An integral model of the perfectoid modular curve

Juan Esteban Rodríguez Camargo

Abstract

We construct a formal integral model of the perfectoid modular curve. Studying this object, we provide some vanishing results in the coherent cohomology at perfectoid level. We also relate the completed cohomology of the modular tower with the integral cusp forms of weight 2.

Introduction

Throughout this document we fix a prime number \( p \). Given an extension \( K \) of \( \mathbb{Q}_p \), we denote by \( G_K \) the absolute Galois group of \( K \). Let \( \hat{\mathbb{Z}}_p \) be the prime-to-\( p \) profinite completion of \( \mathbb{Z} \). Given an integer \( m \) we denote by \( \zeta_m \) a primitive \( m \)-th root of unit over \( \mathbb{Q}_p \). Let \( \mathbb{Z}_p^{cyc} \) be the \( p \)-adic completion of the cyclotomic integers \( \mathbb{Z}_p[\zeta_{p\infty}] \) and \( \mathbb{Q}_p^{cyc} = \mathbb{Z}_p^{cyc}[\frac{1}{p}] \) its fraction field.

Let \( K^p \subset \text{GL}_2(\hat{\mathbb{Z}}_p) \) and \( K_p \subset \text{GL}_2(\mathbb{Z}_p) \) be a neat compact open and a compact open subgroup respectively, we let \( K'_p \) be a compact open subgroup of \( K_p \). Let \( M \) be a positive integer. We denote by \( \Gamma(M) \) the principal congruence subgroup of \( \text{GL}_2(\hat{\mathbb{Z}}) \) of level \( M \). If \( M = p^n \) is a power of \( p \), we denote in the same way the principal congruence subgroup of level \( p^n \) of \( \text{GL}_2(\mathbb{Z}_p) \). It will be clear according to the context whether we talk about a subgroup of \( \text{GL}_2(\hat{\mathbb{Z}}) \) or \( \text{GL}_2(\mathbb{Z}_p) \).

Let \( Y_{K^p K_p} / \text{Spec} \mathbb{Z}_p \) be the Katz-Mazur integral modular curve of level \( K^p K_p \), let \( X_{K^p K_p} \) be its Katz-Mazur normal compactification (cf. [KM85]). We denote by \( \mathfrak{X}_{K^p K_p} \) the completion of \( X_{K^p K_p} \) along its special fiber and by \( \mathfrak{X}^\text{an}_{K^p K_p} \) the analytic generic fiber of \( \mathfrak{X}_{K^p K_p} \) seen as an adic space (cf. [Hub96]).

A natural object appearing in the study of modular curves is the modular tower \( T_{K^p} = \{ X_{K^p K_p} \}_{K_p} \), where \( K_p \) runs over all the open compact subgroups of \( \text{GL}_2(\mathbb{Z}_p) \). For example, Emerton has considered in [Eme06] different types of completed cohomology groups arising from the modular tower. In [Sch15], Scholze gave a meaning to the inverse limit \( \varprojlim_{K_p} \mathfrak{X}_{K^p K_p} \)

\[ X_{K^p K_p} \]
as a perfectoid space over \( \text{Spa}(\mathbb{Q}_p^{ur}, \mathbb{Z}_p^{ur}) \). More precisely, he proved that there exists a unique perfectoid space \( \mathcal{X}_{K^p\Gamma(p^\infty)} \) satisfying the tilde limit property of \([SW13]\):

\[
\mathcal{X}_{K^p\Gamma(p^\infty)} \simeq \lim_{\leftarrow K_p} \mathcal{X}_{K^pK_p}.
\]

The construction of the perfectoid modular curve is not special for \( \text{GL}_2 \), Scholze’s ideas work in much greater generality for Shimura varieties of Hodge type. First, one studies the anticanonical tower of Siegel varieties showing that its inverse limit is a perfectoid space. Then one extends the “perfectoid locus” to the whole space using the Hodge-Tate period map, which for the modular curve looks like

\[
\pi_{HT} : \mathcal{X}_{K^p\Gamma(p^\infty)} \to \mathbb{P}^1_{\overline{\mathbb{Q}}_p}.
\]

Finally, one uses the fact that a Zariski closed subspace of a perfectoid space is perfectoid.

The first result of this paper is the existence of a Katz-Mazur integral model of the perfectoid modular curve. We notice that this object was already constructed by Jacob Lurie in \([Lur20]\). Lurie’s construction is more modular and uses a mixed-characteristic version of Kunz Theorem, a regularity result in terms of flatness of the Frobenius, which reduces the problem to the ordinary locus. The point of view taken in this paper is more elementary and has as core some explicit descriptions of the deformation rings of the modular curves. It is worth to mention that the study of the ordinary locus in both approaches is the same in spirit, compare Proposition \([2.2]\) below and Proposition 2.2 of \([Lur20]\).

We recall the notion of “integral perfectoid”: an \textit{integral perfectoid ring} is a topological ring \( R \) containing a topologically nilpotent element \( \pi \in R \) such that:

1. \( \pi \) is not a zero divisor and \( p \in \pi^pR \),
2. \( R \) is complete and separated for the \( \pi \)-adic topology,
3. the Frobenius \( \varphi : R/\pi R \to R/\pi^pR \) is an isomorphism.

A formal scheme \( \mathcal{S} \) is an \textit{integral perfectoid formal scheme} if it has a covering \( \mathcal{U} = \{U_i\}_i \) by formal affine subschemes \( U_i = \text{Spf}(R_i) \), where \( R_i \) is an integral perfectoid ring.

The following existence theorem of the integral perfectoid modular curve will be proved in Section \([2]\).

**Theorem 0.1.** With the previous notation, the inverse limit \( \mathcal{X}_{K^p\Gamma(p^\infty)} := \lim_{\leftarrow K_p} \mathcal{X}_{K^pK_p} \) exists in the category of \( p \)-adic formal schemes. Moreover, it is an integral perfectoid formal scheme over \( \text{Spf} \mathbb{Z}_p^{ur} \), and its adic generic fiber is naturally isomorphic to the perfectoid modular curve \( \mathcal{X}_{K^p\Gamma(p^\infty)} \).

**Remark.** It is not obvious that we can attach an adic space to the formal scheme \( \mathcal{X}_{K^p\Gamma(p^\infty)} \). Indeed, following Huber \([Hub96]\), this construction is well defined only for locally noetherian formal schemes. Nevertheless, the perfectoid nature of \( \mathcal{X}_{K^p\Gamma(p^\infty)} \) and the tilde limit property of \([SW13]\) allow us to perform the same construction of the generic fiber.

The second part of this document concerns the study of coherent cohomology of the integral modular curves at finite and infinite level. More precisely, let \( \omega_k \) (resp. \( \omega_{\text{cusp}}^k \)) denote the sheaf of modular forms (resp. cusp forms) of weight \( k \) over \( X_{K^pK_p} \). Let \( p_{K_p} : \mathcal{X}_{K^p\Gamma(p^\infty)} \to \mathcal{X}_{K^pK_p} \) be the natural projection, and for \( K_p' \subset K_p \) let \( p_{K_p'} : \mathcal{X}_{K^pK_p} \to \mathcal{X}_{K^pK_p} \) denote the natural map of modular curves. We recall that the sheaves \( \omega_{\text{cusp}}^k \) are not preserved by pullbacks in the modular tower, in fact they depend on the boundary divisor. Nevertheless, we always have \( p_{K_p'}^*\omega_{\text{cusp}}^k \subset p_{K_p'}^*\omega_{\text{cusp}}^k \). Let \( \mathcal{O} = \text{H}^0(X_{K^pK_p}, \mathcal{O}_{X_{K^pK_p}}) \) be the ring of global functions of \( X_{K^pK_p} \) and \( K \) its fraction field, then \( X_{K^pK_p}/\mathcal{O} \) is geometrically connected and has geometrically reduced fibers. We shall prove in Section \([4]\) the following vanishing and duality results:
Theorem 0.2. Let $\mathcal{F} \in \{\omega^{-k}, \omega^{-k}_{\text{cusp}}, \omega^{2+k}, \omega^{2+k}_{\text{cusp}} : k \geq 0\}$. Then the cohomology complex $R\Gamma(X_{K^pK_p}, \mathcal{F})$ is perfect of length $[0, 1]$ with non-torsion cohomology. We have the local duality

$$\text{Hom}_\mathcal{O}(H^0(X_{K^pK_p}, \mathcal{F} \otimes K/\mathcal{O}), K/\mathcal{O}) = H^1(X_{K^pK_p}, \mathcal{F}^\vee \otimes \omega^2_{\text{cusp}}).$$

Moreover, the cohomology of $\omega^{k+2}$ and $\omega^{k+2}_{\text{cusp}}$ is supported in degree 0 for $k > 0$.

Let $\omega^k$ be the pullback to $X_{K^p\Gamma(p^\infty)}$ of the weight $k$ modular sheaf at any finite level, and let $\omega^k_{\infty, \text{cusp}}$ be the $p$-adic completion of the inductive limit of the weight $k$ cusp modular sheaves of finite level

$$\omega^k_{\infty, \text{cusp}} := \varprojlim_{p} \omega^k_{\text{cusp}}.$$

A consequence of the perfectoid nature of $X_{K^p\Gamma(p^\infty)}$ is the vanishing of the higher cohomology of the positive weight modular sheaves, even for $k = 1$!

Theorem 0.3. Let $k > 0$.

(i) The cohomology of $\omega^k_{\infty}$ and $\omega^k_{\infty, \text{cusp}}$ is supported in degree 0 at integral perfectoid level, i.e.

$$H^1(X_{K^p\Gamma(p^\infty)}, \omega^k_{\infty}) = H^1(X_{K^p\Gamma(p^\infty)}, \omega^k_{\infty, \text{cusp}}) = 0.$$

(ii) Similarly, the cohomology of $\omega^k_{\infty}[[\frac{1}{p}]]$ and $\omega^k_{\infty, \text{cusp}}[[\frac{1}{p}]]$ is supported in degree 0 at adic perfectoid level, i.e.

$$H^1(X_{K^p\Gamma(p^\infty)}, \omega^k_{\infty}[[\frac{1}{p}]]) = H^1(X_{K^p\Gamma(p^\infty)}, \omega^k_{\infty, \text{cusp}}[[\frac{1}{p}]]) = 0.$$

On the other hand, using the Local Duality Theorem and the Primitive Comparison Theorem of [Sch13], we can relate the completed cohomology $\widetilde{H}^1 = \varprojlim_m \varprojlim_{K_p} (H^1_{\text{et}}(X_{K^pK_p,c_p}, \mathbb{Z}/p^n\mathbb{Z}))$ of the modular tower $\{X_{K^pK_p,c_p}\}_{K_p \in \text{GL}_2(\mathbb{Z}_p)}$, and the integral weight 2 cusp forms. More precisely, given $K_p^c \subset K_p$ let

$$\text{Tr}_{K_p^c}^{K_p} : H^0(X_{K^pK_p}, \omega^2_{\text{cusp}}) \to H^0(X_{K^pK_p}, \omega^2_{\text{cusp}})$$

be the dual of the pullback $(p_{K_p}^{K_p^c})^* : H^1(X_{K^pK_p}, \mathcal{O}_{X_{K^pK_p}}) \to H^1(X_{K^pK_p^c}, \mathcal{O}_{X_{K^pK_p^c}})$, that is the Trace of Serre duality. Let $K^c[p]$ be the $p$-adic completion of $K[\zeta_p^\infty]$. We have the following theorem

Theorem 0.4. There exists a $G_{K^c[p]} \times \text{GL}_2(\mathbb{Q}_p)$-equivariant isometry of $\mathbb{C}_p$-Banach spaces

$$(\widetilde{H}^1 \otimes_{\mathbb{Z}_p} \mathbb{C}_p)^\vee \cong (\varprojlim_{K_p, \text{Tr}_{K_p^c}^{K_p}} H^0(X_{K^pK_p}, \omega^2_{\text{cusp}})) \otimes_{\mathcal{O}^{\text{cyc}}} \mathbb{C}_p.$$

The outline of the paper is the following: In Section 1 we recall some classical properties of modular curves necessary for the proof of Theorem 0.1. Then we compute the geometric deformation rings of $\mathcal{X}(Np^n) := X_{\Gamma(Np^n)}$ at ordinary points with help of the Serre-Tate parameter [Kat81], where $p \nmid N$. Similarly, we make use of the Tate curve to describe the deformation rings at cusps following [DR72]. By contrast, one does not have an explicit description of the deformation rings at supersingular points. Instead, we shall give explicit generators of the maximal ideals following [KM85].

