A SIMPLE PROOF THAT THE $L_p$-DIAMETER OF $\text{Diff}_0(S,\text{area})$ IS INFINITE.

MICHAŁ MARCINKOWSKI

Abstract. We give a simple proof that the $L_p$-diameter of the group of area preserving diffeomorphisms isotopic to the identity of a compact surface is infinite.

1. Introduction

Let $(M, g)$ be a Riemannian manifold and let $\mu$ be the measure induced by the metric $g$. By $\text{Diff}_0(M, \mu)$ we denote the group of all diffeomorphisms of $M$ preserving $\mu$ and isotopic to the identity.

In [6] A. Shnirelman showed that $L_2$-diameter of $\text{Diff}_0(M, \mu)$ is finite if $M$ is an $n > 2$ dimensional cube (see as well [7]). The same holds true not only for cubes, but as well for all simply connected $n > 2$ dimensional manifolds.

In dimension 2 the situation is different. For simplicity, let us restrict the discussion to orientable compact surfaces. Eliashberg and Ratiu [4] proved that $L_p$-diameter for $p \geq 1$ of $\text{Diff}_0(S, \text{area})$ is infinite if $S$ is a surface with boundary. They show that the Calabi homomorphism is Lipschitz with respect to the $L_p$-norm. Later Gambaudo and Lagrange [5] obtained a similar result for huge class of quasimorphisms on $\text{Diff}_0(S, \text{area})$ if $S$ is the closed disc. Their proof make use of the braid group of the disc and intersection numbers.

If $S$ is a closed hyperbolic surface, it is relatively easy to show that $L_p$-diameter for $p \geq 1$ of $\text{Diff}_0(S, \text{area})$ is infinite (see [2, Theorem 1.2]). In the case of torus one need to know in addition, that the group of hamiltonian diffeomorphisms of the torus is simply connected, which is a non-trivial result from symplectic topology (see [3, Appendix A]).

The last case which was left was the sphere, and it was showed recently by Brandenbursky and Shelukhin [3] that in this case the diameter is as well infinite, and moreover $\text{Diff}_0(S, \text{area})$ contains quasi-isometrically embedded right-angled Artin groups and $\mathbb{R}^m$ for each natural $m$. Their arguments use ideas from [5], however, using intersection numbers in the case of the sphere is not that straightforward and requires considerably more work.
In this paper we give a simpler proof that $L_p$-diameter for $p \geq 1$ of $\text{Diff}_0(S, \text{area})$ is infinite. Our argument works for any compact surface $S$ (with boundary or not). The main simplification comes from the fact that instead of using the braid group and intersection numbers, we directly look at the geometry of the configuration space $C_n(S)$ with a blown-up metric described in Section 3. The second step is to show inequality 4.2 which relates $L_p$-norm of $f \in \text{Diff}_0(S, \text{area})$ to a certain norm (defined using this blown-up metric) of the diffeomorphism on $C_n(S)$ induced by $f$. This inequality is in spirit similar to the one obtained for the disc in [5].

2. THE $L_p$ METERIC

Let $S$ be a surface with a Riemannian metric. Suppose $f \in \text{Diff}_0(S, \text{area})$ and let $X : S \to TS$ be a map to a tangent space of $S$ such that $X(x) \in T_{f(x)}S$. One can think of $X$ as a tangent vector to $\text{Diff}_0(S, \text{area})$ at the point $f$. The $L_p$ norm of $X$ is defined by

$$L_p(X) = \left( \int_S |X(x)|^p \, dx \right)^{\frac{1}{p}}.$$ 

Let $f_t \in \text{Diff}_0(S, \text{area})$, $t \in [0, 1]$, be a smooth isotopy, i.e., it is a smooth map $S \times [0, 1] \to S$ (we always assume that isotopies are smooth). Its $L_p$ length is defined by the formula

$$L_p(f_t) = \int_0^1 L_p(\dot{f}_t) \, dt,$$

where $\dot{f}_t(x) = \frac{d}{dt} f_t(x)|_{t=1} \in T_{f_t(x)}S$. Note that if $p = 1$, then $\int_0^1 |\dot{f}_t(x)| \, dt$ is the length of the path $f_t(x)$, thus $L_1(\{f_t\})$ can be interpreted as the average of the lengths of all possible paths $f_t(x)$.

Let $f \in \text{Diff}_0(S, \text{area})$, we define the $L_p$-norm of $f$ by

$$L_p(f) = \inf L_p(f_t),$$

where the infimum is taken over all smooth isotopies $f_t \in \text{Diff}_0(S, \text{area})$ connecting the identity on $S$ with $f$.

