. Deform $\lambda$ and the induced module $I_{P(\lambda)}$ to $\lambda + t\nu$ where $\nu$ is central for $L(\lambda)$, so that the norm of the parameter becomes larger, and the multiplicities of the cx-relevant $K$-types do not change for small $t$. Let $t_0 > 0$ be the nearest where the multiplicities change; $P(\lambda + t_0\nu)$ changes as well. If the condition in Theorem 3.1 are not satisfied, the induction hypothesis holds, so the form is indefinite on cx-relevant $K$-types, and the semi-continuity of the signature implies that the form was indefinite on cx-relevant $K$-types at $t = 0$. The exceptions are when $J(\lambda + t_0\nu, \lambda + t_0\nu)$ is unitary, or the deformation goes on to “∞”. In the first case we find a nonspherical factor in the deformed induced module with a pair of indefinite cx-relevant $K$-types. In the second case, the Casimir inequality implies that the form is indefinite on the trivial and adjoint $K$-types.

We will henceforth concentrate on the cases when $\lambda$ is NOT regular integral. The cases when $\lambda$ is regular integral, are covered by [E]; the unipotent representations occurring are $\pi_u = \text{Triv}$.

4. Proof of Theorem 3.5 – Type B

In this case $K = SO(2m + 1)$. The $K$-types have highest weights $\eta$ with coordinates integers only. Since $\rho = (m - 1/2, \ldots, 1/2)$, $2\lambda = \{\eta - \rho\} + \rho$, $2\lambda$ must have integer coordinates only; so $\lambda$ has integer and half-integer coordinates. Since we assume that $\lambda$ is regular half-integral but not integral, the integral system determined by $\lambda$ is type $C \times C$. 
4.1. Spherical Representations. In the next few subsections, we will prove the following Proposition.

**Proposition 4.1.** Let $\lambda$ be regular half-integral. The spherical irreducible module $J(\lambda, \lambda)$ is unitary if and only it is unipotent, i.e. the parameter is

$$\lambda = \left( -K_0 + \frac{1}{2}, \ldots, -\frac{1}{2}; -N_0, \ldots, -1 \right)$$

with $N_0 \leq K_0$. This is a unipotent representation attached to the nilpotent orbit $[2^{2N_0}, 1^{2K_0-2N_0+1}]$.

When not unitary, the form is indefinite on the set of cx-relevant $K-$types with highest weights

$$CXB := \{(0, \ldots, 0), \quad (1, \ldots, 1, 0, \ldots, 0), \quad (2, 0, \ldots, 0)\}.$$

The unipotent representation in Proposition 4.1 is unitary because it can be realized via the dual pair correspondence as $\Theta(\text{triv}_{Sp})$, from the pair $Sp(2N_0, \mathbb{C}) \times SO(2K_0+2N_0+1, \mathbb{C})$ in the stable range.

In order to prove the non-unitarity of other parameters, we use the strategy in Section 3.3. We construct an induced module $I_{P(\lambda)}$ having $J(\lambda, \lambda)$ as a quotient. Let $\lambda$ be half-integral and dominant for the standard positive system, i.e.

$$\lambda = (\ldots \lambda_i \geq \lambda_{i+1} \geq \cdots \geq 0), \quad 2\lambda_i \in \mathbb{N}.$$ 

If $\lambda$ is further assumed to be regular, then the above inequalities are strict. We construct a parabolic subgroup $P(\lambda) = L(\lambda)U(\lambda)$ and an induced module $I_{P(\lambda)}$ so that $J(\lambda, \lambda)$ is the spherical irreducible factor in $I_{P(\lambda)}$, and the multiplicities of the cx-relevant $K-$types are the same.

(i) If $1/2$ is a coordinate of $\lambda$, form the longest string

$$\kappa_0 := (-K_0 + 1/2, \ldots, -1/2)$$

such that all the half-integers starting from $1/2$ to $K_0 - 1/2$ are coordinates of $\lambda$, but $K_0 + 1/2$ is not. If the coordinate 1 occurs, form the longest string

$$\sigma_0 := (-N_0, \ldots, -1)$$

where $N_0$ is the largest integer coordinate that occurs in $\lambda$, but $N_0 + 1$ does not. Add a factor to $L(\lambda)$ of type $G(K_0 + N_0) = SO(2K_0 + 2N_0 + 1)$ and the spherical irreducible representation with parameter

$$\left( -K_0 + 1/2 \quad \ldots \quad -1/2 \quad ; \quad -N_0 \quad \ldots \quad -1 \right)$$

$$\left( -K_0 + 1/2 \quad \ldots \quad -1/2 \quad ; \quad -N_0 \quad \ldots \quad -1 \right)$$

If $1/2$ is not a coordinate, let $k_1 - 1/2 > 0$ be the smallest half-integer coordinate, and form the string $\kappa_1 = (k_1 - 1/2, \ldots, K_1 - 1/2)$ with increasing coordinates differing by 1 as before. Add a factor $GL(K_1 - k_1 + 1)$, and the 1-dimensional representation of $GL(K_1 - k_1 + 1)$ with parameter

$$\left( k_1 - 1/2 \quad \ldots \quad K_1 - 1/2 \right)$$

$$\left( k_1 - 1/2 \quad \ldots \quad K_1 - 1/2 \right)$$
to $L(\lambda)$. Similarly if 1 does not occur as a coordinate, form $\sigma_1 = (n_1, \ldots, N_1)$, add a factor $GL(N_1 - n_1 + 1)$ to the Levi component $L(\lambda)$, and the 1-dimensional representation of $GL(N_1 - n_1 + 1)$ with parameter

$$\left( \begin{array}{c} n_1 \\ n_1 \end{array} , \ldots , N_1 \right).$$

(ii) Remove the coordinates in Step (i) from $\lambda$, and repeat on the remainder until there are no half-integer coordinates left. Since the assumption was that at most one coordinate was equal to $1/2$, only $GL$–factors are created.

(iii) Repeat Steps (i) and (ii) on the integer coordinates until there are none left. The process produces a parabolic subgroup, and an induced module on its Levi component. The Levi component is

$$(11) \quad L(\lambda) := \prod_{i>0} GL(\sigma_j) \times \prod_{j>0} GL(\kappa_i) \times G(K_0 + N_0).$$

If $\lambda$ is assumed to be regular, its corresponding strings $\kappa_i, \sigma_j$ satisfy

$$(12) \quad \begin{cases} k_i > 2 & \text{if } 1/2 \text{ is a coordinate}, \\ k_i \geq 2 & \text{otherwise} \end{cases} \quad \text{and} \quad \begin{cases} n_j > 2 & \text{if } 1 \text{ is a coordinate}, \\ n_j \geq 2 & \text{otherwise} \end{cases}$$

In the proof of Proposition 4.1 below, we begin with $J(\lambda, \lambda)$ where $\lambda$ is regular and half-integral. Then we deform some $GL$–strings $\kappa_i, \sigma_j, i, j > 0$ upward and analyze the new parameter $\lambda_{new}$ and its corresponding induced module $I(\lambda_{new})$. Here $\lambda_{new}$ is half-integral but is not necessarily regular (see Example 4.3 below). Nevertheless, by the above construction of $\kappa$ and $\sigma$–strings, it is easy to see that the more general parameters satisfy

$$(13) \quad \begin{cases} k_{i+1} - K_i \geq 2, & \text{or} \\ k_i \leq k_{i+1} \leq K_{i+1} \leq K_i, & \end{cases} \quad \text{and} \quad \begin{cases} n_{j+1} - N_j \geq 2, & \text{or} \\ n_i \leq n_{i+1} \leq N_{i+1} \leq N_i & \end{cases}.$$

We say the strings $\kappa_i, \kappa_{i+1}$ (or $\sigma_j, \sigma_{j+1}$) nested if its parameters satisfy (13) for all $i, j \geq 0$. The parabolic subgroup is determined by the order of the factors, and the integer and half-integer strings are interchangeable.

The main property of the cx-relevant $K$–types is the following Lemma.

**Lemma 4.2.** Let $\lambda$ be dominant whose coordinates are half-integers. Assume that the strings of $\lambda$ satisfy (12) and (13). The multiplicities of the cx-relevant $K$–types in $I_{P(\lambda)}$ coincide with those in $J(\lambda, \lambda)$.

**Proof.** This kind of result can be found in [B2] and [BW]. The main difference is that $(2, 0, \ldots, 0)$ is not petite/single petaled. The condition that the value of $\bar{\alpha}$ for $\alpha$ a long root on the highest weight of the $K$–type be $\leq 3$ is satisfied except for the case of $(2, 0, \ldots, 0)$ and a long root. The crucial property needed is that $SL(2)$–intertwining operators be isomorphisms on these $K$–types. Condition (12) insures that this property is still valid for the larger class of $K$–types. We sketch the steps.
Recall that $\lambda$ was assumed dominant. Then $J(\lambda, \lambda)$ is the image of the long intertwining operator from $I_B(\lambda, \lambda)$ to $I_B(-\lambda, -\lambda)$. The module $I_{P(\lambda)}$ is a homomorphic image of $I_B(\lambda, \lambda)$. The long intertwining operator $A_{w_0}$ factors into

$$I_B(\lambda, \lambda) \rightarrow I_{P(\lambda)} \rightarrow I_B(-\lambda, -\lambda).$$

We only need to show that the intertwining operator on the right is an injection on the cx-relevant $K$–types. We need to “flip” the coordinates of the $\kappa_i$ and $\sigma_j$ into their negatives. This is done by embedding into a larger induced module where it is possible to factor the operator further into ones induced from $SL(2)_{/\mathbb{R}}$. Condition (12) insures that they are isomorphisms on the restrictions of the cx-relevant $K$–types. This is also the reason that we have put $\kappa_0$ and $\sigma_0$ into the Levi component.

