Abstract

Logical transductions provide a very useful tool to encode classes of structures inside other classes of structures. In this paper we study first-order (FO) transductions and the quasiorder they induce on infinite classes of finite graphs. Surprisingly, this quasiorder is very complex, though shaped by the locality properties of first-order logic. This contrasts with the conjectured simplicity of the monadic second order (MSO) transduction quasiorder. We first establish a local normal form for FO transductions, which is of independent interest. Then we prove that the quotient partial order is a bounded distributive join-semilattice, and that the subposet of additive classes is also a bounded distributive join-semilattice. The FO transduction quasiorder has a great expressive power, and many well studied class properties can be defined using it. We apply these structural properties to prove, among other results, that FO transductions of the class of paths are exactly perturbations of classes with bounded bandwidth, that the local variants of monadic stability and monadic dependence are equivalent to their (standard) non-local versions, and that the classes with pathwidth at most \( k \), for \( k \geq 1 \) form a strict hierarchy in the FO transduction quasiorder.

Funding This paper is part of a project that has received funding from the European Research Council (ERC) under the European Union’s Horizon 2020 research and innovation programme (grant agreement No 810115 – DYNASNET) and from the German Research Foundation (DFG) with grant agreement No 444419611.

1 Introduction and statement of results

Transductions provide a model theoretical tool to encode relational structures (or classes of relational structures) inside other (classes of) relational structures. Transductions naturally induce a quasiorder, that is, a reflexive and transitive binary relation, on classes of relational structures. We study here the first-order (FO) and monadic second-order (MSO) transduction quasiorders \( \sqsubseteq_{\text{FO}} \) and \( \sqsubseteq_{\text{MSO}} \) on infinite classes of finite graphs. These quasiorders are very different and both have a sound combinatorial and model theoretic relevance, as we will outline below. To foster the further discussion, let us (slightly informally) introduce the concept of transductions. Formal definitions will be given in Section 2.

A transduction \( T \) (on graphs) is the composition of a copying operation, a coloring operation, and a simple interpretation. The copying operation \( C_k \) maps a graph \( G \) to the graph \( C_k(G) \) obtained by taking \( k \) disjoint copies of \( G \) and making all the copies of a single
Structural properties of the first-order transduction quasiorder

vertex adjacent; the coloring operation maps a graph $G$ to the set $\Gamma(G)$ of all possible colorings of $G$; a simple interpretation $I$ maps a colored graph $G^+$ to a graph $H$, whose vertex set (resp. edge set) is a definable subset of $V(G^+)$ (resp. of $V(G^+ \times V(G^+)$). In this way, the transduction $T$ maps a graph $G$ to a set $T(G)$ of graphs defined as $T(G) := I \circ \Gamma \circ C_k(G) = \{I(H^+) : H^+ \in \Gamma(C_k(G))\}$. This naturally extends to a graph class $\mathcal{C}$ by $T(\mathcal{C}) := \bigcup_{G \in \mathcal{C}} T(G)$.

We say that a class $\mathcal{C}$ is a transduction of a class $\mathcal{D}$ if there exists a transduction $T$ with $\mathcal{C} \subseteq T(\mathcal{D})$, and we denote this by $\mathcal{C} \sqsubseteq \mathcal{D}$. We write $\mathcal{C} \equiv \mathcal{D}$ for $\mathcal{C} \sqsubseteq \mathcal{D}$ and $\mathcal{D} \sqsubseteq \mathcal{C}$, $\mathcal{C} \sqsubset \mathcal{D}$ for $\mathcal{C} \sqsubseteq \mathcal{D}$ and $\mathcal{C} \neq \mathcal{D}$, and $\mathcal{C} \triangleleft \mathcal{D}$ for the property that $(\mathcal{C}, \mathcal{D})$ is a cover, that is, that $\mathcal{C} \sqsubset \mathcal{D}$ and there is no class $\mathcal{F}$ with $\mathcal{C} \sqsubseteq \mathcal{F} \sqsubset \mathcal{D}$. For a logic $\mathcal{L}$ we write $\mathcal{C} \sqsubseteq_\mathcal{L} \mathcal{D}$ to stress that the simple interpretation of the transduction uses $\mathcal{L}$-formulas.

For most commonly studied logics $\mathcal{L}$ transductions compose and in this case $\sqsubseteq_\mathcal{L}$ is a quasiorder. We study here mainly the first-order (FO) and monadic second-order (MSO) transduction quasiorders $\sqsubseteq_{\text{FO}}$ and $\sqsubseteq_{\text{MSO}}$. As with the colorings all vertex subsets become definable, it follows that we can restrict our attention to infinite hereditary classes, that is, infinite classes that are closed under taking induced subgraphs.

MSO transductions are basically understood. Let us write $\mathcal{E}$ for the class of edgeless graphs, $\mathcal{T}_n$ for the class of forests of depth $n$ (where the depth of a (rooted) tree is the maximum number of vertices on a root-leaf path, hence $\mathcal{T}_1 = \mathcal{E}$), $\mathcal{P}$ for the class of all paths, $\mathcal{T}$ for the class of all trees and $\mathcal{G}$ for the class of all graphs. The MSO transduction quasiorder is conjectured to be simply the chain $\mathcal{E} \triangleleft_{\text{MSO}} \mathcal{T}_2 \triangleleft_{\text{MSO}} \mathcal{T}_3 \triangleleft_{\text{MSO}} \mathcal{T}_n \triangleleft_{\text{MSO}} \mathcal{P} \triangleleft_{\text{MSO}} \mathcal{T} \triangleleft_{\text{MSO}} \mathcal{G}$ [3].

In a combinatorial setting this hierarchy has a very concrete meaning and it was investigated using the following notions: a class $\mathcal{C}$ has bounded shrubdepth if $\mathcal{C} \sqsubseteq_{\text{MSO}} \mathcal{T}_n$ for some $n$; $\mathcal{C}$ has bounded linear cliquewidth if $\mathcal{C} \sqsubseteq_{\text{MSO}} \mathcal{P}$; $\mathcal{C}$ has bounded cliquewidth if $\mathcal{C} \sqsubseteq_{\text{MSO}} \mathcal{T}$. These definitions very nicely illustrate the treelike structure of graphs from the above mentioned classes from a logical point of view, which is combinatorially captured by the existence of treelike decompositions with certain properties. It is still open whether the MSO transduction quasiorder is as shown above [10 Open Problem 9.3], though the initial fragment $\mathcal{E} \triangleleft_{\text{MSO}} \mathcal{T}_2 \triangleleft_{\text{MSO}} \mathcal{T}_3 \triangleleft_{\text{MSO}} \mathcal{T}_n$ has been proved to be as stated in [12]. Thus we are essentially left with the following three questions: Does $\mathcal{C} \triangleright_{\text{MSO}} \mathcal{P}$ imply $(\exists n) \mathcal{C} \sqsubseteq_{\text{MSO}} \mathcal{T}_n$? This is equivalent to the question whether one can transduce with MSO arbitrary long paths from any class of unbounded shrubdepth (see [10] for a proof of the CMSO version). Is the pair $(\mathcal{P}, \mathcal{T})$ a cover? Is the pair $(\mathcal{T}, \mathcal{G})$ a cover? This last question is related to a famous conjecture of Seese [25] and the CMSO version has been proved in [6].

As in the MSO case, the FO transduction quasiorder allows to draw important algorithmic and structural dividing lines. For instance MSO collapses to FO on classes of bounded shrubdepth [12]. Classes of bounded shrubdepth are also characterized has being FO transductions of classes of bounded depth [13]. FO transductions give alternative characterizations of other graph class properties mentioned above: a class $\mathcal{C}$ has bounded linear cliquewidth if and only if $\mathcal{C} \sqsubseteq_{\text{FO}} \mathcal{H}$, where $\mathcal{H}$ denotes the class of half-graphs (bipartite graphs with vertex set $\{a_1, \ldots, a_n \} \cup \{b_1, \ldots, b_n \}$ and edge set $\{ab_i : 1 \leq i \leq j \leq n\}$ for some $n$) [5], and bounded cliquewidth if and only if $\mathcal{C} \sqsubseteq_{\text{FO}} \mathcal{T} \mathcal{P}$, where $\mathcal{T} \mathcal{P}$ denotes the class of trivially perfect graphs (comparability graphs of rooted trees) [5]. Also, it follows from [2] that FO transductions allow to give an alternative characterizations of classical model theoretical properties: A class $\mathcal{C}$ is monadically stable if $\mathcal{C} \nsubseteq_{\text{FO}} \mathcal{H}$ and monadically dependent if $\mathcal{C} \nsubseteq_{\text{FO}} \mathcal{G}$. We further call a class $\mathcal{C}$ monadically straight if $\mathcal{C} \nsubseteq_{\text{FO}} \mathcal{T} \mathcal{P}$. To the best of our knowledge this property has not been studied in the literature but seems to play a key role in the study of FO transductions.
The FO transduction quasiorder has not been studied in detail previously and it turns out that it is much more complicated than the MSO transduction quasiorder. This is outlined in Figure 1 and it is the goal of this paper to explore this quasiorder.

We are motivated by three aspects of the $\subseteq_{\text{FO}}$ quasiorder that have been specifically considered in the past and appeared to be highly non-trivial. The first aspect is the conjectured property that every class that cannot FO transduce paths has bounded shrubdepth (hence is an FO transduction of a class of bounded height trees). The second aspect that was studied in detail concerns the chain formed by classes with bounded pathwidth, which is eventually covered by the class of half-graphs. This is related to the fact that in the FO transduction quasiorder there is no class between the classes with bounded pathwidth and the class $\mathcal{H}$ of half-graphs [23, 24]. The third aspect concerns the chain of classes with bounded treewidth, which is eventually covered by the class of trivially perfect graphs. This is related to the fact that if $\mathcal{H} \subseteq_{\text{FO}} \mathcal{E} \subseteq_{\text{FO}} \mathcal{TP}$ (that is, $\mathcal{E}$ is a monadically stable class with bounded...
Structural properties of the first-order transduction quasiorder

cliquewidth), then $C \subseteq_{\text{FO}} \mathcal{T}W_n$ for some $n$, where $\mathcal{T}W_n$ denotes the class of graphs with treewidth at most $n$. \cite{22}.

In this paper, we establish the three kinds of results and show that despite its complexity the FO transduction quasiorder is strongly structured.