The $L_p$-diameter of $\text{Diff}_0(S, \text{area})$ equals

$$\sup\{L_p(f) : f \in \text{Diff}_0(S, \text{area})\}.$$

It is worth to add, that geodesics in $\text{Diff}_0(S, \text{area})$ with $L_2$-metric, i.e., paths $\{f_t\}$ that minimize $L_2(\{f_t\})$ when the endpoints $f_0$ and $f_1$ are fixed, are solutions of the Euler equations of incompressible fluid. For more on the connection between $L_2$-metric and hydrodynamics see [1].

3. BLOWING UP THE METERIC

Let $(X, g)$ be a compact Riemannian manifold and let $D = \bigcup_{i=1}^k D_i$, where $D_i$ are compact submanifolds of $X$. For $x \in X$, by $d(x)$ we denote the distance of $x$ to $D$, i.e.,

$$d(x) = d_g(x, D) = \min\{d_g(x, D_i) : i = 1, \ldots, k\},$$

where $d_g$ is the metric on $X$ induced by $g$. 
It might happen that even if $\pi_1(X - D)$ is infinite, the universal cover of $(X - D, g)$ with the pulled-back Riemannian metric has finite diameter. E.g., if $X$ is a 2-dimensional flat disc of diameter 1 and $D = \{p\}$ is a single point in $X$, then every based loop in $X - D$ is homotopic to a loop of length less then 2. Thus the universal cover has diameter at most 2. The same phenomenon occurs when $X - D$ is the configuration space of $n$ distinct points on a surface, the space we focus on in the second part of this note.

To avoid this, we blow up $g$ by rescaling it by $\frac{1}{d}$, i.e., we define a new Riemannian metric $g_b$ on $X - D$ by:

$$|v|_{g_b} = \frac{|v|_g}{d(x)},$$

where $v \in T_x(X - D)$ is a vector tangent to a point $x \in X - D$.

**Lemma 3.1.** $X - D$ with the metric $g_b$ is complete.

**Proof.** Let $Y = X - D$. To show completeness it amounts to show, that for each $x \in Y$ the ball $B_Y(x, \frac{1}{2})$ is compact. Indeed, let $\{y_i\}$ be a Cauchy sequence in $Y$. There exists $n \in \mathbb{N}$ such that $\{y_i\}_{i>n}$ is contained in $B_Y(y_n, \frac{1}{2})$. Since $B_Y(y_n, \frac{1}{2})$ is compact, $\{y_i\}_i$ converges and $Y$ is complete.

Let $x \in Y$. We show that the distance of $B_Y(x, \frac{1}{2})$ to $D$ is at least $\frac{d(x)}{2}$, i.e.,

$$B_Y(x, \frac{1}{2}) \subset L := \{y \in Y \mid d(y) \geq \frac{d(x)}{2}\}.$$ 

Since $L$ is compact, it follows that $B_Y(x, \frac{1}{2})$ is compact.

Suppose $y \in B_Y(x, \frac{1}{2})$ and $d(y) < d(x)$ (otherwise obviously $y \in L$). Let $\epsilon > 0$ and let $\gamma: [0, l] \to Y$ be a geodesic with respect to $g_b$ connecting $x$ with $y$ such that $l < \frac{1}{2} + \epsilon$. Let

$$t_0 = \sup \{t \in [0, l] : d(\gamma(t)) \geq d(x)\},$$

i.e., $t_0$ is the last time when $d(\gamma(t_0)) = d(x)$. Since $\gamma$ is a geodesic, we have $|\dot{\gamma}(t)|_{g_b} = 1$ and therefore

$$|\dot{\gamma}(t)|_g = d(\gamma(t)) \leq d(x) \text{ if } t \geq t_0.$$ 

Let $\gamma'$ be the restriction of $\gamma$ to the interval $[t_0, l]$. The length of $\gamma'$ in the metric $g$ is at most

$$(l - t_0)d(x) \leq \left(\frac{1}{2} + \epsilon\right)d(x).$$

Therefore the distance of $y$ to $D$ in $g$ is at least

$$d(\gamma(t_0)) - \text{length}_g(\gamma') \geq d(x) - \left(\frac{1}{2} + \epsilon\right)d(x).$$

Since $\epsilon$ is arbitrarily small, $y \in L$ and $B_Y(x, \frac{1}{2}) \subset L$.

