UNSTABLE STOKES WAVES

VERA MIKYOUNG HUR AND ZHAO YANG

Abstract. We prove that a $2\pi/\kappa$ periodic Stokes wave of sufficiently small amplitude, traveling in water of unit depth, under gravity, is spectrally unstable away from the origin of the complex plane, provided that $0.86430 \ldots < \kappa < 1.00804 \ldots$. Numerical investigations predict instability whenever the unperturbed wave is resonant with its infinitesimal perturbations. This has not been studied analytically except the Benjamin–Feir instability, in the vicinity of the origin, provided that $\kappa > 1.3627 \ldots$. We develop a periodic Evans function approach for cylindrical domains, to give an alternative proof of the Benjamin–Feir instability and, also, the first proof of spectral instability away from the origin, whereby we elucidate the numerical findings. The proofs involve center manifold reduction, Floquet theory, and methods of ordinary and partial differential equations.

1. Introduction

Stokes in his 1847 paper [36] (see also [37]) made significant contributions to periodic waves at the free surface of an incompressible inviscid fluid in two dimensions, under the influence of gravity, traveling in permanent form at a constant velocity. For instance, he successfully approximated the solution when the amplitude is small. The existence of Stokes waves was proved in the 1920s for small amplitude [25, 31, 38], and in the early 1960s for large amplitude [22, 23]. Thus it came as a surprise in the mid 1960s when Benjamin [3] and Whitham [40] (see also references cited in [42] for others) discovered that a Stokes wave in sufficiently deep water, so that \( \kappa h > 1.3627 \ldots \), is unstable to long wavelength perturbations—namely, the Benjamin–Feir or modulational instability. Here \( \kappa \) denotes the wave number of the unperturbed wave, and \( h \) the fluid depth. In the 1990s, Bridges and Mielke [4] analytically studied the spectral instability of a Stokes wave of sufficiently small amplitude, rigorously justifying the formal arguments of [3, 40] and others. Some fundamental issues remain open, however.

In the 1980s, McLean [28] (see also [27, 29] in the infinite depth) numerically studied the spectral stability and instability of Stokes waves for \( \kappa h \) greater and less than 1.3627\ldots, and reported instability away from the origin of the complex plane. The Benjamin–Feir instability, by contrast, refers to the spectrum in the vicinity of the origin. Further numerical investigations (see [9], for instance) predicted instability whenever the unperturbed wave is “resonant” with its infinitesimal perturbations (see (6.1)). More recently, Deconinck and Olveras [7] focussed the attention to resonances and numerically found “bubbles of instability”. Thus there seems to exist a Stokes wave which is spectrally unstable even though it is insusceptible to the Benjamin–Feir instability. To the best of the authors’ knowledge, this has not been analytically studied. The present purpose is to make rigorous spectral analysis to elucidate the numerical findings of [7, 9, 28] and others, and, in the process, to give the first proof of the spectral instability of a Stokes wave away from the origin of the complex plane.

Gardner’s periodic Evans function [10, 11] is a powerful tool for locating and tracking the essential spectrum for periodic traveling waves in one dimension, for a wide variety of PDEs, from viscous conservation laws [33, 35] to the generalized Kruumoto–Sivashinsky equations [2], to generalized Korteweg–de Vries equations [6], and to the nonlinear Klein–Gordon equations [19]. Recently, the second author and his collaborators [18] devised a periodic Evans function methodology for discontinuous roll waves of the inviscid Saint-Venant equations. Despite the success in one dimension, however, periodic Evans function techniques have rarely been implemented in higher dimensions. Deng and Nii [8] introduced an infinite-dimensional Evans function approach for a class of elliptic eigenvalue problems in cylindrical domains, but for the stability and instability of solitary waves. Also, it is highly nontrivial to construct an unstable bundle, whose first Chern number equals to the number of eigenvalues, and evaluate such a topological quantity, except few examples. Oh and Sandstede [34] defined an approximate Evans function for periodic traveling waves in cylindrical domains. Unfortunately, it is incapable of exactly locating the spectrum. Here we develop a new periodic Evans function approach for cylindrical domains, which can disclose spectral information through explicit calculations. We pause to remark that Haragus and Scheel [13] defined an Evans function for capillary-gravity solitary waves and proved finite-wavelength stability for sufficiently small amplitude. To the best of the authors’ knowledge, however, a periodic Evans function has not been proposed for the water wave problem.

We begin in Section 2 by “flattening” the free boundary and reformulating the water wave problem as first order PDEs with respect to the \( x \) variable in \( \mathbb{R} \times (0, 1) \) in the \((x, y)\) plane (see (2.7)), where \( x \) is in the direction of the wave propagation, and \( y \) opposite to gravitational acceleration. There are other ways to fix the free boundary, for instance, reformulating the problem in terms of quantities at the fluid surface alone. The resulting equations become nonlocal, however, and
periodic Evans function techniques are inapplicable. Recently, the first author and her collaborators (see [5,15,16], for instance) performed spectral perturbation analysis in the vicinity of the origin of the complex plane for small values of the Floquet exponent, determining modulational stability and instability for a class of nonlinear dispersive equations, permitting nonlocal operators. It is highly nontrivial, however, to extend the argument to the spectrum away from the origin.

After working out in Section 3 the small amplitude asymptotics for periodic traveling waves (see (3.3)), in Section 4.2 we formulate the spectral stability problem for a Stokes wave of sufficiently small amplitude as first order ODEs with respect to the $x$ variable in an infinite-dimensional function space (see (4.8)). In Section 4.3 we focus the attention to zero amplitude and verify that the spectrum is the imaginary axis, and parametrized by the Floquet exponent through the dispersion relation (see (4.15)). Also, at each point of the imaginary axis, we define a finite dimensional eigenspace (see Definition 4.5). In Section 4.4 we turn the attention to nonzero amplitude. We take a center manifold reduction approach (see [30], for instance) to reduce the spectral stability problem in an infinite-dimensional function space, to the finite dimensional eigenspace (see (4.24) and (4.25)), whereby we define Gardner’s periodic Evans function (see (4.26)). In Section 4.5 we work out explicit formulae of the projection operator onto the eigenspace. This is among the most technical parts of the proof. We remark that for zero Floquet exponent, the linearized operator of the water wave problem about a Stokes wave of sufficiently small amplitude, not necessarily zero amplitude, has four eigenvalues at the origin of the complex plane. Bridges and Mielke [4] examined whether the eigenvalues enter the right half plane as the Floquet exponent increases, to determine modulational stability and instability. (See also [5,15,16] for nonlinear nonlocal equations.) Unfortunately, one does not expect to be able to exactly locate the spectrum away from the origin for nonzero amplitude. Our approach, instead, takes advantage of that for zero amplitude, the spectrum is explicitly characterized through the dispersion relation, and we examine how the spectrum varies as the amplitude increases.

In Section 5 we determine the power series expansion of the periodic Evans function for the spectrum in the vicinity of the origin of the complex plane, whereby giving an alternative proof of the Benjamin–Feir instability [4]. See Theorem 5.3 and Corollary 5.4. Also, we demonstrate that the spectrum near the origin consists of two closed loops, one “figure-8” and one “figure-$\infty$”. See Figure 2. Numerical investigations (see [7], for instance) reveal the figure-8 curve, but not the figure-$\infty$ one. In Section 6 we turn the attention to the spectrum away from the origin of the complex plane and prove instability, due to the resonance of order 2 (see (6.1)), provided that $0.86430 \ldots < \kappa h < 1.00804 \ldots$. See Theorem 6.3 and Corollary 6.4. Therefore, we analytically confirm that there exist Stokes waves spectrally unstable even though they are insusceptible to the Benjamin–Feir instability. Our result explains some of the numerical findings [7,16,28], but not all. Particularly, Corollary 6.4 gives an interval of $\kappa h$ for instability, whereas numerical computations suggest instability for all $\kappa h$. Perhaps this is because our proof is for arbitrarily small amplitude, whereas numerical computations are for small but finite amplitude. Evaluating the periodic Evans function involves extremely long and tedious algebraic manipulations, for which we use the Symbolic Math Toolbox in Matlab.

Our approach is robust and can accommodate the effects of surface tension [17] and vorticity [14], transversal perturbations, and many others. This is a subject of future investigation. Also, it can be useful for other PDEs in higher dimensions, for instance, the equations in [8,34].

We conjecture that a Stokes wave of sufficiently small amplitude is spectrally stable if it is insusceptible to the Benjamin–Feir instability and the spectral instability due to the resonance of order 2 (see Theorem 6.3). It is unlikely, however, to be able to prove spectral stability by examining all the coefficients of the series expansion of the spectrum along the imaginary axis. In Section 7 we propose to directly study the discriminant of the Weierstrass polynomial associated with the periodic Evans function.
2. The water wave problem

The water wave problem, in the simplest form, concerns the wave motion at the free surface of an incompressible inviscid fluid in two dimensions, lying below a body of air, acted on by gravity, when the effects of surface tension are negligible. Although an incompressible fluid can have variable density, we assume for simplicity that the density $\rho = 1$. Suppose for definiteness that in Cartesian coordinates, the wave propagation is in the $x$ direction, and the gravitational acceleration in the negative $y$ direction. Suppose that the fluid at rest occupies the region $\{(x, y) \in \mathbb{R}^2 : 0 < y < h\}$, where $h > 0$ is the fluid depth. Let

$$y = h + \eta(x, t), \quad x \in \mathbb{R},$$

denote the fluid surface at time $t$, and $y = 0$ the rigid bed. Physically realistic is that $h + \eta(x, t) > 0$ for all $x \in \mathbb{R}$. Throughout we assume an irrotational flow, whereby a velocity potential $\phi(x, y, t)$ satisfies

$$\phi_{xx} + \phi_{yy} = 0 \quad \text{for } 0 < y < h + \eta(x, t),$$

subject to the boundary condition

$$\phi_y = 0 \quad \text{at } y = 0.$$  

The kinematic and dynamic boundary conditions at the fluid surface,

$$\begin{aligned}
\eta_t - c \eta_x + \eta_x \phi_x &= \phi_y \\
\phi_t - c \phi_x + \frac{1}{2} (\phi_x^2 + \phi_y^2) + g \eta &= 0
\end{aligned} \quad \text{at } y = h + \eta(x, t),$$

state that each fluid particle at the surface remains so for all time and that the pressure is constant at the fluid surface, where $c \neq 0, c \in \mathbb{R}$ is the velocity of the wave, and $g > 0$ the constant of gravitational acceleration. We assume that there is no motion in the air.

We begin by recasting (2.1) in dimensionless variables. Rather than introducing new notation for all the variables, we choose, wherever convenient, to write, for instance, $x \mapsto x/h$. This is to be read “$x$ is replaced by $x/h$”, so that hereafter the symbol $x$ will mean a dimensionless variable. With the understanding, let

$$x \mapsto x/h, \quad y \mapsto y/h, \quad t \mapsto ct/h,$$

and $\eta \mapsto \eta/h, \quad \phi \mapsto \phi/(ch)$.

Correspondingly, let

$$\mu = gh/c^2$$

denote the (dimensionless) inverse square of the Froude number. Inserting (2.2) and (2.3) into (2.1), we arrive at

$$\begin{aligned}
\phi_{xx} + \phi_{yy} &= 0 \quad \text{for } 0 < y < 1 + \eta(x, t), \\
\phi_y &= 0 \quad \text{at } y = 0, \\
\eta_t - \eta_x + \eta_x \phi_x &= \phi_y \quad \text{at } y = 1 + \eta(x, t), \\
\phi_t - \phi_x + \frac{1}{2} (\phi_x^2 + \phi_y^2) + \mu \eta &= 0 \quad \text{at } y = 1 + \eta(x, t).
\end{aligned}$$

It is advantageous to formulate the spectral stability problem for (2.4) as first order ODEs with respect to the $x$ variable (see (4.2)). Thus we introduce

$$u = \phi_x.$$
Notice that (2.4) is a free boundary problem, of which \( \eta \) is part of the solution. Thus we make the change of variables
\[
y \mapsto \frac{y}{1 + \eta(x,t)},
\]
transforming the fluid region \( \{(x,y) \in \mathbb{R}^2 : 0 < y < 1 + \eta(x,t)\} \) into \( \mathbb{R} \times (0, 1) \), whereby “flattening” the free boundary. Clearly, (2.6) is well defined so long as \( 1 + \eta(x,t) > 0 \) for all \( x \in \mathbb{R} \), particularly, when \( \eta \) is small. Substituting (2.5) and (2.6) into (2.4), we use the chain rule and make a straightforward calculation to arrive at
\[
\phi_x - \frac{y \eta_x}{1 + \eta} \phi_y - u = 0 \quad \text{for } 0 < y < 1,
\]
\[
u_x - \frac{y \eta_x}{1 + \eta} u_y + \frac{1}{1 + \eta} \phi_{yy} = 0 \quad \text{for } 0 < y < 1,
\]
\[
\phi_y = 0 \quad \text{at } y = 0,
\]
\[
\eta_t + (u - 1)\eta_x - \frac{1}{1 + \eta} \phi_y = 0 \quad \text{at } y = 1,
\]
\[
\phi_t - u + \frac{(u - 1)\eta_x}{1 + \eta} \phi_y + \frac{1}{2} u^2 - \frac{1}{2(1 + \eta)^2} \phi_y^2 + \mu \eta = 0 \quad \text{at } y = 1.
\]

There are other ways to fix the free boundary, for instance, reformulating the problem in terms of quantities at the fluid surface alone. The resulting equations become nonlocal, however, for which the periodic Evans function and other ODE techniques are inapplicable.

3. Stokes waves of sufficiently small amplitude

By a Stokes wave, we mean a temporally stationary and spatially periodic solution of (2.7). Thus \( \phi, \eta \) and
\[
u = \phi_x - \frac{y \eta_x}{1 + \eta} \phi_y,
\]
by the first equation of (2.7), satisfy
\[
\nu_x - \frac{y \eta_x}{1 + \eta} u_y + \frac{1}{1 + \eta} \phi_{yy} = 0 \quad \text{for } 0 < y < 1,
\]
subject to the boundary conditions
\[
\phi_y = 0 \quad \text{at } y = 0,
\]
and
\[
(u - 1)\eta_x - \frac{1}{1 + \eta} \phi_y = 0 \quad \text{at } y = 1,
\]
\[
u - \frac{1}{2} u^2 - \frac{1}{2(1 + \eta)^2} \phi_y^2 - \mu \eta = 0 \quad \text{at } y = 1,
\]
where (3.2d) follows from (3.2c) and
\[
u - \frac{(u - 1)\eta_x}{1 + \eta} \phi_y - \frac{1}{2} u^2 + \frac{1}{2(1 + \eta)^2} \phi_y^2 - \mu \eta = 0 \quad \text{at } y = 1,
\]
by the fifth equation of (2.7).