In Section 2 we prove Theorem 0.1. The morphisms between the formal modular curves $\mathcal{X}_{K^pK_p} \to \mathcal{X}_{K^pK_p}$ are finite flat, then their projective limit exists. We will show that this inverse
limit is indeed locally integral perfectoid. It suffices to consider $K^p K_p = \Gamma(N p^n)$ for $p \nmid N$ and $n \geq 0$. The difficulties appear when one tries to prove the surjectivity of Frobenius modulo $p$. We use faithfully flat descent to reduce this problem to the deformation rings of the modular curves. Finally, we apply the ring descriptions of Section 1 to prove that the Frobenius is surjective at all closed geometric point of $X(Np^\infty) := X_{\Gamma(Np^\infty)}$ modulo $p$.

In Section 3 we state some important and classical facts of duality and cohomology; we will specialize to the case of local complete intersection (lci) relative curves.

In Section 4 we study the cohomology groups of modular sheaves at finite and infinite level. We prove Theorem 0.2 using the explicit degree of the modular sheaves $\omega^k, \omega^k_{\text{cusp}}$ and the norm map, one reduces the vanishing problem to the smooth curve $X(N) := X_{\Gamma(N)}$. We will see that Theorem 0.3 is a direct consequence of Theorem 0.2 and the fact that the Frobenius is an isomorphism for perfectoid spaces. Finally, we compare the coherent cohomology of $X_{K^p \Gamma(p^\infty)}$ and its generic fiber, which concludes in Theorem 0.4.

Acknowledgments. The construction of the formal model of the perfectoid modular curve began as a problem for a mémoire of M2 in 2019. At the time, the proof of Theorem 0.1 was written but some errors were found in a more careful reading; particularly Proposition 1.4 was not considered in the first draft. I would like to thank Vincent Pilloni for encouraging me to write a paper with these results, the study of the coherent cohomology and its application to the completed cohomology were possible thanks to his guidance. I would like to thank George Boxer and Joaquin Rodrigues for all the fruitful discussions of the subject. This work has been done while the author was a PhD student at the ENS de Lyon.

1 A brief introduction to the Katz-Mazur integral modular curves

Let $N \geq 3$ be a integer prime to $p$ and $n \geq 0$ an integer. Throughout this document we consider $K^p K_p = \Gamma(N p^n) \subset \text{GL}_2(\hat{\mathbb{Z}})$ the principal congruence subgroup of level $N p^n$. We denote by $Y(N p^n)$ and $X(N p^n)$ the affine and compactified integral modular curves of level $\Gamma(N p^n)$ respectively. We use similar notation for the formal and adic modular curves of level $\Gamma(N p^n)$. We write by $X(Np^\infty)$ and $X(Np^\infty)$ the perfectoid and perfectoid integral modular curves.

There is no loss of generality in making these assumptions. Indeed, we can take invariants by finite groups in perfectoid rings:

**Theorem 1.1.** [KL16, Theo. 3.3.26] Let $A$ be a perfectoid ring on which a finite group $G$ acts. Then the invariant subring $A^G$ is a perfectoid ring.

**Remark.** Let $A$ be a perfectoid ring and $A^+ \subset A$ an integrally closed open bounded subring, then $A^+$ is integral perfectoid. Furthermore, if $G$ is a finite group acting on $A$, Theorem 1.1 implies that $(A^+)^G$ is integral perfectoid.

Drinfeld’s basis

We recall the definition of a Drinfeld’s basis for the $M$-torsion of an elliptic curve

**Definition 1.1.** Let $M$ be a positive integer, $S$ a scheme and $E/S$ an elliptic curve over $S$. A Drinfeld’s basis of $E[M]$ is a morphism of group schemes $\psi : (\mathbb{Z}/M\mathbb{Z})^2 \to E[M]$ such the following equality of effective divisors holds

$$E[M] = \sum_{(a,b) \in (\mathbb{Z}/M\mathbb{Z})^2} \psi(a,b). \quad (1.1)$$
We also write \((P, Q) = (\psi(1, 0), \psi(0, 1))\) for the Drinfeld’s basis \(\psi\).

**Remark.** The left-hand-side of (1.1) is an effective divisor of \(E/S\) being a finite flat group scheme over \(S\). The right-hand-side is a sum of effective divisors given by the sections \(\psi(a, b)\) of \(S\) to \(E\). Furthermore, if \(M\) is invertible over \(S\), a homomorphism \(\psi : \mathbb{Z}/M\mathbb{Z} \to E[M]\) is a Drinfeld’s basis if and only if it is an isomorphism of group schemes, cf. [K M85, Lem. 1.5.3].

**Proposition 1.1.** Let \(P, Q\) be a Drinfeld’s basis of \(E[M]\) and \(e_M : E[M] \times E[M] \to \mu_M\) the Weil pairing. Then \(e_M(P, Q) \in \mu_M^*\) is a primitive root of unit, i.e. a root of the \(M\)-th cyclotomic polynomial.

**Proof.** [K M85, Theo. 5.6.3].

**Definition 1.2.** The Katz-Mazur integral modular curve of level \(\Gamma(N p^n)\), denoted by \(Y(N p^n)\), is defined as the moduli space (over \(\mathbb{Z}_p\)) parametrizing elliptic curves \(E\) and Drinfeld’s basis \(\psi\) of \(E[N p^n]\).

The \(j\)-invariant is a finite flat morphism of \(\mathbb{Z}_p\)-schemes \(j : Y(N p^n) \to A_{\mathbb{Z}_p}^1\). The compactified Katz-Mazur integral modular curve of level \(\Gamma(N p^n)\), denoted by \(X(N p^n)\), is the normalization of \(\mathbb{P}^1_{\mathbb{Z}_p}\) in \(Y(N p^n)\) via the \(j\)-invariant. The cusps or the boundary divisor \(D_n\) is the closed reduced subscheme of \(X(N p^n)\) defined by \(\Delta = 0\). We shall refer to \(X(N p^n)\) and \(Y(N p^n)\) simply as the modular curves of level \(\Gamma(N p^n)\).

The modular curve \(Y(N p^n)\) (resp. \(X(N p^n)\)) is an affine (resp. projective) regular curve over \(\mathbb{Z}_p\). Let \(E_{univ}/Y(N p^n)\) be the universal elliptic curve and \((P_{univ}, Q_{univ})\) the universal Drinfeld’s basis of \(E[N p^n]\). Let \(\Phi_{N p^n}(X)\) be the \(N p^n\)-th cyclotomic polynomial, and let \(\mathbb{Z}_p[\mu^\times_{N p^n}]\) denote the ring \(\mathbb{Z}_p[X]/(\Phi_{N p^n}(X))\). The Weil pairing of \((P_{univ}, Q_{univ})\) induces a morphism of \(\mathbb{Z}_p\)-schemes

\[
e_n : Y(N p^n) \to \text{Spec} \mathbb{Z}_p[\mu^\times_{N p^n}] .
\]

Note that \(\mathbb{Z}_p[\mu^\times_{N p^n}]\) is a product of copies of the \(N p^n\)-cyclotomic \(p\)-adic integers \(\mathbb{Z}_p[\zeta_{N p^n}]\). The morphism \(\gamma_n : Y(N p^n) \to \text{Spec} \mathbb{Z}_p[\mu^\times_{N p^n}]\) extends to a morphism \(X(N p^n) \to \text{Spec} \mathbb{Z}_p[\mu^\times_{N p^n}]\) by normality, under this map the modular curve \(X(N p^n)\) is geometrically connected and has geometrically reduced fibers. Thus, we obtain a commutative diagram with finite flat horizontal arrows

\[
\cdots \longrightarrow X(N p^{n+1}) \longrightarrow X(N p^n) \longrightarrow X(N p^{n-1}) \longrightarrow \cdots \\
\downarrow \quad \downarrow \quad \downarrow \\
\cdots \to \text{Spec} \mathbb{Z}_p[\mu^\times_{N p^{n+1}}] \to \text{Spec} \mathbb{Z}_p[\mu^\times_{N p^n}] \to \text{Spec} \mathbb{Z}_p[\mu^\times_{N p^{n-1}}] \to \cdots .
\]

**Deformation rings at closed geometric points**

Let \(\{\zeta_{N p^n}\}_{n \in \mathbb{N}}\) be a fixed sequence of compatible primitive \(N p^n\)-th roots of unit, set \(\zeta_{p^n} = \zeta_{N p^n}\).

In the following paragraph we will study the closed geometric points of the modular curves \(X(N p^n)\). We shall assume that \(X(N p^n)\) is defined over \(\mathbb{Z}_p\), the maximal unramified extension of \(\mathbb{Z}_p\). This amounts to take the base change \(X(N p^n) \times_{\text{Spec} \mathbb{Z}_p} \text{Spec} \mathbb{Z}_p^\text{ur}\); the previous extension of scalars does not modify the deformation rings of closed geometric points.

We have an isomorphism \(\mathbb{Z}_p^\text{ur}[\mu^\times_{N p^n}] \cong \prod_{k \in \mathbb{Z}/(pN \mathbb{Z})} \mathbb{Z}_p^\text{ur}[\zeta_{p^n}]\) given by mapping \(X\) to \(\zeta_{N p^n}\) in each factor. Fixing the Weil pairing \(\epsilon_n(p^n P_{univ}, p^n Q_{univ}) = \zeta_{N p^n}\), we can assume that the map \(\epsilon_n : X(N p^n) \to \text{Spec} \mathbb{Z}_p^\text{ur}[\zeta_{p^n}]\) induced by \(\epsilon_n(P_{univ}, Q_{univ})\) is geometrically connected.
The ordinary points

Let $k = \overline{\mathbb{F}}_p$ be an algebraic closure of $\mathbb{F}_p$. Let $\text{Art}_k$ be the category of local artinian rings with residue field $k$, whose morphisms are the local ring homomorphisms compatible with the reduction to $k$. Following [Kat81], we evoke the Serre-Tate parameter to describe the deformation rings at closed ordinary geometric points of $X(Np^n)$.

Let $E_0$ be an ordinary elliptic curve over $k$ and let $R$ be an object in $\text{Art}_k$. A deformation of $E_0$ to $R$ is a pair $(E, \iota)$ consisting of an elliptic curve $E/R$ and an isomorphism $\iota : E \otimes_R k \to E_0$. We define the deformation functor $\text{Ell}_{E_0} : \text{Art}_k \to \text{Sets}$ by the rule

$$R \mapsto \{(E, \iota) : \text{deformation of } E_0 \text{ to } R\}/\sim.$$ Then $\text{Ell}_{E_0}$ sends an artinian ring $R$ to the set of deformations of $E_0$ to $R$ modulo isomorphism.