4.2. Proof of Proposition 4.1 – $\lambda = \sigma_0$ or $\kappa_0 \cup \sigma_0$. If only $\sigma_0$ occurs, this is the $(\mathfrak{g}, K)$–module $\text{Spin} \otimes \text{Spin}$, and the form is indefinite on the spherical and adjoint $K$–types. Furthermore, the case when $\lambda = \kappa_0 \cup \sigma_0$ with $K_0 \geq N_0$ is unitary. So assume

$$\lambda = \kappa_0 \cup \sigma_0 \quad \text{satisfying} \quad N_0 > K_0 \geq 1.$$  

Let

$$\text{Ind}(\lambda_t) := \text{Ind}^{G_{\text{GL}(\sigma_0) \times G(K_0)}}((1 + t, \ldots, N_0 + t) \otimes \text{triv}),$$

By the same arguments as in Lemma 4.2, the signatures and multiplicities of the fundamental cx-relevant $K$–types on $V_t(1, \ldots, 1, 0, \ldots, 0)$ coincide on $\text{Ind}(\lambda_0)$ and $J(\lambda, \lambda)$. This statement does not hold for $V_4(2, 0, \ldots, 0)$. These values remain unchanged for all $\text{Ind}(\lambda_t)$ with $t \in [0, 1/2]$ because the multiplicities do not change. At $t = 1/2$,

$$\lambda_{1/2} = (3/2, 5/2, \ldots, N_0 + 1/2; -K_0 + 1/2, \ldots, -1/2)$$

$$= (-N_0 - 1/2, \ldots, -1/2) \cup (3/2, \ldots, K_0 - 1/2).$$

So the induced module $I_{P(\lambda_{1/2})}$ defined in Section 4.1 is given by

$$I_{P(\lambda_{1/2})} = \text{Ind}^{G_{\text{GL}(K_0 - 1) \times G(N_0)}}((3/2, \ldots, K_0 - 1/2) \otimes \text{triv}),$$

and differs from $\text{Ind}(\lambda_{1/2})$. More precisely, apart from $J(\lambda_{1/2}, \lambda_{1/2})$, $\text{Ind}(\lambda_{1/2})$ has a non-spherical irreducible factor whose parameter is given by

$$\begin{pmatrix} 1/2, \ldots, K_0 - 1/2; & 3/2, \ldots, K_0 + 1/2; & K_0 + 3/2, \ldots, N_0 + 1/2 \\ 3/2, \ldots, K_0 + 1/2; & 1/2, \ldots, K_0 - 1/2; & K_0 + 3/2, \ldots, N_0 + 1/2 \end{pmatrix}$$

This module has indefinite form on the $K$–types $V_t(\underbrace{1, \ldots, 1, 0, \ldots, 0}_{2K_0})$

$$\begin{cases} V_t(\underbrace{1, \ldots, 1, 1}_{2K_0}) & \text{if } N_0 = K_0 + 1; \\
V_t(\underbrace{1, \ldots, 1, 1, 0, \ldots, 0}_{2K_0}) & \text{otherwise} \end{cases}$$
Indeed, the second $K$–type is bottom layer for the parabolic subgroup with Levi component $GL(K_0) \times G(N_0 - K_0)$. The spherical part of the parameter \( \left( \frac{K_0 + 3}{2}, \ldots, \frac{N_0 + 1}{2} \right) \) is a finite dimensional representation of $G(N_0 - K_0)$, so the form is indefinite on the trivial and adjoint $K$–types.

Consequently, by semicontinuity of signatures, $Ind(\lambda_0)$ and $J(\lambda, \lambda)$ also have indefinite form on the $K$–types given in (15).

4.3. Proof of Proposition 4.1 – Other Strings. Assume $\lambda$ contains strings other than $\kappa_0$ and $\sigma_0$. We do an induction upward on the length of the parameter, downward on the number of strings.

Assume there is a $\kappa_i = (k_i - 1/2, \ldots, K_i - 1/2)$ with $i > 0$ or $\sigma_j = (n_j, \ldots, N_j)$ with $j > 0$. Replace it by $(k_i - 1/2 + t, \ldots, K_i - 1/2 + t)$ (or $(n_j + t, \ldots, N_j + t)$), and denote the new parameter by $\lambda_t$. At $t = 0$, $I_{P(\lambda)} = I_{P(\lambda_0)}$, and the signatures of cx-relevant $K$–types do not change for $0 \leq t < 1/2$. At $t = 1/2$, if the induction hypothesis (condition for the form to be indefinite on the cx-relevant $K$–types) holds for $J(\lambda_1/2, \lambda_1/2)$ we conclude that $J(\lambda, \lambda)$ is not unitary, with form indefinite on the cx-relevant $K$–types. It may happen that $I_{P(\lambda_t)}$ is unchanged, and we can continue to deform $t$ upward. $I_{P(\lambda)}$ may be unchanged as $t \to \infty$. In this case the form is indefinite on the adjoint $K$–type $V_t(1, 1, 0, \ldots, 0)$. We call this an initial case. The other case is when the spherical module $J(\lambda_1/2, \lambda_1/2)$ is unitary. This is the case $\sigma_0 \cup \kappa_0$ with $K_0 \geq N_0$. Note that it includes the case when the spherical module is the trivial representation.

In summary, these cases, which we call initial cases are

(a) There is a string $\kappa_i$ or $\sigma_j$ with $i, j > 0$ such that $P(\lambda_t)$ does not change as $t \to \infty$,
(b) The strings are

\[ (-K_0 + 1/2, \ldots, -1/2; -N_0, \ldots, -1) \quad \text{with} \quad K_0 < N_0 \]
as in the previous Subsection.
(c) The strings are $(-K_0 + 1/2, \ldots, -1/2; -N_0, \ldots, -1) \cup \xi_1$ satisfying

\[ \xi_1 = (K_0, \ldots, K_1) \text{ or } (N_0 + 1/2, \ldots, N_1 + 1/2), \]

so that the deformation to $t = 1/2$ yields a unitary spherical module. This means that $K_1 \leq N_0$ in one case, $N_1 \geq K_0$ in the other case. See Example 4.3 for more details. In Case (a), as already mentioned, the Casimir inequality implies that the spherical irreducible module at $t = 1/2$ has indefinite form on the trivial and adjoint $K$–types $V_t(0, \ldots, 0)$ and $V_t(1, 1, 0, \ldots, 0)$.

Case (b) was discussed in the previous Subsection.

For Case (c), we give details for $\xi_1 = (K_0)$. The other $\xi_1$ are similar. $I_{P(\lambda_{1/2})}$ has another irreducible factor with parameter containing

\[
\begin{pmatrix}
-K_0 + 1/2 & -K_0 - 1/2 & K_0 - 3/2 & \cdots & 1/2 \\
-K_0 - 1/2 & -K_0 + 1/2 & K_0 - 3/2 & \cdots & 1/2 \\
\end{pmatrix}
\]

with the rest of the spherical part formed of integer coordinates coming from $\sigma_0$. 

14 DAN BARBASCH, CHAO-PING DONG, AND KAYUE DANIEL WONG
The lowest $K$–type is $V_\ell(1, 1, 0, \ldots, 0)$ and $V_\ell(2, 0, \ldots, 0)$ is bottom layer. Since for such a parameter the form on the $GL(2)$–factor is indefinite on $(1, 1)$ and $(2, 0) = (1, 1) + (1, -1)$, semicontinuity of the signature implies the same for the parameter at $\lambda$.

The proof of Proposition 4.1 is now complete. □

Example 4.3. Let $\lambda = (-11/2, -9/2, -7/2, -5/2, -3/2, -1/2; -1) \cup (3, 4) \cup (6)$. Note that $\kappa_0$ is longer than $\sigma_0$. Deform all $\sigma_i$ into $\kappa_i$ for $i > 0$:

$$\lambda = (-11/2, -9/2, -7/2, -5/2, -3/2, -1/2; -1) \cup (3, 4) \cup (6)$$
$$\rightarrow (-11/2, -9/2, -7/2, -5/2, -3/2, -1/2; -1) \cup (7/2, 9/2) \cup (13/2)$$
$$= (-13/2, -11/2, -9/2, -7/2, -5/2, -3/2, -1/2; -1) \cup (7/2, 9/2)$$

Deform the new $\kappa_i$ for $i > 0$ and get

$$(-13/2, -11/2, -9/2, -7/2, -5/2, -3/2, -1/2; -1) \cup (7/2, 9/2)$$
$$\rightarrow (-13/2, -11/2, -9/2, -7/2, -5/2, -3/2, -1/2; -1) \cup (13/2)$$
$$= (-15/2, -13/2, -11/2, -9/2, -7/2, -5/2, -3/2, -1/2; -1) \cup (13/2)$$
$$\rightarrow (-17/2, -15/2, -13/2, -11/2, -9/2, -7/2, -5/2, -3/2, -1/2; -1) \cup (9)$$

and we are in Case (c) above.

4.4. Nonspherical Case. By Theorem 4.5, the critical case is $\mu_1 > 0$. If $\mu_1 > 0$, there is no $\kappa_0$, or else the regularity condition is violated. The form on the spherical part of the parameter is indefinite on $V_\ell(1, \ldots, 1, 0, \ldots, 0)$ which give rise to a bottom layer $K$–type. If $\mu_1 = 0$, the $K$–type $V_\ell(2, 0, \ldots, 0)$ also gives rise to a bottom layer $K$–type as well; see the Section on $\lambda = \kappa_0 \cup \sigma_0$. So the parameter is unitary only if the spherical part is unitary; and in this case the representation is a factor in a unitarily induced module from a unitary one.