Stokes in his 1847 paper [36] (see also [37]) made significant contributions to waves of the kind, for instance, successfully approximating the solution when the amplitude is small. The existence of Stokes waves was rigorously established by Nekrasov [31] (see also [24]) and Levi-Civita [25] in the
Recall that $\phi$ is an even function and of mean zero, and $\bar{\eta}$ its derivatives. We pause to remark that (3.3) converges as $\varepsilon \to 0$, where $\bar{\eta}_1, \bar{\eta}_2, \bar{\phi}_2, \bar{\phi}_3, \bar{\phi}_4, \ldots$ are $T$-periodic functions of $x$, and $\bar{\eta}_1, \bar{\eta}_2, \bar{\eta}_3, \ldots$ are each of mean zero over one period with respect to the $x$ variable [3]. Notice that (3.2) does not involve $\phi$, but merely its derivatives. We pause to remark that (3.3) converges as $\varepsilon \to 0$, for instance, in $H^{s+2}(\mathbb{R}/TZ \times (0, 1)) \times H^{s+5/2}(\mathbb{R}/TZ) \times \mathbb{R}$ for any $s > 1$. Thus $\phi(\varepsilon), \eta(\varepsilon)$ and $\mu(\varepsilon)$ depend real analytically on $\varepsilon$. Substituting (3.3) into (3.2) and (3.1), at the order of $\varepsilon$, we gather

$$
\begin{align*}
\phi_{1xx} + \phi_{1yy} &= 0 & \text{for } 0 < y < 1, \\
\phi_{1y} &= 0 & \text{at } y = 0, \\
\eta_{1x} + \phi_{1y} &= 0 & \text{at } y = 1, \\
\bar{\phi}_1 + \phi_{1x} - \mu_0 \bar{\eta}_1 &= 0 & \text{at } y = 1. \\
\end{align*}
$$

Recall that $\phi_1$ and $\eta_1$ are $2\pi/\kappa$ periodic functions of $x$, $\kappa > 0$, $\phi_1$ is an odd function of $x$, $\eta_1$ is an even function and of mean zero, and $\bar{\phi}_1$ and $\mu_0$ are constants. We solve (3.4) by separation of variables, for instance, to obtain

$$
\bar{\phi}_1 = 0, \quad \phi_1(x, y) = \sin(\kappa x) \cosh(\kappa y), \quad \eta_1(x) = \sinh(\kappa) \cos(\kappa x),
$$

*Alternatively, suppose that

$$
\begin{align*}
\phi(x, y; \varepsilon) &= \phi_1(x, y) \varepsilon + \phi_2(x, y) \varepsilon^2 + \phi_3(x, y) \varepsilon^3 + O(\varepsilon^4), \\
\eta(x; \varepsilon) &= \eta_1 \varepsilon + \eta_2 \varepsilon^2 + \eta_3 \varepsilon^3 + O(\varepsilon^4)
\end{align*}
$$

as $\varepsilon \to 0$ and one may choose $\bar{\eta}$ so that $\phi_1, \phi_2, \phi_3, \ldots$ are each of mean zero over one period with respect to the $x$ variable [3]. See also [14]. Here we prefer (3.3) because the dimensionless fluid depth $= 1$. 

\text{In what follows,}

$$
\varepsilon \in \mathbb{R}\text{ denotes the dimensionless amplitude parameter,}
$$

and suppose that

$$
\begin{align*}
\phi(x, y; \varepsilon) &= \bar{\phi}_1 x \varepsilon + \phi_1(x, y) \varepsilon + \phi_2(x, y) \varepsilon^2 + \phi_3(x, y) \varepsilon^3 + O(\varepsilon^4), \\
\eta(x; \varepsilon) &= \eta_1(x) \varepsilon + \eta_2(x) \varepsilon^2 + \eta_3(x) \varepsilon^3 + O(\varepsilon^4), \\
\mu(\varepsilon) &= \mu_0 + \mu_1 \varepsilon + \mu_2 \varepsilon^2 + \mu_3 \varepsilon^3 + O(\varepsilon^4)
\end{align*}
$$

as $\varepsilon \to 0$, where $\bar{\phi}_1, \phi_1, \phi_2, \phi_3, \ldots, \eta_1, \eta_2, \eta_3, \ldots, \mu_0, \mu_1, \mu_2, \mu_3, \ldots$ are to be determined and, hence,

$$
\begin{align*}
u(x, y; \varepsilon) &= u_1(x, y) \varepsilon + u_2(x, y) \varepsilon^2 + u_3(x, y) \varepsilon^3 + O(\varepsilon^4)
\end{align*}
$$

as $\varepsilon \to 0$, where $u_1, u_2, u_3, \ldots$ can be determined in terms of $\bar{\phi}_1, \phi_1, \phi_2, \phi_3, \ldots$ and $\eta_1, \eta_2, \eta_3, \ldots$ by (3.1). We assume that $\phi_1, \phi_2, \phi_3, \ldots$ and $\eta_1, \eta_2, \eta_3, \ldots$ are $T$-periodic functions of $x$, where $T = 2\pi/\kappa$. Thus $\phi(\varepsilon), \eta(\varepsilon)$ and $\mu(\varepsilon)$ depend real analytically on $\varepsilon$.
The linearized problem.

The result agrees with [3, (11)-(12)], for instance, after suitably redefining $\varepsilon$. We remark that (3.6) or, equivalently,

$$c_0 = \sqrt{\frac{g \tanh(\kappa h)}{\kappa}},$$

by (2.2) and (2.3), makes the dispersion relation of Stokes waves. Notice that $\mu_0$ is a monotonically increasing function of $\kappa$, and $\mu_0 > 1$ if $\kappa > 0$. A solitary wave originates in the limit as $\kappa \to 0$ and, hence, $\mu_0 \to 1$.

We proceed likewise, substituting (3.3) into (3.2) and (3.1), and solving at higher orders of $\varepsilon$, to successively obtain $\tilde{\phi}_2, \phi_2, \phi_3, \phi_3, \ldots, \eta_2, \eta_3, \ldots, \mu_1, \mu_2, \mu_3, \ldots$. The result is in Appendix A.

4. The spectral stability problem

Let $\phi(\varepsilon), u(\varepsilon), \eta(\varepsilon)$ and $\mu(\varepsilon)$, for $\varepsilon \in \mathbb{R}$ and $|\varepsilon| \ll 1$, denote a Stokes wave of sufficiently small amplitude, whose existence follows from the previous section, and (3.3), (3.5), (3.6), (A.2), (A.3) hold as $\varepsilon \to 0$. We are interested in its spectral stability and instability.

4.1. The linearized problem. Linearizing (2.7) about $\phi(\varepsilon), u(\varepsilon), \eta(\varepsilon)$ and evaluating the result at $\mu = \mu(\varepsilon)$, we arrive at

$$\begin{align*}
\phi_x - \frac{y\eta_x(\varepsilon)}{1 + \eta(\varepsilon)} \phi_y - \frac{y\phi_y(\varepsilon)}{1 + \eta(\varepsilon)} \eta_x + \frac{y(\eta_x \phi_y(\varepsilon))}{(1 + \eta(\varepsilon))^2} \eta - u & = 0 \quad \text{for } 0 < y < 1, \\
u_x - \frac{y\eta_x(\varepsilon)}{1 + \eta(\varepsilon)} u_y - \frac{y u_y(\varepsilon)}{1 + \eta(\varepsilon)} \eta_x + \frac{y(\eta_x u_y(\varepsilon))}{(1 + \eta(\varepsilon))^2} \eta + \frac{1}{(1 + \eta(\varepsilon))^2} \phi_{yy} - \frac{2 \phi_{yy}(\varepsilon)}{(1 + \eta(\varepsilon))^3} \eta & = 0 \quad \text{for } 0 < y < 1, \\
\eta_t + (u(\varepsilon) - 1) \eta_x + \eta_x u - \frac{1}{1 + \eta(\varepsilon)} \phi_y + \frac{\phi_y(\varepsilon)}{(1 + \eta(\varepsilon))^2} \eta & = 0 \quad \text{at } y = 1, \\
\phi_t - u + \frac{(u - 1) \phi_x(\varepsilon)}{1 + \eta(\varepsilon)} \eta_x + \frac{(\phi_y \eta_x(\varepsilon))}{1 + \eta(\varepsilon)} u + u(\varepsilon) u + \mu(\varepsilon) \eta & = 0 \quad \text{at } y = 1, \\
\phi_y & = 0 \quad \text{at } y = 0,
\end{align*}$$

where the fourth equation of (4.1) follows from the linearization of the fifth equation of (2.7) and (3.2c). Seeking a solution of (4.1) of the form

$$\begin{pmatrix}
\phi(x, y, t) \\
u(x, y, t) \\
\eta(x, t)
\end{pmatrix} = e^{\lambda t} \begin{pmatrix}
\phi(x, y) \\
u(x, y) \\
\eta(x)
\end{pmatrix}, \quad \lambda \in \mathbb{C},$$

we arrive at

$$\begin{align*}
(4.2a) \quad & \phi_x - \frac{y\eta_x(\varepsilon)}{1 + \eta(\varepsilon)} \phi_y - \frac{y\phi_y(\varepsilon)}{1 + \eta(\varepsilon)} \eta_x + \frac{y(\eta_x \phi_y(\varepsilon))}{(1 + \eta(\varepsilon))^2} \eta - u = 0 \quad \text{for } 0 < y < 1, \\
& u_x - \frac{y\eta_x(\varepsilon)}{1 + \eta(\varepsilon)} u_y - \frac{y u_y(\varepsilon)}{1 + \eta(\varepsilon)} \eta_x + \frac{y(\eta_x u_y(\varepsilon))}{(1 + \eta(\varepsilon))^2} \eta + \frac{1}{(1 + \eta(\varepsilon))^2} \phi_{yy} - \frac{2 \phi_{yy}(\varepsilon)}{(1 + \eta(\varepsilon))^3} \eta = 0 \quad \text{for } 0 < y < 1, \\
(4.2b) \quad & + \frac{1}{(1 + \eta(\varepsilon))^2} \phi_{yy} + \left( \frac{y(\eta_x u_y(\varepsilon))}{(1 + \eta(\varepsilon))^2} - \frac{2 \phi_{yy}(\varepsilon)}{(1 + \eta(\varepsilon))^3} \right) \eta = 0 \quad \text{for } 0 < y < 1, \\
(4.2c) \quad & \lambda \eta + (u(\varepsilon) - 1) \eta_x + \eta_x (\varepsilon) u - \frac{1}{1 + \eta(\varepsilon)} \phi_y + \frac{\phi_y(\varepsilon)}{(1 + \eta(\varepsilon))^2} \eta = 0 \quad \text{at } y = 1,
\end{align*}$$
and

\[
\begin{align*}
\lambda \phi + (u(\varepsilon) - 1)u + \frac{\phi_y(\varepsilon)}{(1 + \eta(\varepsilon))^2} \phi_y \\
+ \left( \mu(\varepsilon) - \lambda \frac{\phi_y(\varepsilon)}{1 + \eta(\varepsilon)} - \frac{\phi_y(\varepsilon)^2}{(1 + \eta(\varepsilon))^3} \right) \eta &= 0 & \text{at } y = 1, \\
\phi_y &= 0 & \text{at } y = 0,
\end{align*}
\]

where (4.2d) follows from (4.2c) and

\[
\lambda \phi - u + \left( \frac{(u - 1)\phi_y(\varepsilon)}{1 + \eta(\varepsilon)} \right) \nu_x + \left( \frac{\phi_y \eta_x(\varepsilon)}{1 + \eta(\varepsilon)} \right) u + u(\varepsilon)u + \mu(\varepsilon)\eta = 0 & \text{at } y = 1,
\]

by the fourth equation of (4.1). Roughly speaking, \( \lambda \in \mathbb{C} \) is in the spectrum if (4.2) admits a nontrivial bounded solution in some function space, and a Stokes wave of sufficiently small amplitude is spectrally stable if the spectrum does not intersect the right half plane of \( \mathbb{C} \) for \( \varepsilon \in \mathbb{R} \) and \( |\varepsilon| \ll 1 \). We make these precise in Section 4.2.

Notice that (4.2d) is not autonomous. Thus we introduce

\[
\nu = \left( 1 - u(\cdot, 1; \varepsilon) \right) u - \lambda \phi - \frac{\phi_y(\cdot, 1; \varepsilon)}{(1 + \eta(\varepsilon))^2} \phi_y \left( \mu(\varepsilon) - \frac{\phi_y(\cdot, 1; \varepsilon)^2}{(1 + \eta(\varepsilon))^3} \phi_y \right)^{-1},
\]

so that (4.2d) becomes

\[
\eta - \nu = 0 & \text{at } y = 1.
\]

Clearly, (4.3) is well defined for \( \varepsilon \in \mathbb{R} \) and \( |\varepsilon| \ll 1 \), provided that \( |\text{Re}\lambda| \ll 1 \). Conversely,

\[
u = \left( \frac{\mu(\varepsilon) - \phi_y(\cdot, 1; \varepsilon)}{1 + \eta(\varepsilon)} - \frac{\phi_y(\cdot, 1; \varepsilon)^2}{(1 + \eta(\varepsilon))^3} \nu_x + \lambda \phi_y + \frac{\phi_y(\cdot, 1; \varepsilon)}{(1 + \eta(\varepsilon))^2} \phi_y \right) \left( 1 - u(\cdot, 1; \varepsilon) \right)^{-1}.
\]

is well defined for \( \varepsilon \in \mathbb{R} \) and \( |\varepsilon| \ll 1 \), provided that \( |\text{Re}\lambda| \ll 1 \). It turns out that if \( \lambda \in \mathbb{C} \) is in the spectrum of (4.2) then \( |\text{Re}\lambda| \ll 1 \) for \( \varepsilon \in \mathbb{R} \) and \( |\varepsilon| \ll 1 \). See Section 4.3.