Let $Q$ be a generator of the physical Tate module $T_pE_0(k)$, and denote by $W(k)$ the ring of Witt vectors of $k$. We have the following pro-representability theorem

**Theorem 1.2.** [Kat81] Theo. 2.1

1. The Functor $\text{Ell}_{E_0}$ is pro-representable by the formal scheme

$$\text{Hom}_{\mathbb{Z}_p}(T_p E_0(k) \otimes T_p E_0(k), \mathbb{G}_m).$$

The isomorphism is given by the Serre-Tate parameter $q$, which sends a deformation $E/R$ of $E_0$ to a bilinear form

$$q(E/R; \cdot, \cdot) : T_p E_0(k) \times T_p E_0(k) \to \hat{\mathbb{G}}_m(R).$$

By evaluating at the fixed generator $Q$ of $T_pE_0(k)$, we obtain the more explicit description

$$\text{Ell}_{E_0} = \text{Spf}(W(k)[[X]])$$

where $X = q(E_{\text{univ}}/\text{Ell}_{E_0}; Q, Q) - 1$.

2. Let $E_0$ and $E'_0$ be ordinary elliptic curves over $k$, let $\pi_0 : E_0 \to E'_0$ be a homomorphism and $\pi'_0 : E'_0 \to E_0$ its dual. Let $E$ and $E'$ be liftings of $E_0$ and $E'_0$ to $R$ respectively. The necessary and sufficient condition that $\pi_0$ lift to a homomorphism $\pi : E \to E'$ is that

$$q(E/R; \alpha, \pi'(\beta)) = q(E'/R; \pi(\alpha), \beta)$$

for every $\alpha \in T_pE(k)$ and $\beta \in T_pE'(k)$.

We deduce the following proposition deciribing the ordinary deformation rings of finite level:

**Proposition 1.2.** Let $\overline{\pi} \in X(Np^n)$ be an ordinary closed geometric point, say given by a triple $(E_0, P_0, Q_0)$, write $(P^n_0, Q^n_0) = (NP_0, NQ_0)$. Let $A_{\overline{\pi}}$ be the deformation ring of $X(Np^n)$ at $\overline{\pi}$, then there is an isomorphism

$$A_{\overline{\pi}} \cong W(k)[\zeta_{p^n}][[X]][[T]]/(1 + T)^{p^n} - (1 + X)) = W(k)[\zeta_{p^n}][[T]]$$

such that:

i) the $e$-pairing of the universal deformation $(P^n_{\text{univ}}, Q^n_{\text{univ}})$ of $(P^n_0, Q^n_0)$ is $\zeta_{p^n};$

ii) the variable $1 + X$ equals the Serre-Tate parameter $q(E_{\text{univ}}/A_{\overline{\pi}}; Q, Q);$
iii the variable $1 + T$ equals the Serre-Tate parameter $q(E'_\text{univ}/A_\mathcal{T}, (\pi^t)^{-1}(Q), (\pi^t)^{-1}(Q))$ of the universal deformation $\pi : E_{\text{univ}} \to E'_\text{univ}$ of the étale isogeny $\pi_0 : E_0 \to E_0/K_0$, with $K_0 = E_0[p^n](k)$.

Proof. The group scheme $E_0[N]$ is finite étale over $k$, then a deformation of $(E_0, P_0, Q_0)$ is equivalent to a deformation of $(E_0, P_0^n, Q_0^n)$. The group $\text{GL}_2(\mathbb{Z}/p^n\mathbb{Z})$ acts transitively on the set of Drinfeld’s basis of $E_0[p^n]$ compatible with the Weil pairing and the determinant. Without loss of generality we may assume that $P_0^n = 0$ and that $Q_0^n$ generates $E_0[p^n](k)$, see Theorem 5.5.2 of [KM85]. Let $K \subset E_{\text{univ}}[p^n]$ be the subgroup generated by $Q_0^n$, it is an étale group lifting the étale group $K_0 = E_0[p^n](k)$ generated by $Q_0^n$. The base $(P_0^n, Q_0^n)$ provides a splitting of the exact sequence

$$0 \longrightarrow \mu_{p^n} \longrightarrow E_{\text{univ}}[p^n] \longrightarrow \mathbb{Z}/p^n\mathbb{Z} \longrightarrow 0,$$

and a primitive root of unit $\zeta_{p^n} \in A_\mathcal{T}$ given by $\zeta_{p^n} = e(P_0^n, Q_0^n)$. Conversely, given $R$ a local holomorphic formal group scheme of finite type over $k$ and $E/R$ a deformation of $E_0$, let $\zeta_{p^n}^t$ be a primitive $p^n$-th root of unit in $R$ and $K$ an étale subgroup of $E[p^n]$ of rank $p^n$. Then there exists a unique $Q^n \in K$ lifting to $Q^n_0$, and a unique $P^n \in E[p^n]$ such that $e(P^n, Q^n) = \zeta_{p^n}$. The pair $(P^n, Q^n)$ is then a Drinfeld’s basis of $E[p^n]$ lifting $(P_0^n, Q_0^n)$. We have proved the equivalence of formal functors

$$\{\text{Drinfeld’s basis of } E[p^n]\} \leftrightarrow \mu_{p^n}^\infty \times \{K \subset E[p^n] \text{ étale of rank } p^n\},$$

where $\mu_{p^n}^\infty$ is the formal scheme of primitive $p^n$-th roots of unit. We also have a natural equivalence

$$\{K \subset E[p^n] \text{ étale of rank } p^n\} \leftrightarrow \{\text{étale quotients of } E \text{ of degree } p^n\}.$$

Let $E'_{\text{univ}}/W(k)[[T]]$ denote the universal deformation of $E_0/K_0$. The universal “étale” point $Q^n_{\text{univ}}$ induces an étale isogeny of degree $p^n$

$$\pi : E_{\text{univ}} \to E'_{\text{univ}}$$

lifting the quotient $\pi_0 : E_0 \to E_0/K_0$. Furthermore, the dual morphism $\pi^t : E'_{\text{univ}} \to E_{\text{univ}}$ induces an isomorphism of the physical Tate modules $\pi^t : T_p E'_{\text{univ}}(k) \cong T_p E_{\text{univ}}(k)$. Let $Q \in T_p E_{\text{univ}}(k)$ be the fixed generator, and let $Q' \in T_p E'_{\text{univ}}(k)$ be its inverse by $\pi^t$. Theorem 1.2 implies

$$q(E_{\text{univ}}; Q, Q) = q(E_{\text{univ}}; Q, \pi^t(Q')) = q(E'_{\text{univ}}; \pi(Q), Q') = q(E'_{\text{univ}}; Q', Q')p^n.$$

Thus, we obtain the isomorphism

$$A_\mathcal{T} \cong W(k)[[\zeta_{p^n}]][[X]][[T]]/(1 + T)p^n - (1 + X)) = W(k)[[\zeta_{p^n}]][[T]]$$

with $\zeta_{p^n} = e(P_0^n, Q_0^n)$, $X = q(E_{\text{univ}}; Q, Q) - 1$ and $T = q(E'_{\text{univ}}; Q', Q') - 1$. □

The cusps

Let $\text{Tate}(q)/\mathbb{Z}_p((q))$ be the Tate curve, we recall from [KM85] Ch. 8.8] that it has $j$-invariant equal to

$$1/q + 744 + \cdots.$$
We consider the ring $\mathbb{Z}_p[[q]]$ as the completion of $\mathbb{P}^1_{\mathbb{Z}_p}$ at infinity. The Tate curve provides a description of the formal curve locally around the cusps, for that reason one can actually compute the formal deformation rings by means of this object, see [KM85] and [DR73]. In fact, let $\text{Cusps}[\Gamma(Np^n)]$ be the completion of the modular curve $X(Np^n)$ along the cusps. From the theory developed in [KM85, Ch. 8 and 10], more precisely Theorems 8.11.10 and 10.9.1, we deduce the following proposition:

**Proposition 1.3.** We have an isomorphism of formal $\hat{\mathbb{Z}}_p^{ur}[[q]]$-schemes

$$\text{Cusps}(\Gamma(Np^n)) \xrightarrow{\sim} \bigsqcup_{A \in \text{HomSurj}((\mathbb{Z}/Np^n\mathbb{Z})^2, \mathbb{Z}/Np^n\mathbb{Z})/\pm 1} \text{Spf}(\hat{\mathbb{Z}}_p^{ur}[\zeta_p^n][[q^{1/Np^n}]]).$$

The morphism $\text{Cusps}(\Gamma(Np^{n+1})) \to \text{Cusps}(\Gamma(Np^n))$ is induced by the natural inclusion

$$\hat{\mathbb{Z}}_p^{ur}[\zeta_p^n][[q^{1/Np^n}]] \to \hat{\mathbb{Z}}_p^{ur}[\zeta_p^{n+1}][[q^{1/Np^{n+1}}]]$$

on each respective connected component.

### The supersingular points

Let $k = \mathbb{F}_p$ and let $\{\tau_n \in X(Np^n)\}_{n \in \mathbb{N}}$ be a sequence of compatible supersingular closed geometric points. We denote by $A_{\tau_n}$ the deformation ring of $X(Np^n)$ at $\tau_n$. Let $E/A_{\tau_n}$ be the universal elliptic curve and $(P^n_{\text{univ}}, Q^n_{\text{univ}})$ the universal Drinfeld’s basis of $E[p^n]$. We fix a formal parameter $T$ of $E$, note that as $\tau_n$ is supersingular any $p$-power torsion point belongs to the formal group of $E$. We will use the following lemma as departure point:

**Lemma 1.1.** [KM85, Theo. 5.3.2]. The maximal ideal of the local ring $A_{\tau_n}$ is generated by $T(P^n_{\text{univ}})$ and $T(Q^n_{\text{univ}})$.

By the Serre-Tate Theorem [Kat81, Theo. 1.2.1], and the general moduli theory of 1-dimensional formal groups over $k$ [LT66], the deformation ring of $X(N)$ at a geometric supersingular point is isomorphic to $W(k)[[X]]$. Moreover, the $p$-multiplication modulo $p$ can be written as $[p](T) = V(T^p)$ with $V \in k[[X]][[T]]$ the Verschiebung map $V : E^{(p)} \to E$. Without loss of generality we assume that $V$ has the form

$$V(T) = XT + \cdots,$$

with $V(T) \equiv T^p \mod X$. Using the Weierstrass Preparation Theorem we factorize $V(T)$ as

$$V(T) = T(X + \cdots \hat{\nu}(X)T^{p-1})(1 + XTR(X, T)),$$

where $\hat{\nu}(0) = 1$ and $R \in k[[X, T]]$.

**Proposition 1.4.** The parameter $X$ is a $p$-power in $A_{\tau_n} \mod p$. Moreover, the generators $T(P^n_{\text{univ}})$ and $T(Q^n_{\text{univ}})$ of the maximal ideal of $A_{\tau_n}$ are $p$-powers in $A_{\tau_{n+1}}$ modulo $p$.

**Proof.** The second claim follows from the first and the equality $[p](T) \equiv V(T^p) \mod p$. Consider $n = 1$ and write $P = P^n_{\text{univ}}$ and $Q = Q^n_{\text{univ}}$. Let $F : E \to E^{(p)}$ and $V : E^{(p)} \to E$ denote the Frobenius and Verschiebung homomorphisms respectively. Using the action of $\text{GL}_2(\mathbb{Z}/p\mathbb{Z})$ we may assume that $P$ and $F(Q)$ are generators of $\ker F$ and $\ker V$ respectively (cf. Theorem 5.5.2 of [KM85]). Then we have the equality of divisors on $E^{(p)}/A_{\tau_n}$

$$\ker V = \sum_{i=0}^{p-1} [i \cdot F(Q)].$$

8
The choice of the formal parameter $T$ gives a formal parameter of $E^{(p)}$ such that $T(F(Q)) = T(Q)^p$. Therefore, from (1.3) we see that the roots of $V(T)$ are $\{i^{[p]}(T(Q)^p)\}_{0 \leq i \leq p-1}$ where $i^{[p]}(T)$ is the $i$-multiplication of the formal group of $E^{(p)}$. Then we have from (1.2)

$$\frac{X}{\tilde{u}(X)} = (-1)^{p-1} p^{-1} \prod_{i=1}^{p-1} (i^{[p]}(T(Q)^p)) = \left( \prod_{i=1}^{p-1} [i](T(Q)) \right)^p,$$

proving that $\frac{X}{\tilde{u}(X)}$ is a $p$-power of $A_\infty / p$. As $k[[X]] = k[[X/\tilde{u}(X)]]$ we are done. \hfill \Box

**Corollary 1.4.1.** The Frobenius $\varphi : \varprojlim_n A_\infty / p \to \varprojlim_n A_{\infty} / p$ is surjective.