A local normal form for transductions

In Section 3.1 we introduce a normal form for FO transductions that captures the local character of first-order logic, by proving that every FO transduction can be written as the composition of a copying operation, a transduction that connects only vertices at a bounded distance, and a perturbation, which is a sequence of subset complementations (Theorem 2). In Section 4 we give two applications of this normal form. We first characterize the equivalence class of the class of paths in the FO transduction quasiorder (Theorem 9). Then, we prove that the local versions of monadic stability, monadic straightness, and monadic dependence are equivalent to the non-local versions (Theorem 10). This result is of independent interest and may be relevant e.g. for locality based FO model-checking on these classes.

Structural properties of the transduction quasiorder

In Section 5 we prove that the partial orders obtained as the quotient of the transduction quasiorder and the non-copying transduction quasiorder are bounded distributive join-semilattices (Theorem 15) and discuss some of their properties. In particular we prove that every class closed under disjoint union is join-irreducible. Recall that a partial order $(X, \leq)$ is a join semi-lattice if for all $x, y \in X$ there exists a least upper bound $x \vee y$ of $\{x, y\}$, called the join of $x$ and $y$. It is distributive if, for all $a, b, x \in X$ with $x \leq a \vee b$ there exist $x_1 \leq a$, $x_2 \leq b$, with $x = x_1 \vee x_2$. An element $x \in X$ is join-irreducible if $x$ is not the join of two incomparable elements. Then we consider the subposets induced by additive classes, which are the classes equivalent to the class of disjoint unions of pairs of graphs in the class. We prove that these subposets are also bounded distributive join-semilattices (Theorem 24), but with a different join. We discuss some properties of these subposets and in particular prove that every class closed under disjoint union and equivalent to its subclass of connected graphs is join-irreducible.

The transduction quasiorder on some classes

In Section 6 we focus on the transduction quasiorders on the class of paths, the class of trees, classes of bounded height trees, classes with bounded pathwidth, classes with bounded treewidth, and derivatives. In particular we prove that classes with bounded pathwidth form a strict hierarchy (Theorem 31). This result was the main motivation for this study, and we conjecture that a similar statement holds with treewidth. This would be a consequence of the conjecture that the class of all graphs with treewidth at most $n$ is incomparable with the class of all graphs with pathwidth at most $n + 1$, for every positive integer $n$.

2 Preliminaries and basic properties of transductions

We assume familiarity with first-order logic and graph theory and refer e.g. to \cite{8,15} for background and for all undefined notation. The vertex set of a graph $G$ is denoted as $V(G)$ and its edge set $E(G)$. The complement of a graph $G$ is the graph $\overline{G}$ with the same vertex set, in which two vertices are adjacent if they are not adjacent in $G$. The disjoint union of two graphs $G$ and $H$ is denoted as $G \cup H$, and their complete join $\overline{G} \cup \overline{H}$ as $G + H$. We
denote by $K_t$ the complete graph on $t$ vertices. Hence, $G + K_t$ is obtained from $G$ by adding a new vertex, called an apex, that is connected to all vertices of $G$. For a class $\mathcal{C}$ of graphs we denote by $\mathcal{C} + K_1$ the class obtained from $\mathcal{C}$ by adding an apex to each graph of $\mathcal{C}$. The lexicographic product $G \bullet H$ of two graphs $G$ and $H$ is the graph with vertex set $V(G) \times V(H)$, in which $(u,v)$ is adjacent to $(u',v')$ if either $u$ is adjacent to $u'$ in $G$ or $u = u'$ and $v$ is adjacent to $v'$ in $H$. The pathwidth $pw(G)$ of a graph $G$ is equal to one less than the smallest clique number of an interval graph that contains $G$ as a subgraph, that is, $pw(G) = \min\{\omega(H) - 1 : \text{for an interval graph } H \text{ with } H \supseteq G\}$. The treewidth $tw(G)$ of a graph $G$ is equal to one less than the smallest clique number of a chordal graph that contains $G$ as a subgraph, that is, $tw(G) = \min\{\omega(H) - 1 : \text{for a chordal graph } H \text{ with } H \supseteq G\}$. We write $G^k$ for the $k$-th power of $G$ (which has the same vertex set as $G$ and two vertices are connected if their distance is at most $k$ in $G$). The bandwidth of a graph $G$ is $bw(G) = \min\{\ell : P \in \mathcal{P} \text{ with } P^\ell \supseteq G, \}$.  

In this paper we consider either graphs or $\Sigma$-expanded graphs, that is, graphs with additional unary relations in $\Sigma$ (for a set $\Sigma$ of unary relation symbols). We usually denote graphs by $G$, $H$, . . . and $\Sigma$-expanded graphs by $G^+$, $H^+$, $G^*$, $H^*$, . . . , but sometimes we will use $G$, $H$, . . . for $\Sigma$-expanded graphs as well. We shall often use the term “colored graph” instead of $\Sigma$-expanded graph. In formulas, the adjacency relation will be denoted as $E(x,y)$. For each non-negative integer $r$ we can write a formula $\delta_{\leq r}(x,y)$ such that for every graph $G$ and all $u, v \in V(G)$ we have $G \models \delta_{\leq r}(u,v)$ if and only if the distance between $u$ and $v$ in $G$ is at most $r$. For improved readability we write $\text{dist}(x,y) \leq r$ for $\delta_{\leq r}(x,y)$. For $U \subseteq V(G)$ we write $B_C^r(U)$ for the subgraph of $G$ induced by the union of the closed $r$-neighborhoods of the vertices in $U$. We write $N_C^r(v)$ for the open neighborhood of $v$ (as a set of vertices). For the sake of simplicity we use for balls of radius $r$ the notation $B_C^r(v)$ instead of $B_C^r(\{v\})$ and, if $G$ is clear from the context, we drop the superscript $G$. For a class $\mathcal{C}$ and an integer $r$, we denote by $B_C^r$ the class of all the balls of radius $r$ of graphs in $\mathcal{C}$: $B_C^r = \{B_C^r(v) \mid G \in \mathcal{C} \text{ and } v \in V(G)\}$. For a formula $\varphi(x_1, \ldots, x_k)$ and a graph (or a $\Sigma$-expanded graph) $G$ we define

$$\varphi(G) := \{(v_1, \ldots, v_k) \in V(G)^k \mid G \models \varphi(v_1, \ldots, v_k)\}.$$  

For a positive integer $k$, the $k$-copy operation $C_k$ maps a graph $G$ to the graph $C_k(G)$ consisting of $k$ copies of $G$ where the copies of each vertex are made adjacent (that is, the copies of each vertex induce a clique and there are no other edges between the copies of $G$). Note that for $k = 1$, $C_1$ maps each graph $G$ to itself. (Thus $C_1$ is the identity mapping.)  

For a set $\Sigma$ of unary relations, the coloring operation $\Gamma_\Sigma$ maps a graph $G$ to the set $\Gamma_\Sigma(G)$ of all its $\Sigma$-expansions.

A simple interpretation $I$ of graphs in $\Sigma$-expanded graphs is a pair $(\nu(x), \eta(x,y))$ consisting of two formulas (in the language of $\Sigma$-expanded graphs), where $\eta$ is symmetric and anti-reflexive (i.e. $\models \eta(x,y) \leftrightarrow \eta(y,x)$ and $\models \eta(x,y) \rightarrow \neg(x = y)$). If $G^+$ is a $\Sigma$-expanded graph, then $H = I(G^+)$ is the graph with vertex set $V(H) = \nu(G^+)$ and edge set $E(H) = \eta(G) \cap \nu(G)^2$.  

A transduction $T$ is the composition $I \circ \Gamma_\Sigma \circ C_k$ of a copy operation $C_k$, a coloring operation $\Gamma_\Sigma$, and a simple interpretation $I$ of graphs in $\Sigma$-expanded graphs. In other words, for every graph $G$ we have $T(G) = \{I(H^+) \mid H \in \Gamma_\Sigma(C_k(G))\}$. A transduction $T$ is non-copying if it is the composition of a coloring operation and a simple interpretation, that is if it can written as $I \circ \Gamma_\Sigma \circ C_1$ ($= I \circ \Gamma_\Sigma$). We say that a transduction $T'$ subsumes a transduction $T$ if for every graph $G$ we have $T'(G) \supseteq T(G)$. We denote by $T' \succeq T$ the property that $T'$ subsumes $T$.  

J. Nešetřil, P. Ossona de Mendez and S. Siebertz
6 Structural properties of the first-order transduction quasiorder

For a class $\mathcal{D}$ and a transduction $T$ we define $T(\mathcal{D}) = \bigcup_{G \in \mathcal{D}} T(G)$ and we say that a class $\mathcal{C}$ is a $T$-transduction of $\mathcal{D}$ if $\mathcal{C} \subseteq T(\mathcal{D})$. We also say that $T$ encodes $\mathcal{C}$ in $\mathcal{D}$. A class $\mathcal{C}$ of graphs is a (non-copying) transduction of a class $\mathcal{D}$ of graphs if it is a $T$-transduction of $\mathcal{D}$ for some (non-copying) transduction $T$. We denote by $\mathcal{C} \subseteq_{\text{FO}} ^0 \mathcal{D}$ (resp. $\mathcal{C} \subseteq_{\text{FO}} ^v \mathcal{D}$) the property that the class $\mathcal{C}$ is an FO transduction (resp. a non-copying FO transduction) of the class $\mathcal{D}$. It is easily checked that the composition of two (non-copying) transductions is a (non-copying) transduction (see, for instance [11]). Thus the relations $\mathcal{C} \subseteq_{\text{FO}} ^v \mathcal{D}$ and $\mathcal{C} \subseteq_{\text{FO}} ^0 \mathcal{D}$ are quasiorders on classes of graphs Intuitively, if $\mathcal{C} \subseteq_{\text{FO}} ^v \mathcal{D}$, then $\mathcal{C}$ is at most as complex as $\mathcal{D}$. Equivalences for $\subseteq_{\text{FO}} ^v$ and $\subseteq_{\text{FO}} ^0$ are defined naturally.

We say that a class $\mathcal{C}$ does not need copying if for every integer $k$ the class $\mathcal{C}_k(\mathcal{C})$ is a non-copying transduction of $\mathcal{C}$.

We take time for some observations.

► Observation 1. If $\mathcal{C}$ does not need copying and $\mathcal{C} \equiv_{\text{FO}} \mathcal{D}$, then $\mathcal{D}$ does not need copying.

Proof. This follows from the fact that every class $\mathcal{C}$ is a non-copying transduction of $\mathcal{C}_k(\mathcal{C})$.

► Observation 2. A class $\mathcal{C}$ does not need copying if and only if $\mathcal{C}_2(\mathcal{C}) \equiv_{\text{FO}} \mathcal{C}$.