□

**Lemma 3.2.** Let $X$ be a complete Riemannian manifold. Suppose that $p: Y \to X$ is an infinite cover of $X$. Then for every $x \in X$, the pre-image $p^{-1}(x)$ has infinite diameter.
Proof. Let \( x \in X \) and let \( y \in Y \) be any point. Since \( X \) is complete, so is \( Y \). Therefore for every \( r \) the closed ball \( B(y, r) \subset Y \) is compact. Since the pre-image \( p^{-1}(x) \) is discrete, \( p^{-1}(x) \cap B(y, r) \) is finite for every \( r \). Hence \( p^{-1}(x) \) has infinite diameter.

\[
\square
\]

The following corollary follows immediately from Lemma 3.1 and Lemma 3.2.

**Corollary 3.3.** Every infinite cover of \((X - D, g_b)\) has infinite diameter. Moreover, pre-images of points have infinite diameter.

4. The inequality

We now focus on the particular case where \( X - D \) is a configuration space. Let \((S, g)\) be a compact Riemannian surface of area 1 and \( g^n \) be the product metric on \( S^n \). Let \( D_{ij} = \{x \in S^n : x_i = x_j\} \). Denote by \( C_n(S) = S^n - \bigcup_{i,j} D_{ij} \) the configuration space of \( n \) points in \( S \). On \( S^n \) and \( C_n(S) \) we consider the measure induced by the product metric \( g^n \).

We shall now find a formula for \( d_{g^n}(x, D_{ij}) \) in terms of the metric on \( S \). Let \( x = (x_1, \ldots, x_n) \in S^n \) and let \( m \) be the midpoint of a geodesic connecting \( x_i \) with \( x_j \). If we start moving points \( x_i \) and \( x_j \) towards \( m \) with speed one, we get a geodesic in \( S^n \) connecting \( x \) with a point in \( D_{ij} \). Since \( d_g(m, x_i) = d_g(m, x_j) = \frac{1}{2} d_g(x_i, x_j) \) and we are in the product metric, we get

\[
d_{g^n}(x, D_{ij}) = \sqrt{d_g(m, x_i)^2 + d_g(m, x_j)^2} = \frac{1}{\sqrt{2}} d_g(x_i, x_j).
\]

The distance function \( d \) has the form

\[
d(x) = \frac{1}{\sqrt{2}} \min \{d_g(x_i, x_j) : 1 \leq i < j \leq n\}.
\]

Let \( g_b = (g^n)_b \) be the metric on \( C_n(S) \) as defined in the previous section, namely \( |v|_{g_b} = \frac{|v|_{g^n}}{d(x)} \), where \( v \in T_x(C_n(S)) \).

Let us fix a point \( p \in S \) and let \( x = (x_1, \ldots, x_{n-1}) \in S^{n-1} \). Then \((p, x) \in S^n \) and \( d((p, x)) \) is the minimum over \( \frac{1}{\sqrt{2}} d_g(p, x_i) \) for \( 1 \leq i \leq n - 1 \) and \( \frac{1}{\sqrt{2}} d_g(x_i, x_j) \) for \( 1 \leq i < j \leq n - 1 \).

We need the following technical lemma:

**Lemma 4.1.** There exists \( C \) such that for every \( p \in S \), we have

\[
\int_{S^{n-1}} \frac{1}{d((p, x))} \, dx \leq C.
\]

Proof. It can be easily seen using polar coordinates, that there exists \( C' \) such that for every \( p \in D^2 \), where \( D^2 \) is the euclidean disc, we have

\[
\int_D \frac{1}{|p - x|} \, dx < C'.
\]
Since such $C'$ exists for a disc, we have as well a bound for every surface $S$, i.e., for every $p \in S$ we have:

$$\int_S \frac{1}{d_g(p, x)} dx < C'.$$

After integrating over all possible $p \in S$ we have:

$$\int_{S^2} \frac{1}{d_g(p, x)} dp dx < C'.$$

Let $x = (x_1, \ldots, x_{n-1})$. Since $d((p, x))$ is the minimum over $\frac{1}{\sqrt{2}} d_g(p, x_i)$ for $i = 1, \ldots, n-1$ and $\frac{1}{\sqrt{2}} d_g(x_i, x_j)$ for $1 \leq i < j \leq n-1$, we have that:

$$\frac{1}{d((p, x))} \leq \sum_i \frac{\sqrt{2}}{d_g(p, x_i)} + \sum_{i \neq j} \frac{\sqrt{2}}{d_g(x_i, x_j)}.$$

