# On decay of entropy solutions to multidimensional conservation laws in the case of perturbed periodic initial data 

Evgeny Yu. Panov

#### Abstract

Under a precise genuine nonlinearity assumption we establish the decay of entropy solutions of a multidimensional scalar conservation law with merely continuous flux and with initial data being a sum of periodic function and a function vanishing at infinity (in the sense of measure).

## 1 Introduction

In the half-space $\Pi=\mathbb{R}_{+} \times \mathbb{R}^{n}, \mathbb{R}_{+}=(0,+\infty)$, we consider a first order multidimensional conservation law

$$
\begin{equation*}
u_{t}+\operatorname{div}_{x} \varphi(u)=0, \tag{1.1}
\end{equation*}
$$

with the flux vector $\varphi(u)$ supposed to be only continuous: $\varphi(u)=\left(\varphi_{1}(u), \ldots, \varphi_{n}(u)\right) \in$ $C\left(\mathbb{R}, \mathbb{R}^{n}\right)$. Equation (1.1) is endowed with initial condition

$$
\begin{equation*}
u(0, x)=u_{0}(x) \in L^{\infty}\left(\mathbb{R}^{n}\right) \tag{1.2}
\end{equation*}
$$

We recall the notion of entropy solution of the Cauchy problem (1.1), (1.2) in the sense of S.N. Kruzhkov (5).

Definition 1.1. A bounded measurable function $u=u(t, x) \in L^{\infty}(\Pi)$ is called an entropy solution (e.s. for short) of (1.1), (1.2) if for all $k \in \mathbb{R}$

$$
\begin{equation*}
|u-k|_{t}+\operatorname{div}_{x}[\operatorname{sign}(u-k)(\varphi(u)-\varphi(k))] \leq 0 \tag{1.3}
\end{equation*}
$$

in the sense of distributions on $\Pi$ (in $\mathcal{D}^{\prime}(\Pi)$ ), and

$$
\begin{equation*}
\underset{t \rightarrow 0+}{\operatorname{ess} \lim } u(t, \cdot)=u_{0} \text { in } L_{l o c}^{1}\left(\mathbb{R}^{n}\right) \tag{1.4}
\end{equation*}
$$

Condition (1.3) means that for all test functions $f=f(t, x) \in C_{0}^{1}(\Pi), f \geq 0$

$$
\int_{\Pi}\left[|u-k| f_{t}+\operatorname{sign}(u-k)(\varphi(u)-\varphi(k)) \cdot \nabla_{x} f\right] d t d x \geq 0
$$

(where "." denotes the inner product in $\mathbb{R}^{n}$ ). It is known that e.s. of (1.1), (1.2) always exists but in the case of only continuous flux may be nonunique, see [6, 7]. Nevertheless, if initial function is periodic (at least in $n-1$ independent directions), the uniqueness holds: an e.s. of (1.1), (1.2) is unique and space-periodic, see [8, 9, 10]. In general case there always exists the unique maximal and minimal e.s., see [1, 9, 10].

We also notice that, in view of [11, Corollary 7.1], after possible correction on a set of null measure an e.s. $u(t, x)$ is continuous on $[0,+\infty)$ as a map $t \mapsto u(t, \cdot)$ into $L_{l o c}^{1}\left(\mathbb{R}^{n}\right)$. In order to simplify formulations, we will always suppose that e.s. satisfy this continuity property

$$
u(t, \cdot) \in C\left([0,+\infty), L_{l o c}^{1}\left(\mathbb{R}^{n}\right)\right)
$$

In view of (1.4), we claim that $u(0, x)=u_{0}(x)$ and in (1.4) we may replace the essential limit by the usual one. In the present paper we study the long time decay property of e.s. in the case when initial data is a perturbed periodic function. More precisely, we assume that the initial function $u_{0}(x)=p(x)+v(x)$, where $p(x), v(x) \in L^{\infty}\left(\mathbb{R}^{n}\right), p(x)$ is periodic while $v(x)$ vanishes at infinity in the sense of strong mean value

$$
\begin{equation*}
\lim _{|A| \rightarrow \infty} \frac{1}{|A|} \int_{A}|v(x)| d x=0 \tag{1.5}
\end{equation*}
$$

where $A$ runs over Lebesgue measurable sets $A \subset \mathbb{R}^{n}$ of positive Lebesgue measure $|A|=$ meas $A$. Observe that the functions $p, v$ are uniquely defined (up to equality on a set of full measure) by the function $u_{0}$. Let

$$
\begin{equation*}
G=\left\{e \in \mathbb{R}^{n} \mid p(x+e)=p(x) \text { almost everywhere in } \mathbb{R}^{n}\right\} \tag{1.6}
\end{equation*}
$$

be the group of periods of $p$, it is not necessarily a lattice because $p(x)$ may be constant in some directions. For example, if $p \equiv$ const then $G=\mathbb{R}^{n}$. The periodicity of $p$ means that the linear hull of $G$ coincides with $\mathbb{R}^{n}$, that is, there is a basis of periods of $p$. Denote by $H$ the maximal linear subspace containing in $G$. The dual lattice

$$
G^{\prime}=\left\{\xi \in \mathbb{R}^{n} \mid \xi \cdot e \in \mathbb{Z} \forall e \in G\right\}
$$

is indeed a lattice in the orthogonal complement $H^{\perp}$ of the space $H$ (we will prove this simple statement in Lemma 2.1 below). Observe also that $G^{\prime}=L_{0}^{\prime}$ in $H^{\perp}$, where
$L_{0}=G \cap H^{\perp}$, so that $G=H \oplus L_{0}$. It is rather well-known (at least for continuous periodic functions) that $L_{0}$ is a lattice in $H^{\perp}$. The case of measurable periodic functions requires some little modifications and, for the sake of completeness, we put the proof of this fact in Lemma 2.1. Notice that we use more general notion of period contained in (1.6). For the standard notion $p(x+e) \equiv p(x)$ (where the words "almost everywhere" are omitted) the group $G$ may have more complicate structure. For example, the group of periods of the Dirichlet function on $\mathbb{R}$ is a set of rationals $\mathbb{Q}$, which is not a lattice in $\mathbb{R}$. We introduce the torus $\mathbb{T}^{d}=\mathbb{R}^{n} / G=H^{\perp} / L_{0}$ of dimension $d=\operatorname{dim} H^{\perp}=n-\operatorname{dim} H$ equipped with the normalized Lebesgue measure $d y$. The periodic function $p$ can be considered as a function on this torus $\mathbb{T}^{d}: p=p(y)$. Let

$$
m=\int_{\mathbb{T}^{d}} p(y) d y
$$

be the mean value of this function. Clearly, this value coincides with the mean value of the initial data:

$$
m=\lim _{R \rightarrow \infty} \frac{1}{\left|B_{R}\right|} \int_{B_{R}} u_{0}(x) d x
$$

where $B_{R}$ is the ball $|x|<R$.
We will study the long time decay property of e.s. with respect to the following shift-invariant norm on $L^{\infty}\left(\mathbb{R}^{n}\right)$ :

$$
\begin{equation*}
\|u\|_{X}=\sup _{y \in \mathbb{R}^{n}} \int_{|x-y|<1}|u(x)| d x \tag{1.7}
\end{equation*}
$$

(where we denote by $|z|$ the Euclidean norm of a finite-dimensional vector $z$ ). As was demonstrated in [14], this norm is equivalent to each of more general norms

$$
\begin{equation*}
\|u\|_{V}=\sup _{y \in \mathbb{R}^{n}} \int_{y+V}|u(x)| d x \tag{1.8}
\end{equation*}
$$

where $V$ is any bounded open set in $\mathbb{R}^{n}$ (the original norm $\|\cdot\|_{X}$ corresponds to the unit ball $|x|<1$ ). For the sake of completeness we repeat the proof of this result in Lemma 2.3 below. Obviously, norm (1.7) generates the stronger topology than one of $L_{\text {loc }}^{1}\left(\mathbb{R}^{n}\right)$.