Proof. It is easily checked that for every positive integer $k$ there is a non-copying transduction $T_k$ such that $T_k \circ \mathcal{C}_k \circ C_2$ subsumes $\mathcal{C}_k$. Assume $\mathcal{C}_2(\mathcal{C}) \equiv_{\text{FO}} \mathcal{C}$. Then if $\mathcal{C}_k(\mathcal{C}) \subseteq_{\text{FO}} \mathcal{C}$ we deduce from $\mathcal{C}_2(\mathcal{C}) \subseteq_{\text{FO}} \mathcal{C}$ that $\mathcal{C}_2k(\mathcal{C}) \subseteq_{\text{FO}} \mathcal{C}$. By induction we get $\mathcal{C}_k(\mathcal{C}) \subseteq_{\text{FO}} \mathcal{C}$ for every positive integer $k$.

► Observation 3. A class $\mathcal{D}$ does not need copying if and only if for every class $\mathcal{C}$ we have $\mathcal{C} \subseteq_{\text{FO}} \mathcal{D}$ if and only if $\mathcal{C} \subseteq_{\text{FO}} \mathcal{D}$.

► Observation 4. If a class $\mathcal{C}$ is closed under adding pendant vertices (that is, if $G \in \mathcal{C}$ and $v \in V(G)$, then $G'$, which is obtained from $G$ by adding a new vertex adjacent only to $v$, is also in $\mathcal{C}$) then $\mathcal{C}$ does not need copying.

A subset complementation transduction is defined by the quantifier-free interpretation on a $\Sigma$-expansion (with $\Sigma = \{M\}$) by $q(x,y) := \neg(E(x,y) \leftrightarrow (M(x) \land M(y)))$. In other words, the subset complementation transduction complements the adjacency inside the subset of the vertex set defined by $M$. We denote by $\oplus M$ the subset complementation defined by the unary relation $M$. A perturbation is a composition of a (bounded number of) subset complementations. Let $r$ be a non-negative integer. A formula $\varphi(x_1,\ldots,x_k)$ is $r$-local if for every $(\Sigma$-expanded) graph $G$ and all $v_1,\ldots,v_k \in V(G)$ we have $G \models \varphi(v_1,\ldots,v_k) \iff B_G^C(\{v_1,\ldots,v_k\}) = \varphi(v_1,\ldots,v_k)$. An $r$-local formula $\varphi(x_1,\ldots,x_k)$ is strongly $r$-local if $G \models \varphi(x_1,\ldots,x_k) \rightarrow \text{dist}(x_i,x_j) \leq r$ for all $1 \leq i < j \leq k$ (see [21]).

► Lemma 1 (Gaifman’s Locality Theorem [9]). Every formula $\varphi(x_1,\ldots,x_m)$ is equivalent to a Boolean combination of $t$-local formulas and so-called basic local sentences of the form

$$\exists x_1\ldots\exists x_k \left( \bigwedge_{1 \leq i \leq k} \chi(x_i) \land \bigwedge_{1 \leq i < j \leq k} \text{dist}(x_i,x_j) > 2r \quad \text{where } \chi \text{ is } r \text{-local}. \right)$$

Furthermore, if the quantifier-rank of $\varphi$ is $q$, then $r \leq 7^{q-1}$, $t \leq 7^{q-1}/2$, and $k \leq q + m$.

We call a transduction $T$ immersive if it is non-copying and the formulas in the interpretation associated to $T$ are strongly local.
3 Local properties of FO transductions

3.1 A local normal form

We now establish a normal form for first-order transductions that captures the local character of first-order logic and further study the properties of immersive transductions. The normal form is based on Gaifman’s Locality Theorem and uses only strongly local formulas, while the basic-local sentences are handled by subset complementations. This normal form will be one of the main tools to establish results in the paper.

Theorem 2. Every non-copying transduction $\mathcal{T}$ is subsumed by the composition of an immersive transduction $\mathcal{T}_{imm}$ and a perturbation $\mathcal{P}$, that is $\mathcal{T} \leq \mathcal{P} \circ \mathcal{T}_{imm}$.

Consequently, every transduction $\mathcal{T}$ is subsumed by the composition of a copying operation $\mathcal{C}$, an immersive transduction $\mathcal{T}_{imm}$ and a perturbation $\mathcal{P}$, that is $\mathcal{T} \leq \mathcal{P} \circ \mathcal{T}_{imm} \circ \mathcal{C}$.

Proof. Let $\mathcal{T} = \mathcal{I}_\mathcal{T} \circ \Gamma_\Sigma$ be a non-copying transduction. Without loss of generality, we may assume that the interpretation $\mathcal{I}_\mathcal{T}$ defines the domain directly from the $\Sigma_\mathcal{T}$-expansion. Then the only non-trivial part of the interpretation is the adjacency relation, which is defined by a symmetric and anti-reflexive formula $\eta(x,y)$. We shall prove that the transduction $\mathcal{T}$ is subsumed by the composition of an immersive transduction $\mathcal{T}_\psi$ and a perturbation $\mathcal{P}$.

We define $\Sigma_{\mathcal{T}_\psi}$ as the disjoint union of $\Sigma_\mathcal{T}$ and a set $\Sigma_\psi = \{T_i \mid 1 \leq i \leq n_1\}$ for some integer $n_1$ we shall specify later and let $\Sigma_\mathcal{P} = \{Z_j \mid 1 \leq j \leq n_2\}$ for some integer $n_2$ we shall also specify later. Let $q$ be the quantifier rank of $\eta(x,y)$. According to Lemma 1, $\eta$ is logically equivalent to a formula in Gaifman normal form, that is, to a Boolean combination of $t$-local formulas and basic-local sentences $\theta_1, \ldots, \theta_{n_1}$. To each $\theta_i$ we associate a unary predicate $T_i \in \Sigma_\psi$. We consider the formula $\bar{\eta}(x,y)$ obtained from the Gaifman normal form of $\eta(x,y)$ by replacing the sentence $\theta_i$ by the atomic formula $T_i(x)$. Note that $\bar{\eta}$ is $t$-local.

Under the assumption that $\text{dist}(x,y) > 2t$ every $t$-local formula $\chi(x,y)$ is equivalent to $\chi_1(x) \land \chi_2(y)$ for $t$-local formulas $\chi_1(x)$ and $\chi_2(y)$. Furthermore, $t$-local formulas are closed under boolean combinations. By bringing $\bar{\eta}$ into disjunctive normal form and grouping conjunctions appropriately, it follows that under the assumption $\text{dist}(x,y) > 2t$ the formula $\bar{\eta}$ is equivalent to a formula $\bar{\varphi}(x,y)$ of the form $\bigvee_{(i,j) \in \mathcal{F}} \chi_i(x) \land \chi_j(y)$, where $\mathcal{F} \subseteq [n_2] \times [n_2]$ for some integer $n_2$ and the formulas $\chi_i (1 \leq i \leq n_2)$ are $t$-local. By considering appropriate boolean combinations (or, for those familiar with model theory, by assuming that the $\chi_i$ define local types) we may assume that $\models \forall x \bigwedge_{i \neq j} \neg (\chi_i(x) \land \chi_j(x))$, that is, every element of a graph satisfies at most one of the $\chi_i$. Note also that $\mathcal{F}$ is symmetric as $\eta$ (hence $\bar{\eta}$ and $\bar{\varphi}$) are symmetric.

We define $\psi(x,y) := \neg (\bar{\eta}(x,y) \leftrightarrow \bar{\varphi}(x,y)) \land (\text{dist}(x,y) \leq 2t)$, which is $2t$-strongly local, and we define $\mathcal{I}_\psi$ as the interpretation of graphs in $\Sigma_{\mathcal{T}_\psi}$-structures by using the same definitions as in $\mathcal{I}_\mathcal{T}$ for the domain, then defining the adjacency relation by $\psi(x,y)$. To each formula $\chi_i$ we associate a unary predicate $Z_i \in \Sigma_\mathcal{P}$. We define the perturbation $\mathcal{P}$ as the sequence of subset complementations $\oplus Z_i$ (for $(i,i) \in \mathcal{F}$) and of $\oplus Z_i \oplus Z_j \oplus (Z_i \cup Z_j)$ (for $(i,j) \in \mathcal{F}$ and $i < j$). Denote by $\varphi(x,y)$ the formula defining the edges in the interpretation $\mathcal{I}_\mathcal{P}$. Note that when the $Z_i$ are pairwise disjoint, then $\mathcal{P}$ complements exactly the edges of $Z_i$ or between $Z_i$ and $Z_j$, respectively. The operation $\oplus (Z_i \cup Z_j)$ complements all edges between $Z_i$ and $Z_j$, but also inside $Z_i$ and $Z_j$, which is undone by $\oplus Z_i$ and $\oplus Z_j$.

Now assume that a graph $\mathcal{H}$ is a $\mathcal{T}$-transduction of a graph $G$, and let $G^+$ be a $\Sigma_\mathcal{T}$-expansion of $G$ such that $\mathcal{H} = \mathcal{I}_\mathcal{T}(G^+)$. We define the $\Sigma_\psi$-expansion $G^*$ of $G^+$ (which is thus a $\Sigma_{\mathcal{T}_\psi}$-expansion of $G$) by defining, for each $i \in [n_1]$, $T_i(G^*) = V(G)$ if $G^+ \models \theta_i$ and $T_i(G^*) = \emptyset$ otherwise. Let $K = \mathcal{I}_{\mathcal{I}_\psi}(G^*)$. We define the $\Sigma_\mathcal{P}$-expansion $K^+$ of $K$ by defining,
Structural properties of the first-order transduction quasiorder

for each $j \in [n]$, $Z_j(K^+) = \zeta_j(G^+)$. By the assumption that $\models \forall x \bigwedge_{i \neq j} (\zeta_i(x) \land \zeta_j(x))$ the $Z_j$ are pairwise disjoint. Now, when $\text{dist}(x, y) > 2t$ there is no edge between $x$ and $y$ in $K$, hence $\varphi$ on $K^+$ is equivalent to $\tilde{\varphi}$ on $G^*$, which in turn in this case is equivalent to $\tilde{\eta}(x, y)$ on $G^*$. On the other hand, when $\text{dist}(x, y) \leq 2t$, then the perturbation is applied to the edges defined by $\sim\tilde{\eta}(x, y) \leftrightarrow \tilde{\varphi}(x, y)$, which yields exactly the edges defined by $\tilde{\eta}$ on $G^*$. Thus we have $\eta(G^+) = \tilde{\eta}(G^*) = \varphi(K^+)$, hence $\Gamma_p(K^+) = H$.