We proceed to rewrite (4.2a), (4.2c) and (4.4) for \( \phi, u, \text{ and } \eta \). We begin by replacing \( u \) in (4.2a) by the right side of (4.5), and \( u(\cdot, 1) \) in (4.2c) by the right side of (4.5), evaluated at \( y = 1 \). We replace \( u_y \) in (4.2b) by

\[
\begin{align*}
\frac{d}{dy} u_y &= \left( \frac{\mu(\varepsilon) - \phi_y(\cdot, 1; \varepsilon)}{1 + \eta(\varepsilon)} - \frac{\phi_y(\cdot, 1; \varepsilon)^2}{(1 + \eta(\varepsilon))^3} \right) \phi_y + \lambda \phi_y + \frac{\phi_y(\cdot, 1; \varepsilon)}{(1 + \eta(\varepsilon))^2} \phi_y \phi_y \left( 1 - u(\cdot, 1; \varepsilon) \right)^{-1},
\end{align*}
\]

by (4.5), and likewise \( u_x \) in (4.2b) by

\[
\begin{align*}
\frac{d}{dy} u_x &= \left( \frac{\mu(\varepsilon) - \phi_y(\cdot, 1; \varepsilon)}{1 + \eta(\varepsilon)} - \frac{\phi_y(\cdot, 1; \varepsilon)^2}{(1 + \eta(\varepsilon))^3} \right) \left( 1 - u(\cdot, 1; \varepsilon) \right)^{-1} \nu_x \\
&+ \left( \frac{\mu(\varepsilon) - \phi_y(\cdot, 1; \varepsilon)}{1 + \eta(\varepsilon)} - \frac{\phi_y(\cdot, 1; \varepsilon)^2}{(1 + \eta(\varepsilon))^3} \right) \left( 1 - u(\cdot, 1; \varepsilon) \right)^{-1} \nu_x \\
&+ \lambda \left( 1 - u(\cdot, 1; \varepsilon) \right)^{-1} \phi + \lambda \left( 1 - u(\cdot, 1; \varepsilon) \right)^{-1} \phi_x \\
&+ \left( \frac{\phi_y(\cdot, 1; \varepsilon)^2}{(1 + \eta(\varepsilon))^3} \left( 1 - u(\cdot, 1; \varepsilon) \right)^{-1} \phi_y + \frac{\phi_y(\cdot, 1; \varepsilon)}{(1 + \eta(\varepsilon))^2} \left( 1 - u(\cdot, 1; \varepsilon) \right)^{-1} \phi_y, \phi_y, \phi_x, \phi_y \right)
\end{align*}
\]

where the prime denotes differentiation with respect to the \( x \) variable. Also we rewrite \( \phi_x \) in (4.7) in terms of \( \phi, \nu, \text{ and } \eta \) using (4.2c) and (4.5) and, likewise, \( \phi_{xy} \) in (4.7) in terms of \( \phi, \nu, \text{ and } \eta \) by differentiating (4.2c) with respect to the \( y \) variable and using (4.6).
4.2. Spectral stability and instability. Let \( u = \begin{pmatrix} \phi \\ v \\ \eta \end{pmatrix} \), and we write (4.2) as

\[
(4.8) \quad u_x = L(\lambda) u + B(x; \lambda, \varepsilon) u,
\]

where \( \lambda \in \mathbb{C} \) and \( \varepsilon \in \mathbb{R} \) and \( |\varepsilon| \ll 1 \),

\[
L(\lambda) : \text{dom}(L) \subset Y \to Y \quad \text{and} \quad B(x; \lambda, \varepsilon) : \mathbb{R} \times \text{dom}(L) \subset \mathbb{R} \times Y \to Y,
\]

\[
(4.9) \quad L(\lambda) u = \begin{pmatrix} \lambda \phi + \mu_0 v \\ -\mu_0^{-1}(\phi_{yy} + \lambda^2 \phi + \mu_0 \lambda v) \\ [\lambda \eta - \phi_y]_{y=1} \end{pmatrix},
\]

\[
(4.10) \quad Y = H^1(0,1) \times L^2(0,1) \times \mathbb{C}
\]

and

\[
(4.11) \quad \text{dom}(L) = \{ u \in H^2(0,1) \times H^1(0,1) \times \mathbb{C} : \eta - v(1) = 0, \phi_y(0) = 0 \}.
\]

Notice that \( L(\lambda) \) is the leading part of (4.2a)-(4.2c), by (3.3), (3.6), (4.5), (4.6), (4.7), and \( B(x; \lambda, \varepsilon) \) is a linear operator. Notice that if \( u \in \text{dom}(L) \) then (4.4) and (4.2e) hold. Also, \( B(x; \lambda, 0) = 0 \).

Thus when \( \varepsilon = 0 \), (4.8) becomes \( u_x = L(\lambda) u \). We remark that \( L(\lambda) \) and \( B(x; \lambda, \varepsilon) \) depend analytically on \( \lambda \), and \( B(x; \lambda, \varepsilon) \) depends analytically on \( \varepsilon \). Although \( \phi(\varepsilon) \) is not periodic in the \( x \) variable (see the first equation of (3.3)), (4.2) involves merely its derivatives, whence \( B(x; \lambda, \varepsilon) \) is \( T(=2\pi/\kappa) \) periodic in \( x \). Also, \( B(x; \lambda, \varepsilon) \) is smooth in \( x \). Our proofs do not involve all the details of \( B(x; \lambda, \varepsilon) \), whence we do not include the formula here. Clearly, \( \text{dom}(L) \) is dense in \( Y \).

Let

\[
\mathcal{L}(\lambda, \varepsilon) : \text{dom}(\mathcal{L}) \subset X \to X,
\]

where

\[
(4.12) \quad \mathcal{L}(\lambda, \varepsilon) u = u_x - (L(\lambda) + B(x; \lambda, \varepsilon)) u,
\]

\[
(4.13) \quad X = L^2(\mathbb{R}; Y) \quad \text{and} \quad \text{dom}(\mathcal{L}) = H^1(\mathbb{R}; Y) \cap L^2(\mathbb{R}; \text{dom}(L))
\]

is dense in \( X \), so that (4.8) becomes

\[
(4.14) \quad \mathcal{L}(\lambda, \varepsilon) u = 0.
\]

We regard \( \mathcal{L}(\varepsilon) \) as \( \mathcal{L}(\lambda, \varepsilon) \), parametrized by \( \lambda \in \mathbb{C} \).

**Definition 4.1** (The spectrum of \( \mathcal{L}(\varepsilon) \)). For \( \varepsilon \in \mathbb{R} \) and \( |\varepsilon| \ll 1 \),

\[
\text{spec}(\mathcal{L}(\varepsilon)) = \{ \lambda \in \mathbb{C} : \mathcal{L}(\lambda, \varepsilon) : \text{dom}(\mathcal{L}) \subset X \to X \text{ is not invertible} \}.
\]

We pause to remark that \( \mathcal{L}(\lambda, \varepsilon) \) makes sense, provided that \( |\varepsilon| \ll 1 \). Conversely, if \( \lambda \in \text{spec}(\mathcal{L}(\varepsilon)) \) then \( |\text{Re}\lambda| \ll 1 \) for \( \varepsilon \in \mathbb{R} \) and \( |\varepsilon| \ll 1 \). See Section 4.3

**Definition 4.2** (Spectral stability and instability). A Stokes wave of sufficiently small amplitude is said to be *spectrally stable* if

\[
\text{spec}(\mathcal{L}(\varepsilon)) \subset \{ \lambda \in \mathbb{C} : \text{Re}\lambda \leq 0 \}
\]

for \( \varepsilon \in \mathbb{R} \) and \( |\varepsilon| \ll 1 \), and *spectrally unstable* otherwise.
Since \( B(x; \lambda, \varepsilon) \) and, hence, \( \mathcal{L}(\lambda, \varepsilon) \) are \( T(=2\pi/\kappa) \) periodic in \( x \), by Floquet theory, the point spectrum of \( \mathcal{L}(\varepsilon) \) is empty. Moreover, \( \lambda \) is in the essential spectrum of \( \mathcal{L}(\varepsilon) \) if and only if (4.8) admits a nontrivial solution \( u \in L^\infty(\mathbb{R}; Y) \) satisfying
\[
 u(x + T) = e^{ikT}u(x) \quad \text{for some } k \in \mathbb{R}, \quad \text{the Floquet exponent.}
\]
See [10, 34], for instance, for details.

In what follows, the asterisk means complex conjugation.

**Lemma 4.3** (Symmetries of the spectrum). If \( \lambda \in \text{spec}(\mathcal{L}(\varepsilon)) \) then \( \lambda^*, -\lambda \in \text{spec}(\mathcal{L}(\varepsilon)) \) and, hence, \( -\lambda^* \in \text{spec}(\mathcal{L}(\varepsilon)) \).

**Remark.** A Stokes wave of sufficiently small amplitude is spectrally stable if and only if \( \text{spec}(\mathcal{L}(\varepsilon)) \subset i\mathbb{R} \) for \( \varepsilon \in \mathbb{R} \) and \( |\varepsilon| \ll 1 \).

The proof of Lemma 4.3 is in Appendix B. The symmetries of the spectrum also follow from that the water wave problem (see (2.4)) is Hamiltonian [41].

In Section 4.3, we focus the attention on \( \varepsilon = 0 \) and define the eigenspace of \( \mathcal{L}(\lambda) : \text{dom}(\mathcal{L}) \subseteq Y \rightarrow Y \) associated with its finitely many and purely imaginary eigenvalues. In Section 4.4, we turn to \( \varepsilon \neq 0 \) and take a center manifold reduction approach (see [30], among others) to reduce (4.8) to finite dimensions (see (4.24)), whereby we introduce Gardner’s periodic Evans function (see [10], for instance). In Section 5 and Section 6, we make the power series expansion of the periodic Evans function to locate and track the spectrum of \( \mathcal{L}(\varepsilon) \) for \( \varepsilon \in \mathbb{R} \) and \( |\varepsilon| \ll 1 \).

4.3. **The spectrum of \( \mathcal{L}(0) \). The reduced space.** When \( \varepsilon = 0 \), \( \lambda \in \text{spec}(\mathcal{L}(0)) \) if and only if
\[
i \kappa u = \mathcal{L}(\lambda)u, \quad \text{where } \mathcal{L}(\lambda) : \text{dom}(\mathcal{L}) \subseteq Y \rightarrow Y
\]
is in (4.9), (4.10), (4.11), admits a nontrivial solution for some \( k \in \mathbb{R} \). In other words, \( ik \) is an eigenvalue of \( \mathcal{L}(\lambda) \). We pause to remark that \( \mathcal{L}(\lambda) \) has compact resolvent, so that the spectrum consists of discrete eigenvalues with finite multiplicities. A straightforward calculation reveals that
\[
(4.15) \quad \lambda = i\sigma, \quad \text{where } \sigma \in \mathbb{R} \quad \text{and} \quad (\sigma - k)^2 = \mu_0 k \tanh(k).
\]
Thus \( \text{spec}(\mathcal{L}(0)) = i\mathbb{R} \), implying that the Stokes wave of zero amplitude is spectrally stable. The spectrum of \( \mathcal{L}(\varepsilon) \) varies continuously with \( \varepsilon \), whence if \( \lambda \in \text{spec}(\mathcal{L}(\varepsilon)) \) then \( |\text{Re}\lambda| \ll 1 \) for \( \varepsilon \in \mathbb{R} \) and \( |\varepsilon| \ll 1 \).

![Figure 1.](image)

**Figure 1.** Left: The graphs of \( \sigma_+(k) \) (blue) and \( \sigma_-(k) \) (black) for \( \mu_0 = 2 \). Middle: When \( 0 < \sigma < \sigma_c \), \( \sigma_\pm(k) = \sigma \) have four roots \( k_j(\sigma), \quad j = 1, 2, 3, 4 \). Right: When \( \sigma > \sigma_c, \sigma_\pm(k) = \sigma \) have two roots \( k_j(\sigma), \quad j = 2, 4 \).

Let
\[
(4.16) \quad \sigma_\pm(k) = k \pm \sqrt{\mu_0 k \tanh(k)}, \quad \text{where } k \in \mathbb{R}.
\]
The left panel of Figure 1 shows the graphs of \( \sigma_+ \) for \( \mu_0 = 2 \). Let

\[
\sigma_c = \sigma_+(k_c), \quad \text{such that} \quad \sigma'_+(k_c) = 0.
\]

In other words, \( \sigma_c \) is a (unique) critical value of \( \sigma_+ \). By symmetry, \( -\sigma_c = \sigma_-(\kappa c) \) is a critical value of \( \sigma_- \). Below it suffices to take \( \sigma \geq 0 \). Notice that:

(i) When \( \sigma = 0 \), \( \sigma_+(k) = 0 \) has one simple root at \( k = 0 \), and one negative simple root at \( \kappa = -\kappa \), see (3.6), and \( \sigma_-(k) = 0 \) has one simple root at \( k = 0 \) and one positive simple root at \( k = \kappa \);

(ii) When \( 0 < \sigma < \sigma_c \), \( \sigma_+(k) = \sigma \) has three simple roots, two negative and one positive, and \( \sigma_-(k) = \sigma \) has one positive simple root;

(iii) When \( \sigma = \sigma_c \), \( \sigma_+(k) = \sigma_c \) has one negative double root at \( k = k_c \) and one positive simple root, and \( \sigma_-(k) = \sigma_c \) has one positive simple root;

(iv) When \( \sigma > \sigma_c \), \( \sigma_+(k) = \sigma \) has one positive simple root, and \( \sigma_-(k) = \sigma \) has one positive simple root.

Let \( k_2(\sigma) > 0 \) denote the simple root of \( \sigma_-(k) = \sigma(\geq 0) \), and let \( k_4(\sigma) > 0 \) be the simple root of \( \sigma_+(k) = \sigma(\sigma > 0) \), and \( k_4(0) = 0 \). When \( 0 < \sigma < \sigma_c \), let \( k_1(\sigma) \leq k_3(\sigma) \leq 0 \) be the other two roots of \( \sigma_+(k) = \sigma \). See the middle and right panels of Figure 1. Thus:

(i) When \( \sigma = 0 \), \( k_j(0) = (-1)^j i \kappa \), \( j = 1, 2 \), and \( k_j(0) = 0 \), \( j = 3, 4 \);

(ii) When \( 0 < \sigma < \sigma_c \), \( \sigma_-(k_2) = \sigma_+(k_j) = \sigma \), \( j = 1, 3, 4 \), and \( k_1 < k_3 < 0 < k_4 < k_2 \);

(iii) When \( \sigma = \sigma_c \), \( k_j(\sigma_c) = k_c \), \( j = 1, 3 \), and \( \sigma_-(k_2) = \sigma_+(k_4) = \sigma_c \), \( k_1 = k_3 < 0 < k_4 < k_2 \);

(iv) When \( \sigma > \sigma_c \), \( \sigma_-(k_2) = \sigma_+(k_4) = \sigma \) and \( 0 < k_4 < k_2 \).

**Lemma 4.4 (Spectrum of \( L(i\sigma) \)).** When \( \sigma = 0 \), \( ik_j(0) = (-1)^j i \kappa \), \( j = 1, 2 \), are simple eigenvalues of \( L(0) : \text{dom}(L) \subset Y \to Y \), and

(4.17)

\[
\ker(L(0) - ik_j(0) \mathbf{1}) = \ker((L(0) - ik_j(0) \mathbf{1})^2) = \text{span}\{\phi_j(0)\}, \quad \phi_j(0) = \begin{pmatrix} \mu_0 \cosh(k_j(0)y) \\ ik_j(0) \cosh(k_j(0)y) \\ ik_j(0) \cosh(k_j(0)) \end{pmatrix},
\]

where \( \mathbf{1} \) denotes the identity operator. Also, \( ik_j(0) = 0 \), \( j = 3, 4 \), is an eigenvalue of \( L(0) \) with algebraic multiplicity 2 and geometric multiplicity 1, and

\[
\ker(L(0))^2 = \ker(L(0))^3 = \text{span}\{\phi_3(0), \phi_4(0)\},
\]

where

(4.18)

\[
\phi_3(0) = \begin{pmatrix} 0 \\ 1 \\ 1 \end{pmatrix} \quad \text{and} \quad \phi_4(0) = \begin{pmatrix} \mu_0 \\ 0 \\ 0 \end{pmatrix}.
\]

When \( 0 < \sigma < \sigma_c \), \( ik_j(\sigma) \), \( j = 1, 2, 3, 4 \), are simple eigenvalues of \( L(i\sigma) \), and

(4.19)

\[
\ker(L(i\sigma) - ik_j(\sigma) \mathbf{1}) = \ker((L(i\sigma) - ik_j(\sigma) \mathbf{1})^2) = \text{span}\{\phi_j(\sigma)\}, \quad \phi_j(\sigma) = \begin{pmatrix} \mu_0 \cosh(k_j(\sigma)y) \\ i(k_j(\sigma) - \sigma) \cosh(k_j(\sigma)y) \\ i(k_j(\sigma) - \sigma) \cosh(k_j(\sigma)) \end{pmatrix}.
\]

When \( \sigma > \sigma_c \), \( ik_j(\sigma) \), \( j = 2, 4 \), are simple eigenvalues of \( L(i\sigma) \), and (4.19) holds. When \( \sigma = \sigma_c \), \( ik_j(\sigma_c) \), \( j = 2, 4 \), are simple eigenvalues of \( L(i\sigma_c) \), and (4.19) holds. Also, \( ik_c \) is an eigenvalue with algebraic multiplicity 2 and geometric multiplicity 1, and

\[
\ker((L(i\sigma_c) - ik_c \mathbf{1})^2) = \ker((L(i\sigma_c) - ik_c \mathbf{1})^3) = \text{span}\{\phi_1(\sigma_c), \phi_3(\sigma_c)\},
\]
where

\begin{equation}
\phi_1(\sigma_c) = \begin{pmatrix}
\mu_0 \cosh(k_c y) \\
(i(k_c - \sigma_c) \cosh(k_c y) \\
i(k_c - \sigma_c) \cosh(k_c)
\end{pmatrix}
\quad \text{and} \quad
\phi_2(\sigma_c) = \begin{pmatrix}
-i\mu_0 y \sinh(k_c y) \\
\cosh(k_c y) + (k_c - \sigma_c) y \sinh(k_c y) \\
\cosh(k_c) + (k_c - \sigma_c) \sinh(k_c)
\end{pmatrix}.
\end{equation}

The proof is in Appendix C.