4.5. Spin Groups. This is the case of genuine representations of $G = \text{Spin}(2n + 1, \mathbb{C})$ The $K$–types have highest weights with half-integer coordinates only. As already mentioned, $\rho = (m - 1, \ldots, 1, 0)$, so $2\lambda = \{\eta - \rho\} + \rho$ must have half-integer coordinates only. The integral system for $\lambda$ is type A.

4.6. Lowest $K$–type Spin. We assume the lowest $K$–type of $J(\lambda_L, \lambda_R)$ is

$$V_\ell(1/2, \ldots, 1/2).$$

The parameter is

$$\lambda_L = \left(\frac{1}{4}, \ldots, \frac{1}{4}\right) + (\nu_1, \ldots, \nu_k, -\nu_k, \ldots, -\nu_1)$$
$$\lambda_R = \left(-\frac{1}{4}, \ldots, -\frac{1}{4}\right) + (\nu_1, \ldots, \nu_k, -\nu_k, \ldots, -\nu_1)$$

or

$$\lambda_L = \left(\frac{1}{4}, \ldots, \frac{1}{4}\right) + (\nu_1, \ldots, \nu_k, 0, -\nu_k, \ldots, -\nu_1)$$
$$\lambda_R = \left(-\frac{1}{4}, \ldots, -\frac{1}{4}\right) + (\nu_1, \ldots, \nu_k, 0, -\nu_k, \ldots, -\nu_1)$$

(16)
The symmetry $\nu_i \leftrightarrow -\nu_i$ follows from the assumption that the parameter must be hermitian. Since $2\lambda_L = (\frac{1}{2} + 2\nu_1, \ldots, \frac{1}{2} - 2\nu_1)$ must be regular integral consisting of half-integers, it follows that

\begin{equation}
2\nu_i \in \mathbb{Z} \text{ for all } i,
\end{equation}

satisfying $\nu_i \pm \nu_j \neq 0$, and $\nu_i \neq 0$.

4.6.1. Separate the $\nu_i$ into integers $\nu_a$ and half-integers $\nu_b$. The hermitian property implies that $\nu_a$ must be conjugate to $-\nu_a$ by the symmetric group, and similarly for $\nu_b$.

There are two finite dimensional hermitian representations $F_a$ and $F_b$ (with lowest $K$-types $(\frac{1}{2}, \ldots, \frac{1}{2})$) so that

\begin{equation}
J(\lambda_L, \lambda_R) = \text{Ind}_{GL \times GL}^G (F_a \otimes F_b).
\end{equation}

The restriction of $(\frac{3}{2}, \frac{1}{2}, \ldots, \frac{1}{2})$ to $GL$ contains

\[ (\frac{3}{2}, \frac{1}{2}, \ldots, \frac{1}{2}) = (\frac{1}{2}, \ldots, \frac{1}{2}) + (1, 0, \ldots, 0, -1). \]

As in the previous sections, unless $F_a, F_b$ are unitary characters, the restriction of the form on the $K$-types $(\frac{3}{2}, \frac{1}{2}, \ldots, \frac{1}{2}, \frac{1}{2})$ and $(\frac{1}{2}, \ldots, \frac{1}{2})$ is indefinite.

5. Proof of Theorem 3.5 – Type C

In this case, $K = Sp(2m)$. The $K$-types have highest weights $\eta$ formed of integers only. Since $\rho = (m, \ldots, 1)$, $2\lambda = \{\eta - \rho\} + \rho$ must have positive integer coordinates only. So $\lambda$ must have integers and half integer coordinates only. Since $\lambda$ is regular half-integral but not integral, the integral system determined by $\lambda$ is type $B \times D$.

5.1. Spherical Representations.

**Proposition 5.1.** Let $\lambda$ be regular half-integral. The spherical irreducible module $J(\lambda, \lambda)$ is unitary if and only if it is unipotent, i.e. the parameter is

\[ \lambda = \left(-K_0 + \frac{1}{2}, \ldots, -\frac{1}{2}\right) \]

or

\[ \lambda = (-N_0, \ldots, -1) \]

The first representation is the spherical component of the Oscillator Representation attached to the nilpotent orbit $[2^{2N_0 - 2}]$, and the second case is the Trivial Representation attached to $[1^{2N_0}]$.

When not unitary, the form is indefinite on the set of $cx$-relevant $K$-types with highest weights

\[ CXC := \{(0, \ldots, 0), (1, 1, 0, \ldots, 0), (2, 0, \ldots, 0)\}. \]
Unlike Types $B$ or $D$, only $(1,1,0,\ldots,0)$, rather than $(1,\ldots,1,0,\ldots,0)$ suffices. The only cases when the indefiniteness of the form involves $V_{i}(2,0,\ldots,0)$, is when there is a deformation to a single string $\kappa_{i}$ or $\sigma_{j}$ satisfying $i,j>0$. For example, this holds for a pair of strings $(8,9),(7/2,9/2,11/2)$.

The proof will be given in the next subsection. The unipotent representation is unitary because, when not the Trivial module, it is the Spherical component of the Oscillator representation.

As in the case of Type $B$, we construct a parabolic subgroup $P(\lambda) = L(\lambda)U(\lambda)$ and an induced module $I_{P(\lambda)}$ so that $J(\lambda,\lambda)$ is the spherical irreducible factor in $I_{P(\lambda)}$, and the multiplicities of the ex-relevant $K$-types coincide in the two modules. Write $\lambda$ dominant for the standard positive system, i.e.

$$\lambda = (\ldots \lambda_{i} \geq \lambda_{i+1} \geq \cdots \geq 0), \quad 2\lambda_{i} \in \mathbb{Z}.$$ 

Since the parameters we are going to study are obtained by deforming a regular parameter upward, we can further assume that all $\lambda_{i}$ are positive.

(i) If $1/2$ is a coordinate of $\lambda$, form the longest string

$$\kappa_{0} = (-K_{0} + 1/2, \ldots, -1/2)$$

such that all the half-integers starting from $1/2$ to $K_{0} - 1/2$ are coordinates of $\lambda$, but $K_{0} + 1/2$ is not. If the coordinate $1$ occurs, form the longest string

$$\sigma_{0} = (-N_{0}, \ldots, -1)$$

where $1, \ldots, N_{0}$ occur as coordinates in $\lambda$, but $N_{0}+1$ does not. Add a factor of $L(\lambda)$ of type $G(K_{0} + N_{0}) = Sp(2K_{0} + 2N_{0})$ and the spherical irreducible representation with parameter

$$\begin{pmatrix} -K_{0} + 1/2 & \cdots & -1/2 & -N_{0} & \cdots & -1 \\ -K_{0} + 1/2 & \cdots & -1/2 & -N_{0} & \cdots & -1 \end{pmatrix}$$

If $1/2$ is not a coordinate, let $k_{1} - 1/2 > 0$ be the smallest half-integer coordinate, and form the longest string $\kappa_{1} = (k_{1} - 1/2, \ldots, K_{1} - 1/2)$ increasing by 1, as before. Add a factor $GL(K_{1} - k_{1} + 1)$, and the 1-dimensional representation with parameter

$$\begin{pmatrix} k_{1} - 1/2 & \cdots & K_{1} - 1/2 \\ k_{1} - 1/2 & \cdots & K_{1} - 1/2 \end{pmatrix}$$

to $M(\lambda)$. Similarly if $1$ does not occur as a coordinate, form $\sigma_{1} = (n_{1}, \ldots, N_{1})$ and add a factor $GL(N_{1} - n_{1} + 1)$ to the Levi component $M(\lambda)$.

(ii) Remove the coordinates in Step (i) from $\lambda$, and repeat on the remainder until there are no half-integer coordinates left. Since the assumption was that at most one coordinate was equal to $1/2$, only $GL-$factors are created.

(iii) Repeat Steps (i) and (ii) on the integer coordinates until there are none left.

the
\( K \) certain
The proof follows the one for the analogous result in Type B. We have to show that
Proof.
The main property of the \( cx \)-relevant \( K \)-types is the same in \( I_{P(\lambda)} \) and \( J(\lambda, \lambda) \).
Lemma 5.2. Let \( \lambda \) be such that (20) and (21) are satisfied. The multiplicities of the
\( cx \)-relevant \( K \)-types is the same in \( I_{P(\lambda)} \) and \( J(\lambda, \lambda) \).
Proof. The proof follows the one for the analogous result in Type B. We have to show that
certain \( SL(2)_{\alpha} \)-operators are isomorphisms. For the \( cx \)-relevant \( K \)-types this follows from conditions (20) and (21) and the fact that the coordinates of the highest weights of
the \( K \)-types are \( \leq 2 \).