Thus

$$\int_{S^{n-1}} \frac{1}{d((p, x))} dx \leq$$

$$\leq \sum_i \int_{S^{n-1}} \frac{\sqrt{2}}{d_g(p, x_i)} dx + \sum_{i \neq j} \int_{S^{n-1}} \frac{\sqrt{2}}{d_g(x_i, x_j)} dx =$$

$$= (n-1) \int_S \frac{\sqrt{2}}{d_g(p, x)} dx + \frac{n(n-1)}{2} \int_{S^2} \frac{\sqrt{2}}{d_g(x_1, x_2)} dx_1 dx_2 \leq$$

$$\leq \sqrt{2}(n-1)C' + \frac{n(n-1)}{\sqrt{2}} C' =: C.$$

\[\square\]

Let $f \in \text{Diff}_0(S, \text{area})$. Slightly abusing the notation, for $x = (x_1, \ldots, x_n) \in S^n$ we write $f(x) = (f(x_1), \ldots, f(x_n))$. Note that $f$ seen as a map on $S^n$ preserves the product measure given by $g^\#$. Let $X: S \to TS$ such that $X(x) \in T_{f(x)}S$. Analogously we write $X(x) = (X(x_1), \ldots, X(x_n)) \in T_{f(x)}S^n$ for $x = (x_1, \ldots, x_n) \in S^n$.

The following inequality provides a link between $L_1$-norm of a map $X$ and the metric $g_b$. Note that in the proof of this inequality it is essential that $f$ preserves the area on $S$ (it is the only place where we use this assumption).

**Lemma 4.2.** There exists $C$ such that for every $f \in \text{Diff}_0(S, \text{area})$ and every map $X: S \to TS$ such that $X(x) \in T_{f(x)}S$ we have:

$$\int_{S^n} |X(x)|_{g_b} dx \leq CL_1(X).$$

**Proof.** Let us first note, that $|X(x)|_{g_b}$ is not well defined if $x \in \cup_{i,j} D_{ij}$, but the set $\cup_{i,j} D_{ij} \subset S^n$ has measure 0. Thus we can regard $|X(x)|_{g_b}$ as a measurable function on $S^n$ (and this is why we can integrate it over $S^n$).
\[ \int_{S^n} |X(x)|_g \, dx = \int_{S^n} \sqrt{\left|X(x_1)\right|_g^2 + \ldots + \left|X(x_n)\right|_g^2} \, d(f(x)) \]
\[ \leq \int_{S^n} \frac{|X(x_1)|_g + \ldots + |X(x_n)|_g}{d(f(x))} \, dx \]
\[ = n \int_{S^n} \frac{|X(x_1)|_g}{d(f(x))} \, dx. \]

Since \( f \) preserves the measure on \( S^n \), we have
\[ \int_{S^n} \frac{|X(x_1)|_g}{d(f(x))} \, dx = \int_{S^n} \frac{|X(x_n)|_g}{d(f(x))} \, dx. \]

By Lemma 4.1,
\[ \frac{|X(x_n)|_g}{d(f(x))} = C L_1(X), \]

\[ \square \]

5. PROOF OF THE THEOREM

Before the proof we need to recall one standard lemma.

Lemma 5.1. Let \( X \) be a topological space and \( Z < \pi_1(X) \) be the center of \( \pi_1(X) \). Let \( Y \) be the cover of \( X \) associated to \( Z \). Suppose \( F \) is a homeomorphism of \( X \) isotopic to the identity \( Id_X \) and let \( f_t \) and \( g_t \), \( t \in [0, 1] \), be two isotopies connecting \( Id_X \) with \( F \). Let \( \tilde{g}_t \) and \( \tilde{f}_t \) be lifts of these isotopies to \( Y \) such that \( \tilde{g}_0 = \tilde{f}_0 \). Then \( \tilde{g}_1 = \tilde{f}_1 \).

Proof. Let \( h_t, t \in [0, 1] \), be the concatenation of the isotopies \( f_t \) and \( g_{1-t} \), i.e.,
\[ h_t = \begin{cases} f_{2t} & t \in [0, \frac{1}{2}] \\ g_{2(1-t)} & t \in [\frac{1}{2}, 1]. \end{cases} \]

Then \( h_0 = h_1 = Id_X \). It amounts to show, that for each \( x \in X \) the loop \( h_t(x) \) is in the center of \( \pi_1(X, x) \). Let \( \gamma_s, s \in [0, 1] \), be any loop based at \( x \). Consider the map \( \phi: S^1 \times S^1 \to X \) given by \((t, s) \to h_t(\gamma_s)\), where \( S^1 = [0, 1]/_{0 \sim 1} \). We have that \( \phi(t, 0) = h_t(x) \) and \( \phi(0, s) = \gamma_s \). Thus loops \( h_t(x) \) and \( \gamma_s \) are in the image of the torus \( S^1 \times S^1 \), therefore they commute. \( \square \)