We denote by $F$ the closed set of points $u \in \mathbb{R}$ such that the flux components $\varphi(u) \cdot \xi$ are not affine on any vicinity of $u$ for all $\xi \in G^{\prime}, \xi \neq 0$. In the case when such $\xi$ do not exist (i.e., when $G=H=\mathbb{R}^{n}$ ), we define $F$ as the set of $u$ such that the entire vector $\varphi(u)$ is not affine (that is, at least one its component is not affine) on any vicinity of $u$. Our main result is the following decay property.

Theorem 1.1. Assume that the flux vector $\varphi(u)$ is genuinely nonlinear in the sense that for all $a<m, b>m$ the intervals $(a, m),(m, b)$ intersect with $F:(a, m) \cap F \neq \emptyset$, $(m, b) \cap F \neq \emptyset$. Suppose that $u(t, x)$ is an e.s. of (1.1), (1.2). Then

$$
\begin{equation*}
\lim _{t \rightarrow+\infty}\|u(t, \cdot)-m\|_{X}=0 \tag{1.9}
\end{equation*}
$$

The condition $H=\mathbb{R}^{n}$ means that the function $p(x)$ is constant, $p \equiv m$. In this case, the requirement of Theorem 1.1 reduces to the condition that the flux vector $\varphi(u)$ is not affine on any semivicinity $(a, m),(m, b)$ of the mean $m$. When $m=0$, Theorem 1.1 was proved in [14]. The case of arbitrary $m$ reduces to the case $m=0$ by the change $u \rightarrow u-m, \varphi(u) \rightarrow \varphi(u+m)$. Thus, we may suppose in the sequel that $p \not \equiv$ const and therefore the lattice $G^{\prime}$ is not trivial.

Remark that the genuine nonlinearity requirement in Theorem 1.1 implies that $m \in F$ because of closeness of this set. Generally, under this weaker condition $m \in F$ the decay property fails, cf. Example 2.1 below. But, in periodic case $v \equiv 0$, the decay property (1.9) holds under the weaker condition $m \in F$, that is,

$$
\begin{array}{r}
\forall \xi \in G^{\prime}, \xi \neq 0 \text { the flux components } \varphi(u) \cdot \xi \\
\text { are not affine on any vicinity of } m . \tag{1.10}
\end{array}
$$

In the standard case when $G$ is a lattice (that is, when $\operatorname{dim} H=0$ ) it was proved in [13, Theorem 1.3], see also earlier papers [4, 12, 3]. The general case of arbitrary $H$ easily reduces to the case $\operatorname{dim} H=0$. We provide the details in the following theorem.

Theorem 1.2. Suppose that the initial function $u_{0}=p(x)$ is periodic with a group of periods $G$, and condition (1.10) is satisfied. Then the e.s. $u=u(t, x)$ of problem (1.1), (1.2) exhibits the decay property

$$
\begin{equation*}
\underset{t \rightarrow+\infty}{\operatorname{ess}} \lim u(t, \cdot)=m=\int_{\mathbb{T}^{d}} u_{0}(x) d x \quad \text { in } L^{1}\left(\mathbb{T}^{d}\right) . \tag{1.11}
\end{equation*}
$$

Proof. Observe that for all $e \in G u_{0}(x+e)=u_{0}(x)$ a.e. in $\mathbb{R}^{n}$. Obviously, $u(t, x+e)$ is an e.s. of (1.1), (1.2) with the same initial data $u_{0}(x)$. By the uniqueness of an e.s., known in the case of periodic initial function, we claim that $u(t, x+e)=u(t, x)$ a.e. in $\Pi$, that is, $u(t, x)$ is $G$-periodic in the space variables. In particular, $u(t, \cdot) \in L^{1}\left(\mathbb{T}^{d}\right)$ for a.e. $t>0$ and relation (1.11) is well-defined. We choose a non-degenerate linear operator $Q$ in $\mathbb{R}^{n}$, which transfers the space $H$ into the standard subspace

$$
\mathbb{R}^{n-d}=\left\{x=\left(x_{1}, \ldots, x_{n}\right) \mid x_{i}=0 \forall i=1, \ldots, d\right\} .
$$

After the change $y=Q x$ our problem reduces to the problem

$$
\begin{equation*}
v_{t}+\operatorname{div}_{y} \tilde{\varphi}(v)=0, \quad v(0, y)=v_{0}(y) \doteq u_{0}\left(Q^{-1}(y)\right) \tag{1.12}
\end{equation*}
$$

where the flux $\tilde{\varphi}(v)=Q \varphi(v)$. As is easy to verify, $u(t, x)=v(t, Q x)$, where $v(t, y)$ is an e.s. of (1.12). Observe that $v_{0}(y)$ is periodic with the group of periods $\tilde{G}=Q(G)$. Therefore, the e.s. $v(t, y)$ is space periodic with the group of periods containing $\tilde{G}$. In particular, the functions $v_{0}(y), v(t, y)$ are constant in directions $\mathbb{R}^{n-d}=Q(H): v_{0}(y)=$ $v_{0}\left(y_{1}, \ldots, y_{d}\right), v(t, y)=v\left(t, y_{1}, \ldots, y_{d}\right)$ with $v_{0}\left(y^{\prime}\right) \in L^{\infty}\left(\mathbb{R}^{d}\right), v\left(t, y^{\prime}\right) \in L^{\infty}\left(\mathbb{R}_{+} \times \mathbb{R}^{d}\right)$. This readily implies that $v\left(t, y^{\prime}\right)$ is an e.s. of the low-dimensional problem

$$
\begin{equation*}
v_{t}+\operatorname{div}_{y^{\prime}} \tilde{\varphi}(v)=v_{t}+\sum_{i=1}^{d} \tilde{\varphi}_{i}(u)=0, \quad v\left(0, y^{\prime}\right)=v_{0}\left(y^{\prime}\right) \tag{1.13}
\end{equation*}
$$

Observe that $v_{0}\left(y^{\prime}\right)$ is periodic with the lattice of periods

$$
\tilde{L}=\tilde{G} \cap \mathbb{R}^{d}=\left\{y=\left(y_{1}, \ldots, y_{d}\right) \in \mathbb{R}^{d} \mid\left(y_{1}, \ldots, y_{d}, 0, \ldots, 0\right) \in \tilde{G}\right\}
$$

(by Lemma 2.1 it is indeed a lattice). Using again Lemma 2.1, we find that the dual lattice $\tilde{L}^{\prime}=\tilde{G}^{\prime}=\left(Q^{*}\right)^{-1} G^{\prime}$, where $Q^{*}$ is a conjugate operator. Observe that for each nonzero $\zeta \in \tilde{L}^{\prime}$ the vector $\xi=Q^{*} \zeta \in G^{\prime}$, and

$$
\zeta \cdot \operatorname{pr}_{\mathbb{R}^{d}} \tilde{\varphi}(v)=\zeta \cdot Q \varphi(v)=Q^{*} \zeta \cdot \varphi(v)=\xi \cdot \varphi(v)
$$