5.2. Proof of Proposition 5.1 – \( \lambda = \sigma_0 \cup \kappa_0 \). We claim that if
\( \lambda = \kappa_0 \cup \sigma_0 \), the form is indefinite on fundamental \( cx \)-relevant \( K \)-types. The induced module
\( \text{Ind}_{GL(K_0) \times G(N_0)}[(1/2, \ldots, K_0 - 1/2) \times (-N_0, \ldots, -1)] \)
admits the deformation
\( (1/2 + t, \ldots, K_0 - 1/2 + t) \times (-N_0, \ldots, -1) \)
where the multiplicities of the fundamental \( cx \)-relevant \( K \)-types of the form \( V_\lambda(1, \ldots, 1, 0, \ldots, 0) \) coincide with
those in \( J(\lambda, \lambda) \) for all \( 0 \leq t < 1/2 \). At \( t = 1/2 \), there spherical parameter acquires a \( \sigma_1 \) or
\( \kappa_1 \). The induction hypothesis applies.
The previous results reduce considerations to the initial case when the spherical parameter at \( t = 1/2 \) is either the Trivial representation, or the spherical component of the oscillator representation. These are
\( (-K_0 + 1/2, \ldots, -1/2) \cup (K_0, \ldots, K_1) \) or \( (-N_0, \ldots, -1) \cup (N_0 + 1/2, \ldots, N_1 + 1/2) \)
The argument for type B applies. At \( t = 1/2 \) there is another factor
\[
\begin{pmatrix}
K_0 + 1/2 & -K_0 + 1/2 & K_1 + 1/2 & \ldots & K_0 + 3/2 & K_0 - 3/2 & \ldots & 1/2 \\
K_0 - 1/2 & -K_0 - 1/2 & K_1 + 1/2 & \ldots & K_0 + 3/2 & K_0 - 3/2 & \ldots & 1/2
\end{pmatrix}
\]
respectively
\[
\begin{pmatrix}
N_0 + 1 & -N_0 & N_1 + 1 & \ldots & N_0 + 2 & N_0 - 1 & \ldots & 1 \\
N_0 - 1 & -N_0 - 1 & N_1 + 1 & \ldots & N_0 + 2 & N_0 - 1 & \ldots & 1
\end{pmatrix}
\]
The $K$-types $V_t(2,0,\ldots,0)$ and $V_t(1,1,0,\ldots,0)$ are bottom layer, and the form is indefinite. In this case one can in fact show that at $t = 0$ the form is indefinite on $V_t(1,1,0,\ldots,0)$ and $V_t(0,\ldots,0)$. The reason is that one can deform the string $\kappa_1$ or $\sigma_1$ all the way to a place where the module is unitarily induced irreducible, and $V_t(2,0,\ldots,0)$ occurs with full multiplicity in the spherical irreducible module. So its sign must be the same as that of $V_t(0,\ldots,0)$.

5.3. Proof of Proposition 5.1 – Other Strings. We do an induction, downward on the number of strings, upward on the length of the parameter, as in type B. The claim is that if there is a string $\kappa_1$ or $\sigma_1$ the number of strings, upward on the length of the parameter, as in type B. The claim is that if there is a string $\kappa_1$ or $\sigma_1$, the spherical module cannot be unitary.

Assume there is a string $\xi = (k_1 - 1/2, \ldots, K_1 - 1/2)$ or $(n_1, \ldots, N_1)$. Deform upward $\xi_t = (k_1 - 1/2 + t, \ldots, K_1 - 1/2 + t)$ or $(n_1 + t, \ldots, N_1 + t)$. The signatures and multiplicities of the fundamental cx-relevant $K$-types do not change for $0 \leq t < 1/2$. At $t = 1/2$, one of several cases may occur

(a) $P(\lambda_{1/2}) = P(\lambda_0)$. Continue upwards. If no change occurs as $t \to \infty$, the form is indefinite on $V_t(0,\ldots,0)$ and the adjoint $K$-type $V_t(2,0,\ldots,0)$. Call this an initial case.

(b) $P(\lambda_{1/2}) \neq P(\lambda_0)$, and the spherical module still has a $\xi_1$. Apply the induction hypothesis to the spherical parameter to conclude that the statement of the Proposition holds.

(c) There are just two strings $\kappa_0, \sigma_0$ or the spherical module is unitary. We have dealt with this in the previous section.

5.4. Non-spherical Case. It is enough to consider the case $\mu_1 = 1$ and $\mu_r = 0$ for $r > 1$, and the parameter contains

$$
\begin{pmatrix}
1/2 \\
-1/2
\end{pmatrix}.
$$

There cannot be a $\kappa_0$ present. The fundamental cx-relevant $K$-types for the spherical parameter produce bottom layer $K$-types. We are reduced to the cases when they do not detect nonunitarity. This is the case when there is at most one $\kappa_i, \sigma_j$ with $i, j > 0$. The case when only $\kappa_1 = (3/2, \ldots, K_1 - 1/2)$ occurs, gives a unitary representation. We are reduced to the case when there are other strings, $\kappa_1 \geq 5/2$ and/or $n_1 \geq 2$ respectively. The $K$-types

$$
V_t(1,0,\ldots,0) \quad V_t(2,1,0,\ldots,0)
$$

occur with the same multiplicities in the unitarily induced module from $GL(1) \times G(\mu_0)$ with $J/\lambda^0, \lambda^0)$ on the $G(\mu_0)$-factor, and in $J/\lambda, -s\lambda)$. The form is indefinite on these $K$-types, since they restrict to $K \cap M$-types for which the form on $J/\lambda^0, \lambda^0)$ is indefinite.

6. Proof of Theorem 3.5 – Type D

In this case $K = SO(2m)$. The $K$-types have highest weight with integer coordinates only. Since $\rho = (m - 1, \ldots, 1, 0)$, it follows that $2\lambda = \{\eta - \rho\} + \rho$ has integer coordinates only. So $2\lambda$ is regular integral it has integer coordinates only. Since $\lambda$ is not assumed
integral, its coordinates are integers and half integers, and the integral system is of type \( D \times D \).

**Proposition 6.1.** Let \( \lambda \) be regular half-integral. The spherical irreducible module \( J(\lambda, \lambda) \) is unitary if and only if it is unipotent, i.e.

\[
\lambda = \left( -K_0 + \frac{1}{2}, \ldots, -\frac{1}{2}, -N_0, \ldots, -1, 0 \right)
\]

satisfying \( N_0 \geq K_0 \).

When \( K_0 > 0 \), the representation is attached to the nilpotent orbit \([32^{2K_0} 1^{2N_0 - 2K_0} - 1]\).

When \( K_0 = 0 \), the nilpotent orbit is the trivial one.

When not unitary, the form is indefinite on the set of \( cx \)-relevant \( K \)-types with highest weights

\[
CXD := \{(0, \ldots, 0), (1, \ldots, 1, 0, \ldots, 0), (2, 0, \ldots, 0)\}.
\]

The proof will take up most of the next few subsections. The unipotent representations are unitary because they can be realized via the dual pair correspondence in the stable range, as \( \Theta(\text{triv}_{Sp}) \), with the pair \( Sp(2K_0, \mathbb{C}) \times SO(2K_0 + 2N_0 + 2, \mathbb{C}) \) and one of the components of the the Oscillator Representation on the \( Sp \)-factor.

As in Type B and C, we construct a parabolic subgroup \( P(\lambda) = L(\lambda)U(\lambda) \) and an induced module \( I_{P(\lambda)} \) for each \( \lambda \) dominant for the standard positive system, i.e.

\[
\lambda = (\ldots \lambda_i \geq \lambda_{i+1}, \ldots \geq \lambda_{m-1} \geq |\lambda_m| \geq 0), \quad 2\lambda_i \in \mathbb{Z}.
\]

(i) If \( 1/2 \) is a coordinate of \( \lambda \), form the longest string

\[
\kappa_0 = (-K_0 + 1/2, \ldots, -1/2)
\]

such that all the half-integers staring from \( 1/2 \) to \( K_0 - 1/2 \) are coordinates of \( \lambda \), but \( K_0 + 1/2 \) is not. If the coordinate \( 0 \) occurs, form the longest string

\[
\sigma_0 = (-N_0 + 1, \ldots, -1, 0)
\]

where \( N_0 - 1 \) is the largest integer coordinate that occurs in \( \lambda \), but \( N_0 \) does not.

Add a factor of type \( G(K_0 + N_0) = SO(2K_0 + 2N_0) \) to \( L(\lambda) \), and the spherical irreducible representation with parameter

\[
\left( -K_0 + 1/2, \ldots, -1/2 ; -N_0 + 1, \ldots, -1 0 \right).
\]

If \( 1/2 \) is not a coordinate, let \( k_1 - 1/2 > 0 \) be the smallest half-integer coordinate, and form the longest string \( \kappa_1 = (k_1 - 1/2, \ldots, K_1 - 1/2) \) going up by one as before. Add a factor \( GL(K_1 - k_1 + 1) \), to \( L(\lambda) \), and the 1-dimensional representation with parameter

\[
\left( k_1 - 1/2, \ldots, K_1 - 1/2 \right).
\]

Similarly if \( 0 \) does not occur as a coordinate, form \( \sigma_1 = (n_1, \ldots, N_1) \) and add a factor \( GL(N_1 - n_1 + 1) \) to the Levi component \( L(\lambda) \).
(ii) Remove the coordinates in Step (i) from $\lambda$, and repeat on the remainder of half integer coordinates until there are no half-integer coordinates left. Similarly for the integer coordinates. Since the regularity assumption implies that at most one coordinate can be equal to $1/2$, and at most one coordinate equal to 0, only $GL$--factors are created.

The process produces a parabolic subgroup, and an irreducible module on its Levi component. The Levi component is

$$\prod_{i>0} GL(\sigma_i) \times \prod_{j>0} GL(\kappa_j) \times G(K_0 + N_0).$$

The parameters $\lambda$ we are going to study satisfy:

$$\begin{align*}
\left\{ \begin{array}{ll}
    k_i &> 2 \quad \text{if } 1/2 \text{ is a coordinate,} \\
    k_i &\geq 2 \quad \text{otherwise}
\end{array} \right. \quad \text{and} \quad 
\left\{ \begin{array}{ll}
    n_j &> 1 \quad \text{if } 0 \text{ is a coordinate,} \\
    n_j &\geq 1 \quad \text{otherwise}
\end{array} \right.
\end{align*}$$

and the nested condition

$$\begin{align*}
\left\{ \begin{array}{ll}
    k_{i+1} - K_i &\geq 2, \quad \text{or} \\
    k_i &\leq k_{i+1} \leq K_{i+1} \leq K_i,
\end{array} \right. \quad \text{and} \quad 
\left\{ \begin{array}{ll}
    n_{j+1} - N_j &\geq 2, \quad \text{or} \\
    n_i &\leq n_{i+1} \leq N_{i+1} \leq N_i.
\end{array} \right.
\end{align*}$$

The main property of the cx-relevant $K$--types is the following Lemma.