Theorem 1. Let \( S \) be a compact surface (with or without a boundary). The \( L_p \)-diameter of \( Diff_0(S, area) \) is infinite for every \( p \geq 1 \).
Proof. By Hölder inequality we can assume $p = 1$. Let $z = (z_1, \ldots, z_n) \in C_n(S)$ and denote the pure braid group on $n$ strings by $P_n(S) = \pi_1(C_n(S), z)$. Recall that on $C_n(S)$ we consider the blown-up metric $g_b$. Let $Z < P_n(S)$ be the center and $Y$ be the normal cover associated to $Z$. Assume that $n > 3$, then the deck-transformation group $H = P_n(S)/Z$ is infinite. Fix $z' \in Y$ in the pre-image of $z$.

Suppose $U_i \subset S$ are disjoint discs such that $z_i \in U_i$. Let $U = U_1 \times U_2 \ldots \times U_n \subset C_n(S)$ and let $\tilde{U} \approx U$ be the lift of $U$ to $Y$ containing $z'$.

Let $f_t \in \text{Diff}_0(S, \text{area})$, $t \in [0, 1]$, be an isotopy. Denote by $F_t$ the diffeomorphism of $C_n(S)$ defined by

$$F_t(x) = (f_t(x_1), \ldots, f_t(x_n)), \text{ for } x = (x_1, \ldots, x_n) \in C_n(S).$$

Let $\tilde{F}_t$ be the lift of $F_t$ satisfying $\tilde{F}_0 = Id_Y$. For a given $\gamma \in H$ we can choose $f_t$ such that:

1. $f_0 = Id_S,$
2. $f_1$ is the identity on $U_1 \cup U_2 \cup \ldots \cup U_n$,
3. $\tilde{F}_1(x) = \gamma x$ for every $x \in \tilde{U}$.

In other words, for every $x = (x_1, \ldots, x_n) \in U$, the subset

$$\{(f_t(x_i), t) : t \in [0, 1], 1 \leq i \leq n\} \subset S \times [0, 1],$$

represents the braid $\gamma \in H$.

Denote $f_\gamma := f_1$. We shall show that $L_1(f_\gamma)$ is large if $d_Y(z', \gamma z')$ is large, where $d_Y$ is the distance in $Y$ defined by the Riemannian metric pulled-back from $g_b$.

Let $h_t \in \text{Diff}_0(S, \text{area})$ be any isotopy between $Id_S$ and $f_\gamma$. By $H_t$ we denote the diffeomorphism of $C_n(S)$ defined by

$$H_t(x) = (h_t(x_1), \ldots, h_t(x_n)) \text{ for } x = (x_1, \ldots, x_n) \in C_n(S).$$

Let $\tilde{H}_t$ be the lift to $Y$ such that $\tilde{H}_0 = Id_Y$. Then $\tilde{H}_1 = \tilde{F}_1$ by Lemma 5.1. Thus for every $x \in \tilde{U}$, $\tilde{H}_t(x)$ connects $x$ with $\gamma x$.

The length of $\tilde{H}_t(x)$ in the metric on $Y$ pulled-back from $g_b$ equals $\int_0^1 |\dot{H}_t(x)| g_b$, where $\dot{H}_t(x) = \frac{d}{dt}H_s(x)|_{s=t} \in T_{H_s(x)}C_n(S)$.

Thus for every $x \in U$ we have

$$\int_0^1 |\dot{H}_t(x)| g_b dt \geq d_Y(x, \gamma x) \geq d_Y(z', \gamma z') - 2diam(\tilde{U}) =: D_\gamma,$$

Note that $H_t$ preserves the product measure on $S^n$ ($H_t$ is defined only on $C_n(S)$, but since $C_n(S)$ is a full measure subset of $S^n$, we can regard $H_t$ as a measurable map on $S^n$). Moreover

$$\dot{H}_t(x) = (\dot{h}_t(x_1), \ldots, \dot{h}_t(x_n)).$$

We have:
Since \( h_t \) was arbitrary, we have \( \text{area}(U) D_\gamma \leq CL_1(f_\gamma) \). By Corollary 3.3, the orbit \( H_{z'} \) is unbounded, thus \( D_\gamma \) can be arbitrary large. Moreover, the set \( U \) does not depend on the choice of \( \gamma \). Therefore the \( L_1 \)-norm on \( \text{Diff}_0(S, \text{area}) \) is unbounded.