**Definition 4.5** (Eigenspace and projection). Let \( \sigma \geq 0 \), and \( Y(\sigma) \) denote the \((generalized)\) eigenspace of \( L(i\sigma) : \text{dom}(L) \subset Y \rightarrow Y \) associated with its finitely many and purely imaginary eigenvalues. Let

\[ \Pi(\sigma) : \text{dom}(L) \subset Y \rightarrow Y(\sigma) \]

be the \textit{projection} of \( \text{dom}(L) \) onto \( Y(\sigma) \), which commutes with \( L(i\sigma) \).

Lemma 4.4 says that:

(i) When \( \sigma = 0 \), \( Y(0) = \text{span}\{\phi_j(0) : j = 1, 2, 3, 4\} \), where \( \phi_j(0) \) is in (4.17) and (4.18);

(ii) When \( 0 < \sigma < \sigma_c \), \( Y(\sigma) = \text{span}\{\phi_j(\sigma) : j = 1, 2, 3, 4\} \), where \( \phi_j(\sigma) \) is in (4.19);

(iii) When \( \sigma = \sigma_c \), \( Y(\sigma_c) = \text{span}\{\phi_j(\sigma_c) : j = 1, 2, 3, 4\} \), where \( \phi_j(\sigma_c) \) is in (4.19) and (4.20);

(iv) When \( \sigma > \sigma_c \), \( Y(\sigma) = \text{span}\{\phi_j(\sigma) : j = 2, 4\} \), where \( \phi_j(\sigma) \) is in (4.19).

The formulae of \( \Pi(\sigma) \) are in Section 4.5.

By symmetry, \( ik_j(\sigma) = -ik_j(-\sigma) \), whereby Lemma 4.4 and Definition 4.5 extend to \( \sigma < 0 \).

### 4.4. Reduction of the spectral problem. The periodic Evans function.

We turn the attention to \( |\varepsilon| \neq 0, \ll 1 \). Let

\[ \lambda = i\sigma + \delta, \quad \text{where} \quad \sigma \in \mathbb{R}, \ \delta \in \mathbb{C} \ \text{and} \ |\delta| \ll 1, \]

and we rewrite (4.8) as

\begin{equation}
(4.21) \quad u_x = L(i\sigma)u + (L(i\sigma + \delta) - L(i\sigma))u + B(x; i\sigma + \delta, \varepsilon)u(x) =: L(i\sigma)u + B(x; \sigma, \delta, \varepsilon)u(x),
\end{equation}

where \( L(i\sigma) : \text{dom}(L) \subset Y \rightarrow Y \) is in (4.19), (4.10), (4.11), and

\[ B(x; \sigma, \delta, \varepsilon) : \mathbb{R} \times \text{dom}(L) \subset \mathbb{R} \times Y \rightarrow Y. \]

Notice that \( B(x; \sigma, \delta, \varepsilon) \) is smooth and \( T(= 2\pi/\kappa) \) periodic in \( x \), and it depends analytically on \( \sigma, \delta \) and \( \varepsilon \). Also, \( B(x; \sigma, 0, 0) = 0 \). Our proofs do not involve all the details of \( B(x; \sigma, \delta, \varepsilon) \), and rather its leading order terms as \( \delta, \varepsilon \rightarrow 0 \), whence we do not include the formula here. But see, for instance, (5.7), (6.6) and Appendix D.

For \( u(x) \in \text{dom}(L) \), \( x \in \mathbb{R} \), let

\[ v(x) = \Pi(\sigma)u(x) \quad \text{and} \quad w(x) = (1 - \Pi(\sigma))u(x), \]

where \( 1 \) denotes the identity operator, and (4.21) becomes

\begin{equation}
(4.22) \quad v_x = L(i\sigma)v + \Pi(\sigma)B(x; \sigma, \delta, \varepsilon)(v(x) + w(x)),
\end{equation}

\[ w_x = L(i\sigma)w + (1 - \Pi(\sigma))B(x; \sigma, \delta, \varepsilon)(v(x) + w(x)). \]

Recall from the previous subsection that

\[ Y(\sigma) = \begin{cases} 
\text{span}\{\phi_j(\sigma) : j = 1, 2, 3, 4\} & \text{if} \ |\sigma| \leq \sigma_c, \\
\text{span}\{\phi_j(\sigma) : j = 2, 4\} & \text{if} \ |\sigma| > \sigma_c, 
\end{cases} \]

where \( \phi_j(\sigma) \) is in Lemma 4.4 particularly, \( Y(\sigma) \) is finite dimensional. Thus we appeal to [30] Theorem 1], for instance, and for \( \sigma \in \mathbb{R}, \ \delta \in \mathbb{C} \) and \( |\delta| \ll 1, \) for \( \varepsilon \in \mathbb{R} \) and \( |\varepsilon| \ll 1, \) there exists

\begin{equation}
(4.23) \quad w(x, v(x); \sigma, \delta, \varepsilon) : \mathbb{R} \times Y(\sigma) \rightarrow \text{dom}(L)
\end{equation}
such that \( \mathbf{v} + \mathbf{w} \) makes a bounded solution of (4.21) and, hence, (4.8), provided that

\[
(4.24) \quad \mathbf{v}_x = \mathbf{L}(i\sigma)\mathbf{v} + \Pi(\mathbf{B}(x; \sigma, \delta, \varepsilon)\mathbf{v}(x) + \mathbf{w}(x, \mathbf{v}(x); \sigma, \delta, \varepsilon)).
\]

Therefore, we turn (4.21), for which \( \mathbf{u}(x) \in \text{dom}(\mathbf{L}), \ x \in \mathbb{R}, \) and \( \text{dim}(\text{dom}(\mathbf{L})) = \infty, \) into (4.24), for which \( \mathbf{v}(x) \in \mathbf{Y}(\sigma) \) and \( \text{dim}(\mathbf{Y}(\sigma)) < \infty. \)

For \( \mathbf{v}(x) \in \mathbf{Y}(\sigma), \ x \in \mathbb{R}, \) let

\[
\mathbf{v}(x) = \sum_j a_j(x) \phi_j(\sigma) \quad \text{and} \quad \mathbf{a}(x) = (a_j(x)),
\]

and we may further rewrite (4.24) as

\[
(4.25) \quad \mathbf{a}_x = \mathbf{A}(x; \sigma, \delta, \varepsilon)\mathbf{a},
\]

where \( \mathbf{A}(x; \sigma, \delta, \varepsilon) \) is a square matrix of order 4 if \( |\sigma| \leq \sigma_c, \) and 2 if \( |\sigma| > \sigma_c. \) Notice that \( \mathbf{A}(x; \sigma, \delta, \varepsilon) \) is smooth and \( T(= 2\pi/k) \) periodic in \( x, \) and it depends analytically on \( \sigma, \delta \) and \( \varepsilon. \) Our proofs do not involve all the details of \( \mathbf{A}(x; \sigma, \delta, \varepsilon) \), and rather its leading order terms as \( \delta, \varepsilon \to 0, \) whence we do not include the formula here. But see, for instance, (5.9), (5.10) and (6.8), (6.9). By Floquet theory, if \( \mathbf{a} \) is a bounded solution of (4.25) then, necessarily,

\[
\mathbf{a}(x + T) = e^{ikT} \mathbf{a}(x) \quad \text{for some} \ k \in \mathbb{R}, \quad \text{where} \ T = 2\pi/\kappa
\]

is the period of a Stokes wave.

Following [10],[11] and others, we take a periodic Evans function approach.

**Definition 4.6** (The periodic Evans function). For \( \lambda = i\sigma + \delta, \ \sigma \in \mathbb{R}, \ \delta \in \mathbb{C} \) and \( |\delta| \ll 1, \) for \( \varepsilon \in \mathbb{R} \) and \( |\varepsilon| \ll 1, \) let \( \mathbf{X}(x; \sigma, \delta, \varepsilon) \) denote the fundamental matrix of (4.25) such that \( \mathbf{X}(0; \sigma, \delta, \varepsilon) = \mathbf{I}, \) where \( \mathbf{I} \) is the identity matrix. Let \( \mathbf{X}(T; \sigma, \delta, \varepsilon) \) be the *monodromy matrix* for (4.25), and for \( k \in \mathbb{R}, \)

\[
(4.26) \quad \Delta(\lambda, k; \varepsilon) = \text{det}(e^{ikT} \mathbf{I} - \mathbf{X}(T; \sigma, \delta, \varepsilon))
\]

the *periodic Evans function*, where \( T = 2\pi/\kappa \) is the period of a Stokes wave.

Since \( \mathbf{A}(x; \sigma, \delta, \varepsilon) \) depends analytically on \( \sigma, \delta \) and \( \varepsilon \) for any \( x \in \mathbb{R}, \) so do \( \mathbf{X}(T; \sigma, \delta, \varepsilon) \) and, hence, \( \Delta(\lambda, k; \varepsilon) \) depends analytically on \( \lambda, \ k \) and \( \varepsilon, \) where \( \lambda = i\sigma + \delta \) and \( k \in \mathbb{R}. \) By Floquet theory and [30] Theorem 1], for instance, for \( \varepsilon \in \mathbb{R} \) and \( |\varepsilon| \ll 1, \lambda \in \text{spec}(\mathcal{L}(\varepsilon)) \) if and only if

\[
\Delta(\lambda, k; \varepsilon) = 0 \quad \text{for some} \ k \in \mathbb{R}.
\]

See [10], for instance, for more details.

**Remark.** A Stokes wave of sufficiently small amplitude is spectrally stable if and only if

\[
\text{spec}(\mathcal{L}(\varepsilon)) = \{ \lambda \in \mathbb{C} : \Delta(\lambda, k; \varepsilon) = 0 \quad \text{for some} \ k \in \mathbb{R} \} \subset i\mathbb{R}
\]

for \( \varepsilon \in \mathbb{R} \) and \( |\varepsilon| \ll 1. \)

In what follows, we identify \( \text{spec}(\mathcal{L}(\varepsilon)) \) with the roots of the periodic Evans function.

One should not expect to be able to evaluate the periodic Evans function except for few cases, for instance, completely integrable PDEs. When \( \varepsilon \in \mathbb{R} \) and \( |\varepsilon| \ll 1, \) on the other hand, we shall use the result of Section 3 and determine (4.26) as \( \varepsilon \to 0. \)
4.5. **Computation of $\Pi(\sigma)$.** We begin by constructing the adjoint of $L(\lambda) : \text{dom}(L) \subset Y \to Y$.

For $u_1 := \begin{pmatrix} \phi_1 \\ v_1 \\ \eta_1 \end{pmatrix}$, $u_2 := \begin{pmatrix} \phi_2 \\ v_2 \\ \eta_2 \end{pmatrix} \in Y$, we define the inner product as

$$
(u_1, u_2) = \int_0^1 (\phi_1 \phi_2^* + \phi_1 y \phi_2 y^*) \, dy + \int_0^1 v_1 v_2^* \, dy + \eta_1 \eta_2^*,
$$

(4.27)

where the asterisk means complex conjugation. For $u_1 \in \text{dom}(L) \subset Y$ and $u_2 \in Y$,

$$
\langle L(\lambda)u_1, u_2 \rangle = \left\langle \begin{pmatrix} \lambda \phi_1 + \mu_0 v_1 \\ -\mu_0^{-1}(\phi_1 y_1 + \lambda^2 \phi_1 + \mu_0 \lambda v_1) \\ \lambda \eta_1 - \phi_1 y(1) \end{pmatrix}, \begin{pmatrix} \phi_2 \\ v_2 \\ \eta_2 \end{pmatrix} \right\rangle
$$

$$
= \int_0^1 (\phi_1 (\lambda^* \phi_2)^* + \phi_1 y (\lambda^* \phi_2 y)^* + \mu_0 v_1 \phi_2^* - \mu_0 v_1 \phi_2 y^*) \, dy
$$

$$
+ \int_0^1 (\mu_0^{-1} \phi_1 y v_2^* - \phi_1 (\mu_0^{-1} \lambda^* v_2)^* + v_1 (\lambda^* v_2)^*) \, dy
$$

$$
+ \mu_0 \eta_1 \eta_2^* (1) - \mu_0 v_1 (0) \phi_2 y^*(0) + \lambda \eta_1 \eta_2 - \phi_1 y (1) (\mu_0^{-1} \lambda^* v_2 (1) + \eta_2)^*
$$

$$
= \int_0^1 (\phi_1 (\lambda^* \phi_2)^* + \phi_1 y (\lambda^* \phi_2 y)^* - \phi_1 (\mu_0^{-1} \lambda^* v_2)^* + \mu_0^{-1} \phi_1 y v_2 y^*) \, dy
$$

$$
+ \int_0^1 (v_1 (\mu_0 \phi_2 - \mu_0 \phi_2 y)^* + v_1 (\lambda^* v_2)^*) \, dy + \lambda \eta_1 \eta_2 + \mu_0 \eta_1 \phi_2 y^*(1)
$$

$$
= \left\langle \begin{pmatrix} \phi_1 \\ v_1 \\ \eta_1 \end{pmatrix}, \begin{pmatrix} \lambda \phi_2 + \mu_0^{-1} v_2 \\ \mu_0 \phi_2 y(1) + \lambda^* \eta_2 \\ \mu_0 \phi_2 y^*(1) + \lambda^* \eta_2 \end{pmatrix} \right\rangle - \int_0^1 \mu_0^{-1} \phi_1 (1 + \lambda^* v_2)^* v_2 \, dy
$$

$$
= \left\langle \begin{pmatrix} \phi_1 \\ v_1 \\ \eta_1 \end{pmatrix}, \begin{pmatrix} \lambda \phi_2 + \mu_0^{-1} v_2 \\ \mu_0 \phi_2 y(1) + \lambda^* \eta_2 \\ \mu_0 \phi_2 y^*(1) + \lambda^* \eta_2 \end{pmatrix} \right\rangle + \left\langle \begin{pmatrix} \phi_1 \\ v_1 \\ \eta_1 \end{pmatrix}, \begin{pmatrix} \phi_p \\ \eta_p \end{pmatrix} \right\rangle =: \langle u_1, L(\lambda)^\dagger u_2 \rangle,
$$

where $L(\lambda)^\dagger$ denotes the adjoint of $L(\lambda)$. Here the first equality uses (4.9), and the second equality uses (4.27) and follows after integration by parts, because if $u_1 \in \text{dom}(L)$ then $\eta_1 = v_1 (1)$ and $\phi_1 y (0) = 0$ (see (4.11)). The third equality follows, provided that

$$
(4.28)
$$

$$
v_2 (1) + \mu_0 \eta_2 = 0 \quad \text{and} \quad \phi_2 y (0) = 0,
$$

so that the inner product is continuous with respect to $\phi_1 \in H^1(0, 1)$ and $v_1 \in L^2(0, 1)$ (see (4.10)), and the fourth equality uses (4.27). The fifth equality follows, provided that

$$
- \int_0^1 \mu_0^{-1} \phi_1 (1 + \lambda^* v_2)^* v_2 \, dy = \left\langle \begin{pmatrix} \phi_1 \\ v_1 \\ \eta_1 \end{pmatrix}, \begin{pmatrix} \phi_p \\ v_p \\ \eta_p \end{pmatrix} \right\rangle
$$

$$
= \int_0^1 \phi_1 \phi_p^* + \phi_1 y \phi_p y^* \, dy + \int_0^1 v_1 v_p^* \, dy + \eta_1 \eta_p^*
$$

$$
= \int_0^1 \phi_1 (\phi_p - \phi_p y y^*)^* \, dy + \phi_1 (1) \phi_p y^*(1) - \phi_1 (0) \phi_p y(0),
$$

14
where the last equality assumes that $v_p = 0$ and $\eta_p = 0$, because the left side does not depend on $v_1$ or $\eta_1$, and it follows after integration by parts. This works, provided that

$$
\begin{cases}
\phi_{py} - \phi_p = \mu_0^{-1}(1 + \lambda^* p) v_2 & \text{for } 0 < y < 1, \\
\phi_{py}(1) = 0, \\
\phi_{py}(0) = 0.
\end{cases}
$$

(4.29)

To recapitulate,

$$
L(\lambda)^\dagger : \text{dom}(L^\dagger) \subset Y \to Y,
$$

where

$$
L(\lambda)^\dagger u = \begin{pmatrix} \lambda^* \phi + \mu_0^{-1} u + \phi_p \\ \mu_0 \phi_y(1) + \lambda^* \eta \end{pmatrix},
$$

(4.30)

and

$$
\text{dom}(L^\dagger) = \{ u \in H^2(0,1) \times H^1(0,1) \times \mathbb{C} : v(1) + \mu_0 \eta = 0, \phi(0) = 0 \}. 
$$

Indeed, we solve (4.29) by variation of parameters, for instance, and evaluate the result at $v_2 = v$, to obtain (4.30). If $u \in \text{dom}(L^\dagger)$ then (4.28) holds. Clearly, $\text{dom}(L^\dagger)$ is dense in $Y$.