**Lemma 6.2.** Assume that the strings of $\lambda$ satisfy (23) and (24). The multiplicities of the cx-relevant $K$--types in $I_{P(\lambda)}$ coincide with those in $J(\lambda, \lambda)$.

**Proof.** The proof follows the analogous result for Type B. In this case all cx-relevant $K$--types are petite/single petaled. This is because $(\check{\alpha}, \lambda) \leq 3$ for all roots. \qed

We finish this subsection by giving a necessary condition on the spherical parameter:

**Lemma 6.3.** If $J(\lambda, \lambda)$ is unitary, then the string $\sigma_0 = (-N_0 + 1, \ldots, 1, 0)$ must appear in $(\lambda, \lambda)$.

**Proof.** The coordinates on the spherical part of $I_1$ in Equation 9 are all $\geq 1/2$. The Casimir inequality implies that the form is indefinite on the adjoint $V_t(1, 1, 0, \ldots, 0)$ $K$--type and the trivial $V_t(0, \ldots, 0)$ $K$--type. These give rise to bottom layer $K$--types of $I_1$, and hence the irreducible $J(\lambda, \lambda)$ is not unitary. \qed

6.2. **Proof of Proposition 6.1** $\lambda = \kappa_0 \cup \sigma_0$. The case when $N_0 \geq K_0$ is unitary. So assume

$$\begin{align*}
(25) \quad \lambda = \kappa_0 \cup \sigma_0 \quad \text{satisfying} \quad K_0 > N_0.
\end{align*}$$

By Lemma 6.3 we assume $N_0 > 0$, and let

$$\text{Ind}(\lambda_\ell) := \text{Ind}^{G \times G(N_0)}_{GL(\kappa_0) \times G(N_0)} [(1/2 + t, \ldots, K_0 - 1/2 + t) \otimes \text{Triv}].$$

The multiplicities of the cx-relevant $K$--types in $\text{Ind}(\lambda_\ell)$ and $J(\lambda, \lambda)$ still coincide for small $t$. This is as before: $\text{Ind}(\lambda)$ is

- a homomorphic image of $\text{Ind}^{G}_{B}(\lambda, \lambda)$
the intertwining operator changing $(1/2, \ldots, K_0 - 1/2)$ to $(-K_0 + 1/2, \ldots, -1/2)$ involves only $(\alpha, w\lambda)$ which are half-integers or $\geq 2$:

\[
\begin{pmatrix} 1/2, 0 \\ 1/2, 0 \end{pmatrix} \mapsto \begin{pmatrix} 0, -1/2 \\ 1/2, 0 \end{pmatrix}
\]

or

\[
\begin{pmatrix} 1/2, 3/2 \\ 1/2, 3/2 \end{pmatrix} \mapsto \begin{pmatrix} -3/2, -1/2 \\ 1/2, 3/2 \end{pmatrix}
\]

depending whether $K_0$ is even or odd. In the first case, the $SL(2)-$intertwining operator is an isomorphism, in the other case the kernel of the intertwining operator has lowest $K-$type $(2, 2)$. So the intertwining operator is an isomorphism on the cx-relevant $K-$types.

The signatures (and multiplicities) of the fundamental cx-relevant $K-$types do not change for $0 \leq t < 1/2$. At $t = 1/2$, the parameter is

\[
\lambda_{1/2} = (1, \ldots, K_0; -N_0 + 1, \ldots, -1, 0) = (-K_0, \ldots, -1, 0) \cup (1, \ldots, N_0 - 1).
\]

As in the case in Type B, $J(\lambda_{1/2}, \lambda_{1/2})$ and $\text{Ind}(\lambda_{1/2})$ are different on the level of fundamental $K-$types, and $\text{Ind}(\lambda_{1/2})$ has another factor with parameter

\[
(26) \begin{pmatrix} -N_0 + 1 & \ldots & N_0 \\ -N_0 & \ldots & N_0 + 1 \end{pmatrix} \underbrace{\vdots}_{2N_0} \begin{pmatrix} -K_0 & \ldots & -N_0 - 1 \\ -K_0 & \ldots & -N_0 - 1 \end{pmatrix}
\]

and lowest $K-$type $\mu_0 = (1, \ldots, 1, 0, \ldots, 0)$.

If $K_0 - N_0$ is odd, the factor is not hermitian, and there are two of them which are hermitian dual to each other; one of the coordinates $-K_0, \ldots, -N_0 - 1$ is changed to its negative in both $\lambda_L$ and $\lambda_R$. When $K_0 - N_0 > 0$ is even, the signature is indefinite on $\mu_0$ and $\mu_1 = (1, \ldots, 1, 0, \ldots, 0)$.

In both cases, $\text{Ind}(\lambda_{1/2})$, and hence $\text{Ind}(\lambda)$ and $J(\lambda, \lambda)$, has indefinite signature on the fundamental cx-relevant $K-$types.

6.3. Proof of Proposition [6.1] – Other Strings. We follow the reasoning for type B. We do a downward induction on the length of $\lambda$ and the number of strings. The case when there are no strings other than $\kappa_0, \sigma_0$, was dealt with in the previous section. So assume there is another string, $\kappa_1 = (k_1 - 1/2, \ldots, K_1 - 1/2)$ or $\sigma_1 = (n_1, \ldots, N_1)$. Replace it by $(k_1 - 1/2 + t, \ldots, K_1 - 1/2 + t)$ or $(n_1 + t, \ldots, N_1 + t)$ in the other case, and denote the new parameter by $\lambda_t$. At $t = 1/2$ the strings, and the multiplicities corresponding to $\lambda_t$ may change. If they do not, continue $t$ on upward.

If the deformation can continue to “$\infty$” without change in the multiplicities, the Casimir inequality implies that the form is indefinite on the trivial and adjoint $K-$types in $J(\lambda_t, \lambda_t)$. This is one of the initial steps of the induction. So assume that the multiplicities change at $t = 1/2$. 

For instance, suppose \( \sigma_0 = (-N_0 + 1, \ldots, -1, 0) \) (which always exists by Lemma 6.3) and
\[
\kappa_1 = (k_1 - 1/2, \ldots, K_1 - 1/2) \text{ satisfies } \begin{cases} 
(a) & N_0 < k_1 \\
(b) & k_1 \leq N_0 = K_1 \\
(c) & k_1 \leq N_0 < K_1 \\
(d) & K_1 < N_0 
\end{cases}
\]

For (a), we can deform \( \kappa_1 \) to \( \infty \). For (d), we can continue deforming \( \kappa_1 \) upwards until the first time (27) holds, i.e. until one reaches case (b). So the critical cases are (b) and (c); The argument in Type B applies. For case (b), one can reduce to studying \( k_1 = K_1 = N_0 \) as in Example 4.3. At \( t = 1/2 \) there is another factor with parameter
\[
\begin{pmatrix}
N_0 + 1 & N_0; & 0 & \ldots & k_1 - 2 \\
N_0 & N_0 + 1; & 0 & \ldots & k_1 - 2
\end{pmatrix}
\]
with lowest \( K \)-type \( V_\ell(1, 1, 0, \ldots, 0) \). In case (b) the spherical part of the factor is unitary. The bottom layer argument applied to the nonspherical part implies that the form is indefinite on the fundamental \( cx \)-relevant \( K \)-types \( V_\ell(2, 0, \ldots, 0) \) and \( V_\ell(1, 1, 0, \ldots, 0) \).

In case (c), there is another factor at \( t = 1/2 \) with parameter
\[
\begin{pmatrix}
-N_0 + 1 & \ldots & -k_1 + 1; & k_1 & \ldots & N_0; & N_0 + 1 & \ldots & K_1 & 0 & \ldots & k_1 - 2 \\
-N_0 & \ldots & -k_1 & k_1 - 1 & \ldots & N_0 - 1 & N_0 + 1 & \ldots & K_1 & 0 & \ldots & k_1 - 2
\end{pmatrix}
\]
with lowest \( K \)-type \( V_\ell(1, \ldots, 1, 0, \ldots, 0) \). The spherical part is a finite dimensional nonunitary module, and applying the bottom layer \( K \)-type argument, we conclude that the form is indefinite on \( V_\ell(1, \ldots, 1, 0, \ldots, 0) \) and \( V_\ell(1, \ldots, 1, 0, \ldots, 0) \).

6.4. **Nonspherical case.** It is enough to consider the case \( \mu_1 \neq 0 \) and \( \mu_r = 0 \) for \( r > 1 \). The parameter contains
\[
\begin{pmatrix}
1 & 0 \\
0 & -1
\end{pmatrix} \quad \text{or} \quad \begin{pmatrix}
1/2 \\
-1/2
\end{pmatrix}
\]
We will show that the form is indefinite on \( K \)-types which give rise to bottom layer \( K \)-types in the general case.

Assume that \( \begin{pmatrix}
1 & 0 \\
0 & -1
\end{pmatrix} \) occurs. If the parameter has no spherical part, there is nothing to be done; the parameter is unitary. If the parameter has a spherical part, there cannot be a \( \sigma_0 \) or else the regularity of the parameter is violated. Lemma 6.3 implies that the hermitian form is indefinite on the trivial and adjoint \( K \)-types. Both are bottom layer if the lowest \( K \)-type has coordinates greater than one.