It follows that the transduction $T$ is subsumed by the composition of the immersive transduction $T_\wedge$ and a sequence of subset complementations, the perturbation $P$. ◀

▶ Corollary 3. For every immersive transduction $T$ and every perturbation $P$, there exist immersive transduction $T'$ and a perturbation $P'$, such that $P' \circ T'$ subsumes $T \circ P$.

3.2 Immersive transductions

Intuitively, copying operations and perturbations are simple operations. The main complexity of a transduction is captured by its immersive part. The strongly local character of immersive transductions is the key tool in our further analysis. It will be very useful to give another (seemingly) weaker property for the existence of an immersive transduction in another class, which is the existence of a transduction that does not shrink the distances too much, as we prove now.

▶ Lemma 4. Assume there is a non-copying transduction $T$ encoding $\mathcal{C}$ in $\mathcal{D}$ with associated interpretation $I$ and an $\epsilon > 0$ with the property that for every $H \in \mathcal{C}$ and $G \in \mathcal{D}$ with $H \in T(G)$ we have $\text{dist}_H(u, v) \geq \epsilon \text{dist}_G(u, v)$ (for all $u, v \in V(H)$). Then there exists an immersive transduction encoding $\mathcal{C}$ in $\mathcal{D}$ that subsumes $T$.

Proof. Let $T = I \circ \Gamma_\Sigma$ with $I = (\nu(x), \varphi(x, y))$. By Gaifman’s locality theorem, there is a set $\Sigma' \supseteq \Sigma$ of unary relations and a formula $\varphi(x, y)$, such that for every $\Sigma'$-expanded graph $G^+$ there is a $\Sigma'$-expansion $G^\ast$ of $G^+$ with $G^\ast \models \varphi(x, y)$ if and only if $G^+ \models \eta(x, y)$, where $\varphi$ is $t$-local for some $t$ (as in the proof of Theorem 2). We further define a new mark $M$ and let $I' = (M(x), \varphi(x, y) \land \text{dist}(x, y) \leq 1/\epsilon)$. The transduction $T' = I' \circ \Gamma_{\Sigma' \cup \{M\}}$ is immersive and subsumes the transduction $T$. ◀

Recall that $G + K_1$ is obtained from $G$ by adding a new vertex, called an apex, that is connected to all vertices of $G$. Of course, by adding an apex we shrink all distances in $G$. The next lemma shows that when we can transduce $\mathcal{C} + K_1$ in a class $\mathcal{F}$ with an immersive transduction, then we can in fact transduce $\mathcal{C}$ in the local balls of $\mathcal{F}$.

▶ Lemma 5. Let $\mathcal{C}, \mathcal{F}$ be graph classes, and let $T$ be an immersive transduction encoding a class $\mathcal{D}$ in $\mathcal{F}$ with $\mathcal{D} \supseteq \{G + K_1 \mid G \in \mathcal{C}\}$. Then there exists an integer $r$ such that $\mathcal{C} \subseteq^\circ_{\text{FO}} B_r^\mathcal{F}$.

Proof. Let $T = I \circ \Gamma_\Sigma$ be an immersive transduction encoding $\mathcal{D}$ in $\mathcal{F}$. For every graph $G \in \mathcal{C}$ there exists a graph $F \in \mathcal{F}$ such that $G + K_1 = I(F^+)$, where $F^+$ is a $\Sigma$-expansion of $F$. Let $v$ be the apex of $G + K_1$. By the strong locality of $I$ we get $I(F^+) = I(\bigcup B_r^{F^+}(v))$ for some fixed $r$ depending only on $T$. Let $U$ be a transduction allowing to take an induced subgraph, then $G$ can be encoded in the class $B_r^\mathcal{F}$ by the non-copying transduction $U \circ T$. ◀

Finally, we show that when transducing an additive class $\mathcal{C}$ in a class $\mathcal{D}$, then we do not need perturbations at all.

▶ Lemma 6. Let $\mathcal{C}$ be an additive class with $\mathcal{C} \subseteq^\circ_{\text{FO}} \mathcal{D}$. Then there exists an immersive transduction encoding $\mathcal{C}$ in $\mathcal{D}$.
Then there exists a copy operation (by composing with the generic induced subgraph transduction) that is a transduction encoding \( \tau \). As vertex

\[
\text{Corollary 7} \quad \text{Elimination of the perturbation.} \quad \text{Let } C \text{ be an additive class with } C \subseteq_{\text{FO}} D. \quad \text{Then there exists a copy operation } C \text{ and an immersive transduction } T_{\text{imm}} \text{ such that } T_{\text{imm}} \circ C \text{ is a transduction encoding } C \text{ in } D.
\]

We finish our study of the local properties of transductions by considering classes that locally have a certain property, such as classes with locally bounded treewidth. Formally, let \( f \) be a graph invariant, that is, an isomorphism invariant mapping from graphs to natural numbers. A hereditary class \( C \) has locally bounded \( f \) if there exists a function \( g \) with \( f(G) \leq g(r) \) for every \( G \in C \) with radius at most \( r \). The invariant \( f \) is apex-friendly if \( f(G + K_1) \) is bounded by a function of \( f(G) \).

\[
\text{Lemma 8.} \quad \text{Assume } f_1 \text{ and } f_2 \text{ are graph invariants, and that } f_1 \text{ is apex-friendly. Assume that every class with locally bounded } f_1 \text{ can be encoded by a non-copying transduction in a class with locally bounded } f_2. \quad \text{Then every class with bounded } f_1 \text{ can be encoded by a non-copying transduction in a class with bounded } f_2.
\]

**Proof.** Let \( C \) be a class with bounded \( f_1 \). Let \( C' \) be the closure of \( \{G + K_1 \mid G \in C \} \) by disjoint union. Then \( C' \) has locally bounded \( f_1 \) (as \( f_1 \) is apex-friendly). By assumption there exists a class \( D \) with locally bounded \( f_2 \) such that \( C' \subseteq_{\text{FO}} D \). It follows from Lemma 8 that there is an immersive transduction of \( C' \) in \( D \) (with interpretation \( I = (\nu, \eta) \)). Thus for every \( G \in C \) there exists a vertex coloring \( H^+ \) of \( H \in D \) such that \( G + K_1 = I(H^+) \). By the strong locality of \( \eta \), the radius of \( H \) is at most some \( r \), thus \( f_2(H) \leq C(r) \). We deduce (by composing with the generic induced subgraph transduction) that \( C \) is a non-copying transduction of the class of graphs \( H \) with \( f_2(H) \leq C(r) \).

The assumption that \( f_1 \) is apex-friendly is necessary. Consider for instance \( f_1 \) to be the maximum degree, while \( f_2 \) is the treewidth. A class with locally bounded maximum degree is simply a class with bounded maximal degree, thus has locally bounded treewidth. However, the class of grids (which has bounded maximum degree) cannot be transduced in any class of bounded tree-width as it cannot be transduced in the class of tree-orders.
4 Some applications of the local normal form

4.1 Transductions in paths

Theorem 9. A class \( \mathcal{C} \) is FO transduction equivalent to the class of paths if and only if it is a perturbation of a class with bounded bandwidth that contains graphs with arbitrarily large connected components.

Proof. Assume \( T \) is a transduction of \( \mathcal{C} \) in \( \mathcal{P} \). According to Theorem 2, \( T \leq P \circ T_{imm} \circ \mathcal{C}_k \), where \( k \geq 1 \), \( T_{imm} \) is immersive, and \( P \) is a perturbation. Observe first that \( \mathcal{C}_k(\mathcal{P}) \) is included in the class of all subgraphs of the \((k+1)\)-power of paths. By the strong locality property of immersive transductions, every class obtained from \( \mathcal{P} \) by the composition of a copy operation and an immersive transduction has its image included in the class of all the subgraphs of the \( \ell \)-power of paths, for some integer \( \ell \) depending only on the transduction, hence, in a class of bounded bandwidth. Conversely, assume that \( \mathcal{C} \) is a perturbation of a class \( \mathcal{D} \) containing graphs with arbitrarily large connected components. Then \( \mathcal{D} \) is a subclass of the monotone closure (containing all subgraphs of the class) of the class \( \mathcal{P}^\ell \) of \( \ell \)-powers of paths, which has bounded star chromatic number. We show in Lemma 34 in Appendix B that we can obtain the monotone closure of a class with bounded star chromatic number as a transduction. By this result and the observation that taking the \( \ell \)-power is obviously a transduction, we get that \( \mathcal{C} \leq_{FO} \mathcal{P} \).

To see that vice versa \( \mathcal{P} \leq_{FO} \mathcal{C} \) observe that we can first undo the perturbation by carrying out the edge complementations in reverse order. Then we have arbitrarily large connected components, which in a graph of bounded bandwidth have unbounded diameter. From this we can transduce arbitrarily long paths by extracting an induced subgraph.

4.2 Local monadically stable, straight, and dependent classes

A class \( \mathcal{C} \) is locally monadically dependent if, for every integer \( r \), the class \( B_r^\mathcal{C} \) is monadically dependent; a class \( \mathcal{C} \) is locally monadically stable if, for every integer \( r \), the class \( B_r^\mathcal{C} \) is monadically stable; a class \( \mathcal{C} \) is locally monadically straight if, for every integer \( r \), the class \( B_r^\mathcal{C} \) is monadically straight.

Theorem 10. For a class \( \mathcal{C} \) of graphs we have the following equivalences:
1. \( \mathcal{C} \) is locally monadically dependent if and only if \( \mathcal{C} \) is monadically dependent;
2. \( \mathcal{C} \) is locally monadically straight if and only if \( \mathcal{C} \) is monadically straight;
3. \( \mathcal{C} \) is locally monadically stable if and only if \( \mathcal{C} \) is monadically stable.

Proof. The proof will follow from the following claim.

Claim 11. Let \( \mathcal{C} \) be a class such that the class \( \mathcal{C}' = \{n(G + K_1) \mid n \in \mathbb{N}, G \in \mathcal{C}\} \) is a transduction of \( \mathcal{C} \). Then, for every class \( \mathcal{D} \) we have \( \mathcal{C} \leq_{FO} \mathcal{D} \) if and only if there exists some integer \( r \) with \( \mathcal{C} \leq_{FO} B_r^\mathcal{D} \).