By condition (1.10) we claim that the functions $v \rightarrow \zeta \cdot \operatorname{pr}_{\mathbb{R}^{d}} \tilde{\varphi}(v)$ are not affine in any vicinity of $m$, for every $\zeta \in \tilde{L}^{\prime}$. By the decay property [13, Theorem 1.3] applied to the e.s. $v\left(t, y^{\prime}\right)$ of (1.13) we claim that

$$
\begin{equation*}
\underset{t \rightarrow+\infty}{\operatorname{ess} \lim } v(t, \cdot)=\tilde{m}=\int_{\tilde{\mathbb{T}}^{d}} v_{0}\left(y^{\prime}\right) d y^{\prime} \text { in } L^{1}\left(\tilde{\mathbb{T}}^{d}\right) \tag{1.14}
\end{equation*}
$$

where $\tilde{T}^{d}=\mathbb{R}^{d} / \tilde{L}=\mathbb{R}^{n} / \tilde{G}$ is a torus corresponding to the lattice $\tilde{L}$, and $d y^{\prime}$ denotes the normalized Lebesgue measure on this torus. Making the change of variables $y=Q x$, which induces an isomorphism $Q: \mathbb{T}^{d} \rightarrow \tilde{\mathbb{T}}^{d}$, we find that

$$
\tilde{m}=\int_{\mathbb{T}^{d}} u_{0}(x) d x=m
$$

and that (1.14) reduces to the relation (1.11). The proof is complete.

Notice that condition (1.10) is precise. In fact, if it fails, we may find a nonzero vector $\xi \in G^{\prime}$ and constants $\delta>0, k \in \mathbb{R}$ such that $\xi \cdot \varphi(u)-k u=$ const on the segment $|u-m| \leq \delta$. We define the hyperspace $E=\left\{x \in \mathbb{R}^{n} \mid \xi \cdot x=0\right\}$. The linear functional $\xi$ is a homomorphism of the group $G$ into $\mathbb{Z}$. The range of this homomorphism is a subgroup $r \mathbb{Z} \subset \mathbb{Z}$ for some $r \in \mathbb{N}$. Denote by $G_{1}=E \cap G$ the kernel of $\xi$. There exists an element $e_{0} \in G$ such that $\xi \cdot e_{0}=r$. Then, as is easy to verify, the map $(e, m) \rightarrow e+m e_{0}$ forms a group isomorphism of $G_{1} \oplus \mathbb{Z}$ onto $G$. We choose $n-1$ independent vectors $\zeta_{i}$ such that $\zeta_{i} \cdot e_{0}=0, i=1, \ldots, n-1$ and make the linear change $y=y(t, x)$

$$
\begin{equation*}
y_{i}=\zeta_{i} \cdot x, i=1, \ldots, n-1, \quad y_{n}=\xi \cdot x-k t \tag{1.15}
\end{equation*}
$$

which reduces (1.1) to the conservation law

$$
\begin{equation*}
u_{t}+\operatorname{div}_{y} \tilde{\varphi}(u)=0 \tag{1.16}
\end{equation*}
$$

with the last flux component $\tilde{\varphi}_{n}(u)=\xi \varphi(u)-k u$ being constant on the segment $|u-m| \leq$ $\delta$. If an initial data $\tilde{u}_{0}(y)$ satisfies the condition $\left|\tilde{u}_{0}-m\right| \leq \delta$ then a corresponding e.s. $u=\tilde{u}(t, x)$ of (1.16) also satisfies the condition $|\tilde{u}(t, x)-m| \leq \delta$ a.e. on $\Pi$, by the maximum-minimum principle [2, Corollary 2.1]. Since $\tilde{\varphi}_{n}(u)$ is constant on the segment $|u-m| \leq \delta, \tilde{u}(t, y)$ is an e.s. of the equation

$$
\begin{equation*}
u_{t}+\operatorname{div}_{y^{\prime}} \tilde{\varphi}(u)=u_{t}+\sum_{i=1}^{n-1}\left(\tilde{\varphi}_{i}(u)\right)_{y_{i}}=0 \tag{1.17}
\end{equation*}
$$

where $y^{\prime}=\left(y_{1}, \ldots, y_{n-1}\right) \in \mathbb{R}^{n-1}$. This readily implies that for a.e. fixed $y_{n} \in \mathbb{R}$ the function $\tilde{u}\left(t, y^{\prime}, y_{n}\right)$ is an e.s. of the Cauchy problem for the low-dimensional equation (1.17), considered in the domain $\mathbb{R}_{+} \times \mathbb{R}^{n-1}$, with the corresponding initial function $\tilde{u}_{0}\left(y^{\prime}, y_{n}\right)$. Assume that the function $\tilde{u}_{0}\left(y^{\prime}, y_{n}\right)$ is $y^{\prime}$-periodic (with some group of periods) with the mean value $m\left(y_{n}\right)=\frac{1}{|P|} \int_{P} u_{0}\left(y^{\prime}, y_{n}\right) d y^{\prime}, P \subset \mathbb{R}^{n-1}$ being the periodicity cell (or, the same, the corresponding torus). Then for a.e. $y_{n} \in \mathbb{R}$ the mean value of $\tilde{u}\left(t, \cdot, y_{n}\right)$ does not depend on $t$ and equals $m\left(y_{n}\right)$ (see, for instance, [8]). If this function $m\left(y_{n}\right)$ is not constant (a.e. in $\mathbb{R}$ ) then the e.s. $\tilde{u}(t, y)$ cannot satisfy the decay property. In fact, if $\tilde{u}(t, \cdot)-m \rightarrow 0$ as $t \rightarrow+\infty$ in $L_{l o c}^{1}\left(\mathbb{R}^{n}\right)$, then for each interval $I \subset \mathbb{R}$

$$
\left|\int_{I}\left(m\left(y_{n}\right)-m\right) d y_{n}\right|=\frac{1}{|P|}\left|\int_{P \times I}(\tilde{u}(t, y)-m) d y\right| \leq \frac{1}{|P|} \int_{P \times I}|\tilde{u}(t, y)-m| d y
$$

which implies, in the limit as $t \rightarrow+\infty$, that $\int_{I}\left(m\left(y_{n}\right)-m\right) d y_{n}=0$. Since $I$ is an arbitrary interval, we find that $m\left(y_{n}\right)=m$ a.e. in $\mathbb{R}$, which contradicts to our assumption.