The proof of the claim is reduced to the case when \( \mu_1 = 1 \) with nonspherical parameter \( \begin{pmatrix}
1/2 \\
-1/2
\end{pmatrix} \). The case when \( \kappa_1 = (3/2, \ldots, K_1 - 1/2) \cup \sigma_0 \) with \( K_1 \leq N_0 \) is unitary.
The cases when the spherical part of the parameter is indefinite on fundamental cx-relevant $K$–types are not unitary by the bottom layer arguments. This is case (c) of (27).

The only non-unitary spherical case when the form is indefinite on cx-relevant $K$–types which are not fundamental, is case (b) of (27), and $\kappa_1$ satisfies $k_1 - 1/2 \geq 5/2$. The fact that $k_1 - 1/2 \geq 5/2$ implies that the $K$–types $V_k(1, 1, 1, 0, , , , 0)$ and $V_k(1, 1, 0, , , , 0)$ occur with the same multiplicity in $J(\lambda, -s\lambda)$ and in the unitarily induced module from the spherical part. Since their restrictions to the Levi component contain $K$–types with indefinite form, the conclusion follows. These give rise to bottom layer $K$–types in the case of $r > 1$.

6.5. Spin Groups. We consider genuine representations of $G = Spin(2n, \mathbb{C})$. The $K$–types have highest weights with half-integer coordinates only. As already mentioned, $\rho = (m - 1, , , , 1, 0)$, so $2\lambda = (\eta - \rho) + \rho$ must have half-integer coordinates only. The integral system for $\lambda$ is type A.

6.5.1. Lowest $K$–type Spin. We assume the lowest $K$–type of $J(\lambda_L, \lambda_R)$ is

$$\left(\frac{1}{2}, \ldots, \frac{1}{2}, \pm \frac{1}{2}\right).$$

We treat the case $\left(\frac{1}{2}, \ldots, \frac{1}{2}, \frac{1}{2}\right)$ only. The parameter is

$$\lambda_L = (1/4, , , , 1/4) + (\nu_1, , , , \nu_k, -\nu_k, , , , -\nu_l)$$

$$\lambda_R = (-1/4, , , , -1/4) + (\nu_1, , , , \nu_k, -\nu_k, , , , -\nu_l)$$

or

$$\lambda_L = (1/4, , , , 1/4) + (\nu_1, , , , \nu_k, 0, -\nu_k, , , , -\nu_l)$$

$$\lambda_R = (-1/4, , , , -1/4) + (\nu_1, , , , \nu_k, 0, -\nu_k, , , , -\nu_l).$$

Since $2\lambda_L = (\frac{1}{2} + 2\nu_1, , , , \frac{1}{2} - 2\nu_l)$ must be regular integral and formed of half-integers, it follows that $2\nu_l$ must be integers, so the parameter can be split into two sets,

$$(a) \quad \nu_l \in \mathbb{Z},$$

$$(b) \quad \nu_l \in \frac{1}{2} + \mathbb{Z}.$$

satisfying $\nu_i \pm \nu_j \neq 0$, and $\nu_i \neq 0$. The symmetry $\nu_i \leftrightarrow -\nu_i$ follows from the assumption that the parameter must be hermitian.

6.5.2. Separate the $\nu_i$ into integers $\nu_a$ and half-integers $\nu_b$. The hermitian property implies that $\nu_a$ must be conjugate to $-\nu_a$ by the symmetric group, and similarly for $\nu_b$. We conclude that there are two finite dimensional hermitian representations $F_a$ and $F_b$ (with lowest $K$–types $(\frac{1}{2}, , , , \frac{1}{2})$) so that

$$J(\lambda_L, \lambda_R) = Ind_{GL \times GL}(F_a \otimes F_b).$$

As in the previous sections, unless $F_a, F_b$ are one dimensional, the form is indefinite on the lowest $K$–type $(\frac{1}{2}, , , , \frac{1}{2})$ and “adjoint” $K$–type $(\frac{3}{2}, , , , \frac{1}{2}, -\frac{1}{2})$. 

7. A Positivity Result

In this section, we sharpen the results in Section 5.4-5.6 in [BP]. We investigate the PRV-components of \( \pi_u \otimes V_t(\rho) \) when \( \pi_u \) is a unipotent representation with half-integral regular infinitesimal character for a classical group. The case when \( \pi_u \) is the Trivial representation is clear. So we assume that \( G \) of classical type, and nontrivial \( \pi_u \in \hat{G} \) given in Theorem 3.1.

By [BP] Section 5.4-5.6], all \( \pi_u \in \hat{G}^d \) for Type \( B_n \), while for Type \( C_n \) and \( D_n \), \( H_D(\pi^\text{even/odd}) \in \hat{G}^d \) if and only if \( n \) is even/odd. Moreover, the spin-lowest \( K \)-type is unique for all such \( \pi_u \)’s (this will be verified in Proposition 7.1 below).

Since the \( K \)-types of \( \pi_u \) are multiplicity free, Theorem 1.7 holds for all \( \pi_u \in \hat{G}^d \). In order to prove Theorems 1.5 and 1.7 for general \( \pi \in \hat{G}^d \), we need the following refinement of the results in [BP]:

**Proposition 7.1.** Let \( G \) be a connected complex classical simple Lie group and \( \pi_u = J(\lambda, -s\lambda) \) be a unipotent representation given above with \( \lambda \) regular half-integral. If \( \pi_u \in \hat{G}^d \), then there is a unique \( K \)-type \( V_t(\eta) \) in \( \pi_u \) such that \( \delta := \{\eta - \rho\} = 2\lambda - \rho \) realizes the minimum of \( \{\eta' - \rho\} \) over the \( K \)-spectrum of \( \pi_u \). Furthermore,

\[
\pi_u \otimes V_t(\rho) = V_t(\delta) \oplus \bigoplus_{\delta' \neq \delta} m_{\delta'} V_t(\delta'),
\]

where \( m_{\delta'} \) are positive integers and

\[
\delta' = \delta + \sum_{i=1}^t m_i \alpha_i, \text{ satisfying } m_i \in \mathbb{Z}_{\geq 0}.
\]

If \( \pi_u \notin \hat{G}^d \), then all \( \tilde{K} \)-types of \( \pi_u \otimes V_t(\rho) \) have extremal weights of the form (32) for \( \delta \) with norm strictly greater than \( \|2\lambda - \rho\| \).

**Proof.** Let \( \eta' \) be any \( K \)-type of \( \pi_u \) other than a spin-lowest \( K \)-type \( \eta \). Put \( \delta' := \{\eta' - \rho\} \). In view of Theorem 2.2 it suffices to prove that (32) holds for \( \delta \) and \( \delta' \).

**Type \( B_n \):** Let \( V_t(\eta') = V_t(\alpha_1, \alpha_1, \ldots, \alpha_a, 0, \ldots, 0) \) be a \( K \)-type in \( \pi_u \). Since \( \rho = \left( b-a \right) / (n-1/2, n-3/2, \ldots, 1/2) \), the \( \text{PRV-component} \) \( \delta' \) is, up to the action of \( W(B_n) \),

\[
x\delta' = (n - 2a - 1/2, n - 2a - 3/2, \ldots, 1/2, B_1, \ldots, B_{2a})
\]

The minimum is attained when all \( B_i = 1/2 \), and this can only be achieved from

\[
\eta = (n-1, n-1, n-3, \ldots, n-2a-1, n-2a-1, 0, \ldots, 0).
\]

It follows that

\[
\delta = (n - 2a - 1, \ldots, 1/2, 1/2, \ldots, 1/2).
\]

Any other \( K \)-type must give rise to a \( \delta' \) with at least \( B_1 \geq 3/2 \), and \( B_i \geq 1/2 \). The difference \( x\delta' - \delta \), from (33) and (34), is a sum of short positive roots; on each nonzero
coordinate it is \( B_1 - 1/2 \) times the corresponding short root. The difference \( x \delta' - \delta' \), as in (33), is clearly a sum of positive roots since the two are conjugate, and \( \delta' \) is dominant.

**Type C_n:** Here \( V_t(\gamma') = V_t(2k,0,\ldots,0) \) or \( V_t(2k+1,0,\ldots,0) \) and \( \rho = (n,n-1,\ldots,1) \). The PRV-component is, up to \( W(33) \), is clearly a sum of positive roots since the two are conjugate, and \( \delta' \) is odd.

The PRV-component is, up to \( W(33) \), is clearly a sum of positive roots since the two are conjugate, and \( \delta' \) is odd.

The argument for Type B applies to derive the conclusion in the statement of the Proposition.

Also, since \( \delta + \rho \) is equal to \( 2\lambda = (2n-1,\ldots,3,1) \) if and only if \( \delta = (n-1,n-2,\ldots,1,0) \), it also follows that \( H_D(\pi^{even}) \neq 0 \) and \( H_D(\pi^{odd}) = 0 \) if \( n \) is even, and the reverse is true if \( n \) is odd.

**Type D_n:** We only consider \( b > a > 0 \) and omit the easier case when \( b = a \). Here
\[
V_t(\gamma') = V_t(\alpha_1,\ldots,\alpha_{2\alpha},0,\ldots,0),
\]
where \( \sum \alpha_i \) is even/odd if \( \pi_u^{even/odd} \) is being considered, and \( \rho = (n-1,\ldots,1,0) \). Then the PRV-component, up to the action of \( W(D_n) \), is
\[
\delta' = (n-2a-1,\ldots,1,0,|n-1-a_1|,\ldots,|n-2a-a_2|)
\]
Even though \( W(D_n) \) only allows an even number of sign changes, in the case \( b > a \) there is a coordinate equal to 0, so we can change all coordinates to \( \geq 0 \). As in type C,
\[
\delta = (n-2a-1,\ldots,1,0,\ldots,0) \quad \text{or} \quad (n-2a-1,\ldots,1,1,0,\ldots,0),
\]
and \( H_D(\pi_u^{even}) \neq 0 \) if and only if \( \delta \) take the first value. We omit further details which are as in Types B and C.