Proof. Obviously, if there exists some integer \( r \) with \( \mathcal{C} \leq_{FO} B_r^\mathcal{D} \), then \( \mathcal{C} \leq_{FO} \mathcal{D} \). Now assume \( \mathcal{C} \leq_{FO} \mathcal{D} \). As \( \mathcal{C}' \equiv_{FO} \mathcal{C} \) we prove as in Lemma 8 that there is a transduction of \( \mathcal{C}' \) in \( \mathcal{D} \) that is the composition of a copy operation \( \mathcal{C} \) and an immersive transduction \( T \). Let \( \mathcal{D}' = C(T) \). According to Lemma 5 there is an integer \( r \) such that \( \mathcal{C} \leq_{FO} B_r^{\mathcal{D}'} \) thus, as \( B_r^{\mathcal{D}'} = C(B_r^\mathcal{D}) \), we have \( \mathcal{C} \leq_{FO} B_r^\mathcal{D} \).
dependent. The class \{n(G + K_1) \mid n \in \mathbb{N}, G \in TP\} is a transduction of \(TP\). Hence, according to Claim 11 a class \(c\) is locally monadically straight if and only if it is monadically straight. The class \{n(G + K_1) \mid n \in \mathbb{N}, G \in H\} is a transduction of \(H\). Hence, according to Claim 11 a class \(c\) is locally monadically stable if and only if it is monadically stable.

Example 12. Although the class of unit interval graphs has unbounded clique-width, every proper hereditary subclass of unit interval graphs has bounded clique-width [18]. This is in particular the case for the class of unit interval graphs with bounded radius. As classes with bounded clique-width are monadically dependent, the class of unit interval graphs is locally monadically dependent, hence monadically dependent.

5 Structural properties of the transduction quasiorders

Many properties will be similar when considering \(\sqsubseteq_{FO}\) and \(\sqsubseteq_{\neg FO}\). To avoid unnecessary repetitions of the statements and arguments, we shall use the notations \(\sqsubseteq, \sqsubset, \equiv\) to denote either \(\sqsubseteq_{FO}, \sqsubseteq_{\neg FO}\) or \(\sqsubseteq_{FO}, \sqsubseteq_{\neg FO}\).

For two classes \(c_1\) and \(c_2\) define \(c_1 + c_2 = \{G_1 \cup G_2 : G_1 \in c_1, G_2 \in c_2\}\). A class \(c\) is additive if \(c + c \equiv c\), for instance every class closed under disjoint union is additive. Note that if \(c_1\) and \(c_2\) are additive then \(c_1 + c_2\) is also additive. We further say that a class \(c\) is essentially connected if it is equivalent to the subclass \(Conn(c)\) of all its connected graphs.

In this section we will consider the quasiorders \(\sqsubseteq_{FO}\) and \(\sqsubseteq_{\neg FO}\), as well as their restrictions to additive classes of graphs. Let \(C\) be the collection of all graph classes, and let \(A\) be the collection of all additive graph classes. While speaking about these quasiorders, we will implicitly consider their quotient by the equivalence relation \(\equiv\), which are partial orders. For instance, when we say that \((C, \sqsubseteq)\) is a join-semilattice, we mean that \((C / \equiv, \sqsubseteq)\) is a join semilattice. The symbol \(<\) will always been used with reference to \((C, \sqsubseteq)\), \(C < D\) expressing that there exist no class \(F\) with \(C \sqsubseteq F \sqsubseteq D\). When we shall consider covers in \((A, \sqsubseteq)\) we will say explicitly that \((C, D)\) is a cover in \((A, \sqsubseteq)\), expressing that there exists no additive class \(F\) with \(C \sqsubseteq F \sqsubseteq D\).

5.1 The transduction semilattices \((C, \sqsubseteq_{FO})\) and \((C, \sqsubseteq_{\neg FO})\)

The aim of this section is to prove that \((C, \sqsubseteq_{FO})\) and \((C, \sqsubseteq_{\neg FO})\) are distributive join-semilattices and to state some of their properties.

Lemma 13. If \(D \sqsubseteq C_1 \cup C_2\), then there is a partition \(P_1 \cup P_2\) of \(D\) with \(P_1 \sqsubseteq C_1\) and \(P_2 \sqsubseteq C_2\). If \(D\) is additive, then \(D \sqsubseteq C_1 \cup C_2\) \iff \(D \sqsubseteq C_1\) or \(D \sqsubseteq C_2\).

Proof. The first statement is straightforward. We now prove the second statement. For an integer \(n\), let \(G_n\) be the disjoint union of all the graphs in \(D\) with at most \(n\) vertices.

Assume that \(D\) is additive and \(D \sqsubseteq C_1 \cup C_2\). According to the first statement, there exists a partition \(P_1 \cup P_2\) of \(D\) with \(P_1 \sqsubseteq C_1\) and \(P_2 \sqsubseteq C_2\). For \(G \in D\) define \(F(G) = \{H \cup G : H \in D\}\). Note that \(F(G) \subseteq D \cup D\). Let \(D' = D \cup D\). As \(D \subseteq P_1 \cup P_2\) there exists a partition \(P_1' \cup P_2'\) of \(D\) with \(P_1' \subseteq P_1\) and \(P_2' \subseteq P_2\). If, for every \(G \in D\) we have \(F(G) \cap P_1' \neq \emptyset\) then \(D \subseteq P_1'\) (by the generic transduction extracting an induced subgraph) thus \(D \equiv P_1 \sqsubseteq C_1\). Similarly, if for every \(G \in D\) we have \(F(G) \cap P_2' \neq \emptyset\) then \(D \sqsubseteq C_2\). Assume for contradiction that there exist \(G_1, G_2 \in D\) with \(F(G_1) \cap P_1' = \emptyset\). Then \(G_1 \cup G_2\) belongs neither to \(P_1'\) nor to \(P_2'\), contradicting the assumption that \(P_1'\) or \(P_2'\) is a partition of \(D' = D \cup D\).

Lemma 14. If \(C_1\) and \(C_2\) are incomparable, then \(C_1 \cup C_2\) is not equivalent to an additive class. In particular, \(C_1 \cup C_2 \neq C_1 + C_2\).
12 Structural properties of the first-order transduction quasiorder

Proof. We prove by contradiction that \( \mathcal{C} \cup \mathcal{D} \) is not equivalent to an additive class. Assume that we have \( \mathcal{D} \subsetneq \mathcal{C} \cup \mathcal{D} \), where \( \mathcal{D} \) is additive. According to Lemma 13, we have \( \mathcal{D} \subsetneq \mathcal{C} \) or \( \mathcal{D} \subsetneq \mathcal{C} \) if \( \mathcal{C} \cup \mathcal{D} \subsetneq \mathcal{D} \). If \( \mathcal{C} \cup \mathcal{D} \subsetneq \mathcal{D} \), then \( \mathcal{C} \cup \mathcal{D} \) or \( \mathcal{D} \subsetneq \mathcal{C} \), contradicting the hypothesis that \( \mathcal{C} \) and \( \mathcal{D} \) are incomparable.

Theorem 15. The quasiorder \((\mathcal{C}, \sqsubseteq)\) is a distributive join-semilattice, where the join of \( \mathcal{C} \) and \( \mathcal{D} \) is \( \mathcal{C} \cup \mathcal{D} \). In this quasiorder, additive classes are join-irreducible. This quasiorder has a minimum \( \mathcal{E} \) and a maximum \( \mathcal{G} \).

Proof. Of course we have \( \mathcal{C} \subsetneq \mathcal{C} \cup \mathcal{D} \) and \( \mathcal{D} \subsetneq \mathcal{C} \cup \mathcal{D} \). Now assume \( \mathcal{D} \) is such that \( \mathcal{C} \cup \mathcal{D} \subsetneq \mathcal{D} \). Let \( I \) and \( T_2 \) be transductions encoding \( \mathcal{C} \) and \( \mathcal{D} \) in \( \mathcal{D} \), with associated interpretations \( I_1 = (\nu_1, \eta_1) \) and \( I_2 = (\nu_2, \eta_2) \). By relabeling the colors, we can assume that the set \( \Sigma_1 \) of unary relations used by \( I_1 \) is disjoint from the set \( \Sigma_2 \) of unary relations used by \( I_2 \).

Let \( M \) be a new unary relation. We define the interpretation \( I = (\nu, \eta) \) by \( \nu := (\exists \nu M(\nu)) \land \nu_1 \lor (\exists \nu M(\nu)) \land \nu_2 \) and \( \eta := (\exists \nu M(\nu)) \land \eta_1 \lor (\exists \nu M(\nu)) \land \eta_2 \). Let \( G \in \mathcal{C} \cup \mathcal{D} \). If \( G \in \mathcal{C} \), then there exists a coloring \( H^+ \) of \( H \in \mathcal{C} \) with \( G = l_1(H^+) \). We define \( H^+ \) as the expansion of \( H^+ \) where all vertices also belong to the unary relation \( M \). Then \( G = l(H^+) \). Otherwise, if \( G \in \mathcal{D} \), then there exists a coloring \( H^+ \) of \( H \in \mathcal{D} \) with \( G = l_2(H^+) \). As we did not introduce new copying transductions we deduce \( \mathcal{C} \cup \mathcal{D} \subsetneq \mathcal{D} \). It follows that \((\mathcal{C}, \sqsubseteq)\) is a join semi-lattice, which is distributive according to Lemma 13.

That additive classes are join-irreducible follows from Lemma 13.

We now state an easy lemma on covers in distributive join-semilattices.

Lemma 16. Let \((X, \leq)\) be a distributive join-semi-lattice (with join \( \lor \)). If \( a < b \) and \( b \not\leq a \lor c \), then \( a \lor c < b \lor c \).

Proof. Assume \( a \lor c \leq x \leq b \lor c \). As \((X, \leq)\) is distributive there exist \( b' \leq b \) and \( c' \leq c \) with \( x = b' \lor c' \). Thus \( a \leq a \lor b' \leq b \). As \( a < b \), either \( a = a \lor b' \) (thus \( b' \leq a \)) and thus \( x = a \lor c \), or \( a \lor b' = b \) and then \( b \lor c \leq a \lor b' \lor c \leq a \lor x \land c = x \leq b \lor c \) thus \( x = b \lor c \). Hence either \( a \lor c = b \lor c \) (which would contradict \( b \not\leq a \lor c \)), or \( a \lor c < b \lor c \).

Corollary 17. If \( \mathcal{C} \cup \mathcal{D} \) and \( \mathcal{C} \cup \mathcal{D} \subsetneq \mathcal{C} \cup \mathcal{D} \), then \( \mathcal{C} \cup \mathcal{D} \subseteq \mathcal{C} \cup \mathcal{D} \).

Corollary 18. If \( \mathcal{C} \cup \mathcal{D}, \mathcal{C} \subseteq \mathcal{D} \), and \( \mathcal{D} \) and \( \mathcal{C} \) are incomparable, then \( \mathcal{C} \cup \mathcal{D} \subseteq \mathcal{C} \cup \mathcal{D} \).