The spectrum of $L(i\sigma)^\dagger : \text{dom}(L^\dagger) \subset Y \to Y$ consists of discrete eigenvalues with finite multiplicities $\gamma \in \mathbb{C}$, say, and a straightforward calculation reveals that

$$
(\sigma - i\gamma)^2 = \mu_0(i\gamma) \tanh(i\gamma).
$$

Thus $\gamma = -ik$, where $ik$ is an eigenvalue of $L(i\sigma)^\dagger : \text{dom}(L) \subset Y \to Y$. Compare (4.15). Also, the corresponding eigenfunction is

$$
\begin{pmatrix}
-\frac{(1 - \sigma^2)(\gamma + i\sigma)}{\mu_0^2(\gamma^2 + 1)} u(1) \cosh(y) \sinh(1) + \frac{\gamma - i\sigma}{\mu_0(\gamma^2 + 1)} u(y) \\
\frac{1}{\mu_0} u(y) \\
\frac{1}{\mu_0} u(1)
\end{pmatrix},
$$

where $u$ satisfies

$$
u(y) = \left( -\frac{(\gamma + i\sigma)^2}{\mu_0} u(1) + (\gamma^2 + 1) \int_0^1 \cosh(1 - y) u(y) dy \right) \frac{\cosh(y)}{\sinh(1)} \\
\frac{- (\gamma^2 + 1) \int_0^y \sinh(y - y') u(y') dy'}{\cosh(y)}.
$$

When $\sigma = 0$, we infer from Lemma 4.3 that $-ik_j(0) = i(-1)^{j+1} \kappa$, $j = 1, 2$, are simple eigenvalues of $L(0)^\dagger : \text{dom}(L^\dagger) \subset Y \to Y$, and a straightforward calculation reveals that the corresponding eigenfunctions are

$$
\psi_j(0) = \begin{pmatrix}
\frac{i k_j(0) p_j}{\mu_0^2} \cosh(k_j(0)) \cosh(y) \sinh(1) - \mu_0 \cosh(k_j(0)y) \\
p_j \cosh(k_j(0)y) \\
- \frac{p_j}{\mu_0} \cosh(k_j(0))
\end{pmatrix},
$$

(4.31)

where

$$
p_j = -\frac{i \cosh(k_j(0))}{\cosh(k_j(0))^2 \sinh(k_j(0)) - \mu_0 \sinh(k_j(0))},
$$

(4.32)

so that $\langle \phi_j(0), \psi_{j'}(0) \rangle = \delta_{jj'}$, $j, j' = 1, 2$, where $\phi_j(0)$, $j = 1, 2$, are in (4.17).
Also, when $\sigma = 0$, $-ik_j(0) = 0$, $j = 3, 4$, is an eigenvalue of $L(0)^{\dagger}$ with algebraic multiplicity 2 and geometric multiplicity 1, by Lemma [4.1] and the corresponding eigenfunctions are

$$
\psi_3(0) = \begin{pmatrix}
\frac{0}{\mu_0 - 1} \\
\frac{0}{\mu_0 - 1} \\
\frac{1}{\mu_0 - 1}
\end{pmatrix}
$$

and

$$
\psi_4(0) = \begin{pmatrix}
\frac{1}{(\mu_0 - 1)\mu_0} & -\frac{\cosh(y)}{\sinh(1)} \\
\frac{0}{(\mu_0 - 1)\mu_0} & 0 \\
0 & 0
\end{pmatrix},
$$

whence $\langle \phi_j(0), \psi_{j'}(0) \rangle = \delta_{jj'}$, $j, j' = 3, 4$, where $\phi_j(0)$, $j = 3, 4$, are in (4.18). Notice that

$$
\langle \phi_j(0), \psi_{j'}(0) \rangle = \delta_{jj'}, \quad j, j' = 1, 2, 3, 4.
$$

Therefore,

$$
\Pi(0)u = \langle u, \psi_1(0) \rangle \phi_1(0) + \langle u, \psi_2(0) \rangle \phi_2(0) + \langle u, \psi_3(0) \rangle \phi_3(0) + \langle u, \psi_4(0) \rangle \phi_4(0).
$$

Clearly, $\Pi(0)$ commutes with $L(0)$.

**Remark.** The first entry of (4.31) appears to be not defined when $\kappa = 1$. On the other hand, recall (3.6) and a straightforward calculation leads to that

$$
limit \frac{\cosh(\kappa)\cosh(y) - \mu_0(\kappa)\cosh(\kappa y)}{1 - \kappa} = limit \frac{\cosh(\kappa)\cosh(y) - \kappa\cosh(\kappa)\cosh(\kappa y)}{1 - \kappa}
$$

$$
= \frac{\cosh(1)}{\sinh(1)^2}(\sinh(1)\cosh(y) - \cosh(1)\cosh(y) + y\sinh(1)\sinh(y))
$$

is well defined. Thus we may define $\psi_j(0) = \lim_{\kappa \to 1} \psi_j(0)$, $j = 1, 2$, when $\kappa = 1$, and verify that $\langle \phi_j(0), \psi_{j'}(0) \rangle = \delta_{jj'}$, $j, j' = 1, 2, 3, 4$.

When $\sigma > \sigma_c$, we infer from Lemma [4.4] that $-ik_j(\sigma)$, $j = 2, 4$, are simple eigenvalues of $L(i\sigma)^{\dagger}$, and a straightforward calculation reveals that the corresponding eigenfunctions are

$$
\psi_j(\sigma) = \begin{pmatrix}
p_{1,j}\cosh(y) + p_{2,j}\cosh(k_j(\sigma)y) \\
-ip_{0,0}p_{2,j}(k_j(\sigma)^2 - 1) \cosh(k_j(\sigma)y) \\
-ip_{2,j}(k_j(\sigma)^2 - 1) \cosh(k_j(\sigma)y)
\end{pmatrix},
$$

where

$$
p_{1,j} = \frac{2\cosh(k_j(\sigma))(\sigma^2 - 1)(k_j(\sigma) - \sigma)^2}{\mu_0^2\sinh(1)(k_j(\sigma)^2 - 1)(k_j(\sigma)\sinh(2k_j(\sigma)) + \sigma\sinh(2k_j(\sigma)) + 2k_j(\sigma)\sigma - 2k_j(\sigma)^2)},
$$

$$
p_{2,j} = \frac{2k_j(\sigma)^2 - 2\sigma^2}{\mu_0(k_j(\sigma)^2 - 1)(k_j(\sigma)\sinh(2k_j(\sigma)) + \sigma\sinh(2k_j(\sigma)) + 2k_j(\sigma)\sigma - 2k_j(\sigma)^2)},
$$

so that $\langle \phi_j(\sigma), \psi_{j'}(\sigma) \rangle = \delta_{jj'}$, $j, j' = 2, 4$, where $\phi_j(\sigma)$, $j = 2, 4$, are in (4.19). Thus

$$
\Pi(\sigma)u = \langle u, \psi_2(\sigma) \rangle \phi_2(\sigma) + \langle u, \psi_4(\sigma) \rangle \phi_4(\sigma).
$$

When $0 < \sigma \leq \sigma_c$, we proceed likewise to define $\Pi(\sigma)$. We do not include the formulae here.
5. The Benjamin–Feir Instability

Recall the notation of the previous section. When $\sigma, \delta = 0$ and $\varepsilon = 0$, (4.24) becomes $v_x = L(0)v$, and Lemma 4.4 says that

$$L(0)\phi_j(0) = ik_j(0)\phi_j(0), \quad k_j(0) = (-1)^j\kappa, \quad j = 1, 2,$$

and

$$L(0)\phi_3(0) = \phi_4(0), \quad L(0)\phi_4(0) = 0,$$

where $\phi_j(0), j = 1, 2, 3, 4$, are in (4.17) and (4.18). Thus the monodromy matrix (see Definition 4.6) becomes

$$X(T; 0, 0, 0) = \begin{pmatrix} e^{-i\kappa T} & 0 & 0 & 0 \\ 0 & e^{i\kappa T} & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & T & 1 \end{pmatrix} = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & T & 1 \end{pmatrix},$$

where $T = 2\pi/\kappa$ is the period of a Stokes wave. Correspondingly, the periodic Evans function (see (4.26)) becomes

$$\Delta(0, p\kappa; 0) = 0 \quad \text{for all } p \in \mathbb{Z}.$$ 

We shall examine the roots of $\Delta(\lambda, k; \varepsilon)$ for $(\lambda, k, \varepsilon)$ in the vicinity of $(0, p\kappa, 0), p \in \mathbb{Z}$, whereby reproducing the celebrated Benjamin–Feir instability for a Stokes wave of sufficiently small amplitude $\varepsilon$ (see also [3, 40]). Since $\Delta(\lambda, k; \varepsilon)$ depends analytically on $\lambda, k$ and $\varepsilon$, let

$$\lambda \in \mathbb{C} \quad \text{and} \quad |\lambda| \ll 1, \quad k = p\kappa + \gamma, p \in \mathbb{Z}, \gamma \in \mathbb{R} \quad \text{and} \quad |\gamma| \ll 1, \quad \varepsilon \in \mathbb{R} \quad \text{and} \quad |\varepsilon| \ll 1,$$

and let

$$\Delta(\lambda, p\kappa + \gamma; \varepsilon) = \sum_{\ell, m, n = 0}^{\infty} d(\ell, m, n)\lambda^\ell \gamma^m \varepsilon^n$$

as $\lambda, \gamma, \varepsilon \to 0$. Our effort goes into determining $d(\ell, m, n), \ell, m, n = 0, 1, 2, \ldots$.

5.1. Expansion of the monodromy matrix. Throughout the subsection, $\sigma = 0$. Let

$$(v_1 \ v_2 \ v_3 \ v_4)(x; \delta, \varepsilon) = (\phi_1(0) \ \phi_2(0) \ \phi_3(0) \ \phi_4(0)) X(x; 0, \delta, \varepsilon)$$

denote a fundamental matrix of (4.25), where $\phi_j(0), j = 1, 2, 3, 4$, are in (4.17) and (4.18), and $X(x; 0, \delta, \varepsilon)$ in Definition 4.6. We write

$$v_k(x; \delta, \varepsilon) = \sum_{j=1}^{4} \left( \sum_{m+n=0}^{\infty} a_{jk}^{(m,n)}(x)\delta^m \varepsilon^n \right)\phi_j(0)$$

as $\delta, \varepsilon \to 0$, where $a_{jk}^{(m,n)}(x), j, k = 1, 2, 3, 4$ and $m, n = 0, 1, 2, \ldots$, are to be determined. We pause to remark that $X(x; 0, \delta, \varepsilon)$ depends analytically on $\delta$ and $\varepsilon$ for any $x \in [0, T]$, for $\delta \in \mathbb{C}$ and $|\delta| \ll 1$ for $\varepsilon \in \mathbb{R}$ and $|\varepsilon| \ll 1$, whence (5.4) converges for any $x \in [0, T]$ as $\delta, \varepsilon \to 0$. Let

$$a_{jk}^{(m,n)}(x) = (a_{jk}^{(m,n)}(x))_{j,k=1,\ldots,4},$$

and we may assume that

$$a_{0,0}^{(0,0)}(0) = I \quad \text{and} \quad a_{mn}^{(m,n)}(0) = 0 \quad \text{for } m + n \geq 1.$$ 

Our task is to evaluate $a_{mn}^{(m,n)}(T)$, $m, n = 0, 1, 2, \ldots$. We write (4.23) as

$$w(x, v_k(x); 0, \delta, \varepsilon) = \sum_{m+n=1}^{\infty} w_{k}^{(m,n)}(x; 0)\delta^m \varepsilon^n$$

as $\delta, \varepsilon \to 0$, where $w_{k}^{(m,n)}(x; 0)$ is to be determined. We pause to remark that $w_{k}^{(m,n)}(x; 0)$ depends analytically on $\delta$ and $\varepsilon$ for any $x \in [0, T]$, for $\delta \in \mathbb{C}$ and $|\delta| \ll 1$ for $\varepsilon \in \mathbb{R}$ and $|\varepsilon| \ll 1$, whence (5.6) converges for any $x \in [0, T]$ as $\delta, \varepsilon \to 0$. Let

$$a_{mn}^{(m,n)}(x) = (a_{mn}^{(m,n)}(x))_{j,k=1,\ldots,4}.$$
as \( \delta, \varepsilon \to 0 \), where \( w^{(0,0)}_k(x;0) = 0 \), \( k = 1, 2, 3, 4 \), and \( w^{(m,n)}_k(x;0) \), \( k = 1, 2, 3, 4 \) and \( m + n \geq 1 \), are to be determined. Recall (4.21), and we write

\[
B(x;0,\delta,\varepsilon) = \sum_{m+n=1}^{\infty} B^{(m,n)}(x;0) \delta^m \varepsilon^n
\]
as \( \delta, \varepsilon \to 0 \), where \( B^{(0,0)}(x;0) = 0 \), and \( B^{(m,n)}(x;\sigma) \), \( 1 \leq m + n \leq 2 \), are in Appendix E. Notice that \( B^{(m,0)}(x;0) \), \( m \geq 1 \), do not involve \( x \).