The above proposition demonstrates a strong positivity result on the \( \tilde{K} \)-types appearing in the tensor product decomposition of \( \pi_u \otimes V_t(\rho) \) for unipotent representations \( \pi_u \). In fact, similar calculations have been carried out for other irreducible unitary representations, and so far there are no counter-examples to the following conjecture, which sharpens Conjecture 1.6 in view of Proposition 2.4.

**Conjecture 7.2.** Proposition 7.1 holds for any \( \pi \in \tilde{G}^d \).

### 8. Proof of Theorems 1.5 and 1.7

In view of Conjecture 2.5, it suffices to show that for all \( \pi = J(\lambda,-s\lambda) = \text{Ind}^G_M(\mathbb{C}_\xi \otimes \pi_u) \) in Theorem 3.1,
\[
[\pi \otimes V_t(\rho) : V_t(2\lambda - \rho)] = \begin{cases} 
1 & \text{if } \pi_u \in \tilde{M}^d \\
0 & \text{if } \pi_u \notin \tilde{M}^d
\end{cases}
\]

Note that the special case when \( M = G \) and \( \pi = \pi_u \) is proved in the previous Section.
We sharpen the results in Section 2.2 of [BP]. To conform to the notation in that section, write $\pi_m = J(\lambda_m, -s\lambda_m)$ for a unitary representation such that the center of $M$ acts trivially. We assume that $\lambda_m$ is regular integral dominant for a positive system $\Delta_M$, and $\lambda$ is regular half-integral. The relations
\[
\begin{align*}
\lambda_m + s\lambda_m &= \mu_m, & 2\lambda_m &= \mu_m + \nu_m, \\
\lambda_m - s\lambda_m &= \nu_m, & 2s\lambda_m &= \mu_m - \nu_m, \\
\lambda &= \frac{\xi}{2} + \lambda_m, & \mu &= \xi + \mu_m, \\
\lambda &= \frac{\xi}{2} + s\lambda_m, & \nu &= \nu_m.
\end{align*}
\] (39)
hold, with $s \in W_M \subset W$. The unitary character $\xi$ can be assumed dominant for a choice of $\Delta(n)$. We denote $\Delta = \Delta_M \cup \Delta(n)$. However $\lambda$ may not be dominant for $\Delta$, so let $\Delta'$ be the positive system for which $\lambda$ is dominant. Since $\lambda$ is dominant for $\Delta_M$,
\[
\Delta_M \subset \Delta' \cap \Delta.
\]
For $\pi_m$, we assume in addition that
(i) $\pi_m$ is unitary,
(ii) $\lambda$ is regular half-integral,
(iii) $\pi_m \otimes V_{\tau_m}(\rho_m)$ contains only $\widetilde{K} \cap M-$types of the form
\[
\delta' = \delta_M + \sum_{\gamma \in \Delta_M} m_\gamma \gamma, \quad m_\gamma \in \mathbb{N}, \quad \text{with} \quad \delta_M = 2\lambda_m - \rho_m
\]
By Proposition 7.1 this includes all $\pi_u$ in Theorem 3.1 with $H_D(\pi_u) \neq 0$.

By Proposition 2.4 the only $\widetilde{K}$-type that can appear in the Dirac cohomology of $\pi$ must have extremal weight $\tau' := 2\lambda - \rho'$, where $2\rho'$ is the sum of all positive roots in $\Delta'$. By abuse of notations, we write $V_{\xi}(\tau')$ as the $\widetilde{K}$-type with extremal weight $\tau'$. The relation
\[
\begin{align*}
\tau' &= 2\lambda - \rho' = \xi + \mu_m + \nu_m - \rho' = \xi + 2\lambda_m - \rho' = \xi + \delta_M + \rho_m - \rho' = \\
\xi + \delta_M - w_m \rho + \rho_m - \rho' &= \delta_M + (\xi + \rho_n) - (w_m \rho + \rho'),
\end{align*}
\] (40)
because $w_m \rho = -\rho_m + \rho_n$. Furthermore,
\[
w_m \rho + \rho' = \sum_{\beta \in \Delta \cap \Delta(n)} \beta
\]
(41)
Continuing with the proof of [BP] Theorem 2.4 in Section 2.2,
\[
[\pi \otimes V_{\xi}(\rho) : V_{\xi}(\tau')] = [\pi : V_{\xi}(\tau') \otimes V_{\xi}(\rho)]
\]
(42)
= $[\pi_m \otimes C_\xi : V_{\xi}(\tau') \otimes V_{\xi}(\rho)]$
= $[\pi_m \otimes C_\xi \odot V_{\xi}(\rho) | M : V_{\xi}(\tau') | M]$
= $[\pi_m \otimes C_\xi \odot (V_{\tau_m}(\rho_m) \otimes C_{\rho_n} \odot \bigwedge^* n^* : V_{\xi}(\tau') | M]$
= $[\pi_m \otimes V_{\tau_m}(\rho_m) \otimes C_{\xi + \rho_n} \odot \bigwedge^* n^* : V_{\xi}(\tau') | M]$. 

DIRAC SERIES FOR COMPLEX CLASSICAL LIE GROUPS 27
The penultimate step above uses [BP] Lemma 2.3, and that $\wedge^* n^*$ consists of weights of the form $-\sum_{\alpha \in S} \alpha$, where $S$ is a subset of the roots in $\Delta(n)$.

**Proposition 8.1.** Let $\pi = \text{Ind}_M^G(\mathbb{C}\xi \otimes \pi_m)$ be an irreducible, unitary representation with $\pi_m$ satisfying (i)-(iii). Then

\begin{equation}
[\pi_m \otimes V_{\delta m}(\rho_m) \otimes \mathbb{C}_{\xi + \rho_n} \otimes \wedge^* n^* : V\ell(\tau')|_M] = [\pi_m \otimes V_{\delta m}(\rho_m) : V_{\delta m}(\delta_M)].
\end{equation}

(Recall that $H_D(\pi_m)$ is either zero or a multiple of $V_{\delta m}(\delta_M)$).

**Proof.** We use (iii); the fact that $\pi_m \otimes V_{\delta m}(\rho_m)$ is a sum of $\widehat{K} \cap M$–types of the form

$$
\delta'_M = \delta_M + \sum_{\gamma \in \Delta_M} m_{\gamma \gamma},
$$

Tensoring with $\mathbb{C}_{\xi + \rho_n} \otimes \wedge^* n^*$, the $\widehat{K} \cap M$-types that appear must have highest weights of the form

$$
\delta'_M + \xi + \rho_n - \sum_{\alpha \in S} \alpha
$$

for some $S \subseteq \Delta(n)$.

Combining the arguments above, any $\widehat{K} \cap M$-type appearing on the left module in (43) must have highest weights of the form

\begin{equation}
\delta'_M + \xi + \rho_n - \sum_{\alpha \in S} \alpha
\end{equation}

(44)

\begin{align*}
\delta'_M + \xi + \rho_n - \sum_{\alpha \in S} \alpha & = \left( \delta_M + \sum_{\gamma \in \Delta_M, m_{\gamma \gamma} \geq 0} m_{\gamma \gamma} \right) + \xi + \rho_n - \left( \sum_{\alpha \in S \cap \Delta'} \alpha + \sum_{\beta \in S \cap (-\Delta')} \beta \right) \\
& = \left( \delta_M + \sum_{\gamma \in \Delta_M, m_{\gamma \gamma} \geq 0} m_{\gamma \gamma} \right) + \xi + \rho_n - \left( \sum_{\alpha \in \Delta(n) \cap \Delta'} \alpha - \sum_{\beta' \in (\Delta(n) \setminus S) \cap \Delta'} \beta' + \sum_{\beta \in S \cap (-\Delta')} \beta \right) \\
& = \tau' + \sum_{\gamma \in \Delta_M, m_{\gamma \gamma} \geq 0} m_{\gamma \gamma} + \sum_{\beta' \in S_1} \beta' - \sum_{\beta \in S_2} \beta,
\end{align*}

where $S_1 := (\Delta(n) \setminus S) \cap \Delta'$ and $S_2 := S \cap (-\Delta')$.

Consider the squared norm of the weight in (44):

\begin{equation}
\tau' + \sum_{\gamma \in \Delta_M, m_{\gamma \gamma} \geq 0} m_{\gamma \gamma} + \sum_{\beta' \in S_1} \beta' - \sum_{\beta \in S_2} \beta
\end{equation}

\begin{align*}
2 \left( \tau', \sum_{\gamma \in \Delta_M, m_{\gamma \gamma} \geq 0} m_{\gamma \gamma} + \sum_{\beta' \in S_1} \beta' - \sum_{\beta \in S_2} \beta \right) + \sum_{\gamma \in \Delta_M, m_{\gamma \gamma} \geq 0} m_{\gamma \gamma} + \sum_{\beta' \in S_1} \beta' - \sum_{\beta \in S_2} \beta
\end{align*}
By construction, \( \tau' \) is a dominant weight in \( \Delta' \). On the other hand, we have seen from above that
\[
\gamma \in \Delta_M \subset \Delta'; \quad \beta' \in \Delta'; \quad -\beta \in \Delta'.
\]
Thus \( \langle \tau', \gamma \rangle \), \( \langle \tau', \beta' \rangle \), \( \langle \tau', -\beta \rangle \) are all non-negative. Therefore,
\[
\left\| \tau' + \sum_{\gamma \in \Delta_M, m_\gamma \geq 0} m_\gamma \gamma + \sum_{\beta' \in S_1} \beta' - \sum_{\beta \in S_2} \beta \right\|^2 \geq \| \tau' \|^2.
\]
Equality occurs exactly when \( \delta'_M = \delta_M \), and \( S_1, S_2 \) are both empty. The latter condition further implies that \( S = \Delta(n) \cap \Delta' \).