Proof. As \( \mathcal{C} \cup \mathcal{D} \neq \mathcal{D} \) and \( \mathcal{C} \subseteq \mathcal{D} \), we have \( \mathcal{C} \cup \mathcal{D} \subseteq \mathcal{C} \cup \mathcal{D} \).

Corollary 19. If \( \mathcal{C} \cup \mathcal{D} \) and \( \mathcal{D} \) are incomparable and \( \mathcal{C} \) is additive, then \( \mathcal{C} \cup \mathcal{D} \subseteq \mathcal{C} \cup \mathcal{D} \).

5.2 The transduction semilattices \((\mathcal{A}, \sqsubseteq_{\mathcal{FO}})\) and \((\mathcal{A}, \sqsubseteq_{\mathcal{FO}})\)

The aim of this section is to prove that \((\mathcal{A}, \sqsubseteq_{\mathcal{FO}})\) and \((\mathcal{A}, \sqsubseteq_{\mathcal{FO}})\) are distributive join-semilattices and to state some of their properties.

Lemma 20. If \( \mathcal{C} \) and \( \mathcal{D} \) are incomparable, then \( \mathcal{C} \cup \mathcal{D} \) is not essentially connected.

Proof. We prove by contradiction that \( \mathcal{C} \cup \mathcal{D} \) is not essentially connected. It is immediate that \( \text{Conn}(\mathcal{C} \cup \mathcal{D}) \subseteq \mathcal{C} \cup \mathcal{D} \). So if \( \mathcal{C} \cup \mathcal{D} \) is essentially connected, then \( \mathcal{C} \cup \mathcal{D} \) and \( \mathcal{C} \cup \mathcal{D} \) are equivalent, contradicting Lemma 14.
Lemma 21. A class $\mathcal{D}$ is additive if and only if for all classes $\mathcal{C}_1, \mathcal{C}_2$ we have

$$\mathcal{C}_1 + \mathcal{C}_2 \subseteq \mathcal{D} \iff \mathcal{C}_1 \subseteq \mathcal{D} \text{ and } \mathcal{C}_2 \subseteq \mathcal{D}.$$ 

Proof. Assume $\mathcal{D}$ is additive. If $\mathcal{C}_1 + \mathcal{C}_2 \subseteq \mathcal{D}$, then $\mathcal{C}_1 \cup \mathcal{C}_2 \subseteq \mathcal{D}$ thus $\mathcal{C}_1 \subseteq \mathcal{D}$ and $\mathcal{C}_2 \subseteq \mathcal{D}$. Conversely, assume $\mathcal{C}_1 \subseteq \mathcal{D}$ and $\mathcal{C}_2 \subseteq \mathcal{D}$. Let $T = \mathcal{T}(\mathcal{D})$, where $\mathcal{T} = (A(x), \varphi(x))$ with $A \in \Sigma$, and where $\mathcal{C}$ is either a copying operation if $\subseteq$ is $\subseteq_{\text{FO}}$, or the identity mapping if $\subseteq$ is $\subseteq_{\text{FO}}$. Let $\Sigma'$ be the signature obtained from $\Sigma$ by adding two unary predicates $A(x)$ and $B(x)$. We define $\varphi_A(x,y)$ (resp. $\varphi_B(x,y)$) by replacing in $\varphi(x,y)$ the predicate $M$ by the predicate $A$ (resp. by the predicate $B$). Let $\varphi'(x,y) = (A(x) \wedge A(y) \wedge \varphi_A(x,y)) \vee (B(x) \wedge B(y) \wedge \varphi_B(x,y))$, let $\Gamma = (A(x) \vee B(x), \varphi'(x,y))$, and let $T = \Gamma \circ \mathcal{L}_\Sigma \circ \mathcal{C}$. Then it is easily checked that $\mathcal{C}_1 + \mathcal{C}_2 \subseteq \mathcal{T}(\mathcal{D})$. Conversely, assume that for all classes $\mathcal{C}_1, \mathcal{C}_2$ we have $\mathcal{C}_1 + \mathcal{C}_2 \subseteq \mathcal{D} \iff \mathcal{C}_1 \subseteq \mathcal{D}$ and $\mathcal{C}_2 \subseteq \mathcal{D}$. Then (by choosing $\mathcal{C}_1 = \mathcal{C}_2 = \mathcal{D}$) we deduce $\mathcal{D} \equiv \mathcal{D} \equiv \mathcal{D}$. ◁

Lemma 22. Assume $\mathcal{D}$ is additive and $\mathcal{C}_1$ and $\mathcal{C}_2$ are incomparable. If $\mathcal{D} \subseteq \mathcal{C}_1 + \mathcal{C}_2$, then there exist classes $\mathcal{D}_1$ and $\mathcal{D}_2$ such that $\mathcal{D} \equiv \mathcal{D}_1 + \mathcal{D}_2$, $\mathcal{D}_1 \subseteq \mathcal{C}_1$ and $\mathcal{D}_2 \subseteq \mathcal{C}_2$. Moreover, if $\mathcal{C}_1$ and $\mathcal{C}_2$ are additive we can require that $\mathcal{D}_1$ and $\mathcal{D}_2$ are additive.

Proof. According to Corollary 4 there exists a copy operation $\mathcal{C}$ (which reduces to the identity if $\subseteq$ is $\subseteq_{\text{FO}}$) and an immersive transduction $\mathcal{T}_\text{imm}$ such that $\mathcal{D} \subseteq \mathcal{T}_\text{imm} \circ \mathcal{C}(\mathcal{C}_1 + \mathcal{C}_2)$. Let $\mathcal{T}$ be the interpretation part of $\mathcal{T}_\text{imm}$. Let $G \in \mathcal{D}$ and let $H^+ = \mathcal{L}(\mathcal{D})$, with $K \in \mathcal{C}_1 + \mathcal{C}_2$ and $G = l(H^+)$. As $\mathcal{T}_\text{imm}$ is immersive, each connected component of $G$ comes from a connected component of $H^+$ hence from a connected component of $K$. By grouping the connected components used in $K$ by their origin (of $\mathcal{C}_1$ or $\mathcal{C}_2$) we get that $G$ is the disjoint union of $G_1 \in \mathcal{T}_\text{imm} \circ \mathcal{C}(K_1)$ and $G_2 \in \mathcal{T}_\text{imm} \circ \mathcal{C}(K_2)$, where $K_1 \in \mathcal{C}_1$ and $K_2 \in \mathcal{C}_2$. So $\mathcal{D} \subseteq \mathcal{D}_1 + \mathcal{D}_2$, where $\mathcal{D}_1 \subseteq \mathcal{C}_1$ and $\mathcal{D}_2 \subseteq \mathcal{C}_2$. Moreover, as obviously $\mathcal{D}_1 \subseteq \mathcal{D}$ and $\mathcal{D}_2 \subseteq \mathcal{D}$ we derive from Lemma 21 that we have $\mathcal{D}_1 + \mathcal{D}_2 \subseteq \mathcal{D}$. Hence $\mathcal{D} \equiv \mathcal{D}_1 + \mathcal{D}_2$. For $i = 1, 2$, if $\mathcal{C}_i$ is additive, then we can assume that $\mathcal{D}_i$ is also additive. ◁

Corollary 23. If $\mathcal{D}$ is additive and essentially connected, then

$$\mathcal{D} \subseteq \mathcal{C}_1 + \mathcal{C}_2 \iff \mathcal{D} \subseteq \mathcal{C}_1 \text{ or } \mathcal{D} \subseteq \mathcal{C}_2.$$ 

Proof. According to Lemma 22 there exist $\mathcal{D}_1$, $\mathcal{D}_2$ with $\mathcal{D} \equiv \mathcal{D}_1 + \mathcal{D}_2$, $\mathcal{D}_1 \subseteq \mathcal{C}_1$ and $\mathcal{D}_2 \subseteq \mathcal{C}_2$. However, as $\mathcal{D}$ is essentially connected, $\mathcal{D}_1$ and $\mathcal{D}_2$ cannot be incomparable. Thus $\mathcal{D} \subseteq \mathcal{C}_1$ or $\mathcal{D} \subseteq \mathcal{C}_2$. ◁

Theorem 24. The quasiorder $(\mathfrak{A}, \subseteq)$ is a distributive join-semilattice, where the join of $\mathcal{C}_1$ and $\mathcal{C}_2$ is $\mathcal{C}_1 + \mathcal{C}_2$. In this quasiorder, essentially connected (additive) classes are join-irreducible. This quasiorder has a minimum $\mathcal{E}$ and a maximum $\mathcal{G}$.

Proof. That $(\mathfrak{A}, \subseteq)$ is a join-semilattice follows from Lemma 22 that it is distributive follows from Lemma 20 The last statement follows from Lemma 20. ◁

Corollary 25. Assume that $\mathcal{C}_1$ and $\mathcal{C}_2$ are incomparable and additive, $\mathcal{D}$ is additive and essentially connected, $\mathcal{C}_1 \subseteq \mathcal{D}$, and $\mathcal{C}_2 \subseteq \mathcal{D}$. Then we have

$$\mathcal{C}_1 + \mathcal{C}_2 \subseteq \mathcal{C}_1 + \mathcal{C}_2 \subseteq \mathcal{D}.$$ 

Corollary 26. Assume that $\mathcal{C}_1$ and $\mathcal{C}_2$ are incomparable and additive, $\mathcal{D}$ is additive and essentially connected, $\mathcal{D}$ is incomparable with $\mathcal{C}_1$ and $\mathcal{C}_2 \subseteq \mathcal{D}$. Then $\mathcal{C}_1 + \mathcal{C}_2$ is incomparable with $\mathcal{D}$. ◁
Structural properties of the first-order transduction quasiorder

Proof. Assume for contradiction that $\mathcal{C}_1 + \mathcal{C}_2 \subseteq \mathcal{D}$. According to Theorem 24 we have $\mathcal{C}_1 \subseteq \mathcal{D}$, contradicting the assumption that $\mathcal{D}$ is incomparable with $\mathcal{C}_1$.