Inserting (5.4), (5.6) and (5.7) into the former equation of (4.22), we recall Lemma 4.4 or, equivalently, (5.1) and (5.2), and make a straightforward calculation to obtain

\[
a^{(0,0)}(x) = \begin{pmatrix} e^{-i\kappa x} & 0 & 0 & 0 \\ 0 & e^{i\kappa x} & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & x & 1 \end{pmatrix},
\]
and for \( m + n \geq 1 \), we arrive at

\[
B^{(m,n)}(x;0) = \sum_{0 \leq m' \leq m} B^{(m',n')} \left( w^{(m-m',n-n')}_k(x;0) + \sum_{j=1}^{4} a^{(m-m',n-n')}_j \phi_j(0) \right).
\]

Inserting (5.4), (5.6) and (5.7) into the latter equation of (4.22), at the order of \( \delta^m \varepsilon^n \), \( m + n \geq 1 \), let \( w^{(m,n)}_k(x;0) \), by abuse of notation, and we arrive at

\[
\begin{align*}
\phi_{xx} + \phi_{yy} &= ((1 - \Pi(0))f^{(m,n)}_k(x;0))_1 + \mu_0((1 - \Pi(0))f^{(m,n)}_k(x;0))_2 \quad \text{for } 0 < y < 1, \\
v &= \mu_0^{-1} \phi_x - \mu_0^{-1}((1 - \Pi(0))f^{(m,n)}_k(x;0))_2 \quad \text{for } 0 < y < 1, \\
\eta_x &= -\phi_y + ((1 - \Pi(0))f^{(m,n)}_k(x;0))_3 \quad \text{at } y = 1, \\
\eta &= v \quad \text{at } y = 1, \\
\phi_y &= 0 \quad \text{at } y = 0.
\end{align*}
\]

Notice that since \( B^{(0,0)}(x;0) = 0 \), the right side of (5.10) does not involve \( w^{(m,n)}_k(x;0) \), and it is made up of lower order terms. Also notice that the fourth and fifth equations of (5.11) ensure that \( w^{(m,n)}_k(x;0) \in \text{dom}(L) \) (see (1.11)). Recall (4.17), (4.18) and (4.31), (4.32), (4.33). We use the result of Appendix E and solve the first and the last equations of (5.11) by the method of undetermined coefficients, for instance, subject to that \( w^{(m,n)}_k(x;0) \in (1 - \Pi(0))Y \), so that \( \Pi(0)w^{(m,n)}_k(x;0) = 0 \), to determine \( \phi \), and we determine \( u \) and \( \eta \) by the second and fourth equations of (5.11). The result is in Appendix E.

**Lemma 5.1.** We have \( a^{(0,n)}_{j4}(x) = 0 \) for \( j = 1, 2, 3, 4 \) for all \( n \geq 1 \).

**Proof.** By the change of unknown (4.3) for the spectral problem (4.2), we verify that the term \( B(x;\sigma,\delta,\varepsilon)\phi_4(0) \) in (4.21) is \( 0 \) for \( \sigma = \delta = 0 \), whence \( B^{(0,n)}(x;0)\phi_4(0) = 0 \) for all \( n \geq 1 \) by (5.7).
When \( n = 1 \), (5.10) leads to
\[
\begin{align*}
f_1^{(0,1)}(x;0) = B^{(0,1)}(x;0)\phi_4(0) &= 0
\end{align*}
\]
by (5.6) and (5.8), and we solve (5.9) and (5.5) to obtain \( a_j^{(0,1)}(x) = 0, 1 \leq j \leq 4 \). We in turn solve (5.11) to obtain \( w_4^{(0,1)}(x;0) = 0 \). The assertion then follows by the induction on \( n \), because \( f_1^{(0,n)}(x;0) = 0 \) for all \( n \geq 1 \).

\[\square\]

**Corollary 5.2** (Translational invariance). For \( \varepsilon \in \mathbb{R} \) and \( \varepsilon \ll 1 \), \( \Delta(0,p;\varepsilon) = 0, p \in \mathbb{Z} \).

**Proof.** Notice that \( \Delta(0,p;\varepsilon) = \text{det}(I - X(T;0,0,\varepsilon)) \), and Lemma 5.1 and (5.5) assert that the fourth column of \( I - X(T;0,0,\varepsilon) \) vanishes. \[\square\]

For \( m + n \geq 1 \), we rearrange (5.9) as
\[
(5.12) \quad \frac{d}{dx} \begin{pmatrix} a_{(m,n)}^{(1)}(x) \\ a_{(m,n)}^{(2)}(x) \\ a_{(m,n)}^{(3)}(x) \\ a_{(m,n)}^{(4)}(x) \end{pmatrix} = \begin{pmatrix} A(0) & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix} \begin{pmatrix} a_{(m,n)}^{(1)}(x) \\ a_{(m,n)}^{(2)}(x) \\ a_{(m,n)}^{(3)}(x) \\ a_{(m,n)}^{(4)}(x) \end{pmatrix} + \begin{pmatrix} F_{(m,n)}^{(1)}(x;0) \\ F_{(m,n)}^{(2)}(x;0) \\ F_{(m,n)}^{(3)}(x;0) \\ F_{(m,n)}^{(4)}(x;0) \end{pmatrix},
\]
where \( A(0) \) collects the coefficients of \( a_{(m,n)}^{(k)} \) on the right side, \( \psi_j(0) \), \( j = 1,2,3,4 \), are in (4.31), (4.32), and (4.33), and \( \langle , \rangle \) in (4.27). Recall from Section 4.5 that \( \langle \phi_j(0), \psi_{j'}(0) \rangle = \delta_{jj'}, j = 1,2,3,4 \). We write the solution of (5.12) and (5.5) symbolically as
\[
a_{(m,n)}^{(k)}(x) = e^{A(0)x} \int_0^x e^{-A(0)x'} F_{(m,n)}^{(k)}(x';0) \, dx'.
\]
Recalling the result of Appendix D and Appendix E, we make straightforward calculations to show that:
\[
\begin{align*}
a^{(1,0)}(T) &= \begin{pmatrix} 4\pi c^3 \\ 0 \\ 0 \\ 0 \end{pmatrix} \\
&= \begin{pmatrix} \mu_0 s(s^2 - \mu_0 + 1) \\ 0 \\ 0 \\ \frac{s^2 + 1}{\mu_0(\mu_0 - 1)s} \end{pmatrix},
\end{align*}
\]
\[
(5.13)
\]
and
\[
\begin{align*}
a^{(0,1)}(T) &= \begin{pmatrix} 4\pi c^3 \\ 0 \\ 0 \\ 0 \end{pmatrix} \\
&= \begin{pmatrix} \mu_0 s(s^2 - \mu_0 + 1) \\ 0 \\ 0 \\ \frac{s^2 + 1}{\mu_0(\mu_0 - 1)s} \end{pmatrix},
\end{align*}
\]
\[
(5.14)
\]
and
\[
\begin{align*}
a^{(2,0)}(T) &= \begin{pmatrix} a_{(2,0)}^{(1,1)} & 0 & 0 \\ 0 & a_{(2,0)}^{(2,0)} & 0 \\ a_{(2,0)}^{(3,0)} & a_{(2,0)}^{(4,0)} & 0 \\ 0 & 0 & a_{(2,0)}^{(5,0)} \end{pmatrix},
\end{align*}
\]
\[
(5.15)
\]
and
\[
\begin{align*}
a^{(1,1)}(T) &= \begin{pmatrix} a_{(1,1)}^{(1,1)} & a_{(1,1)}^{(2,1)} & a_{(1,1)}^{(3,1)} \\ a_{(1,1)}^{(1,1)} & a_{(1,1)}^{(2,1)} & a_{(1,1)}^{(3,1)} \\ a_{(1,1)}^{(1,1)} & a_{(1,1)}^{(2,1)} & 0 \\ a_{(1,1)}^{(1,1)} & a_{(1,1)}^{(2,1)} & a_{(1,1)}^{(3,1)} \end{pmatrix},
\end{align*}
\]
\[
(5.16)
\]
where
\[
\begin{align*}
a_{11}^{(2,0)} &= \frac{8\pi^2 e^6}{\mu_0^2 (\mu_0 - e^2)^2 (c^2 - 1)} + \frac{2\pi c^4 (c^4 + 4\mu_0^2 e^2 - 3\mu_0^2 - 2\mu_0 c^2)i}{\mu_0^3 (\mu_0 - c^2)^3 (c^2 - 1)}, \\
a_{31}^{(2,0)} &= \frac{4\pi (s^2 + 1)(s^2 - 3\mu_0 s^2 - 2\mu_0 + \mu_0^2 + 1)}{\mu_0 s (\mu_0 - 1)^2 (s^2 - \mu_0 + 1)}, \\
a_{34}^{(2,0)} &= \frac{2\pi c(e + s)}{\mu_0 + cs + c^2 - \mu_0 c^2 - \mu_0 cs - 1}, \\
a_{44}^{(2,0)} &= \frac{-2\pi^2 (s^2 + 1)}{\mu_0^2 s^2 (\mu_0 - 1)},
\end{align*}
\]
and
\[
\begin{align*}
a_{11}^{(1,1)} &= -\frac{2\pi (c + 2c^3)}{(\mu_0 - c^2)(\mu_0 - 1)}, \\
a_{14}^{(1,1)} &= \frac{2\pi (s^2 + 1)}{s^2 - \mu_0 + 1}, \\
a_{31}^{(1,1)} &= -\frac{2\pi i(4c^4 + 4sc^3 - 5c^2 - 3sc + 1)(-2c^4 \mu_0^2 - 4c^4 \mu_0 + 2c^4 + 3c^2 \mu_0^2 + 2c^2 \mu_0 - \mu_0^3)}{c(\mu_0 - 1)^2 (-c^2 + \mu_0)(-4c^3 - 4sc^2 + 3c + s)}.
\end{align*}
\]
Here and elsewhere, we employ the notation
\[
s = \sinh(\kappa) \quad \text{and} \quad c = \cosh(\kappa)
\]
wherever it is convenient to do so.

Our proof does not involve other entries of \(a^{(2,0)}(T)\) and \(a^{(1,1)}(T)\), whence we do not include the formulae here. We emphasize that \(a_{11}^{(2,0)}\) in (5.15) is the complex conjugate of \(a_{11}^{(2,0)}\). Additionally, we calculate that
\[a_{11}^{(0,2)}(T) = -i\mu_0 \pi (24s^2 - 21\mu_0 s^2 - 20\mu_0 s^4 - 8\mu_0 s^6 - 9\mu_0 + 40s^4 + 16s^6 + 15\mu_0^2 s^2 + 16\mu_0^2 s^4 + 8\mu_0^2 s^6 + 9\mu_0^2)(4(s^2 + 1)(\mu_0 - 1)(s^2 - \mu_0 + 1))^{-1},
\]
and
\[a_{ij}^{(0,2)}(T) = 0, \quad j = 1, 2, 3, 4.
\]
We remark that \(a_{jk}^{(m,n)}(T), 1 \leq m + n \leq 2\), suffices for the Benjamin–Feir instability.

5.2. The modulational instability index. Let
\[
\lambda \in \mathbb{C} \quad \text{and} \quad |\lambda| \ll 1, \quad k = pk + \gamma, \quad p \in \mathbb{Z}, \quad \gamma \in \mathbb{R} \quad \text{and} \quad |\gamma| \ll 1, \quad \varepsilon \in \mathbb{R} \quad \text{and} \quad |\varepsilon| \ll 1,
\]
and we turn the attention to (5.3). Putting together (5.5), (5.13), (5.14), (5.15), (5.16), (5.17), (5.18), (5.19), we arrive at
\[
\Delta(\lambda, pk + \gamma; \varepsilon) = d^{(4,0,0)} \lambda^4 + d^{(3,1,0)} \lambda \gamma + d^{(2,2,0)} \lambda^2 \gamma^2 + d^{(1,3,0)} \lambda^3 \gamma + d^{(0,4,0)} \gamma^4
\]
\[+ d^{(3,0,2)} \lambda^3 \varepsilon^2 + d^{(2,0,3)} \lambda^2 \varepsilon^3 + d^{(0,3,2)} \lambda \varepsilon^3 + d^{(0,2,3)} \varepsilon^3
\]
\[+ d^{(2,1,2)} \lambda^2 \gamma \varepsilon^2 + d^{(1,2,2)} \lambda \gamma^2 \varepsilon^2 + d^{(1,1,3)} \lambda \gamma \varepsilon^3 + d^{(1,0,5)} \lambda \varepsilon^5 + d^{(0,1,5)} \varepsilon^5
\]
\[+ o((|\lambda| + |\gamma|)^4 + |\lambda|^3 |\varepsilon|^2 + |\lambda|^2 |\varepsilon|^3 + |\lambda| |\varepsilon|^4 + |\gamma|^3 |\varepsilon|^3 + |\lambda| |\varepsilon|^5 + |\gamma| |\varepsilon|^5)
\]
as \(\lambda, \gamma, \varepsilon \to 0\), where \(d^{(\ell,m,n)}\), \(\ell, m, n = 0, 1, 2, \ldots\) can be determined in terms of \(a_{jk}^{(m,n)}(T)\), \(j, k = 1, 2, 3, 4\) and \(m, n = 0, 1, 2, \ldots\), where \(T = 2\pi / \kappa\) is the period of a Stokes wave. We may regard \(a_{jk}^{(m,n)}(T)\) and, hence, \(d^{(\ell,m,n)}\) as functions of \(T\) or, equivalently, \(\kappa\). Below we suppress \(T\) for the simplicity of notation. We remark that \(d^{(0,m,n)} = 0\) when \(\lambda^4 \gamma^m e^n\) is of lower order than
\[
(\lambda + \gamma)^4, \lambda^3 \varepsilon^2, \lambda^2 \varepsilon^3, \gamma^3 \varepsilon^2, \gamma^2 \varepsilon^3, \lambda \gamma \varepsilon^2 (\lambda + \gamma + \varepsilon), \lambda e^5, \gamma e^5.
\]
When $\varepsilon = 0$, we deduce from Section 4.3 that $\Delta(i\sigma(k), k; 0) = 0$ for any $k \in \mathbb{R}$, where $\sigma$ is in (4.15). Particularly, $\Delta(\lambda_j(k_j(0), 0), k_j(0); 0) = 0$, $j = 1, 2, 3, 4$, where

$$k_j(0) = (-1)^j \kappa \quad \text{for } j = 1, 2, \quad k_j(0) = 0 \quad \text{for } j = 3, 4.$$ 

In other words, $\lambda = 0$ and $k = k_j(0)$, $j = 1, 2, 3, 4$, are the four roots of $\Delta(\cdot, \cdot; 0) = 0$. For $\gamma, \varepsilon \in \mathbb{R}$ and $|\gamma|, |\varepsilon| \ll 1$, we are interested in determining $\lambda_j(k_j(0) + \gamma, \varepsilon)$ such that

$$\lambda_j(k_j(0) + 0, 0) = 0 \quad \text{and} \quad \Delta(\lambda_j(k_j(0) + \gamma, \varepsilon), k_j(0) + \gamma; \varepsilon) = 0$$

as $\gamma, \varepsilon \to 0$.