Now we choose a function $v(x) \in C(E)$ such that $\|v\|_{\infty} \leq \delta / 2$ and that $v(x)$ is periodic with the group of periods $G_{1}$ and with zero mean value. Since $G_{1}=H \oplus\left(E \cap L_{0}\right)$, such $v(x)$ actually exists, this function is constant in the direction $H$ and is periodic in $E \cap H^{\perp}$ with exactly the lattice of periods $E \cap L_{0}$. We set

$$
u_{0}(x)=m+v(\operatorname{pr}(x))+\frac{\delta}{2} \sin (2 \pi \xi \cdot x / r),
$$

where $\operatorname{pr}(x) \in E$ is the projection of $x$ on $E$ along the vector $e_{0}$ (so that $\left.x-\operatorname{pr}(x) \| e_{0}\right)$. Then $\left\|u_{0}-m\right\|_{\infty} \leq \delta$. Let us show that $u_{0}(x)$ is periodic with the group of periods $G$. Since vectors $e \in G_{1}$ and $e_{0}$ are periods of $u_{0}$, then the group $G=G_{1}+\mathbb{Z} e_{0}$ consists of period of $u_{0}$. On the other hand, if $e \in \mathbb{R}^{n}$ is a period of $u_{0}$ then it can be decomposed into a sum $e=e_{1}+\lambda e_{0}$, where $e_{1} \in E, \lambda \in \mathbb{R}$. For $x=x^{\prime}+s e_{0}, x^{\prime} \in E$, we have

$$
u_{0}(x+e)=m+v\left(x^{\prime}+e_{1}\right)+\frac{\delta}{2} \sin (2 \pi(s+\lambda))=u_{0}(x)=m+v\left(x^{\prime}\right)+\frac{\delta}{2} \sin (2 \pi s) .
$$

Averaging this equality over $x^{\prime}$, we obtain that $\sin (2 \pi(s+\lambda))=\sin (2 \pi s)$ for all $s \in \mathbb{R}$, which implies that $\lambda \in \mathbb{Z}$ and that $v\left(x^{\prime}+e_{1}\right)=v\left(x^{\prime}\right)$ for all $x^{\prime} \in E$. Therefore, $e_{1} \in G_{1}$ (remind that $G_{1}$ is the group of periods of $v$ ). Hence $e=e_{1}+\lambda e_{0} \in G_{1}+\mathbb{Z} e_{0}=G$. We proved that the group of periods of $u_{0}$ is exactly $G$. It is clear that $m$ is the mean value of $u_{0}$.

Now, we are going to show that an e.s. $u(t, x)$ of (1.1), (1.2) with the chosen initial data does not satisfy decay property (1.11). After the change (1.15) the initial function $u_{0}(x)$ transforms into $\tilde{u}_{0}(y)=m+\tilde{v}\left(y^{\prime}\right)+\frac{\delta}{2} \sin \left(2 \pi y_{n} / r\right)$, the function $\tilde{v}\left(y^{\prime}\right) \in C\left(\mathbb{R}^{n-1}\right)$ is determined by the identity $v(x)=\tilde{v}(y(x))$, where $y(x)=y(0, x), x \in E$, is a linear isomorphism $E \rightarrow \mathbb{R}^{n-1}$. Obviously, the function $\tilde{v}\left(y^{\prime}\right)$ is periodic with the group of periods $y\left(G_{1}\right)$ and zero mean value. Therefore, the mean value of initial data over the variables $y^{\prime}$ equals $m\left(y_{n}\right)=m+\frac{\delta}{2} \sin \left(2 \pi y_{n} / r\right)$ and it is not constant. In this case it has been already demonstrated that an e.s. $\tilde{u}(t, y)$ of the Cauchy problem for equation (1.16) does not satisfy the decay property. Due to the identity $u(t, x)=\tilde{u}(t, y(t, x))$, we see that an e.s. of original problem does not satisfy (1.11) either.

## 2 Proof of the main results

### 2.1 Auxiliary lemmas

Lemma 2.1. Let $G$ be the group of periods of a periodic function $p(x) \in L^{\infty}\left(\mathbb{R}^{n}\right)$, and let, as in Introduction, $H$ be a maximal linear subspace of $G, L_{0}=G \cap H^{\perp}$, and let $G^{\prime}$
be a dual group to $G$. Then
(i) $L_{0}$ is a lattice of dimension $d=\operatorname{dim} H^{\perp}$;
(ii) $G^{\prime}$ is a lattice in $H^{\perp}$ of dimension $d$, and $G^{\prime}=L_{0}^{\prime}$ in $H^{\perp}$.

Proof. (i) We have to prove that the group $L_{0}$ is discrete, that is, all its points are isolated. Since $L_{0}$ is a group it is sufficient to show that 0 is an isolated point of $L_{0}$. Assuming the contrary, we find a sequence $h_{k} \in L_{0}$, such that $h_{k} \neq 0, h_{k} \rightarrow 0$ as $k \rightarrow \infty$. By compactness of the unit sphere $|x|=1$, we may suppose that the sequence $\left|h_{k}\right|^{-1} h_{k} \rightarrow \xi$ as $k \rightarrow \infty$, where $\xi \in H^{\perp},|\xi|=1$. Let $w(x) \in C_{0}^{1}\left(\mathbb{R}^{n}\right)$ and $v(x)$ be the convolution $v=p * w(x)=\int_{\mathbb{R}^{n}} p(x-y) w(y) d y$. By known property of convolution $v(x) \in C^{1}\left(\mathbb{R}^{n}\right)$. Further, for each $e \in G$ and $x \in \mathbb{R}^{n}$

$$
v(x+e)=\int_{\mathbb{R}^{n}} p(x-y+e) w(y) d y=\int_{\mathbb{R}^{n}} p(x-y) w(y) d y=v(x)
$$

and in particular $v\left(x+h_{k}\right)=v(x) \forall k \in \mathbb{N}$. Since $v$ is differentiable,

$$
\begin{equation*}
0=\left|h_{k}\right|^{-1}\left(v\left(x+h_{k}\right)-v(x)\right)=\nabla v(x) \cdot\left|h_{k}\right|^{-1} h_{k}+\varepsilon_{k} \tag{2.1}
\end{equation*}
$$

where $\varepsilon_{k} \rightarrow 0$ as $k \rightarrow \infty$. Passing in (2.1) to the limit as $k \rightarrow \infty$, we obtain that $\frac{\partial v(x)}{\partial \xi}=$ $\nabla v(x) \cdot \xi=0$ for all $x \in \mathbb{R}^{n}$. Therefore, $v$ is constant in the direction $\xi: v(x+s \xi)=v(x)$ for all $s \in \mathbb{R}, x \in \mathbb{R}^{n}$. We choose a nonnegative function $w(x) \in C_{0}^{1}\left(\mathbb{R}^{n}\right)$ such that $\int_{\mathbb{R}^{n}} w(x) d x=1$ and set $\omega_{r}(x)=r^{n} \omega(r x), r \in \mathbb{N}$. This sequence (an approximate unity) converges to Dirac $\delta$-function as $r \rightarrow \infty$ weakly in the space of distributions $\mathcal{D}^{\prime}\left(\mathbb{R}^{n}\right)$. The corresponding sequence of averaged functions $v_{r}=p * w_{r}(x)$ converges to $p$ as $r \rightarrow \infty$ in $L_{l o c}^{1}\left(\mathbb{R}^{n}\right)$. As was already established, the functions $v_{r}$ are constant in the direction $\xi$. Therefore, for each $\alpha \in \mathbb{R}, R>0$