**Proof.** By induction in the graded pieces of the filtration defined by the ideal $(T(P^n), T(Q^n))$, one shows that $A_{\infty} / p$ is in the image of the Frobenius restricted to $A_{\infty+1} / p$. \hfill \Box

# 2 Construction of the perfectoid integral model

We keep the notations of Section 1. Let us state the main theorem of this section:

**Theorem 2.1.** Let $X(Np^n)$ be the completion of $X(Np^n)$ along its special fiber. Then the inverse limit $X(Np^\infty) := \varprojlim_n X(Np^n)$ exists in the category of $p$-adic formal schemes. Moreover, it is an integral perfectoid formal scheme over $\text{Spf} \mathbb{Z}_p[[\zeta_N]]$ and its adic generic fiber is naturally isomorphic to the perfectoid modular curve $X(Np^\infty)$.

**Proof.** We note that the maps between (formal) modular curves are finite flat, therefore the inverse limit $X(Np^\infty) := \varprojlim_n X(Np^n)$ exists in the category of $p$-adic formal $\mathbb{Z}_p$-schemes. Fix $n_0 \geq 0$ and consider a formal affine subscheme $\text{Spf} \hat{R} \subset X(Np^{n_0})$ arising from an open affine $\text{Spec} R \subset X(Np^{n_0})$.

For $n \geq n_0$, let $\text{Spec} R_n$ (resp. $\text{Spf} \hat{R}_n$) denote the pullback of $\text{Spec} R$ (resp. $\text{Spf} \hat{R}$) to $\text{Spec} X(Np^n)$ (resp. $X(Np^n)$). Let $R_\infty := \varprojlim_n R_n$ and let $\hat{R}_\infty$ denote its $p$-adic completion.

**Claim.** $\hat{R}_\infty$ is an integral perfectoid ring.

If the claim holds we deduce that

$$\text{Spa}(\mathbb{Q}_p, \mathbb{Z}_p) \times_{\text{Spf} \mathbb{Z}_p} \text{Spf} \hat{R}_\infty = \text{Spa}(\hat{R}_\infty[1/p], \hat{R}_\infty) \sim \varprojlim_n \text{Spa}(\hat{R}_n[1/p], \hat{R}_n)$$

is a perfectoid space. While $R$ runs over all the open affine subschemes of the curves $X(Np^n)$, the perfectoid spaces $\text{Spa}(\hat{R}_\infty[1/p], \hat{R}_\infty)$ glue to a perfectoid space $\mathcal{X}(Np^\infty)$ satisfying the tilde limit condition $\mathcal{X}(Np^\infty) \sim \varprojlim_n \mathcal{X}(Np^n)$, ending the proof of Theorem 2.1. \hfill \Box

**Proof of the Claim.** The $e_n$-pairings evaluated at the universal Drinfeld’s basis $(P_n, Q_n)$ of $E[p^n]$ induce compatible homomorphisms $\mathbb{Z}_p[\zeta_{p^n}] \to R_n$, these give rise to a ring homomorphism of the $p$-adic completions $\mathbb{Z}_p^{\text{yc}} \to \hat{R}_\infty$ (which are extended to the cusps by normalization). Thus, we find $\pi \in \hat{R}_\infty$ such that $\pi^n = pa$ with $a \in \hat{R}_\infty^\times$. Let

$$\varphi : R_\infty / \pi R_\infty \to R_\infty / pR_\infty,$$

be the absolute Frobenius. Since $R_\infty$ is integrally closed in $R_\infty[1/p]$, $\varphi$ is injective. It remains to show that $\varphi$ is surjective. The relative Frobenius is an isomorphism for pro-finite-étale base
change. Then, by faithfully flat descent we may suppose that the rings $R_n$ are defined over $\hat{\mathbb{Z}}_{\mathfrak{p}}^{ur}$.

The scheme $X(Np^n)$ is of finite type over $\hat{\mathbb{Z}}_{\mathfrak{p}}^{ur}$, in particular every point has a closed point as specialization. We are reduced to show that for every closed point $x \in \text{Spf} \hat{R}_{\infty} = \varprojlim \text{Spf} \hat{R}_n$, the homomorphism

\[
\begin{array}{c}
R_{\infty}/pR_{\infty} \otimes_{R_{\infty}} R_{\infty,x} \\
\varphi \mapsto \text{id}
\end{array}
\]

is surjective.

Write $x = (x_{n_0}, x_{n_0+1}, \ldots) \in \varprojlim \text{Spf} \hat{R}_n$, note that $R_{\infty,x} = \varprojlim R_{n,x_n}$. Since $R_n$ is finite flat over $R$, the local completion $\hat{R}_{n,x_n}$ is equal to $R_{n,x_n} \otimes_{R_{n,x_n}} \hat{R}_{x_0}$. By faithfully flat descent over $R_{x_0}$ we are reduced to show that the following homomorphism is surjective

\[
\begin{array}{c}
\lim R_{n,x_n}/pR_{n,x_n} \\
\varphi \otimes \text{id}
\end{array}
\]

The ring $R_n$ is of finite type over $\hat{\mathbb{Z}}_{\mathfrak{p}}^{ur}$ so that the absolute Frobenius $\varphi : R_n/pR_n \rightarrow R_n/pR_n$ is finite, this implies that the $\hat{R}_{x_0}$-module $\hat{R}_{n,x_n}/p\hat{R}_{n,x_n}$ with the Frobenius action is also finite. Therefore the natural map

\[
\hat{R}_{n,x_n}/p\hat{R}_{n,x_n} \otimes_{\varphi,\hat{R}_{x_0}} \hat{R}_{x_0} \rightarrow \varprojlim R_{n,x_n}/(pR_{n,x_n}, m_{R}^{mp} R_{n,x_n}) \cong R_{n,x_n}/pR_{n,x_n},
\]

with $m_R$ the maximal ideal of $R_{x_0}$, is an isomorphism. The composite equals $a \otimes b \mapsto ab^p$ obtaining a commutative diagram

\[
\begin{array}{c}
R_{n,x_n}/pR_{n,x_n} \otimes_{\varphi,\hat{R}_{x_0}} \hat{R}_{x_0} \\
\varphi \otimes \text{id}
\end{array}
\]

Thus, we are reduced to prove that the absolute Frobenius $\varphi : \varprojlim R_{n,x_n}/pR_{n,x_n} \rightarrow \varprojlim R_{n,x_n}/pR_{n,x_n}$ is surjective. Indeed, we deal with the cusps, the supersingular and the ordinary points separately; we use the descriptions reached in Section 4.

- **In the ordinary case**, the local ring $\hat{R}_{n,x_n}$ is isomorphic to $\mathbb{Z}_{\mathfrak{p}}^{ur}[\zeta_{p^n}][[X_n]]$. From the proof of Proposition 1.2, one checks that the inclusion $\hat{R}_{n,x_n} \rightarrow R_{n+1,x_{n+1}}$ is given by $X_n = (1 + X_{n+1})^p - 1$. Therefore, we obtain the surjectivity of Frobenius when reducing modulo $p$.  

1Let $R$ and $R'$ be excellent noetherian regular rings, let $X_R(Np^n)$ denote the compactified modular curve of level $\Gamma(Np^n)$ defined over $R$. Suppose we have given a ring homomorphism $R \rightarrow R'$. By definition, we have a natural isomorphism of affine modular curves $Y_R(Np^n) \otimes_R R' \cong Y_{R'}(Np^n)$. However, in general this equality does not extend to compactified modular curves. Assume that $R \rightarrow R'$ is flat and has geometrically regular fibers, then Proposition 8.6.7 of [KM85] says that $X_R(Np^n) \otimes_R R' \cong X_{R'}(Np^n)$. In particular, we have the isomorphism $X_{\mathbb{Z}_p}(Np^n) \otimes_{\mathbb{Z}_p} \mathbb{Z}_p^{ur} \cong X_{\mathbb{Z}_p^{ur}}(Np^n)$.
• The supersingular case is Corollary 1.4.1.

• Finally, if we are dealing with a cusp \( x \), the ring \( \hat{R}_{n,x} \) is isomorphic to \( \mathbb{Z}_p[[q^{1/Np^n}]] \) and \( \hat{R}_{n,x} \to \hat{R}_{n+1,x_{n+1}} \) is the natural inclusion by Proposition 1.3. The surjectivity of \( \varphi \) is clear.

\[ \square \]

3 Local duality theory of flat coherent cohomology of curves

Let \( K \) be a finite extension of \( \mathbb{Q}_p \) and \( \mathcal{O}_K \) its valuation ring. In this section we specialize the classical Grothendieck-Serre duality theorem of proper morphisms to the case of a local complete intersection (lci) projective curve over \( \mathcal{O}_K \), we follow [Har66].

Let \( X \) be a locally noetherian scheme, and let \( \mathcal{D}(X) \) be the derived category of \( \mathcal{O}_X \)-modules. We use subscripts \( c,qc \) on \( \mathcal{D}(X) \) for the derived category of \( \mathcal{O}_X \)-modules with coherent and quasi-coherent cohomology, the subscripts \( fTd \) and \( fid \) on \( \mathcal{D}(X) \) will mean the subcategory of complexes with finite Tor and finite injective dimension. We use superscripts \( +,−,b \) for the derived category of bounded below, bounded above and bounded complexes respectively. For instance, \( \mathcal{D}^b_{qc}(X)_{fTd} \) is the derived category of bounded complexes of \( \mathcal{O}_X \)-modules of finite Tor dimension and coherent cohomology. If \( X = \text{Spec} \ A \) is affine, we set \( \mathcal{D}(A) := \mathcal{D}_{qc}(X) \), the derived category of \( A \)-modules.

Let us first state the Duality Theorem for projective lci morphisms

**Theorem 3.1** ([Har66, Theo. III.11.1]). Let \( f : X \to Y \) be a lci morphism between noetherian schemes of finite Krull’s dimension. Then there exists an exceptional inverse image functor \( f! : \mathcal{D}(Y) \to \mathcal{D}(X) \). In addition, if \( f \) is projective then:

1. there is a natural transformation of endofunctors \( \text{Tr} : Rf_*f! \to 1 \) of \( \mathcal{D}_{qc}^+(Y) \) called the trace;

2. the trace \( \text{Tr} \) induces an adjunction isomorphism

\[
\theta : Rf_*R\mathcal{H}om_X(\mathcal{F}, f!\mathcal{G}) \sim R\mathcal{H}om_Y(Rf_*\mathcal{F}, \mathcal{G})
\]

for \( \mathcal{F} \in \mathcal{D}_{qc}^-(X) \) and \( \mathcal{G} \in \mathcal{D}_{qc}^+(Y) \).

Moreover, the formation of the exceptional inverse image is functorial. More precisely, given a composition \( X \xrightarrow{f} Y \xrightarrow{g} Z \) with \( f,g \) and \( g \) lci, there is a natural isomorphism \( (gf)^! \cong f^!g^! \). This functor commutes with flat base change, that means the following:

let \( u : Y' \to Y \) be a flat morphism, \( f' : X' \to Y' \) the base change of \( X \) to \( Y' \) and \( v : X' \to X \) the projection. Then there is a natural isomorphism of functors \( v^*f^! = f'^!u^* \).

**Example 3.1.** Let \( f : X \to Y \) be a morphism locally of finite type of locally noetherian schemes of finite Krull’s dimension.