Assume for contradiction that $\mathcal{D} \subseteq \mathcal{C}_1 + \mathcal{C}_2$. According to Theorem 24 there exists (by distributivity) classes $\mathcal{D}_1$ and $\mathcal{D}_2$ with $\mathcal{D}_1 \subseteq \mathcal{C}_1$, $\mathcal{D}_2 \subseteq \mathcal{C}_2$, and $\mathcal{D} = \mathcal{D}_1 + \mathcal{D}_2$. As $\mathcal{D}$ is essentially connected, according to Theorem 24 it is join-irreducible. Thus $\mathcal{D}_1$ and $\mathcal{D}_2$ are comparable. Thus $\mathcal{D} \subseteq \mathcal{C}_1$ or $\mathcal{D} \subseteq \mathcal{C}_2$. The first case does not hold as $\mathcal{D}$ is incomparable with $\mathcal{C}_1$, and the second case does not hold as $\mathcal{C}_2 \subseteq \mathcal{D}$.

Using the distributive join-semilattice structure of $(\mathfrak{A}, \sqsubseteq)$, the following corollaries follow from Lemma 16.

- **Corollary 27.** In the poset $(\mathfrak{A}, \sqsubseteq)$, if $(\mathcal{C}_1, \mathcal{C}_2)$ is a cover and $\mathcal{C}_2 \not\sqsubseteq \mathcal{C}_1 + \mathcal{D}$ then $(\mathcal{C}_1 + \mathcal{D}, \mathcal{C}_2 + \mathcal{D})$ is a cover.

- **Corollary 28.** If $(\mathcal{C}_1, \mathcal{C}_2)$ is a cover of $(\mathfrak{A}, \sqsubseteq)$, $\mathcal{C}_1 \subseteq \mathcal{D}$, and $\mathcal{C}_2$ and $\mathcal{D}$ are incomparable, then $(\mathcal{D}, \mathcal{D} + \mathcal{C}_2)$ is a cover of $(\mathfrak{A}, \sqsubseteq)$.

- **Corollary 29.** If $(\mathcal{C}_1, \mathcal{C}_2)$ is a cover of $(\mathfrak{A}, \sqsubseteq)$, $\mathcal{C}_2$ and $\mathcal{D}$ are incomparable, and $\mathcal{C}_2$ is essentially connected, then $(\mathcal{D}, \mathcal{D} + \mathcal{C}_2)$ is a cover of $(\mathfrak{A}, \sqsubseteq)$.

6 The transduction quasiorder on some classes

In this section we consider the poset $(\mathfrak{C}, \sqsubseteq \text{FO})$. We focus on the structure of the partial order in the region of classes with bounded tree-width. A schematic view of the structure of $(\mathfrak{C}, \sqsubseteq \text{FO})$ on classes with tree-width at most 2 is shown Figure 3.

Recall that since MSO collapses to FO on colored trees of bounded depth we have the following chain of covers $\mathcal{E} \subset_{\text{FO}} \mathcal{T}_2 \subset_{\text{FO}} \mathcal{T}_3 \subset_{\text{FO}} \ldots$. We first prove that parallel to this chain we have a chain of covers $\mathcal{E} \subset_{\text{FO}} \mathcal{P} \subset_{\text{FO}} \mathcal{P} \cup \mathcal{T}_2 \subset_{\text{FO}} \mathcal{P} \cup \mathcal{T}_3 \subset_{\text{FO}} \ldots$ and for all $n \geq 1$ we have $\mathcal{T}_n \subset_{\text{FO}} \mathcal{P} \cup \mathcal{T}_n$.

- **Theorem 30** (proved in the appendix). We have $\mathcal{E} \subset_{\text{FO}} \mathcal{P}$ and, for every $n \geq 1$, the chain of covers

  $$(\mathcal{P} + \mathcal{T}_n) \subset_{\text{FO}} (\mathcal{P} + \mathcal{T}_n) \cup \mathcal{T}_{n+1} \subset_{\text{FO}} (\mathcal{P} + \mathcal{T}_n) \cup \mathcal{T}_{n+2} \subset_{\text{FO}} \ldots$$

  In particular, for $n = 1$ we get $\mathcal{P} \subset_{\text{FO}} \mathcal{P} \cup \mathcal{T}_2 \subset_{\text{FO}} \mathcal{P} \cup \mathcal{T}_3 \subset_{\text{FO}} \ldots$

  Moreover, for all $n \geq 1$ we have $\mathcal{T}_n \subset_{\text{FO}} \mathcal{P} \cup \mathcal{T}_n$.

The difficult part of the next theorem is to prove that $\mathcal{T}_{n+2} \not\subset_{\text{FO}} \mathcal{P} \mathcal{W}_n$. We use that the class $\mathcal{T}_{n+2}$ is additive, which by Corollary 7 implies that we can eliminate perturbations and focus on immersive transductions. This allows us to consider host graphs in $\mathcal{P} \mathcal{W}_n$ that have bounded radius, where we can find a small set of vertices whose removal decreases the pathwidth. We encode the adjacency to these vertices by colors and proceed by induction.

- **Theorem 31** (proved in the appendix). For $n \geq 1$ we have $\mathcal{T}_{n+1} \subset_{\text{FO}} \mathcal{P} \mathcal{W}_n$ but $\mathcal{T}_{n+2} \not\subset_{\text{FO}} \mathcal{P} \mathcal{W}_n$.

Consequently, for $m > n \geq 1$ we have

$$\mathcal{T}_m + \mathcal{P} \mathcal{W}_n \subset_{\text{FO}} (\mathcal{T}_m + \mathcal{P} \mathcal{W}_n) \cup \mathcal{T}_{m+1} \subset_{\text{FO}} (\mathcal{T}_m + \mathcal{P} \mathcal{W}_n) \cup \mathcal{T}_{m+2} \subset_{\text{FO}} \ldots$$

$$\mathcal{T}_m + \mathcal{P} \mathcal{W}_n \subset_{\text{FO}} (\mathcal{T}_m + \mathcal{P} \mathcal{W}_n) \cup \mathcal{T}_{m+1} \subset_{\text{FO}} \mathcal{T}_{m+1} + \mathcal{P} \mathcal{W}_n$$

In particular, fixing $m = n + 1$ we get that for $n \geq 1$ we have

$$\mathcal{P} \mathcal{W}_n \subset_{\text{FO}} \mathcal{P} \mathcal{W}_n \cup \mathcal{T}_{n+2} \subset_{\text{FO}} \mathcal{P} \mathcal{W}_n \cup \mathcal{T}_{n+3} \subset_{\text{FO}} \ldots \subset_{\text{FO}} \mathcal{P} \mathcal{W}_n \cup \mathcal{T}$$

$$\mathcal{P} \mathcal{W}_n \subset_{\text{FO}} \mathcal{P} \mathcal{W}_n \cup \mathcal{T}_{n+2} \subset_{\text{FO}} \mathcal{P} \mathcal{W}_n \cup \mathcal{T}_{n+3} + \mathcal{P} \mathcal{W}_n \subset_{\text{FO}} \mathcal{P} \mathcal{W}_{n+1}$$
Theorem 32 (proved in the appendix). For \( m > n \geq 2 \), \( T_m + PW_n \) is incomparable with \( T \).
Consequently, we have
\[
T \subseteq_{FO} T \cup PW_2 \subseteq_{FO} T \cup (T_4 + PW_2) \subseteq_{FO} \cdots \subseteq_{FO} T + PW_2 \subseteq_{FO} TW_2.
\]

With the above results in hand we obtain for \((C, \subseteq_{FO})\) and \((A, \subseteq_{FO})\) the structures sketched in Figure 2.

Figure 2 A fragment of \((C, \subseteq_{FO})\) (top) and a fragment of \((A, \subseteq_{FO})\) (bottom). Thick edges are covers.
Structural properties of the first-order transduction quasiorder

References

A Missing proofs from Section 6

Lemma 33. A class $C$ is a transduction in $E$ (or, equivalently, $C \equiv_{FO} E$) if and only if $C$ is a perturbation of a class whose members have uniformly bounded size connected components. Furthermore, a class $C$ is a non-copying transduction in $E$ if and only if $C$ is a perturbation of $E$.

Proof. Assume that $C$ is a perturbation of a class $D$ and that all graphs in $D$ have connected components of size at most $n$. Then $D$ can obviously be obtained from $E$ by the composition of an $n$-copy transduction composed with some (immersive) transduction. Conversely, if $C$ is a transduction of $E$ then, according to Theorem 30, $C$ is a perturbation of a class $D \subseteq T_{imm} \circ C(E)$, where $T_{imm}$ is immersive and $C$ is a $k$-copy transduction for some number $k$. By the strong locality of the interpretation associated to $T_{imm}$ no connected component of a graph in $D$ can have size greater than $k$. The last statement is obvious, as every immersive transduction of $E$ is included in $E$.

Theorem 30. We have $E \prec_{FO} P$ and, for every $n \geq 1$, the chain of covers

$$(P + T_n) \prec_{FO} (P + T_n) \cup T_{n+1} \prec_{FO} (P + T_n) \cup T_{n+2} \prec_{FO} \ldots$$

In particular, for $n = 1$ we get $P \prec_{FO} P \cup T_2 \prec_{FO} P \cup T_3 \prec_{FO} \ldots$

Moreover, for all $n \geq 1$ we have $T_n \prec_{FO} P \cup T_n$.

Proof. Obviously $E \subseteq_{FO} P$. Assume towards a contradiction that there exists a class $C$ with $E \subseteq_{FO} C \subseteq_{FO} P$. As in the first part of the proof of Theorem 9, we see that the class $C$ is a perturbation of a class $D$ with bounded bandwidth. The connected components of the graphs in $D$ have unbounded size as otherwise $D$ (and thus $C$) can be transduced in $E$ (according to Lemma 33). But then $C \equiv_{FO} P$ by Theorem 9, contradicting our assumption. Hence $E \prec_{FO} P$.

Let $m \geq n \geq 1$. We have $(P + T_n) \not\subseteq_{FO} T_{m+1}$ and $T_{m+1} \not\subseteq_{FO} (P + T_n) \cup T_m$ as otherwise, according to Lemma 33, we would have $T_{m+1} \subseteq_{FO} P + T_n$ or $T_{m+1} \subseteq_{FO} T_m$ as $T_{m+1}$ is additive. As $T_{m+1}$ is additive and essentially connected $T_{m+1} \subseteq_{FO} P + T_n$ would imply $T_{m+1} \subseteq_{FO} P$ or $T_{m+1} \subseteq_{FO} T_n$. According to Corollary 17 we have $(P + T_n) \cup T_m \prec_{FO} (P + T_n) \cup T_{m+1}$.

(Note that $T_1 = E$ and thus $P \cup T_1 = P$, and that $(P + T_n) \cup T_n = P + T_n$.)

Let $n \geq 1$. According to Corollary 18 as $E \prec_{FO} P$, $E \subseteq_{FO} T_n$, and $P$ is incomparable with $T_n$, we have $T_n \prec_{FO} P \cup T_n$.