$$
\int_{|x|<R}\left|v_{r}(x+\alpha \xi)-v_{r}(x)\right| d x=0
$$

Passing in this relation to the limit as $r \rightarrow \infty$, we obtain that

$$
\int_{|x|<R}|p(x+\alpha \xi)-p(x)| d x=0 \quad \forall R>0
$$

which implies that $p(x+\alpha \xi)=p(x)$ a.e. in $\mathbb{R}^{n}$, that is, $\alpha \xi \in G$. Thus, the linear subspace $H_{1}=\{x+\alpha \xi \mid x \in H, \alpha \in \mathbb{R}\} \subset G$. Since $\xi \in H^{\perp}, \xi \neq 0$, then $H \subsetneq H_{1}$. But this contradicts to the maximality of $H$. This contradiction proves that $L_{0}$ is a discrete additive subgroup of $\mathbb{R}^{n}$, i.e., a lattice. By the construction, $G=H \oplus L_{0}$. Since $G$ generates the entire space $\mathbb{R}^{n}$, then $L_{0}$ must generate $H^{\perp}$, that is, $\operatorname{dim} L_{0}=d$.
(ii) Since $\operatorname{dim} G=n$, we can choose a basis $e_{k}, k=1, \ldots, n$, of the linear space $\mathbb{R}^{n}$ laying in $G$. We define $R=\max _{k=1, \ldots, n}\left|e_{k}\right|, \delta=1 / R$. Let $\xi \in G^{\prime},|\xi|<\delta$. Then $\left|\xi \cdot e_{k}\right| \leq|\xi|\left|e_{k}\right| \leq|\xi| R<1$. Since $\xi \cdot e_{k} \in \mathbb{Z}$ we claim that $\xi \cdot e_{k}=0$ for all $k=1, \ldots, n$. Since $e_{k}, k=1, \ldots, n$, is a basis, this implies that $\xi=0$. We obtain that the ball $|\xi|<\delta$ contains only zero element of the group $G^{\prime}$. This means that this group is discrete and therefore it is a lattice. If $\xi \in G^{\prime}, e \in H$ then $\alpha \xi \cdot e=\xi \cdot \alpha e \in \mathbb{Z}$ for all $\alpha \in \mathbb{R}$. This is possible only if $\xi \cdot e=0$. This holds for every $e \in H$, that is, $\xi \in H^{\perp}$. Obviously, for such $\xi$, the requirement $\xi \in G^{\prime}$ reduces to the condition $\xi \cdot e \in \mathbb{Z}$ for all $e \in L_{0}$. We conclude that $G^{\prime}=L_{0}^{\prime}$. Since $L_{0}$ is a lattice, this in particular implies that $\operatorname{dim} G^{\prime}=\operatorname{dim} L_{0}=d$.

It is useful to rewrite condition (1.5) in the following equivalent form
Lemma 2.2. Condition (1.5) is equivalent to the following one:

$$
\begin{equation*}
\forall \lambda>0 \quad \operatorname{meas}\left\{x \in \mathbb{R}^{n}:|v(x)|>\lambda\right\}<+\infty . \tag{2.2}
\end{equation*}
$$

Proof. Assuming (2.2), we denote $A_{\lambda}=\left\{x \in \mathbb{R}^{n}:|v(x)|>\lambda\right\}, \lambda>0$, so that $\left|A_{\lambda}\right|<+\infty$. Then for every measurable set $A$ of finite measure

$$
\int_{A}|v(x)| d x=\int_{A \backslash A_{\lambda}}|v(x)| d x+\int_{A \cap A_{\lambda}}|v(x)| d x \leq \lambda|A|+\|v\|_{\infty}\left|A_{\lambda}\right| .
$$

Therefore,

$$
\limsup _{|A| \rightarrow \infty} \frac{1}{|A|} \int_{A}|v(x)| d x \leq \lim _{|A| \rightarrow \infty}\left(\lambda+\|v\|_{\infty}\left|A_{\lambda}\right| /|A|\right)=\lambda .
$$

Since $\lambda>0$ is arbitrary, we deduce (1.5). Conversely, suppose that (1.5) holds. Assuming that (2.2) is violating, we can find $\lambda>0$ such that the set $A_{\lambda}$ has infinite measure. Then we can choose the sequence of measurable subsets $A_{m} \subset A_{\lambda}$ such that $\left|A_{m}\right|=m, m \in \mathbb{N}$. Obviously,

$$
\frac{1}{\left|A_{m}\right|} \int_{A_{m}}|v(x)| d x \geq \lambda
$$

while $\left|A_{m}\right|=m \rightarrow \infty$ as $m \rightarrow \infty$. Since this contradicts (1.5), we conclude that (2.2) is satisfied.

We will denote by $L_{0}^{\infty}\left(\mathbb{R}^{n}\right)$ the subspace of functions from $L^{\infty}\left(\mathbb{R}^{n}\right)$ satisfying (2.2). Obviously, $L_{0}^{\infty}\left(\mathbb{R}^{n}\right)$ contains functions vanishing at infinity as well as functions from the spaces $L^{p}\left(\mathbb{R}^{n}\right), p>0$.

Lemma 2.3. The norms $\|\cdot\|_{V}$ defined in (1.8) are mutually equivalent.
Proof. Let $V_{1}, V_{2}$ be open bounded sets in $\mathbb{R}^{n}$, and $K_{1}=\mathrm{Cl} V_{1}$ be the closure of $V_{1}$. Then $K_{1}$ is a compact set while $y+V_{2}, y \in K_{1}$, is its open covering. By the compactness there is a finite set $y_{i}, i=1, \ldots, m$, such that $K_{1} \subset \bigcup_{i=1}^{m}\left(y_{i}+V_{2}\right)$. This implies that for every $y \in \mathbb{R}^{n}$ and $u=u(x) \in L^{\infty}\left(\mathbb{R}^{n}\right)$

$$
\int_{y+V_{1}}|u(x)| d x \leq \sum_{i=1}^{m} \int_{y+y_{i}+V_{2}}|u(x)| d x \leq m\|u\|_{V_{2}} .
$$

Hence, $\forall u=u(x) \in L^{\infty}\left(\mathbb{R}^{n}\right)$

$$
\|u\|_{V_{1}}=\sup _{y \in \mathbb{R}^{n}} \int_{y+V_{1}}|u(x)| d x \leq m\|u\|_{V_{2}} .
$$

Changing the places of $V_{1}, V_{2}$, we obtain the inverse inequality $\|u\|_{V_{2}} \leq l\|u\|_{V_{1}}$ for all $u \in L^{\infty}\left(\mathbb{R}^{n}\right)$, where $l$ is some positive constant. This completes the proof.

Proposition 2.1. Let $G$ be a lattice and values $\alpha^{+}, \alpha^{-} \in F$ be such that $\alpha^{-}<m<\alpha^{+}$. Then an e.s. $u(t, x)$ of (1.1), (1.2) satisfies the property

$$
\limsup _{t \rightarrow 0}\|u(t, \cdot)-m\|_{X} \leq 2^{n}\left(\alpha^{+}-\alpha^{-}\right)
$$

Proof. Let $e_{k}, k=1, \ldots, n$, be a basis of the lattice $G$. We define for $r \in \mathbb{N}$ the parallelepiped

$$
P_{r}=\left\{x=\sum_{k=1}^{n} x_{k} e_{k}:-r / 2 \leq x_{k}<r / 2, k=1, \ldots, n\right\} .
$$

It is clear that $P_{r}$ is a fundamental parallelepiped for a lattice $r G \subset G$. We introduce the functions

$$
v_{r}^{+}(x)=\sup _{e \in G} v(x+r e), \quad v_{r}^{-}(x)=\inf _{e \in G} v(x+r e), \quad V_{r}(x)=\sup _{e \in G}|v(x+r e)| .
$$