1. We can define the functor \( f^! \) for finite (not necessarily lci) morphisms as

\[
f^!\mathcal{F} = R\mathcal{H}om_{\mathcal{O}_Y}(f_*\mathcal{O}_X, \mathcal{F}) \text{ for } \mathcal{F} \in \mathcal{D}(Y).
\]

The duality theorem is then equivalent to the (derived) \( \otimes \)-Hom adjunction.
2. Let \( f \) be smooth of relative dimension \( n \), then one has \( f^! \mathcal{F} = \mathcal{F} \otimes \omega_{X/Y}^{n} \) where \( \omega_{X/Y}^{n} = \bigwedge^{n} \Omega_{X/Y}^{1} \), cf. [Har66, Section III.2].

**Lemma 3.1.** Let \( f : X \to Y \) be a lci morphism of relative dimension \( n \) between locally noetherian schemes of finite Krull’s dimension. Then \( f^! \mathcal{O}_{Y} = \omega_{X/Y}^{n} \) with \( \omega_{X/Y}^{n} \) an invertible \( \mathcal{O}_{X} \)-module.

**Proof.** Working locally on \( Y \) and \( X \), we may assume that \( f \) factors as \( X \xrightarrow{\iota} S \xrightarrow{g} Y \), where \( g \) is a smooth morphism of relative dimension \( m \), and \( \iota \) is a regular closed immersion of codimension \( m - n \) defined by an ideal \( \mathcal{I} = (f_{1}, \ldots, f_{m-n}) \). Let \( \omega_{S/Y}^{n} = \bigwedge^{m} \Omega_{S/Y}^{1} \) be the sheaf of \( m \)-differentials of \( S \) over \( Y \), then

\[
f^! \mathcal{O}_{S} = \iota^! g^! \mathcal{O}_{S} = R \mathcal{H}om_{\mathcal{O}_{S}}(\iota^{!}, \mathcal{O}_{X}, \omega_{S/Y}^{n}[m]) = R \mathcal{H}om_{\mathcal{O}_{S}}(\mathcal{O}_{S}/\mathcal{I}, \omega_{S/Y}^{n})[m]
\]

Let \( K(\mathcal{I}) \) be the Koszul complex of the regular sequence \( f = (f_{1}, \ldots, f_{m-n}) \). Then \( K(\mathcal{I}) \) is a flat resolution of \( \mathcal{O}_{S}/\mathcal{I} \), its dual \( K(\mathcal{I})^{\vee} = \mathcal{H}om_{\mathcal{O}_{S}}(K(\mathcal{I}), \mathcal{O}_{S}) \) is a flat resolution of \( (\mathcal{O}_{S}/\mathcal{I})[-(m-n)] \). Therefore

\[
f^! \mathcal{O}_{S} \simeq \mathcal{H}om_{\mathcal{O}_{S}}(K(\mathcal{I}), \omega_{S/Y}^{n})[m] = K(\mathcal{I})^{\vee} \otimes \omega_{S/Y}^{n}[n] \sim \mathcal{O}_{X}/\mathcal{I} \otimes L \omega_{S/Y}^{n}[n] = (\omega_{S/Y}^{n}/\mathcal{I})[n],
\]

which is an invertible sheaf of \( \mathcal{O}_{X} \)-modules as required. \( \square \)

**Remark.** Let \( f : X \to Y \) be a regular closed immersion of codimension \( n \) defined by the ideal \( \mathcal{I} \). From the proof of Lemma 3.1 one can deduce that \( f^! \mathcal{O}_{Y} = \bigwedge^{n}(\mathcal{I}/\mathcal{I}^{2})^{\vee}[-n] \) is the normal sheaf concentrated in degree \( n \).

The compatibility of \( f^! \) with tensor products allows us to compute \( f^! \mathcal{F} \) in terms of \( f^* \mathcal{F} \) and \( f^! \mathcal{O}_{Y} \):

**Proposition 3.1** ([Har66 Prop. III.8.8]). Let \( f : X \to Y \) be a local complete intersection of locally noetherian schemes of finite Krull’s dimension. Then there are functorial isomorphisms

i. \( f^! \mathcal{F} \otimes \mathcal{L} f^* \mathcal{G} \to f^!(\mathcal{F} \otimes \mathcal{L} \mathcal{G}) \) for \( \mathcal{F} \in \mathcal{D}_{qc}^{+}(Y) \) and \( \mathcal{G} \in \mathcal{D}_{qc}^{b}(Y)_{fTd} \)

ii. \( R \mathcal{H}om_{X}(\mathcal{L} f^* \mathcal{F}, f^! \mathcal{G}) \to f^!(R \mathcal{H}om_{Y}(\mathcal{F}, \mathcal{G})) \) for \( \mathcal{F} \in \mathcal{D}_{c}^{-}(Y) \) and \( \mathcal{G} \in \mathcal{D}_{qc}^{b}(Y) \).

In particular, as \( f^! \mathcal{O}_{Y} \) is invertible we have \( f^! \mathcal{G} \simeq f^! \mathcal{O}_{Y} \otimes \mathcal{L} f^* \mathcal{G} \) for \( \mathcal{G} \in \mathcal{D}_{qc}^{b}(Y)_{fTd} \).

We now prove the Local Duality Theorem for locally free sheaves of finite rank over projective lci curves:

**Proposition 3.2.** Let \( f : X \to \text{Spec} \mathcal{O}_{K} \) be a projective lci curve, and let \( \omega_{X/\mathcal{O}_{K}}^{n} \) be the invertible sheaf such that \( \omega_{X/\mathcal{O}_{K}}^{n}[1] = f^! \mathcal{O}_{K} \). Let \( \mathcal{F} \) be a locally free \( \mathcal{O}_{X} \)-module of finite rank, then:

1. \( \mathcal{R} f_* \mathcal{F} \) is representable by a perfect complex of length \([0,1] \);

2. we have a perfect pairing

\[
H^{0}(X, \mathcal{F} \otimes K/\mathcal{O}_{K}) \times H^{1}(X, \mathcal{F}^{\vee} \otimes \omega_{X/\mathcal{O}_{K}}^{n}) \to K/\mathcal{O}_{K},
\]

2This is still true for Gorenstein morphisms, i.e. morphisms \( f : X \to Y \) with \( f^! \mathcal{O}_{Y} \) invertible.
given by the composition of the cup product and the trace $\text{Tr} : \omega_{X/\mathcal{O}_K}^2 \to \mathcal{O}_K$.

Proof. As $\mathcal{F}$ is flat-coherent and $f$ is projective of relative dimension 1, the cohomology groups of $\mathcal{R} f_* \mathcal{F}$ are finitely generated over $\mathcal{O}_K$ and they are concentrated in degrees 0 and 1. Then, $\mathcal{R} f_* \mathcal{F}$ is quasi-isomorphic to a complex $0 \to M_0 \xrightarrow{d} M_1 \to 0$ with $M_i$ a free $\mathcal{O}_K$-module of finite rank for $i = 0, 1$. Moreover, the complex $0 \to M_0 \otimes K/\mathcal{O}_K \xrightarrow{d\otimes 1} M_1 \otimes K/\mathcal{O}_K \to 0$ is quasi-isomorphic to $\mathcal{R} f_*(\mathcal{F} \otimes K/\mathcal{O}_K)$ in $D(\mathcal{O}_K)$, see [MRM74, Theo. 5.2].

Duality Theorem 3.1 gives a quasi-isomorphism

$$
\mathcal{R} f_*(\mathcal{F}^\vee \otimes \omega_{X/\mathcal{O}_K}^0)[1] = \mathcal{R} f_* \mathcal{R} \mathcal{H}om_X(\mathcal{F}, f^! \mathcal{O}_K) \simeq \mathcal{R} \mathcal{H}om_Y(\mathcal{R} f_* \mathcal{F}, \mathcal{O}_K).
$$

This implies that $\mathcal{R} f_*(\mathcal{F}^\vee \otimes \omega_{X/\mathcal{O}_K}^0)$ is quasi-isomorphic to $0 \to M_1^0 \xrightarrow{d^\vee} M_0^0 \to 0$. Finally, Pontryagin duality for $\mathcal{O}_K$ implies that the natural pairing $\ker(d \otimes 1) \times \text{coker} d^\vee \to K/\mathcal{O}_K$ is perfect, which is exactly the statement in cohomology.

\[\square\]

Remark. The $\mathcal{O}_K$-module $H^0(X, \mathcal{F} \otimes K/\mathcal{O}_K)$ is co-free of rank $r$, that is isomorphic to $(K/\mathcal{O}_K)^r$, if and only if $H^1(X, \mathcal{F}^\vee \otimes \omega_{X/\mathcal{O}_K}^0)$ is free of rank $r$. In that case, the module $H^0(X, \mathcal{F})$ is free and $H^0(X, \mathcal{F}/p^n) \to H^0(X, \mathcal{F}/p^n)$ is an isomorphism for all $n \in \mathbb{N}$. Furthermore, Grothendieck-Serre duality provides a perfect pairing

$$
H^0(X, \mathcal{F}) \times H^1(X, \mathcal{F}^\vee \otimes \omega_{X/\mathcal{O}_K}^0) \to \mathcal{O}_K.
$$

The $\mathcal{O}_K$-module $H^0(X, \mathcal{F})$ (resp. $H^1(X, \mathcal{F} \otimes K/\mathcal{O}_K)$) is free (resp. cofree) for any locally free $\mathcal{O}_X$-module. In the notation of the proof of the previous proposition, Pontryagin duality implies that $\text{coker}(d \otimes 1) \times \ker d^\vee \to K/\mathcal{O}_K$ is also a perfect pairing, that is

$$
H^1(X, \mathcal{F} \otimes K/\mathcal{O}_K) \times H^0(X, \mathcal{F}^\vee \otimes \omega_{X/\mathcal{O}_K}^0) \to K/\mathcal{O}_K.
$$

4 Cohomology of modular sheaves

Throughout this section we denote by $X_n$ the modular curve $X(Np^n)$. We set $\mathcal{O}_n = H^0(X_n, \mathcal{O}_{X_n})$, $K_n = \mathcal{O}_n[1]/\mathcal{O}_n$, $\mathcal{O}^{\text{gcd}}$ the $p$-adic completion of $\lim\mathcal{O}_n$ and $K^{\text{gcd}} = \mathcal{O}^{\text{gcd}}[1]$. We write $\mathcal{O} = \mathcal{O}_0$ and $K = K_0$. Let $\pi_n : X_n \to \text{Spec} \mathcal{O}_n$ be the structure morphism and let $D_n \subset X_n$ be the boundary divisor. We denote by $\omega_{X_n/\mathcal{O}_n}^k = \omega_{X_n/\mathcal{O}_n}$ the modular sheaf of weight $k$ over $X_n$, it is defined as the $k$-th power of the invariant differentials of the generalized elliptic curve $E/X_n$. Similarly, we define the sheaf of cusp forms of weight $k$ as $\omega_{n,\text{cusp}}^k := \omega_{n}^k(-D_n)$. Finally, we write $\mathcal{X}_n$ (resp. $\mathcal{X}_\infty$) for the $p$-adic completion (resp. the adic generic fiber) of $X_n$. We denote by $\mathcal{X}_\infty$ the integral perfectoid modular curve $\mathcal{X}(Np^\infty)$ constructed in Section 2 and by $\mathcal{X}_\infty$ the perfectoid modular curve $\mathcal{X}(Np^\infty)$.