Since \( V_{\pi}(\tau')|_{\widetilde{M}} \) has \( K \cap \widetilde{M} \)-types of norm less than or equal to \( \tau' \), the left module in \( (43) \) contains \( V_{\pi \cap \tau}(\tau') \) with multiplicity equal to \( [\pi \otimes V_{\tau}(\rho) : V_{\pi \cap \tau}(\tau')] \).

Proof of Theorem 1.5 and Theorem 1.7. As discussed in the beginning of the section, it suffices to prove Equation 38. By applying \( \pi = \pi_u \in \widetilde{M}^d \) to (42) and (43),
\[
[\pi \otimes V_{\pi}(\rho) : V_{\pi}(\tau')] = [\pi_u \otimes V_{\pi \cap \tau}(\rho) : V_{\pi \cap \tau}(\tau')].
\]
Since \( \pi_u \in \widetilde{M}^d \), the proof in Proposition 7.1 implies that \( \pi_u \) has a unique spin-lowest \( K \)-type and hence the right hand side of the above equation is equal to 1.

Now look at the case when \( H_D(\pi_u) = 0 \), which shows up in Type C and Type D only. By the proof of Proposition 8.1, in particular Equation (44), the \( \widetilde{K} \cap \widetilde{M} \)-types appearing in the left module on the last line of (42) has highest weights
\[
(46) \quad \tau' + \sum_{\gamma \in \Delta_M, m_\gamma \geq 0} m_\gamma \gamma + \sum_{\beta' \in S_1} \beta' - \sum_{\beta \in S_2} \beta + e_1,
\]
where \( e_1 \) is the unit vector corresponding to the bolded 1 in the proof of Proposition 7.1. Consider the sum of coordinates of the expression in (46): since all the roots are of the form \( 2e_1 \) and/or \( e_1 \pm e_3 \) in Type C and D, the sum of coordinates in (46) must be of opposite parity with that of \( \tau' \). Therefore, the multiplicity \( [\pi \otimes V_{\pi}(\rho) : V_{\pi}(\tau')] \) in (42) is zero, and hence (38) holds.

Appendix A. Some Atlas Calculations

In this section, we illustrate some of the results on signatures on \( cx \)-relevant \( K \)-types considered in Sections 4–6 using the software atlas [ALTv] [AL]. The calculations are carried out using the function print_sigs_irr_long, which is available at
\[
http://math.mit.edu/~dav/atlassem/.
\]
A.1. Equation (15), Section 4.2. Let \( G = SO(7, \mathbb{C}) \), and \( \lambda = (-1/2, -2, -1) \). The atlas is

```
set G = complexification(SO(7))
set all = all_parameters_gamma(G,[4,2,1,4,2,1]/2)
all[0]
```

Value: final parameter(x=47, lambda=[5,3,1,5,3,1]/2, nu=[4,2,1,4,2,1]/2)

The signature of some of the \( K \)-types are given by:

```
print_sig_irr_long(all[0], KGB(G,0), 15)
```

<table>
<thead>
<tr>
<th>sig</th>
<th>lambda</th>
<th>hw</th>
<th>dim</th>
</tr>
</thead>
<tbody>
<tr>
<td>s</td>
<td>[1, 1, 1, 1, -1, -1, -1]</td>
<td>[-2, -1, 0, 2, 1, 0]</td>
<td>1</td>
</tr>
<tr>
<td>s</td>
<td>[1, 1, 1, 1, 1, -1]</td>
<td>[-2, -1, 0, 3, 2, 0]</td>
<td>21</td>
</tr>
<tr>
<td>1</td>
<td>[1, 1, 1, 1, 1, 1]</td>
<td>[-2, -1, 0, 3, 2, 1]</td>
<td>35</td>
</tr>
</tbody>
</table>

The \( K \)-types of \( J(\lambda, -s\lambda) \) are in the column labelled \( hw \). More precisely, by adding the \( i \)-th-coordinate and the \( (i + \text{rank}(G)) \)-th-coordinate of the vector in the \( hw \) column, one can get the highest weight of a \( K \)-type in usual coordinates. For example, \( [-2, -1, 0, 3, 2, 0] \) corresponds to the highest weight \( (1, 1, 0) \) in the usual coordinates.

The \( sig \) column represents the signature of the Hermitian form of \( J(\lambda_{rel}, -s\lambda_{rel}) \). The form is definite if and only if the entries of the \( sig \) column are all scalars or all scalar multiples of \( s \). In particular, the above output shows that the form is indefinite on the \( K \)-types \( V_{\ell}(1,1,0) \) and \( V_{\ell}(1,1,1) \), which matches Equation (15).

A.2. Case (c), Section 4.3. Let \( G = SO(9, \mathbb{C}) \) and \( \lambda = (-5/2, -3/2, -1/2) \cup (2) \). We are in the setting of Case (c). Its \( K \)-type signatures are given by

```
print_sig_irr_long(all[0], KGB(G,0),15)
```

<table>
<thead>
<tr>
<th>sig</th>
<th>lambda</th>
<th>hw</th>
<th>dim</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>[1, 1, 1, 1, -1, -1, -1, -1]</td>
<td>[-3,-2,-1, 0, 3, 2, 1, 0]</td>
<td>1</td>
</tr>
<tr>
<td>1</td>
<td>[1, 1, 1, 1, 1, 1, -1, -1]</td>
<td>[-3,-2,-1, 0, 4, 3, 1, 0]</td>
<td>36</td>
</tr>
<tr>
<td>s</td>
<td>[3, 1, 1, 1, 1, 1, -1, -1, -1]</td>
<td>[-2,-2,-1, 0, 4, 2, 1, 0]</td>
<td>44</td>
</tr>
<tr>
<td>1</td>
<td>[3, 3, 1, 1, 1, 1, -1, -1]</td>
<td>[-2,-1,-1, 0, 4, 3, 1, 0]</td>
<td>495</td>
</tr>
<tr>
<td>s</td>
<td>[3, 1, 1, 1, 1, 3, -1, -1, -1]</td>
<td>[-2,-2,-1, 0, 5, 3, 1, 0]</td>
<td>910</td>
</tr>
</tbody>
</table>

In this case, the \( K \)-types \( V_{\ell}(1,1,0,0) \) and \( V_{\ell}(2,0,0,0) \) have different signatures.

A.3. Nonspherical Type C, Section 5.4. Let \( G = Sp(8, \mathbb{C}) \) and parameter \( \left( \begin{array}{c} 1/2 \\ -1/2 \end{array} \right) \cup (-2, -1) \cup (3/2) \). The atlas code for this parameter is

```
set G = Sp(8,\mathbb{C})
set all = all_parameters_gamma(G,[4,3,2,1,4,3,2,1]/2)
LKT(all[1])
```

Value: (KGB element #0, [1, 0, 0, 0, 0, 0, 0, 0 ]/1)

The signatures of the \( K \)-types are:
The $K$-types $V_k(1,0,0,0)$ and $V_k(1,1,0)$ have different signatures.

A.4. **Equation (26), Section 6.2.** This is an example where the Hermitian form is indefinite on a single $K$-type. Let $G = SO(6, \mathbb{C})$ and the parameter be given by $(-3/2, -1/2; 0)$. Then the signatures are given by:

\[
\begin{array}{cccc}
s & 0 & [0, 0, 0, 0, 0, 0, 0, 0, 0, 0] / 1 & [-3, -2, -1, 0, 2, 1, 0] 1 \\
1 + s & 0 & [1, 0, 0, 0, 0, 0, 0, 0, 0, 0] / 1 & [-3, -2, -1, 0, 2, 1, 0] 15 \\
1 & 0 & [1, 1, 0, 0, 0, 0, 0, 0, 0, 0] / 1 & [-3, -2, -1, 0, 2, 1, 0] 20 \\
s & 0 & [1, 1, 1, 0, 0, 0, 0, 0, 0, 0] / 1 & [-3, -2, -1, 0, 2, 1, 0] 45 \\
\end{array}
\]

The $K$-type $V_k(1,1,0)$ has indefinite signature as in Equation (26) with an odd number of spherical coordinates.

A.5. **Nonspherical Type D, Section 6.4.** Let $G = SO(10, \mathbb{C})$. Let \( \left( \frac{1/2}{-1/2} \right) \cup (-2, -1, 0) \cup (5/2) \) be the parameter, where the spherical part satisfies Case (b) of Equation (27). Then the signatures of the $K$-types are given by:

\[
\begin{array}{cccc}
s & 0 & [1,0,0,0,0,0,0,0,0,0] / 1 & [-3,-3,-2,-1,0,4,3,2,1,0] 10 \\
s & 0 & [1,1,1,0,0,0,0,0,0,0] / 1 & [-3,-2,-1,0,4,3,2,1,0] 120 \\

s & 0 & [1,1,1,1,0,1,0,0,0,0] / 1 & [-3,-2,-1,0,0,5,3,2,1,0] 1728 \\
\end{array}
\]

The $K$-types $V_k(1,1,1,0,0)$ and $V_k(2,1,0,0,0)$ have opposite signatures. Moreover, this is the only place where the signatures are different on the level of ex-relevant $K$-types.

**Funding**

Barbasch is supported by NSF grant 2000254. Dong is supported by the National Natural Science Foundation of China (grant 12171344). Wong is supported by the Presidential Fund of CUHK(Shenzhen) and the National Natural Science Foundation of China (grant 11901491).

**Acknowledgements**

This work was initiated at the Workshop on Lie Group Representations and Automorphic Forms at Sichuan University in October 2018. The authors would like to thank the institution for their hospitality.