Since $G$ is countable, these functions are well-defined in $L^{\infty}\left(\mathbb{R}^{n}\right)$, and $\left|v_{r}^{ \pm}\right| \leq V_{r}(x) \leq$ $C_{0} \doteq\|v\|_{\infty}$ for a.e. $x \in \mathbb{R}^{n}$. It is clear that $v_{r}^{ \pm}(x)$ are $r G$-periodic and

$$
\begin{equation*}
v_{r}^{-}(x) \leq v(x) \leq v_{r}^{+}(x) \tag{2.3}
\end{equation*}
$$

Let us show that under condition (2.2)

$$
\begin{equation*}
M_{r}=\frac{1}{\left|P_{r}\right|} \int_{P_{r}} V_{r}(x) d x \rightarrow 0 \quad \text { as } r \rightarrow+\infty \tag{2.4}
\end{equation*}
$$

For that we fix $\varepsilon>0$ and define the set $A=\left\{x \in \mathbb{R}^{n}:|v(x)|>\varepsilon\right\}$. In view of (2.2) the measure of this set is finite, meas $A=q<+\infty$. We also define the sets

$$
A_{r}^{e}=\left\{x \in P_{r}: x+r e \in A\right\} \subset P_{r}, \quad r>0, e \in G, \quad A_{r}=\bigcup_{e \in G} A_{r}^{e}
$$

By the translation invariance of Lebesgue measure and the fact that $\mathbb{R}^{n}$ is the disjoint union of the sets $r e+P_{r}, e \in G$, we have

$$
\sum_{e \in G} \operatorname{meas} A_{r}^{e}=\sum_{e \in G} \operatorname{meas}\left(r e+A_{r}^{e}\right)=\sum_{e \in G} \operatorname{meas}\left(A \cap\left(r e+P_{r}\right)\right)=\operatorname{meas} A=q
$$

This implies that

$$
\begin{equation*}
\text { meas } A_{r} \leq \sum_{e \in G} \text { meas } A_{r}^{e}=q \tag{2.5}
\end{equation*}
$$

If $x \notin A_{r}$ then $|v(x+r e)| \leq \varepsilon$ for all $e \in G$, which implies that $V_{r}(x) \leq \varepsilon$. Taking (2.5) into account, we find

$$
\int_{P_{r}} V_{r}(x) d x=\int_{A_{r}} V_{r}(x) d x+\int_{P_{r} \backslash A_{r}} V_{r}(x) d x \leq C_{0} \text { meas } A_{r}+\varepsilon \text { meas } P_{r} \leq C_{0} q+\varepsilon\left|P_{r}\right|
$$

It follows from this estimate that

$$
\limsup _{r \rightarrow+\infty} M_{r} \leq \lim _{r \rightarrow+\infty}\left(\frac{C_{0} q}{\left|P_{r}\right|}+\varepsilon\right)=\varepsilon
$$

and since $\varepsilon>0$ is arbitrary, we conclude that (2.4) holds. Let

$$
\varepsilon_{r}^{ \pm}=\frac{1}{\left|P_{r}\right|} \int_{P_{r}} v_{r}^{ \pm}(x) d x
$$

be mean values of $r G$-periodic functions $v_{r}^{ \pm}(x)$. In view of (2.4)

$$
\begin{equation*}
\left|\varepsilon_{r}^{ \pm}\right| \leq M_{r} \underset{r \rightarrow \infty}{\rightarrow} 0 \tag{2.6}
\end{equation*}
$$

By (2.6) we claim that $\left|\varepsilon_{r}^{ \pm}\right|<\min \left(\alpha^{+}-m, m-\alpha^{-}\right)$for sufficiently large $r \in \mathbb{N}$. We introduce for such $r$ the $r G$-periodic functions

$$
u_{0}^{+}(x)=p(x)+v_{r}^{+}(x)+\alpha^{+}-m-\varepsilon_{r}^{+}, \quad u_{0}^{-}(x)=p(x)+v_{r}^{-}(x)-\left(m-\alpha^{-}+\varepsilon_{r}^{-}\right)
$$

with the mean values $\alpha^{+}, \alpha^{-}$, respectively. In view of (2.3) and the conditions $\alpha^{+}-m-$ $\varepsilon_{r}^{+}>0, m-\alpha^{-}+\varepsilon_{r}^{-}>0$, we have

$$
\begin{equation*}
u_{0}^{-}(x) \leq u_{0}(x) \leq u_{0}^{+}(x) \tag{2.7}
\end{equation*}
$$

Let $u^{ \pm}$be unique (by [8, Corollary 3]) e.s. of (1.1), (1.2) with initial functions $u_{0}^{ \pm}$, respectively. Taking into account that $(r G)^{\prime}=\frac{1}{r} G^{\prime}$, we see that condition (1.10), corresponding to the lattice $r G$ and the mean values $\alpha^{-}, \alpha^{+}$, is satisfied. By Theorem 1.2 (or [13, Theorem 1.3]) we find that

$$
\begin{equation*}
\lim _{t \rightarrow+\infty} \int_{P_{r}}\left|u^{ \pm}(t, x)-\alpha^{ \pm}\right| d x=0 \tag{2.8}
\end{equation*}
$$

By the periodicity, for each $y \in \mathbb{R}^{n}$

$$
\int_{y+P_{r}}\left|u^{ \pm}(t, x)-\alpha^{ \pm}\right| d x=\int_{P_{r}}\left|u^{ \pm}(t, x)-\alpha^{ \pm}\right| d x
$$

which readily implies that for $V=\operatorname{Int} P_{r}$

$$
\left\|u^{ \pm}(t, x)-\alpha^{ \pm}\right\|_{V}=\int_{P_{r}}\left|u^{ \pm}(t, x)-\alpha^{ \pm}\right| d x .
$$

In view of Lemma 2.3 we have the estimate

$$
\left\|u^{ \pm}(t, x)-\alpha^{ \pm}\right\|_{X} \leq C \int_{P_{r}}\left|u^{ \pm}(t, x)-\alpha^{ \pm}\right| d x, C=C_{r}=\text { const. }
$$

By (2.8) we claim that

$$
\begin{equation*}
\lim _{t \rightarrow+\infty}\left\|u^{ \pm}(t, \cdot)-\alpha^{ \pm}\right\|_{X}=0 \tag{2.9}
\end{equation*}
$$

Let $u=u(t, x)$ be an e.s. of the original problem (1.1), (1.2) with initial data $u_{0}(x)$. Since the functions $u_{0}^{ \pm}$are periodic, then it follows from (2.7) and the comparison principle [8, Corollary 3] that $u^{-} \leq u \leq u^{+}$a.e. in $\Pi$. This readily implies the relation

$$
\begin{array}{r}
\|u(t, \cdot)-m\|_{X} \leq\left\|u^{-}(t, \cdot)-m\right\|_{X}+\left\|u^{+}(t, \cdot)-m\right\|_{X} \leq \\
\left\|u^{-}(t, x)-\alpha^{-}\right\|_{X}+\left\|u^{+}(t, x)-\alpha^{+}\right\|_{X}+c\left(\alpha^{+}-m+m-\alpha^{-}\right) \tag{2.10}
\end{array}
$$

where $c<2^{n}$ is Lebesgue measure of the unit ball $|x|<1$ in $\mathbb{R}^{n}$. In view of (2.9) it follows from (2.10) in the limit as $t \rightarrow+\infty$ that

$$
\limsup _{t \rightarrow+\infty}\|u(t, \cdot)-m\|_{X} \leq c\left(\alpha^{+}-\alpha^{-}\right) \leq 2^{n}\left(\alpha^{+}-\alpha^{-}\right)
$$

as was to be proved.