Consider the tower of modular curves

$$
\cdots \longrightarrow X_{n+1} \xrightarrow{p_{n+1}} X_n \xrightarrow{p_n} X_{n-1} \longrightarrow \cdots
$$

$$
\downarrow \pi_{n+1} \quad \downarrow \pi_n \quad \downarrow \pi_{n-1}
$$

$$
\cdots \longrightarrow \text{Spec}(\mathcal{O}_{n+1}) \longrightarrow \text{Spec}(\mathcal{O}_n) \longrightarrow \text{Spec}(\mathcal{O}_{n-1}) \longrightarrow \cdots.
$$

Set $\omega_{n}[1] := \pi_n^! \mathcal{O}_n$. Note that the sheaf $\omega_{n}^0$ is invertible since $X_n$ is a local complete intersection over $\mathcal{O}_n$. The modular curve $X_0/\mathcal{O}$ is smooth of relative dimension 1, then we have $\omega_{0}^0 = \Omega_{X_0/\mathcal{O}}^1$. Moreover, the Kodaira-Spencer map provides an isomorphism $KS : \omega_{0,\text{cusp}}^2 \cong \Omega_{X/\mathcal{O}}^1$. 

13
Fixing $n$, we denote the base change of $X_n$ to $\mathcal{O}_n$ also by $X_{n-1}$. Then we have a commutative triangle
\[
\begin{array}{c}
X_n \\
\downarrow p_n \\
\pi_{n-1} \\
\Spec(\mathcal{O}_n) \\
\end{array}
\]

**Proposition 4.1.** There exists a natural isomorphism $\xi'_n : p^*(\omega_{n-1}^o)(p_n^* D_{n-1} - D_n) \xrightarrow\sim \omega_n^o$ induced by the normalized trace $\frac{1}{p} \Tr_n : \mathcal{O}_{X_n} \to p_n^! \mathcal{O}_{X_{n-1}}$. Moreover, the composition of $\xi'_n \circ \cdots \circ \xi'_1$ and the Kodaira-Spencer map gives an isomorphism $\omega_{n,cusp}^2 \cong \omega_n^o$.

**Proof.** By Proposition 3.1 we have an isomorphism
\[
\xi_n : p^!_n(\mathcal{O}_{X_{n-1}}) \otimes p^*_n \omega_{n-1}^o \xrightarrow\sim p^!_n(\omega_{n-1}^o) = \omega_n^o. 
\]
(4.1)
The map $p_n$ is finite flat, then $p^!_n(\mathcal{O}_{X_{n-1}}) = \mathcal{H}om_{\mathcal{O}_{X_{n-1}}}(p_{n*} \mathcal{O}_{X_{n}}, \mathcal{O}_{X_{n-1}})$. The sheaf $p^!_n(\mathcal{O}_{X_{n-1}})$ is invertible as $X_{n-1}$ is a lci projective curve, then we are reduce to study the ordinary points and the cusps. Indeed, the supersingular points are of codimension 2 in $X_n$. Let $\Tr_n \in p^!_n \mathcal{O}_{n-1}$ denote the trace.

Let $x \in X_{n-1}$ be a geometric closed ordinary point. Then we have a cartesian square
\[
\begin{array}{c}
\bigcup_{x_n \to x} \Spec \hat{\mathcal{O}}_{X_n,x_n} \\
\downarrow \\
\Spec \hat{\mathcal{O}}_{X_{n-1},x} \\
\end{array} \longrightarrow
\begin{array}{c}
\longrightarrow \hat{\mathcal{O}}_{X_n,x_n} \\
\downarrow p_n \\
\hat{\mathcal{O}}_{X_{n-1},x} \\
\end{array} 
\]
(4.2)
By Theorem 1.2 we have isomorphisms
\[
\hat{\mathcal{O}}_{X_{n-1},x} \cong W(\bar{\mathbb{F}}_p)[\zeta_{p^n}][[T_{n-1}]'], \quad \hat{\mathcal{O}}_{X_n,x} \cong W(\bar{\mathbb{F}}_p)[\zeta_{p^n}][[T]]
\]
with relations $(1 + T_n)^p = 1 + T_{n-1}$. We deduce
\[
\Hom \hat{\mathcal{O}}_{X_{n-1},x} \left( \hat{\mathcal{O}}_{X_n,x}, \hat{\mathcal{O}}_{X_{n-1},x} \right) \cong \frac{1}{p} \hat{\mathcal{O}}_{X_n,x} \cdot \Tr_n.
\]
On the other hand, let $x \in X_{n-1}$ be a closed geometric cusp. Analogously we have a cartesian square (4.2) and isomorphisms
\[
\hat{\mathcal{O}}_{X_{n-1},x} \cong W(\bar{\mathbb{F}}_p)[\zeta_{p^n}][[q^{1/p^{n-1}}]], \quad \hat{\mathcal{O}}_{X_n,x} \cong W(\bar{\mathbb{F}}_p)[\zeta_{p^n}][[q^{1/p^n}]].
\]
Hence we obtain the equality
\[
\Hom \hat{\mathcal{O}}_{X_{n-1},x} \left( \hat{\mathcal{O}}_{X_n,x}, \hat{\mathcal{O}}_{X_{n-1},x} \right) \cong \frac{1}{p} q^{1/p^{n-1}/p^{n-1}} \hat{\mathcal{O}}_{X_n,x} \cdot \Tr_n.
\]
The previous computations show that the trace of $\mathcal{O}_{X_n}/\mathcal{O}_{X_{n-1}}$ induces an isomorphism of invertible sheaves
\[
\frac{1}{p} \Tr_n : \mathcal{O}_{X_n}(p_n^* D_{n-1} - D_n) \xrightarrow\sim p^!_n(\mathcal{O}_{X_{n-1}}).
\]
Then, from (4.1) we obtain an isomorphism
\[
\xi'_n : p^!_n(\omega_{n-1}^o)(p_n^* D_{n-1} - D_n) \to \omega_n^o
\]
with $\xi'_n = \xi_n \circ (\frac{1}{p} \Tr_n \otimes 1)$.

The isomorphism $\omega_{n,cusp}^2 \cong \omega_n^o$ follows by a straightforward induction on the composition $\xi'_n \circ \cdots \circ \xi'_1$ and the Kodaira-Spencer map $KS$. $\square$

\footnote{We make an abuse of notation writing $\xi'_n \circ \xi'_{n-1}$ instead of $\xi'_n \circ \xi'_{n-1}(p_n^* D_{n-1} - D_n)$.}
Remark. Let \( x \in X_{n-1} \) be a closed geometric point, either an ordinary point or a cusp. Then the trace map \( \overline{\text{Tr}}_n : \mathcal{O}_{X_n}(p_n^*D_{n-1} - D_n) \to \mathcal{O}_{X_{n-1}} \) of Duality Theorem defines a \( \mathcal{O}_n \)-linear map

\[
\overline{\text{Tr}}_n = \sum_{x \to x} \partial_{X_{n-1}} \otimes (q^{1/p^n-1/p^{n-1}}) \to \partial_{X_{n-1}}
\]

Moreover, the explicit description found in the proof of the previous proposition shows that \( \overline{\text{Tr}}_n \) is surjective on each direct summand. Therefore, if \( f \) is a modular form of weight \( k \) over \( X_{n-1} \) we have \( \overline{\text{Tr}}_n(p_n^*f) = p^2f \).

Next we prove some vanishing results of modular sheaves of weight \( k \neq 1 \) at finite level.

**Proposition 4.2.** The following hold.

1. \( H^0(X_n, \omega^k_n \otimes K/\mathcal{O}) = H^0(X_n, \omega^k_{n,cusp} \otimes K/\mathcal{O}) = 0 \) for \( k < 0 \).

2. Dually, \( H^1(X_n, \omega^k_n) = H^1(X_n, \omega^k_{n,cusp}) = 0 \) for \( k > 2 \).

3. \( H^0(X_n, \mathcal{O}_{X_n}(-D_n) \otimes K/\mathcal{O}) = H^1(X_n, \omega^2_n) = 0 \) and \( H^0(X_n, \mathcal{O}_{X_n} \otimes K/\mathcal{O}) = H^1(X_n, \omega^2_{n,cusp}) \otimes K/\mathcal{O} = K_n/\mathcal{O}_n \).

**Proof.** By Proposition 3.2 and the remark after loc. cit., it suffices to show (1) and (3) for \( \mathcal{O}_{X_n} \) and \( \mathcal{O}_{X_n}(-D_n) \).

Let \( \nu_n \) denote the closed point of Spec \( \mathcal{O}_n \), by Nakayama’s lemma it suffices to prove \( H^0(X_{n,\nu_n}, \omega^k_{n}) = 0 \) for \( k < 0 \). Let \( \lambda \in H^0(X_{n,\nu_n}, \omega^k_{n}) \) be non-zero. Tensoring with an algebraic closure \( \overline{\mathbb{F}}_p \) and using the action of \( \text{GL}_2(\mathbb{Z}/p^n\mathbb{Z}) \) we may assume that \( \lambda \) is non-zero in an open dense subscheme of \( X_{n,\nu_n} \). In fact, this holds for some linear combination \( \sum_{\gamma \in \text{GL}_2(\mathbb{Z}/p^n\mathbb{Z})} a_n \gamma^* \lambda \) with \( a_n \in \overline{\mathbb{F}}_p \). The norm \( N_{X_n/X_0}(\omega^k_n) \) of \( \omega^k_n \) to \( X_0 \) is \( \omega^d_0 \) where \( d = \deg(X_n/X_0) \), hence if \( k < 0 \) the sheaf \( N_{X_n/X_0}(\omega^k_n) \) has negative degree in the smooth curve \( X_0 \). This implies that \( H^0(X_{0,\nu_0}, N_{X_n/X_0}(\omega^k_n)) = 0 \) and \( N_{X_n/X_0}(\lambda) = 0 \), a contradiction. Therefore \( H^0(X_{n,\nu_n}, \omega^k_{n}) = 0 \) for \( k < 0 \). Since \( \omega^k_{n,cusp} = \omega^k_{n}(-D_n) \), we trivially deduce \( H^0(X_{n,\nu_n}, \omega^k_{n,cusp}) = 0 \). The results for \( \mathcal{O}_{X_n} \) and \( \mathcal{O}_{X_n}(-D_n) \) are clear as \( X_n/\mathcal{O}_{K,n} \) is proper, flat and geometrically connected and has geometrically reduced fibers.

**Corollary 4.2.1.** Let \( \mathcal{F} \in \{ \omega^k_n, \omega^k_{n,cusp}, \omega^{k+2}_n, \omega^{k+2}_{n,cusp} : k \geq 0 \} \), the following hold:

1. The cohomology groups \( H^0(X_n, \mathcal{F} \otimes K/\mathcal{O}) \) and \( H^1(X_n, \mathcal{F}) \) are cofree and free \( \mathcal{O}_n \)-modules respectively.

2. We have a perfect duality pairing

\[
H^0(X_n, \mathcal{F} \otimes K/\mathcal{O}) \times H^1(X_n, \mathcal{F}^\vee \otimes \omega^2_{n,cusp}) \to K_n/\mathcal{O}_n.
\]

**Proof.** This is a consequence of the Local Duality Theorem (Proposition 3.2) and Proposition 4.2.

Let \( m \geq n \), we have the inequality of divisors \( D_m \leq D_n \). Therefore \( \mathcal{O}_{X_m}(-D_n) \subset \mathcal{O}_{X_m}(-D_m) \), and the pullback of \( \omega^k_{cusp,m} \) injects into \( \omega^k_{cusp,n} \). We get the following vanishing of higher cohomology at infinite level of positive weight modular sheaves, surprisingly the theorem applies even for \( \omega^1_{\infty} \).

**Theorem 4.1.** Let \( \omega^k_{\infty} \) denote the pullback of \( \omega^k_n \) to \( X_{\infty} \), and let \( \omega^k_{cusp,\infty} \) be the \( p \)-adic completion of \( \lim_{n \to \infty} \omega^k_{cusp,n} \). Then
1. \( H^i(\mathfrak{X}_\infty, \omega_{\infty}^k/p^m) = \lim_{n \to \infty} H^i(\mathfrak{X}_n, \omega_n^k/p^m) \) for all positive integers \( m, k \in \mathbb{Z} \), and \( i = 0, 1 \) (resp. for \( \omega_{\infty,\text{cusp}}^k \) and \( \omega_{\infty,\text{cusp}}^k \)).