Let

$$\lambda_j(k_j(0) + \gamma, \varepsilon) = \alpha_j^{(1,0)}(0) + \alpha_j^{(2,0)}(0)^2 + \alpha_j^{(1,1)}(0)\varepsilon + o(|\gamma|^2 + |\gamma|\varepsilon), \quad j = 1, 2, 3, 4,$$

as $\gamma, \varepsilon \to 0$, where $\alpha_j^{(1,0)}(0), \alpha_j^{(2,0)}(0), \alpha_j^{(1,1)}(0)$, $j = 1, 2, 3, 4$, are to be determined in terms of $d^{(\ell,m,n)}$, hence, $a_j^{(m,n)}$, $j,k = 1, 2, 3, 4$ and $m,n = 0, 1, 2, \ldots$. We pause to remark about the form of (5.22).

When $\varepsilon = 0$, $\sigma(k_j(0) + \gamma)$, where $\sigma$ is in (4.15), admit power series expansions about $\gamma = 0$, and they must agree with

$$\lambda_j(k_j(0) + \gamma, 0) = \alpha_j^{(1,0)}(0) + \alpha_j^{(2,0)}(0)^2 + \ldots$$

for $|\gamma| \ll 1$. Also, Corollary 5.2 says that $\lambda = 0$ is a root of $\Delta(\cdot, p; \varepsilon)$ for all $p \in \mathbb{Z}$ for $\varepsilon \in \mathbb{R}$ and $|\varepsilon| \ll 1$. Let $n \neq 0$ be the smallest for which $\gamma^m \varepsilon^n$ appears in (5.22) for some $m \neq 0$. Inserting

$$\lambda_j(k_j(0) + \gamma, \varepsilon) = \alpha_j^{(m,n)}(0)^m \varepsilon^n + \alpha_j^{(1,0)}(0)\gamma + \alpha_j^{(2,0)}(0)^2 \gamma^2 + \ldots$$

into (5.20), upon inspection, we obtain $m = n = 1$.

Substituting (5.22) into (5.20), after straightforward calculations, we learn that $\gamma^4$ is the leading order whose coefficient reads

$$d^{(4,0)}(0)^4 + d^{(3,1)}(0)^3 + d^{(2,2)}(0)^2 + d^{(1,3)}(0) + d^{(0,4)} = -\left(-a_{11}^{(1,0)}(0) + iT\right)^2 \left((Ta_{34}^{(2,0)} - a_{33}^{(1,0)}a_{44}^{(1,0)})^2 + 4T(a_{33}^{(1,0)} + a_{44}^{(1,0)})^2 + T^2,\right),$$

where $a_{11}^{(1,0)}, a_{33}^{(1,0)}, a_{44}^{(1,0)}, a_{34}^{(2,0)}$ are in (5.13) and (5.16). Solving the latter equation of (5.21) at the order of $\gamma^4$, (5.23) must vanish, whence

$$\alpha_j^{(1,0)} = \frac{iT}{a_{11}^{(1,0)}} \quad \text{or} \quad \alpha_j^{(1,0)} = \frac{iT}{a_{33}^{(1,0)}} + \frac{iT}{a_{44}^{(1,0)}} \pm T \sqrt{\frac{a_{33}^{(1,0)^2} + 2a_{33}^{(1,0)}a_{44}^{(1,0)} - (a_{44}^{(1,0)})^2}{2(Ta_{34}^{(2,0)} - a_{33}^{(1,0)}a_{44}^{(1,0)})}}.$$

Notice that $\alpha_j^{(1,0)}, j = 1, 2, 3, 4$, are purely imaginary by (5.13) and (5.16). On the other hand, (5.24) must agree with power series expansions of (4.16) about $k_j(0), j = 1, 2, 3, 4$. Thus

$$\alpha_j^{(1,0)} = \frac{iT}{a_{11}^{(1,0)}} \quad \text{for } j = 1, 2,$$

and the latter equation of (5.24) holds for $j = 3, 4$.

Substituting (5.22) and (5.25) into (5.20), after straightforward calculations, we verify that the $\gamma^5$ term vanishes, and solving at the order of $\gamma^6$, we arrive at

$$\alpha_j^{(2,0)} = \pm \frac{T^2(-a_{11}^{(1,0)}a_{44}^{(1,0)})}{2(a_{11}^{(1,0)})^3}, \quad j = 1, 2,$$
where \(a_{11}^{(1,0)}\) and \(a_{11}^{(2,0)}\) are in (5.13) and (5.16). We remark that \(\alpha_{j}^{(2,0)}, j = 1, 2,\) are purely imaginary because \((a_{11}^{(1,0)})^2\) offsets the real part of \(2a_{11}^{(2,0)}\). The \pm signs explain the oppositeness of the convexity of the curves (1.16) at \(k_{j}(0), j = 1, 2\). See Figure 1.

To proceed, substituting (5.22) and (5.25), (5.26) into (5.20), after straightforward calculations, we verify that the \(\gamma^{3}\varepsilon^{2}\) term vanishes, and the coefficient of \(\gamma^{4}\varepsilon^{2}\) reads

\[
(5.27) \quad f_1(\alpha_{j}^{(1,1)})^2 = \frac{T^4(2a_{11}^{(2,0)} - (a_{11}^{(1,0)})^2)}{(a_{11}^{(1,0)})^4} f_2,
\]

where

\[
(5.28) \quad f_1 = T^2(Ta_{34}^{(2,0)} + a_{11}^{(1,0)} a_{33}^{(1,0)} + a_{11}^{(1,0)} a_{44}^{(1,0)} - a_{33}^{(1,0)} a_{44}^{(1,0)} - (a_{11}^{(1,0)})^2),
\]

\[
(5.28) \quad f_2 = a_{11}^{(0,2)}(a_{11}^{(1,0)})^2 - Ta_{11}^{(0,2)} a_{34}^{(2,0)} + Ta_{11}^{(1,1)} a_{31}^{(1,1)} - a_{11}^{(0,2)} a_{11}^{(1,0)} a_{33}^{(1,0)}
\]

\[
+ a_{11}^{(1,0)} a_{44}^{(1,0)} - a_{11}^{(1,0)} a_{44}^{(1,0)} + a_{11}^{(1,0)} a_{44}^{(1,0)} + a_{11}^{(1,0)} a_{33}^{(1,0)} a_{44}^{(1,0)}
\]

\[
- a_{33}^{(1,0)} a_{44}^{(1,0)} + a_{13}^{(1,0)} a_{44}^{(1,0)} - a_{11}^{(1,0)} a_{44}^{(1,0)} - a_{11}^{(1,0)} a_{33}^{(1,0)} a_{44}^{(1,0)},
\]

and \(a_{jk}^{(m,n)}\) is in the previous subsection.

**Theorem 5.3** (Spectral instability near \(0 \in C\)). A \(2\pi/\kappa\) periodic Stokes wave of sufficiently small amplitude is spectrally unstable in the vicinity of \(0 \in C\) provided that \(\text{ind}_1(\kappa) > 0\), where

\[
(5.29) \quad \text{ind}_1(\kappa) = 8 \cosh(2\kappa) + 24\kappa \sinh(2\kappa) + 2\kappa \sinh(4\kappa) + 19 \cosh(2\kappa)^2 - 8 \cosh(2\kappa)^3
\]

\[
- 10 \cosh(2\kappa)^4 - 8\kappa^2 \cosh(2\kappa)^2 - 28\kappa^2 + 8\kappa \cosh(2\kappa)^3 \sinh(2\kappa) - 9.
\]

**Proof.** Solving the latter equation of (5.21), \(j = 1, 2\), at the order of \(\gamma^{4}\varepsilon^{2}\), (5.27) must vanish, whence

\[
(5.30) \quad \alpha_{j}^{(1,1)} = \pm \sqrt{\frac{T^4(2a_{11}^{(2,0)} - (a_{11}^{(1,0)})^2)}{(a_{11}^{(1,0)})^4} f_2}
\]

where \(f_1\) and \(f_2\) are in (5.28), and \(\alpha_{j}^{(1,1)} \in \mathbb{R}\) implies spectral instability. We recall the result of the previous subsection and make straightforward calculations to show that

\[
(5.31) \quad f_2 = \frac{i\pi^3(s^2 + 1)^2}{4s^4(\mu_0 - 1)(s^2 - \mu_0 + 1)^3} \text{ind}_1(\kappa),
\]

where \(\text{ind}_1(\kappa)\) is in (5.29), and that (5.30) is real if \(\text{ind}_1(\kappa) > 0\). This completes the proof. \(\square\)

Numerical evaluation reveals that \(\text{ind}_1(\kappa)\) has only one zero at \(\kappa = \kappa_{c} \approx 1.362782756726421\) and \(\text{ind}_1(\kappa) > 0\) if \(\kappa > \kappa_{c}\).

**Corollary 5.4** (The Benjamin–Feir instability). A \(2\pi/\kappa\) periodic Stokes wave of sufficiently small amplitude is spectrally unstable if \(\kappa > \kappa_{c}\), where \(\kappa_{c}\) is the unique zero of (5.29) and \(\kappa_{c} \approx 1.3628\).

Since \(\mu_0\) is a monotonically increasing function of \(\kappa\) (see (4.9)), we may regard \(\text{ind}_1(\mu_0)\) as a function of \(\mu_0\). Numerical evaluation reveals that \(\text{ind}_1(\mu_0) = 0\) when \(\mu_0 \approx 1.553848798953821\). Also, we may regard \(\text{ind}_1\) as a function of \(F := 1/\sqrt{\mu_0}\), where \(F\) is the Froude number in the linear limit (see (2.3)). Numerical evaluation reveals that \(\text{ind}_1(\mu_0) = 0\) when \(F \approx 0.802223946850146\). Moreover, comparing (5.29) with the index \(\nu(F)\) of [4, (6.17)], we verify that

\[
\nu(F) = -\frac{\mu_0 \text{ind}_1(\kappa)}{32s^4(2s^2 - 6\mu_0s^2 - 4\mu_0s^4 - 2\mu_0 + s^4 + \mu_0^2 + 1)},
\]
where $s = \sinh(\kappa)$. Therefore, Corollary 5.4 agrees with [4, Theorem 2]. We remark that $\nu(F)$ is the same as those functions in [3, pp.68] and [10] (57), (58), among others.

Figure 2 shows schematic plots of (5.22), $j = 1, 2$, for $\lambda \in \mathbb{C}$ and $|\lambda| \ll 1$ for $\gamma, \varepsilon \in \mathbb{R}$ and $|\gamma|, |\varepsilon| \ll 1$ when $\kappa > \kappa_c$, namely, the spectral curves in the vicinity of $0 \in \mathbb{C}$ for $|k \pm \kappa| \ll 1$ and $|\varepsilon| \ll 1$ when the Benjamin–Feir instability occurs. On the left, there are two curves in the first quadrant, where $\text{Re}\lambda > 0$ and $\text{Im}\lambda > 0$, and they extend in other quadrangles by symmetry (see Lemma 4.3). We expect that each curve in the first quadrant will make a closed loop, one “figure-8” and one “figure-\infty”. The middle panel shows the figure-8 curve, corresponding to $\sigma_-(k)$, $k > k_2(0) = \kappa$, and the right panel shows the figure-\infty curve, corresponding to $\sigma_+(k)$, $k > k_1(0) = -\kappa$. Numerical studies (see [7, Figure 7], for instance, among others) reveal the figure-8 curve but not the figure-\infty curve, to the best of our knowledge. Perhaps this is because the figure-\infty curve is much smaller in size than the figure-8 for $|\varepsilon| \ll 1$. Indeed, we infer from (5.25), (5.26), (5.30) that

$$\text{Re}(\alpha_j^{(1,0)}(1) \gamma + \alpha_j^{(2,0)}(\gamma \gamma^2 + \alpha_j^{(1,1)}(\gamma \varepsilon)) = \alpha_j^{(1,1)}(\gamma \varepsilon) =: x,$$

$$\text{Im}(\alpha_j^{(1,0)}(1) \gamma + \alpha_j^{(2,0)}(\gamma \gamma^2 + \alpha_j^{(1,1)}(\gamma \varepsilon)) = -i \alpha_j^{(1,0)}(\gamma) - i \alpha_j^{(2,0)}(\gamma^2) =: y$$

as $\gamma, \varepsilon \to 0$, whence (5.22) makes a parabolic shape

$$y = -\frac{i \alpha_j^{(2,0)}}{(\alpha_j^{(1,1)}(\gamma \varepsilon)^2 \alpha_j^{(1,1)}(\gamma \varepsilon)} x^2 - \frac{i \alpha_j^{(1,0)}}{\alpha_j^{(1,1)}(\gamma \varepsilon)} x$$

as $\gamma, \varepsilon \to 0$. Notice that the axis of symmetry at $x = \frac{\alpha_j^{(1,0)}(1)}{2 \alpha_j^{(2,0)}}$ approaches the imaginary axis as $\varepsilon \to 0$ while the parabola opens up wider as $\varepsilon \to 0$.

6. The spectrum away from the origin

We turn the attention to the spectrum away from $0 \in \mathbb{C}$.

Recall from Section 4.3 that

$$\text{spec}(\mathcal{L}(0)) = \{i\sigma : \sigma \in \mathbb{R} \text{ and } (\sigma - k)^2 = \mu_k \text{ tanh}(k) \text{ for some } k \in \mathbb{R}\}.$$

Recall that $k_2(\sigma) > 0$ is the simple root of $\sigma_-(k) = \sigma \geq 0$, $k_4(\sigma) \geq 0$ the simple root of $\sigma_+(k) = \sigma > 0$, and $k_4(0) = 0$. Recall that $0 \leq k_4(\sigma) < k_2(\sigma)$. See Figure 1. Numerical investigations (see [7,9,28], among others) report spectral instability in the vicinity of $i\sigma \in \mathbb{C}$ when

$$k_2(\sigma) - k_4(\sigma) = r\kappa$$

for some $r > 0, \in \mathbb{Z}$,

where $\kappa > 0$ is the wave number of a Stokes wave. Also, in view of Hamiltonian systems, MacKay and Saffman [26] argued that (6.1) is a necessary condition of spectral instability. We shall make
rigorous analysis to elucidate the numerical findings and, in the process, to give the first proof of spectral instability of a Stokes wave away from 0 ∈ ℂ.

When σ = 0, recall from Section 4.3 that k₂(0) = κ and k₄(0) = 0, whence (6.1) holds for r = 1. Also, k₁(0) = −κ and k₂(0) = 0. Theorem 5.3 addresses spectral instability near i0 ∈ ℂ.

We verify that k₂(σ) − k₄(σ) is a monotonically increasing function of σ ≥ 0, and k₂(σ) − k₄(σ) → ∞ as σ → ∞. See Figure 1. Also, numerical evaluation reveals that κ < k₂(σ) − k₄(σ) < 2κ, where σ_c is the critical value of σ. Thus, when 0 < σ ≤ σ_c, (6.1) does not hold for any r > 0, ∈ Z. Also, 0 ≤ k₃(σ) − k₁(σ) < κ. See Figure 1. When σ > σ_c, on the other hand, there are

σ_c < σ₂ < · · · < σ_r < · · · → ∞ as r → ∞,

for which k₂(σ_r) − k₄(σ_r) = rκ.

In what follows, let σ > σ_c. The result of Lemma 4.4 leads to that

\[ \Delta(iσ, kj(σ) + pk; 0) = 0, \quad j = 2, 4, \quad \text{for all } p \in ℤ. \]

We shall proceed as in the previous section and examine the roots of \( \Delta(\lambda, k; ε) \) for \( (λ, k, ε) \) in the vicinity of \( (iσ, kj(σ) + pk, 0) \), j = 2, 4 and \( p \in ℤ \). We begin by determining the monodromy matrix.