### 2.2 Proof of Theorem 1.1

We are going to establish that the statement of Proposition 2.1 remains valid in the case of arbitrary $G$. We will suppose that $\operatorname{dim} H<n$, otherwise $p \equiv$ const and this case has been already considered in Introduction.

Proposition 2.2. Assume that $m \in\left(\alpha^{-}, \alpha^{+}\right)$, where $\alpha^{ \pm} \in F$, and $u=u(t, x)$ is an e.s. of (1.1), (1.2). Then,

$$
\begin{equation*}
\limsup _{t \rightarrow+\infty}\|u(t, \cdot)-m\|_{X} \leq 2^{n+3}\left(\alpha^{+}-\alpha^{-}\right) \tag{2.11}
\end{equation*}
$$

Proof. Suppose firstly that $v(x) \in L^{\infty}\left(\mathbb{R}^{n}\right)$ is a finite function, that is, its closed support $\operatorname{supp} v$ is compact. Let $A=H+\operatorname{supp} v=H \oplus K$, where $K$ is the orthogonal projection of supp $v$ on the space $H^{\perp}$. We define the functions $v^{ \pm}(x)= \pm\|v\|_{\infty} \chi_{A}(x)$, where $\chi_{A}(x)$ is the indicator function of the set $A$. We define functions $u_{0}^{ \pm}(x)=p(x)+v^{ \pm}(x)$ and let $u^{-}(t, x)$ be the smallest e.s. of (1.1), (1.2) with initial data $u_{0}^{-}(x), u^{+}(t, x)$ be the largest e.s. of (1.1), (1.2) with initial data $u_{0}^{+}(x)$, existence of such e.s. was established in (9, Theorems 1, $\left.1^{\prime}\right]$. Since $u_{0}^{-}(x) \leq u_{0}(x) \leq u_{0}^{+}(x)$ a.e. on $\mathbb{R}^{n}$, we derive that $u^{-} \leq u \leq u^{+}$by the property of monotone dependence of the smallest and the largest e.s. on initial data, cf. [9, Corollary 4]. Observe that the initial functions $u_{0}^{ \pm}(x)$ are constant in direction $H$. Therefore, for any $e \in H$, the functions $u^{ \pm}(t, x+e)$ are the largest and the smallest e.s. of the same problems as $u^{ \pm}(t, x)$. By the uniqueness we claim that $u^{ \pm}(t, x+e)=u^{ \pm}(t, x)$ a.e. in $\Pi$. Hence, $u^{ \pm}(t, x)=u^{ \pm}\left(t, x^{\prime}\right), x^{\prime}=\operatorname{pr}_{H^{\perp}} x$. As is easy to see, $u^{ \pm}\left(t, x^{\prime}\right)$ are the largest and the smallest e.s. of $d$-dimensional problem

$$
u_{t}+\operatorname{div}_{x^{\prime}} \tilde{\varphi}(u)=0, \quad u\left(0, x^{\prime}\right)=u_{0}^{ \pm}\left(x^{\prime}\right)
$$

on the subspace $H^{\perp}$, where $\tilde{\varphi}(u)=\operatorname{pr}_{H^{\perp}} \varphi(u)$. In the same way as in the proof of Theorem 1.2 this problem can be written in the standard way (like (1.12) ) by an appropriate change of the space variables. Since the initial functions $u_{0}^{ \pm}\left(x^{\prime}\right)=p\left(x^{\prime}\right)+v^{ \pm}\left(x^{\prime}\right)$, where $p\left(x^{\prime}\right)$ is periodic with the lattice of periods $L_{0}$, while $v^{ \pm}\left(x^{\prime}\right)$ are bounded functions with compact support $K$ (so that $v^{ \pm}\left(x^{\prime}\right) \in L_{0}^{\infty}\left(H^{\perp}\right)$ ), we may apply Proposition 2.1. By this proposition,

$$
\begin{array}{r}
\limsup \\
t \rightarrow 0 \tag{2.12}
\end{array}\left\|u^{ \pm}(t, x)-m\right\|_{X} \leq \limsup _{t \rightarrow 0} 2^{n-d}\left\|u^{ \pm}\left(t, x^{\prime}\right)-m\right\|_{X} \leq, ~ 子 2^{n-d} 2^{d}\left(\alpha^{+}-\alpha^{-}\right)=2^{n}\left(\alpha^{+}-\alpha^{-}\right), ~ \$
$$

where the first $X$-norm is taken in $L^{\infty}\left(\mathbb{R}^{n}\right)$ while the second $X$-norm is on $L^{\infty}\left(H^{\perp}\right)$. Since the e.s. $u(t, x)$ is situated between $u^{-}$and $u^{+}$, then

$$
\|u(t, \cdot)-m\|_{X} \leq\left\|u^{+}(t, \cdot)-m\right\|_{X}+\left\|u^{-}(t, \cdot)-m\right\|_{X}
$$

and in view of (2.12)

$$
\begin{equation*}
\limsup _{t \rightarrow 0}\|u(t, \cdot)-m\|_{X} \leq 2^{n+1}\left(\alpha^{+}-\alpha^{-}\right) \tag{2.13}
\end{equation*}
$$

Now we suppose that $v \in L^{1}\left(\mathbb{R}^{n}\right) \cap L^{\infty}\left(\mathbb{R}^{n}\right)$. For fixed $\varepsilon>0$ we can find a function $\tilde{v} \in L^{\infty}\left(\mathbb{R}^{n}\right)$ with compact support such that $\|v-\tilde{v}\|_{1} \leq \varepsilon$. We denote by $u^{+}=u^{+}(t, x)$, $u^{-}=u^{-}(t, x)$ the largest and the smallest e.s. of (1.1), (1.2) with initial function $u_{0}=p(x)+v(x)$. Similarly, by $\tilde{u}^{+}=\tilde{u}^{+}(t, x), \tilde{u}^{-}=\tilde{u}^{-}(t, x)$ we denote the largest and the smallest e.s. of (1.1), (1.2) with initial function $\tilde{u}_{0}=p(x)+\tilde{v}(x)$. It is known, cf. [9, Theorems 1, 1'], that the largest and the smallest e.s. exhibit the $L^{1}$-contraction property. In particular, for all $t>0$

$$
\begin{equation*}
\int_{\mathbb{R}^{n}}\left|u^{ \pm}(t, x)-\tilde{u}^{ \pm}(t, x)\right| d x \leq \int_{\mathbb{R}^{n}}\left|u_{0}(x)-\tilde{u}_{0}(x)\right| d x=\|v-\tilde{v}\|_{1}<\varepsilon \tag{2.14}
\end{equation*}
$$

Since the function $\tilde{v}$ has finite support, relation (2.13) holds for the e.s. $\tilde{u}^{ \pm}(t, x)$, i.e.,

$$
\begin{equation*}
\limsup _{t \rightarrow 0}\left\|\tilde{u}^{ \pm}(t, \cdot)-m\right\|_{X} \leq 2^{n+1}\left(\alpha^{+}-\alpha^{-}\right) \tag{2.15}
\end{equation*}
$$