2. \( H^0(\mathfrak{X}_\infty, \omega_{\infty}^k) = H^1(\mathfrak{X}_\infty, \omega_{\infty}^k) = 0 \) for \( k > 0 \) (resp. for \( \omega_{\infty,\text{cusp}}^k \) and \( \omega_{\infty,\text{cusp}}^k \)).

3. \( H^0(\mathfrak{X}_\infty, \omega_{0,\text{cusp}}^k) = 0 \) and \( H^0(\mathfrak{X}_\infty, \mathcal{O}_{\mathfrak{X}_\infty}) = \mathcal{O}^\text{cyc} \).

**Proof.** Let \( \mathcal{U} = \{ U_i \}_{i \in I} \) be a finite affine cover of \( X_0 \), let \( \mathcal{U}_n \) (resp. \( \mathcal{U}_\infty \)) be its pullback to \( X_n \) (resp. \( X_\infty \)). Since all the sheaves involved are quasi-coherent, and the (formal) schemes are separated, we can use the Čech complexes to compute the cohomology groups. By definition we have

\[
\mathcal{C}^\bullet(\mathcal{U}_\infty, \omega_{\infty}^k/p^m) = \lim_{n \to \infty} \mathcal{C}^\bullet(\mathcal{U}_n, \omega_n^k/p^m)
\]

\[
\mathcal{C}^\bullet(\mathcal{U}_\infty, \omega_{\infty,\text{cusp}}^k/p^m) = \lim_{n \to \infty} \mathcal{C}^\bullet(\mathcal{U}_n, \omega_n^k/p^m),
\]

from which (1) follows.

Moreover, \( \omega_{\infty}^k = \lim_{n \to \infty} \omega_n^k/p^m \) and \( \omega_{\infty,\text{cusp}}^k = \lim_{n \to \infty} \omega_{\infty,\text{cusp}}^k/p^m \). Then we obtain quasi-isomorphisms

\[
R \Gamma(\mathfrak{X}_\infty, \omega_{\infty}^k) \cong R \lim_{n \to \infty} R \Gamma(\mathfrak{X}_\infty, \omega_n^k/p^m)
\]

\[
R \Gamma(\mathfrak{X}_\infty, \omega_{\infty,\text{cusp}}^k) \cong R \lim_{n \to \infty} R \Gamma(\mathfrak{X}_\infty, \omega_n^k/p^m).
\]

Let \( p^{1/p} \in \mathcal{O}^\text{cyc} \) be such that \( |p^{1/p}| = |p|^{1/p} \). As \( \mathfrak{X}_\infty \) is integral perfectoid the Frobenius \( F : \mathfrak{X}_\infty/p^{1/p} \to \mathfrak{X}_\infty/p \) is an isomorphism. Note that \( F^*(\omega_{\infty}^k/p^m) = \omega_{\infty}^k/p^{1/p} \) and \( F^*(\omega_{\infty,\text{cusp}}^k/p^m) = \omega_{\infty,\text{cusp}}^k/p^{1/p} \). Proposition 1.2 shows

\[
H^1(\mathfrak{X}_\infty, \omega_{\infty}^k/p^m) \cong H^1(\mathfrak{X}_\infty, \omega_{\infty}^k/p^{1/p}) = 0 \quad \text{for } k > 0,
\]

similarly for \( \omega_{\infty,\text{cusp}}^k \) and \( k < 0 \). Then the cohomology of the complexes \( \{ R \Gamma(\mathfrak{X}_\infty, \omega_{\infty}^k/p^m) \}_m \) and \( \{ R \Gamma(\mathfrak{X}_\infty, \omega_{\infty,\text{cusp}}^k/p^m) \}_m \) satisfy the Mittag-Leffler condition for all \( k \in \mathbb{Z} \). In fact, the transition maps are surjective. Thus

\[
H^i(\mathfrak{X}_\infty, \omega_{\infty}^k) = \lim_{m \to \infty} H^i(\mathfrak{X}_\infty, \omega_{\infty}^k/p^m),
\]

\[
H^i(\mathfrak{X}_\infty, \omega_{\infty,\text{cusp}}^k) = \lim_{m \to \infty} H^i(\mathfrak{X}_\infty, \omega_{\infty,\text{cusp}}^k/p^m).
\]

The proposition follows from the computations of cohomology at finite level and 1.3. \( \square \)

A consequence of the vanishing of coherent cohomology at integral perfectoid level is the respective vanishing results over the perfectoid adic modular curve:

**Corollary 4.1.1.** Let \( \omega_{\infty}^{k}(\frac{1}{p}) \) and \( \omega_{\infty,\text{cusp}}^{k}(\frac{1}{p}) \) denote the generic fiber over \( \mathfrak{X}_\infty \) of the modular sheaves \( \omega_{\infty}^{k} \) and \( \omega_{\infty,\text{cusp}}^{k} \). We have

1. \( H^0_{\text{an}}(\mathcal{X}_\infty, \omega_{\infty}^{k}(\frac{1}{p})) = H^1_{\text{an}}(\mathcal{X}_\infty, \omega_{\infty}^{k}(\frac{1}{p})) = 0 \) for \( k > 0 \) (resp. for \( \omega_{\infty,\text{cusp}}^{k}(\frac{1}{p}) \) and \( \omega_{\infty,\text{cusp}}^{k}(\frac{1}{p}) \)).

2. \( H^0_{\text{an}}(\mathcal{X}_\infty, \omega_{\infty,\text{cusp}}^{0}(\frac{1}{p})) = 0 \) and \( H^0_{\text{an}}(\mathcal{X}_\infty, \mathcal{O}_{\mathfrak{X}_\infty}) = K^\text{cyc} \).
Proof. We proceed with $\omega_{k_c}$, the proof for $\omega_{c,\text{cusp}}$ is similar. Let $U = \{U_i\}$ be a finite covering of $X_\infty$ by formal affine integral perfectoid spaces arising from finite level, we further assume that the covering trivializes $\omega_{k_c}$. Let $U^{\text{aff}} = \{U_i\}$ be the corresponding covering of $X_\infty$ by affinoid perfectoids. Then the Čech complexes $C^*(U, \omega_{k_c})[\frac{1}{p}]$ and $C^*(U^{\text{aff}}, \omega_{k_c})[\frac{1}{p}]$ are equal. As the formal affine schemes and the affinoid perfectoid are (almost) acyclic for the structure sheaf, we have

$$H^i_{\text{et}}(X_\infty, \omega_{k_c}[\frac{1}{p}]) = H^i(X_\infty, \omega_{k_c}[\frac{1}{p}]).$$

The corollary follows from the vanishing results at integral perfectoid level. \hfill \square

Recall that given a modular curve $X_n$, we consider all the base changes with respect to the morphism $X_n \to \text{Spec } O_n$.

Let $\tilde{H}^1 := \varprojlim_n (\varprojlim_m H^1_{\text{et}}(X_n, Z/p^m Z))$ be the completed cohomology of tame level $\Gamma(N)$. We end this section by comparing the dual completed cohomology $(\tilde{H}^1 \otimes_{\mathbb{Z}_p} \mathbb{C}_p)^\vee$, and the projective limit of integral weight-2 cusp forms $\varprojlim_n H^0(X_\infty, \omega_{c,\text{cusp}})$, with transition morphisms the traces $\tilde{T}_p$. First, let’s show that these two spaces have natural structures of Banach spaces.

**Lemma 4.1.** The completed cohomology $\tilde{H}^1$ is $p$-adically complete and separated, and has torsion of bounded exponent. In particular, $\tilde{H}^1[\frac{1}{p}]$ has a unique structure of a $\mathbb{Q}_p$-Banach space such that the image of $\tilde{H}^1$ is the unitary ball.

Moreover, there is a unique structure of $\mathbb{Q}_p$-Banach space on the continuous dual $(\tilde{H}^1[\frac{1}{p}])^\vee$ such that the image of $\tilde{H}^1 := \text{Hom}_{\mathbb{Z}_p}(\varprojlim_n H^1_{\text{et}}(X_n, \mathbb{Q}_p/Z_p); \mathbb{Q}_p/Z_p)$ is the unitary ball.

**Proof.** Theorem 2.15 of [Eme06] implies that the group $\tilde{H}^1$ is $p$-adically complete and separated, and that its $p^\infty$-torsion is $p$-power bounded. Then $\tilde{H}^1[\frac{1}{p}]$ has a natural structure of Banach $\mathbb{Q}_p$-algebra, for which the image of $\{p^m \tilde{H}^1\}_m$ is a basis of neighbourhoods of 0. Let $X_\infty, \mathbb{C}_p$ be the base change of the perfectoid modular curve to $\mathbb{C}_p$. We can write the completed cohomology in terms of the pro-étale cohomology of $X_\infty, \mathbb{C}_p$. Indeed, using Corollary 7.18 of [Sch12] one shows $\tilde{H}^1 = H^1_{\text{proet}}(X_\infty, \mathbb{C}_p; \hat{\mathbb{Z}}_p)$.

On the other hand, we have

$$\text{Hom}_{\mathbb{Z}_p}(\tilde{H}^1, \mathbb{Z}_p) = \varprojlim_m \text{Hom}_{\mathbb{Z}_p}(\tilde{H}^1, Z/p^m Z) = \varprojlim_m \text{Hom}_{\mathbb{Z}_p}(\tilde{H}^1/p^m, Z/p^m Z) = \text{Hom}_{\mathbb{Z}_p}(\tilde{H}^1 \otimes \mathbb{Q}_p/Z_p, \mathbb{Q}_p/Z_p).$$

We want to compare the duals of $H^1_{\text{proet}}(X_\infty, \mathbb{C}_p; \hat{\mathbb{Z}}_p) \otimes_{\mathbb{Q}_p} \mathbb{Z}_p$ and $H^1_{\text{proet}}(X_\infty, \mathbb{C}_p, \mathbb{Q}_p/Z_p)$. From the short exact sequence $0 \to \hat{\mathbb{Z}}_p \to \hat{\mathbb{Q}}_p \to \mathbb{Q}_p/Z_p \to 0$ we obtain a short exact sequence of cohomology groups

$$0 \to H^1_{\text{proet}}(X_\infty, \mathbb{C}_p; \hat{\mathbb{Z}}_p) \otimes_{\mathbb{Q}_p} \mathbb{Z}_p \to H^1_{\text{proet}}(X_\infty, \mathbb{C}_p, \mathbb{Q}_p/Z_p) \to H^2_{\text{proet}}(X_\infty, \mathbb{C}_p; \hat{\mathbb{Z}}_p)[p^\infty] \to 0. \quad (4.4)$$

Taking duals we obtain an exact sequence

$$0 \to \text{Hom}_{\mathbb{Z}_p}(\tilde{H}^2[p^\infty], \mathbb{Q}_p/Z_p) \to \text{Hom}_{\mathbb{Z}_p}(\tilde{H}^1(\mathbb{Q}_p/Z_p); \mathbb{Q}_p/Z_p) \to \text{Hom}_{\mathbb{Z}_p}(\tilde{H}^1 \otimes \mathbb{Q}_p/Z_p, \mathbb{Q}_p/Z_p) \to 0.$$
Where \( \tilde{H}^2 := H^2_{\text{proet}}(X_{\infty, c_p}, \hat{Z}_p) \), and \( \tilde{H}^1(Q_p/\mathbb{Z}_p) := H^1_{\text{proet}}(X_{\infty, c_p}, Q_p/\mathbb{Z}_p) \). By Theorem 2.15 of [Eme06], the group \( H^2_{\text{proet}}(X_{\infty, c_p}, \hat{Z}_p)[p^\infty] \) has bounded exponent. Then we obtain an isomorphism of \( Q_p \)-Banach spaces

\[
\text{Hom}_{Z_p}(\tilde{H}^1(Q_p/\mathbb{Z}_p), Q_p/\mathbb{Z}_p)[1/p] \cong \text{Hom}_{Z_p}(\tilde{H}^1 \otimes Q_p/\mathbb{Z}_p, Q_p/\mathbb{Z}_p)[1/p] = (\tilde{H}^1[1/p])^\vee.
\]

This proves the lemma. \( \square \)

**Remark.** The previous argument seems to work for more general towers of Shimura varieties. In the case of modular curves we can be more precise; the Primitive Comparison Theorem of Scholze implies that

\[
H^i_{\text{proet}}(X_{\infty, c_p}, \hat{Z}_p) \otimes \mathcal{O}_{c_p} =_{\text{ae}} H^i_{\text{proet}}(X_{\infty, c_p}, \mathcal{O}_{X_{\infty, c_p}}^+).
\]

Since the modular tower is a tower of curves, the second coherent cohomology group of \( X_{\infty, c_p} \) (almost) vanishes. Thus \( H^2_{\text{proet}}(X_{\infty, c_p}, \hat{Z}_p) = 0 \) and the left arrow of (4.4) is an isomorphism. This implies that

\[
\lim_{\leftarrow m} \tilde{H}^1/p^m \tilde{H}^1 = \lim_{\leftarrow m} H^1_{\text{proet}}(X_{\infty, c_p}, \mathbb{Z}/p^m\mathbb{Z}) = \tilde{H}^1.
\]

On the other hand, the respective exact sequence (4.4) for \( i = 0, 1 \) shows that \( \tilde{H}^1 \) has no torsion.