Theorem 31. For $n \geq 1$ we have $T_{n+1} \subseteq_{FO} PW_n$ but $T_{n+2} \not\subseteq_{FO} PW_n$. Consequently, for $m > n \geq 1$ we have

$$T_m + PW_n \prec_{FO} (T_m + PW_n) \cup T_{m+1} \prec_{FO} (T_m + PW_n) \cup T_{m+2} \prec_{FO} \ldots$$

$$T_m + PW_n \prec_{FO} (T_m + PW_n) \cup T_{m+1} \subseteq_{FO} T_{m+1} + PW_n$$

In particular, fixing $m = n + 1$ we get that for $n \geq 1$ we have

$$PW_n \prec_{FO} PW_n \cup T_{n+2} \prec_{FO} PW_n \cup T_{n+3} \prec_{FO} \ldots \subseteq_{FO} PW_n \cup T$$

$$PW_n \prec_{FO} PW_n \cup T_{n+2} \subseteq_{FO} T_{n+2} + PW_n \subseteq_{FO} PW_{n+1}$$

Proof. For convenience, we define $T_1 = PW_0 = E$, which is consistent with our definitions. Then $T_n \subseteq_{FO} PW_{n-1}$ as for $n = 1$ this reduces to $E \subseteq_{FO} E$ and, if $n > 1$, $T_n \subseteq_{FO} P \cup T_n \subseteq_{FO} PW_{n-1}$. 

...
\(\mathcal{PW}_n\). We now prove \(T_{n+1} \subseteq \mathcal{PW}_n\) by induction on \(n\). For \(n = 1\), this follows from Lemma 33 (or from the known fact \(T_2 \supseteq \mathcal{E}\)). Now assume that we have proved the statement for \(n \geq 1\) and assume towards a contradiction that \(T_{n+2} \subseteq \mathcal{PW}_n\). The class \(\mathcal{PW}_n\) is the monotone closure of the class \(T_{n+1}\) of interval graphs with clique number at most \(n+1\). As the class \(T_{n+1}\) has bounded star chromatic number, it follows from Lemma 34 that \(\mathcal{PW}_n \subseteq \mathcal{FO} T_{n+1}\). Let \(T\) be the composition of the respective transductions, so that \(T_{n+2} \subseteq T(I_{n+1})\). As \(T_{n+3}\) is additive, it follows from Corollary 7 that there is a copy operation \(C\) and an immersive transduction \(T_0\) such that \(T_0 \circ C \subseteq T\). As \(\{G + K_1 : G \in T_{n+1}\} \subseteq T_{n+2}\) if follows from Lemma 5 that there exists an integer \(r\) such that \(T_{n+1} \subseteq FO B_r^{(I_{n+1})} \subseteq C(B_r^{n+1})\). According to Lemma 6, as \(T_{n+1}\) is additive, there exists an immersive transduction \(T_1\) with \(T_{n+1} \subseteq T_1 \circ C \circ T_2(I_{n+1})\), which contradicts our induction hypothesis.

Let us now prove the cover chain, that is that for \(k \geq m > n \geq 1\) we have \((T_m + \mathcal{PW}_n) \cup T_k \subseteq \mathcal{FO} (T_m + \mathcal{PW}_n) \cup T_{k+1}\). To deduce this from the cover \(T_k \subseteq \mathcal{FO} T_{k+1}\) using Corollary 17 we need to check \((T_m + \mathcal{PW}_n) \subseteq \mathcal{FO} T_{k+1} \mathcal{FO} (T_m + \mathcal{PW}_n) \cup T_k\). According to Lemma 23 as \((T_m + \mathcal{PW}_n)\) and \(T_{k+1}\) are both additive, \((T_m + \mathcal{PW}_n) \subseteq \mathcal{FO} T_{k+1}\) is equivalent to \(T_m \subseteq \mathcal{FO} T_{k+1}\) and \(\mathcal{PW}_n \subseteq \mathcal{FO} T_{k+1}\). However, \(\mathcal{PW}_n \subseteq \mathcal{FO} T_{k+1}\) as \(\mathcal{PW}_n \subseteq \mathcal{FO}\) \(\mathcal{PW}_n\) and \(\mathcal{PW}_n\) is incomparable with \(T_{k+1}\). Thus \((T_m + \mathcal{PW}_n) \subseteq \mathcal{FO} T_{k+1}\). Now assume for contradiction that we have \(T_k \subseteq \mathcal{FO} (T_m + \mathcal{PW}_n) \cup T_k\). As \(T_{k+1}\) is additive, it follows from Lemma 13 that we have \(T_{k+1} \subseteq \mathcal{FO} (T_m + \mathcal{PW}_n)\) as \(T_{k+1} \subseteq \mathcal{FO} T_k\). As \(T_{k+1}\) is additive and essentially connected, according to Corollary 23 we deduce that \(T_{k+1} \subseteq \mathcal{FO} T_m\) or \(T_{k+1} \subseteq \mathcal{FO} \mathcal{PW}_n\). The first case does not hold as \(k+1 > m\). The second case does not hold as \(k+1 > n+2\) and \(T_{n+2} \subseteq \mathcal{FO} \mathcal{PW}_n\).

\[\textbf{Theorem 32.} \text{ For } m > n \geq 2, T_m + \mathcal{PW}_n \text{ is incomparable with } T. \text{ Consequently, we have } T \subseteq \mathcal{FO} T \cup \mathcal{PW}_2 \subseteq \mathcal{FO} T \cup (T_4 + \mathcal{PW}_2) \subseteq \mathcal{FO} \cdots \subseteq \mathcal{FO} T + \mathcal{PW}_2 \subseteq \mathcal{FO} T \mathcal{W}_2.\]

\textbf{Proof.} We establish that \(\mathcal{PW}_2 \subseteq \mathcal{FO} T\), from which \(T \mathcal{W}_2 \subseteq \mathcal{FO} T\) immediately follows. Assume for contradiction that \(\mathcal{PW}_2 \subseteq \mathcal{FO} T\). As \(\mathcal{PW}_2\) is additive and does not need copying (Observation 5), by Corollary 7 there is an immersive transduction of \(\mathcal{PW}_2\) in \(T\). In particular, there exists an integer \(r\) such that the class \(\{K_1 + P_n : n \in \mathbb{N}\}\) is the transduction of \(T\), which contradicts the property \(\mathcal{PW}_2 \subseteq \mathcal{FO} T\). Thus \(\mathcal{PW}_2 \subseteq \mathcal{FO} T\).

We prove that the classes \(\mathcal{PW}_n\) \((n \geq 2)\) are incomparable with \(T\). The class \(T\) has unbounded linear cliquewidth, hence \(T \subseteq \mathcal{FO} H\), and thus \(T \subseteq \mathcal{FO} \mathcal{PW}_n\) for every integer \(n\) (recall that a class \(\mathcal{E}\) has bounded linear cliquewidth if and only if \(\mathcal{E} \subseteq \mathcal{FO} H\)). As \(\mathcal{PW}_2 \subseteq \mathcal{FO} T\) it follows that, for \(n \geq 2\), \(\mathcal{PW}_n \subseteq \mathcal{FO} T\), thus \(\mathcal{PW}_n\) and \(T\) are incomparable. (This settles the case where \(m = n + 1\) as \(T_{n+1} + \mathcal{PW}_n = \mathcal{PW}_n\).) For \(m > n + 1\) the classes \(T_m\) and \(\mathcal{PW}_n\) are additive and incomparable and \(T_m \subseteq \mathcal{FO} T\). As \(T\) is additive, essentially connected and incomparable with \(\mathcal{PW}_n\) we deduce by Corollary 26 that \(T_m + \mathcal{PW}_n\) is incomparable with \(T\).
B Transduction of the monotone closure in a class with bounded star coloring number

Recall that a star coloring of a graph $G$ is a proper coloring of $V(G)$ such that any two color classes induce a star forest (or, equivalently, such that no path of length four is 2-colored), and that the star chromatic number $\chi_{st}(G)$ of $G$ is the minimum number of colors in a star coloring of $G$ [1]. The star chromatic number is bounded on classes of graphs excluding a minor [19] and, more generally, on every bounded expansion class [20].

Lemma 34. Let $\mathcal{C}$ be a class with bounded star chromatic number. Then there is an immersive transduction from $\mathcal{C}$ onto its monotone closure.

Proof. We consider the immersive transduction $T$ with $\Sigma_T = \{M_1, \ldots, M_C, N_1, \ldots, N_C, X\}$ and $I_T = (\nu(x), \eta(x,y))$, where $C = \max_{G \in \mathcal{C}} \chi_{st}(G)$, $\nu(x) = X(x)$, and

$$\eta(x,y) = E(x,y) \land \left( \bigvee_{i=1}^{C} M_i(x) \land N_i(y) \right) \land \left( \bigvee_{i=1}^{C} M_i(y) \land N_i(x) \right).$$

Let us prove that $T$ is a transduction from $\mathcal{C}$ onto its monotone closure. Let $H$ be a graph in the monotone closure of $\mathcal{C}$ and let $G \in \mathcal{C}$ be a supergraph of $H$ (we identify $H$ with a subgraph of $G$). We consider an arbitrary star coloring $\gamma: V(G) \to [C]$ and define the $\Sigma_T$-expansion $G^+$ of $G$ as follows:

$$X(G) = V(H),$$

$$M_i(G) = \{v \in V(G) \mid \gamma(v) = i\} \quad \text{(for } 1 \leq i \leq C),$$

$$N_i(G) = \{v \in V(G) \mid (\exists u \in N_H(v)) \gamma(u) = i\} \quad \text{(for } 1 \leq i \leq C).$$

According to the definitions of $\nu$ and as $\models \eta(x,y) \rightarrow E(x,y)$, it is clear that $I_T(G^+)$ is a subgraph of $G[V(H)]$. According to our definitions of $M_i$ and $N_i$, it is also clear that $H$ is a subgraph of $I_T(G^+)$. Thus, in order to prove that $H = I_T(G^+)$, we have only to prove that $I_T(G^+)$ contains no more edges than $H$. Assume towards a contradiction that $u, v \in V(H)$ are adjacent in $I_T(G^+)$ and not in $H$. According to the definition of $M_i$ and $N_i$ it follows that $u$ has a neighbor $v'$ in $H$ with $\gamma(v') = \gamma(v)$ and that $v$ has a neighbor $u'$ in $H$ with $\gamma(u') = \gamma(u)$. It follows that the path $v', u, v, u'$ of $G$ is 2-colored by $\gamma$, contradicting the hypothesis that $\gamma$ is a star coloring.

$\blacksquare$