In view of (2.14)

$$
\left\|u^{ \pm}(t, \cdot)-\tilde{u}^{ \pm}(t, \cdot)\right\|_{X} \leq\left\|u^{ \pm}(t, \cdot)-\tilde{u}^{ \pm}(t, \cdot)\right\|_{1}<\varepsilon
$$

and (2.15) implies the estimates

$$
\limsup _{t \rightarrow 0}\left\|u^{ \pm}(t, \cdot)-m\right\|_{X} \leq 2^{n+1}\left(\alpha^{+}-\alpha^{-}\right)+\varepsilon
$$

and since $\varepsilon>0$ is arbitrary, we find that

$$
\begin{equation*}
\limsup _{t \rightarrow 0}\left\|u^{ \pm}(t, \cdot)-m\right\|_{X} \leq 2^{n+1}\left(\alpha^{+}-\alpha^{-}\right) \tag{2.16}
\end{equation*}
$$

Since $u^{-} \leq u \leq u^{+}$, then $\|u(t, \cdot)-m\|_{X} \leq\left\|u^{+}(t, \cdot)-m\right\|_{X}+\left\|u^{-}(t, \cdot)-m\right\|_{X}$ and it follows from (2.16) that

$$
\begin{equation*}
\limsup _{t \rightarrow 0}\|u(t, \cdot)-m\|_{X} \leq 2^{n+2}\left(\alpha^{+}-\alpha^{-}\right) \tag{2.17}
\end{equation*}
$$

In the general case $v \in L_{0}^{\infty}\left(\mathbb{R}^{n}\right)$ we choose such $\delta>0$ that $\alpha^{-}<m-\delta<m+\delta<\alpha^{+}$ and set $v_{+}(x)=\max (v(x)-\delta, 0), v_{-}(x)=\min (v(x)+\delta, 0)$. Observe that these functions vanish outside of the set $|v(x)|>\delta$ of finite measure. Therefore, $v_{ \pm} \in L^{1}\left(\mathbb{R}^{n}\right)$. Obviously,

$$
\begin{equation*}
u_{0}(x) \leq u_{0+}(x)=p(x)+\delta+v_{+}(x), \quad u_{0}(x) \geq u_{0-}(x)=p(x)-\delta+v_{-}(x) \tag{2.18}
\end{equation*}
$$

Notice that $p(x) \pm \delta$ are periodic functions with the same group of periods $G$ as $p(x)$ and with the mean values $m \pm \delta \in\left(\alpha_{-}, \alpha_{+}\right)$. Let $u_{+}(t, x)$ be the largest e.s. of problem (1.1), (1.2) with initial function $u_{0+}(x)$, and $u_{-}(t, x)$ be the smallest e.s. of this problem with initial data $u_{0-}(x)$. In view of (2.18), we have $u_{-}(t, x) \leq u(t, x) \leq u_{+}(t, x)$. As we have already established, the e.s. $u_{ \pm}(t, x)$ satisfy relation (2.17):

$$
\limsup _{t \rightarrow 0}\left\|u_{ \pm}(t, \cdot)-(m \pm \delta)\right\|_{X} \leq 2^{n+2}\left(\alpha^{+}-\alpha^{-}\right)
$$

This implies that

$$
\begin{equation*}
\limsup _{t \rightarrow 0}\left\|u_{ \pm}(t, \cdot)-m\right\|_{X} \leq 2^{n+2}\left(\alpha^{+}-\alpha^{-}\right)+2^{n} \delta \tag{2.19}
\end{equation*}
$$

where we use the fact that measure of a unit ball in $\mathbb{R}^{n}$ is not larger than $2^{n}$. Since the e.s. $u$ is situated between $u_{-}$and $u_{+}$, we derive from (2.19) that

$$
\limsup _{t \rightarrow 0}\left\|u_{ \pm}(t, \cdot)-m\right\|_{X} \leq 2^{n+3}\left(\alpha^{+}-\alpha^{-}\right)+2^{n+1} \delta
$$

and to complete the proof it only remains to notice that a sufficiently small $\delta>0$ is arbitrary.

Under the assumption of Theorem 1.1 the value $\alpha^{+}-\alpha^{-}$in (2.11) may be arbitrarily small. Therefore, (1.9) follows from (2.11). This completes the proof of our main Theorem 1.1. Remark that in the case when the perturbation $v \geq 0(v \leq 0)$ we can weaken the genuine nonlinearity assumption in Theorem 1.1 by the requirement $\forall b>m$ $(m, b) \cap F \neq \emptyset$ (respectively, $\forall a<m(a, m) \cap F \neq \emptyset)$. However, it is not possible, to weaken this assumption by the condition $m \in F$, as in the periodic case $v \equiv 0$. Let us confirm this by the following example.

Example 2.1. In the case of a single space variable we consider the equation

$$
\begin{equation*}
u_{t}+(\max (0,-u))_{x}=0 \tag{2.20}
\end{equation*}
$$

Let $p(x)$ be 2-periodic function such that $p(x)=\left\{\begin{array}{lll}1 & , & 0 \leq x<1, \\ -1, & 1 \leq x<2\end{array}\right.$. The mean value of this function $m=\int_{0}^{2} p(x) d x=0$ while $0 \in F$ (the flux function $\varphi(u)=\max (0,-u)$ is not affine in any vicinity of 0 ). Moreover, $F=\{0\}$ and the genuine nonlinearity assumption of Theorem 1.1 is violated. The e.s. $\tilde{u}(t, x)$ of Cauchy problem for equation
(2.20) with initial data $p(x)$ can be constructed explicitly. It is 2-periodic with respect to $x$, while for $x \in[0,2)$

$$
\tilde{u}(t, x)=\left\{\begin{array}{lrr}
1 & 0 \leq x<1-t / 2 \\
-1 & , & 1-t / 2 \leq x<2-t \\
0 & , & 2-t \leq x<2
\end{array}\right.
$$

see Fig. 1
In particular, $\tilde{u}(t, x) \equiv 0$ for all $t>2$, which is consistent with the statement of Theorem 1.2. Now we consider the small perturbation $v(x)=\varepsilon \chi_{[0,1)}(x)$, where $\varepsilon>0$ and $\chi_{[0,1)}(x)$ is the indicator function of the interval $[0,1)$. Let $u(t, x)$ be the e.s. of (2.20) with initial condition $u(0, x)=p(x)+v(x)$. As is easy to verify, this e.s. $u(t, x)=\tilde{u}(t, x)$ if $x \notin[0,2)$ while for $x \in[0,2)$

$$
u(t, x)=\left\{\begin{array}{lrr}
1+\varepsilon & , & 0 \leq x<\max (1-t /(2+\varepsilon), \varepsilon /(1+\varepsilon)) \\
-1 & , & 1-t /(2+\varepsilon) \leq x<2-t \\
0 & \max (2-t, \varepsilon /(1+\varepsilon)) \leq x<2
\end{array}\right.
$$

see Fig. 2,

Figure 1: The solution $u(t, x)$ with the periodic initial data.

Figure 2: The solution $u(t, x)$ with the perturbed initial data.
In particular, $u(t, x) \equiv(1+\varepsilon) \chi_{[0, \varepsilon /(1+\varepsilon))}(x)$ for $t \geq 2$ and the decay property (1.9) fails.