**Lemma 4.2.** The generic fiber of the projective limit \( \lim_{\leftarrow n, \mathcal{T}_n} H^0(X_n, \mathcal{O}_{c_p}, \omega^2_{n, \text{cusp}})(1/p) \) has a natural structure of \( K^\text{cusp} \)-Banach space.

**Proof.** By Proposition 1.2 the \( \mathcal{O}_n \) module \( H^0(X_n, \omega^2_{n, \text{cusp}}) \) is free of finite rank over \( \mathcal{O}_n \). Moreover, we can see \( \lim_{\leftarrow n, \mathcal{T}_n} H^0(X_n, \mathcal{O}_{c_p}, \omega^2_{n, \text{cusp}}) \) as the kernel of the linear map

\[
\prod_{n \in \mathbb{N}} H^0(X_n, \mathcal{O}_{c_p}, \omega^2_{n, \text{cusp}}) \twoheadrightarrow \prod_{n \in \mathbb{N}} H^0(X_n, \mathcal{O}_{c_p}, \omega^2_{n, \text{cusp}}).
\]

But the product of finite free \( \mathcal{O}_{c_p}^{\text{cusp}} \)-modules is \( p \)-adically complete, separated and \( \mathcal{O}_{c_p}^{\text{cusp}} \)-flat. This implies that \( \ker(1 - (\mathcal{T}_n)) \) is a flat, \( p \)-adically and separated \( \mathcal{O}_{c_p}^{\text{cusp}} \)-module. \( \square \)

**Remark.** Furthermore, \( \{H^0(X_n, \mathcal{O}_{c_p}, \omega^2_{n, \text{cusp}})\}_n \) is a projective system of finite free \( \mathcal{O}_{c_p}^{\text{cusp}} \)-modules satisfying the Mittag-Leffler condition. Indeed, by the remark after Proposition 1.1 we know that the traces \( \mathcal{T}_n \) are surjective. Thi implies that the projections from the projective limit to their factors are surjective as well.

**Theorem 4.2.** There exists a \( G_{K^\text{cusp}} \times \text{GL}_2(Q_p) \)-equivariant isomorphism of \( \mathbb{C}_p \)-Banach spaces

\[
(\hat{H}^1 \otimes Z_p \mathbb{C}_p)^\vee = \hat{H}^1 \otimes Z_p \mathbb{C}_p \cong (\lim_{\leftarrow n, \mathcal{T}_n} H^0(X_n, \mathcal{O}_{c_p}, \omega^2_{n, \text{cusp}})) \otimes \mathcal{O}_{c_p} \mathbb{C}_p.
\]

Moreover, each of these spaces admit a norm with respect to which the previous isomorphism is an isometry, and such that the action of \( G_{K^\text{cusp}} \times \text{GL}_2(Q_p) \) is isometric.

The action of \( G_{K^\text{cusp}} \) in the right-hand-side of (4.5) is trivial on the projective limit, and the natural one in \( \mathbb{C}_p \). In the left-hand-side of (4.5), the group \( G_{K^\text{cusp}} \) acts on \( \hat{H}^1 = H^1_{\text{proet}}(X_{\infty, c_p}, \hat{Z}_p) \) via the extension of scalars \( K^\text{cusp} \to \mathbb{C}_p \).

Let us recall the \( \text{GL}_2(Q_p) \)-action on \( \lim_{\leftarrow n, \mathcal{T}_n} H^0(X_n, \mathcal{O}_{c_p}, \omega^2_{n, \text{cusp}}) \) and \( \hat{H}^1 \). Let \( g \in \text{GL}_2(Q_p) \) and \( n \geq 0 \), let \( m \geq 1 \) be such that \( \Gamma(p^m) \subset \Gamma(p^n) \cap g \Gamma(p^n) g^{-1} \). Let \( \phi_g : \text{GL}_2(Q_p) \to \text{GL}_2(Q_p) \) denote the conjugation by \( g \). The composition of group homomorphisms

\[
\Gamma(p^m) \hookrightarrow \Gamma(p^n) \cap g \Gamma(p^n) g^{-1} \xrightarrow{c_g^{-1}} g^{-1} \Gamma(p^n) g \cap \Gamma(p^n) \hookrightarrow \Gamma(p^n)
\]
induces the (right) multiplication by $g$ in the tower $\{X_n\}_{n \geq 1}$, seen as the inverse limit of the maps

$$g : X_m \xrightarrow{p} X_{\Gamma(p^n) \cap \Gamma(p^n) g^{-1}} \xrightarrow{g} X_{\Gamma(p^n) g \cap \Gamma(p^n)} \xrightarrow{q} X_n.$$ 

These maps define a left $\text{GL}_2(\mathbb{Q}_p)$-action on $\tilde{H}^1$ and $H^1(\mathcal{X}_\infty, \mathcal{O}_{\mathcal{X}_\infty})$ via pullbacks. Let $\chi : \text{Gal}(\mathbb{K}^{cyc}/K) \xrightarrow{\sim} \mathbb{Z}_p^\times$ be the $p$-adic cyclotomic character. Given $g \in \text{GL}_2(\mathbb{Q}_p)$, let $\psi(g) = \chi^{-1}(p^{-v_p(\det g)} \det g)$. By the Duality Theorem we have a commutative diagram of perfect pairings

$$H^0(X_m, \omega^2_{m,cusp}) \times H^1(X_m, \mathcal{O}_X) \xrightarrow{\psi} O^{\text{cyc}}.$$ 

Thus, the right action of $g \in \text{GL}_2(\mathbb{Q}_p)$ on a tuple $f_n = (f_n) \in \varprojlim_{n \to \overline{n}, \tilde{\text{Tr}}_n} H^0(X_n, \mathcal{O}_{\mathcal{X}_\infty}, \omega^2_{n,cusp})$ is given by

$$(f_{g})_n = (\tilde{\text{Tr}}_q \circ g^{-1} \circ \tilde{\text{Tr}}_p (f_m))$$

with $m$, $p$ and $g$ as in the diagram (4.6).

**Proof of Theorem 4.2** By the Primitive Comparison Theorem [Sch13 Theo. 5.1], we have almost isomorphisms for all $m \geq 1$

$$H^1_{et}(\mathcal{X}_\infty, \mathbb{Z}/p^m \mathbb{Z}) \otimes_{\mathbb{Z}_p} \mathcal{O}_{\mathbb{C}_p} =^{ae} H^1_{\text{proet}}(\mathcal{X}_\infty, \mathcal{O}_{\mathcal{X}_\infty}^+/p^m) =^{ae} H^1_{an}(\mathcal{X}_\infty, \mathcal{O}_{\mathcal{X}_\infty}^+/\mathcal{O}_{\mathbb{C}_p}).$$

Moreover, the Primitive Comparison Theorem is $G_{K^{cyc}}$-equivariant and functorial with respect to maps of proper smooth adic spaces. Therefore, we get a $G_{K^{cyc}} \times \text{GL}_2(\mathbb{Q}_p)$-equivariant almost isomorphism by taking direct and inverse limits in (4.7)

$$\tilde{H}^1 \otimes_{\mathbb{Z}_p} \mathcal{O}_{\mathbb{C}_p} =^{ae} H^1_{\text{proet}}(\mathcal{X}_\infty, \mathcal{O}_{\mathcal{X}_\infty}^+/\mathcal{O}_{\mathbb{C}_p}) =^{ae} H^1_{an}(\mathcal{X}_\infty, \mathcal{O}_{\mathcal{X}_\infty}^+/\mathcal{O}_{\mathbb{C}_p}).$$

Let $\mathcal{U} = \{U_i \to \mathcal{X}_\infty\}$ be a finite covering of $\mathcal{X}_\infty$ by open formal affine subschemes arising from some finite level, let $\mathcal{U}^m = \{U_i \to \mathcal{X}_\infty\}$ be the covering of $\mathcal{X}_\infty$ induced by passage to the generic fiber. Then, by the (almost) vanishing of $H^i(V, \mathcal{O}_{\mathcal{V}}^{(+)}$) $(i \geq 1)$ for formal affine $p$-adic schemes and affinoid perfectoid spaces, we obtain (almost) isomorphisms with Čech cohomology:

$$H^1(\mathcal{X}_\infty, \mathcal{O}_{\mathcal{X}_\infty}) = \tilde{H}^1(\mathcal{U}, \mathcal{O}_{\mathcal{X}_\infty}),$$ 

$$H^1_{an}(\mathcal{X}_\infty, \mathcal{O}_{\mathcal{X}_\infty}^+) =^{ae} \tilde{H}^1(\mathcal{U}^m, \mathcal{O}_{\mathcal{X}_\infty}^+).$$

But the Čech complexes $C^\bullet(\mathcal{U}, \mathcal{O}_{\mathcal{X}_\infty})$ and $C^\bullet(\mathcal{U}^m, \mathcal{O}_{\mathcal{X}_\infty}^+)$ are equal. Therefore we have a $G_{K^{cyc}} \times \text{GL}_2(\mathbb{Q}_p)$-almost isomorphism

$$H^1_{an}(\mathcal{X}_\infty, \mathcal{O}_{\mathcal{X}_\infty}^+) =^{ae} H^1(\mathcal{X}_\infty, \mathcal{O}_{\mathcal{X}_\infty}).$$
Finally, we deduce from Lemma 4.1 and the Local Duality Theorem the following $G_{K^{\text{cyc}} \times GL_2(\mathbb{Q}_p)}$-equivariant (almost) isomorphisms

$$
\tilde{H}^{1V}(\mathcal{O}_p) = \text{Hom}_{O^{\text{cyc}}}(H^1_{\text{et}}(X_{\infty}, \mathcal{O}_{X_{\infty}}^+) \otimes \mathbb{Q}_p / \mathbb{Z}_p, K^{\text{cyc}} / O^{\text{cyc}}) \otimes_{O^{\text{cyc}}} \mathcal{O}_p = \lim_{\leftarrow n} (H^0(X_n, \mathcal{O}_{X_n}^+) \otimes \mathbb{Q}_p / \mathbb{Z}_p, K^{\text{cyc}} / O^{\text{cyc}}) \otimes_{O^{\text{cyc}}} \mathcal{O}_p.
$$

We obtain the desired $G_{K^{\text{cyc}} \times GL_2(\mathbb{Q}_p)}$-equivariant isometry by inverting $p$.