6.1. Expansion of the monodromy matrix. Throughout the subsection, σ > σ_c. Let

\[ \begin{pmatrix} v_1 & v_2 \end{pmatrix} (x; σ, δ, ε) = \begin{pmatrix} \phi_2(σ) & \phi_4(σ) \end{pmatrix} X(x; σ, δ, ε) \]

denote a fundamental matrix of (1.25), where \( \phi_j(σ) \), j = 2, 4, are in (1.19) and \( X(x; σ, δ, ε) \) in Definition 4.6. We write

\[ v_k(x; σ, δ, ε) = \sum_{j=1}^{2} \left( \sum_{m+n=0}^{∞} a^{j,m,n}_{jk}(x) δ^m ε^n \right) φ_{2j}(σ) \]

as δ, ε → 0, where \( a^{j,m,n}_{jk}(x) \), j, k = 1, 2 and m, n = 0, 1, 2, . . . , are to be determined. Let

\[ a^{m,n}(x) = (a^{m,n}_{jk}(x))_{j,k=1,2}, \]

and we may assume that

\[ a^{(0,0)}(0) = I \quad \text{and} \quad a^{(m,n)}(0) = 0 \quad \text{for } m + n \geq 1. \]

Our task is to evaluate \( a^{m,n}(T) \), m, n = 0, 1, 2, . . . . We write (1.23) as

\[ w(x, v_k(x); σ, δ, ε) = \sum_{m+n=1}^{∞} w^{m,n}_{k}(x; σ) δ^m ε^n \]

as δ, ε → 0, where \( w^{(0,0)}(x; σ) = 0 \), k = 1, 2, and \( w^{(m,n)}(x; σ), k = 1, 2 \) and \( m + n \geq 1 \), are to be determined. Recall (1.21) and we write

\[ B(x; σ, δ, ε) = \sum_{m+n=1}^{∞} B^{m,n}(x; σ) δ^m ε^n \]

as δ, ε → 0, where \( B^{(0,0)}(x, σ) = 0 \), and \( B^{(m,n)}(x; σ), 1 \leq m + n \leq 2 \), are in Appendix D. Notice that \( B^{(m,0)}(x, σ), m \geq 1 \), do not involve x.

Inserting (6.3), (6.5) and (6.6) into the former equation of (1.22), we recall Lemma 4.4 and make a straightforward calculation to obtain

\[ a^{(0,0)}(x) = \begin{pmatrix} e^{ik_2(σ)x} & 0 \\ 0 & e^{ik_4(σ)x} \end{pmatrix}, \]
and for \( m + n \geq 1 \), we arrive at

\[
(6.8) \quad \sum_{j=1}^{2} \left( \frac{d}{dx} a^{(m,n)}_{jk} \right) \phi_{2j}(\sigma) = i k_2(\sigma) a^{(m,n)}_{1k} \phi_2(\sigma) + i k_4(\sigma) a^{(m,n)}_{2k} \phi_4(\sigma) + \Pi(\sigma) f^{(m,n)}_k(x; \sigma),
\]

where \( \Pi(\sigma) \) is in (4.37) and

\[
(6.9) \quad f^{(m,n)}_k(x; \sigma) = \sum_{0 \leq m' \leq m, 0 \leq n' \leq n} B^{(m',n')}(x; \sigma) (w_k^{(m-m',n-n')}(x; \sigma) + \sum_{j=1}^{2} a^{(m-m',n-n')}_{jk} \phi_{2j}(\sigma)).
\]

Inserting (6.3), (6.5) and (6.6) into the latter equation of (4.22), at the order of \( \delta^m e^n, m + n \geq 1 \), we arrive at (4.11), where \( \Pi(\sigma) \) (see 4.37) replaces \( \Pi(0) \), and (6.9) replaces \( f^{(m,n)}_k(x; \sigma) \). Notice that since \( B^{(0,0)}(x; \sigma) = 0 \), the right side of (6.9) does not involve \( w_k^{(m,n)}(x; \sigma) \), and it is made up of lower order terms. We solve this, as we do (4.11), to determine \( w_k^{(m,n)}(x; \sigma) \). The result is in Appendix E. We pause to remark that we use the Symbolic Math Toolbox in Matlab for extremely long and tedious algebraic manipulations.

For \( m + n \geq 1 \), we write the solution of (6.8) and (6.4) as (6.10)

\[
a^{(m,n)}_{jk}(x) = e^{ik_2(\sigma)x} \int_{0}^{x} e^{-ik_2(\sigma)x'} f^{(m,n)}_k(x'; \sigma, \psi_{2j}(\sigma)) \, dx'
\]

\[
= e^{ik_2(\sigma)x} \sum_{0 \leq m' \leq m, 0 \leq n' \leq n} \int_{0}^{x} e^{-ik_2(\sigma)x'} B^{(m',n')}(x'; \sigma) (w_k^{(m-m',n-n')}(x'; \sigma)
\]

\[
+ \sum_{j'=1}^{2} a^{(m-m',n-n')}_{jk} \phi_{2j'}(\sigma)) \, dx', \psi_{2j}(\sigma)\),
\]

where \( \phi_{2j}(\sigma) \) and \( \psi_{2j}(\sigma), \; j = 1, 2, \) are in (4.19) and (4.35), (4.36), and \( \langle , \rangle \) in (4.27). When \( m' = m \) and \( n' = n \), for instance, we recall (6.5) and (6.7), and the integral on the right side of (6.10) becomes (6.11)

\[
\int_{0}^{x} e^{-ik_2(\sigma)x'} B^{(m,n)}(x'; \sigma) e^{ik_2(\sigma)x} \phi_{2j'}(\sigma) \, dx' = \int_{0}^{x} e^{i(k_2(\sigma)-k_{2j'}(\sigma)x} B^{(m,n)}(x'; \sigma) \phi_{2j'}(\sigma) \, dx'.
\]

We deduce from the result of Appendix A, Appendix D and (4.19), (4.35) that \( B^{(m,n)}(x; \sigma) \phi_{2j'}(\sigma), \; j' = 1, 2, \) are made up of \( \sin(pkx) \) or \( \cos(pkx) \) with respect to \( x, \; p > 0, \in \mathbb{Z} \), and

\[
\int_{0}^{x} e^{i(k_2(\sigma)-k_{2j'}(\sigma)x} \sin(pkx') \, dx'
\]

\[
= \left\{ \begin{array}{ll}
\frac{pk - pk \cos(pkx)e^{i(k_2-j_{2j})(\sigma)x} + i(k_2_{2j} - k_{2j}) \sin(pkx)e^{i(k_2-j_{2j})(\sigma)x}}{p^2k^2 - (k_2 - k_{2j})^2} & \text{if } |k_2 - k_{2j}| \neq pk, \\
\pm i \frac{x}{2} + \frac{1 - e^{\pm 2i\pi pk}}{4pk} & \text{if } k_2 - k_{2j} = \pm pk,
\end{array} \right.
\]

for instance. Thus the result is different, depending on whether (6.11) holds or not. When \( 0 \leq m' \leq m, 0 \leq n' \leq n \) and \( m' + n' \neq m + n \), likewise, we deduce from the result of Appendix A, Appendix D and Appendix E that \( B^{(m',n')}(x; \sigma)w_k^{(m-m',n-n')}(x; \sigma) \) are made up of \( \sin(pkx) \) or \( \cos(pkx) \) with respect to \( x, \; p > 0, \in \mathbb{Z} \), and the integral on the right side of (6.10) can be treated as we do for (6.11) and (6.12). Therefore, the result of (6.10) is different, depending on whether (6.11) holds or not.
In what follows, we focus the attention to $k_2(\sigma) - k_4(\sigma) = \kappa$ for some $r \geq 2, \in \mathbb{Z}$, where $\kappa > 0$ is the wave number of a Stokes wave, for which it turns out that spectral instability is possible in the vicinity of $i\sigma \in \mathbb{C}$. We write $k_2 = k_2(\sigma)$ and $k_4 = k_4(\sigma)$, for the simplicity of notation.

**Lemma 6.1.** If (6.1) holds then

\[
(6.13) \quad a^{(0,0)}(T) = e^{ik_2 T} \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}, \quad a^{(1,0)}(T) = \begin{pmatrix} a_{11}^{(1,0)} & 0 \\ 0 & a_{22}^{(1,0)} \end{pmatrix}, \quad a^{(0,1)}(T) = \begin{pmatrix} 0 & 0 \\ 0 & 0 \end{pmatrix},
\]

where $a_{jj}^{(1,0)} \neq 0, j = 1, 2$.

**Proof.** If (6.1) holds then we evaluate (6.7) at $x = T$ and verify the first equation of (6.13).
A straightforward calculation reveals that

\[
(6.14) \quad a_{11}^{(1,0)}(x) = \frac{2k_2 s_2(2)}{k_2 s_2(2) + \sigma s_2(2) + 2k_2 \sigma - 2k_2^2 x e^{ik_2 x}},
\]

\[
a_{12}^{(1,0)}(x) = a_{12,c}^{(1,0)}(e^{ik_2 x} - e^{ik_4 x}),
\]

\[
a_{21}^{(1,0)}(x) = a_{21,c}^{(1,0)}(e^{ik_4 x} - e^{ik_2 x}),
\]

\[
a_{22}^{(1,0)}(x) = \frac{2k_4 s_4(2)}{k_4 s_4(2) + \sigma s_4(2) + 2k_4 \sigma - 2k_4^2 x e^{ik_4 x}},
\]

where

\[
a_{12,c}^{(1,0)} = \frac{-k_2 k_4^2 c_4 s_2 + k_2^2 k_4 c_4 s_4 + 2k_2^2 k_4 c_4 s_4 - k_2 \sigma^2 c_4 s_4 + k_4 \sigma^2 c_4 s_4 - 2k_2 k_4 \sigma c_4 s_4 - 2k_2 k_4 \sigma c_4 s_2}{\kappa (k_2 + k_4)(k_2 - \sigma)(k_2 s_2(2) + \sigma s_2(2) + 2k_2 \sigma - 2k_2^2)}
\]

\[
a_{21,c}^{(1,0)} = \frac{2k_2 k_4^2 c_4 s_2 + k_2^2 k_4 c_4 s_4 + 2k_2^2 k_4 c_4 s_4 + k_2 \sigma^2 c_4 s_4 - 2k_2 k_4 \sigma c_4 s_4 + 2k_2 k_4 \sigma c_4 s_2}{\kappa (k_2 + k_4)(k_4 - \sigma)(k_4 s_4(2) + \sigma s_4(2) + 2k_4 \sigma - 2k_4^2)}
\]

Here and elsewhere, we use the notation

\[
s_2 = \sinh(k_2), \quad c_2 = \cosh(k_2), \quad s_2(2) = \sinh(2k_2),
\]

\[
s_4 = \sinh(k_4), \quad c_4 = \cosh(k_4), \quad s_4(2) = \sinh(2k_4).
\]

If (6.1) holds then we evaluate (6.13) at $x = T$ and obtain the second equation of (6.13). If (6.1) does not hold for any $r \geq 2, \in \mathbb{Z}$, then $a_{jk}^{(0,0)}(T) \neq 0, j, k = 1, 2$.

When $m = 0$ and $n = 1$, we rewrite (6.10) as

\[
a_{jj}^{(0,1)}(T) = e^{ik_2 T} \left( \int_0^T e^{-ik_2 x} B^{(0,1)}(x; \sigma) e^{ik_2 x} \phi_{2j}(\sigma) \ dx, \psi_{2j}(\sigma) \right)
\]

\[
= e^{ik_2 T} \left( \int_0^T B^{(0,1)}(x; \sigma) \phi_{2j}(\sigma) \ dx, \psi_{2j}(\sigma) \right).
\]

We deduce from (1.2), (3.3) and (4.19) that $B^{(0,1)}(x; \sigma) \phi_{2j}(\sigma), j = 1, 2$, depends linearly on $\sin(\kappa x)$ and $\cos(\kappa x)$, whence it vanishes after the integration over one period. Thus $a_{jj}^{(0,1)}(T) = 0, j = 1, 2$. 

26
On the other hand,
\[ a_{12}^{(0,1)}(T) = e^{ik_1T} \left\langle \int_0^T e^{i(k_2 - k_1)x} B^{(0,1)}(x; \sigma) \phi_2(\sigma) \, dx, \psi_4(\sigma) \right\rangle. \]

If (6.1) holds then we deduce that \( e^{i(k_2 - k_1)x} B^{(0,1)}(x; \sigma) \phi_2(\sigma) \) depends linearly on \( e^{ir\kappa x} \sin(\kappa x) \) and \( e^{ir\kappa x} \cos(\kappa x) \), whence we proceed as in the former of (6.12), and it vanishes after the integration over one period. Likewise, \( a_{21}^{(0,1)}(T) = 0 \). Indeed, a straightforward calculation leads to
\[ a_{jk}^{(0,1)}(x) = c_{jk,1} e^{i(k_2 + \kappa)x} + c_{jk,2} e^{i(k_2 - \kappa)x} - (c_{jk,1} + c_{jk,2}) e^{ik_{21}x} \]
for nonzero constants \( c_{jk,1} \) and \( c_{jk,2} \). Evaluating (6.15) at \( x = T \), we obtain \( a_{jk}^{(0,1)}(T) = 0 \), \( j, k = 1, 2 \). If (6.1) does not hold for any \( r \geq 2, \in \mathbb{Z} \), then we evaluate (6.15) at \( x = T \), and \( a_{jk}^{(0,1)}(T), a_{21}^{(0,1)}(T) \neq 0 \). This completes the proof.

**Lemma 6.2.** If (6.1) holds for some \( r \geq 3, \in \mathbb{Z} \) then \( a_{jk}^{(0,2)}(T) = 0 \), \( j \neq k \), and \( a_{jj}^{(0,2)}(T), j = 1, 2 \), do not necessarily vanish.

**Proof.** When \( m = 0 \) and \( n = 2 \), we rewrite (6.10) as (6.16)
\[ a_{jk}^{(0,2)}(T) = e^{ik_{21}T} \left\langle \int_0^T e^{i(k_2 - k_1)x} B^{(0,2)}(x; \sigma) \phi_2(\sigma) \, dx, \psi_2(\sigma) \right\rangle + e^{ik_{21}T} \left\langle \int_0^T B^{(0,1)}(x; \sigma)e^{-ik_{21}x}(w_k^{(0,1)}(x; \sigma) + 2 \sum_{j'=1}^2 a_{jk}^{(0,1)}(x)\phi_{2j'}(\sigma)) \, dx, \psi_2(\sigma) \right\rangle, \]
where \( B^{(0,1)}(x; \sigma) \) and \( B^{(0,2)}(x; \sigma) \) are in Appendix D, \( w_k^{(0,1)}(x; \sigma) \), \( k = 1, 2 \), are in Appendix F, and (6.15) holds.

If (6.1) holds for some \( r \geq 2, \in \mathbb{Z} \) then we deduce from the result of Appendix D (5.5), (A.2) and (4.19) that \( B^{(0,2)}(x; \sigma) \phi_2(\sigma) \) depends linearly on
\[ \sin(2\kappa x), \cos(2\kappa x), \sin(\kappa x), \cos(\kappa x), \]
\[ \sin(\kappa x)^2 = \frac{1}{2}(1 - \cos(2\kappa x)), \cos(\kappa x)^2 = \frac{1}{2}(\cos(2\kappa x) + 1), \sin(\kappa x)\cos(\kappa x) = \frac{1}{2}\sin(2\kappa x) \]
with respect to \( x \). Notice that \( k_{21} - k_{22} = \pm r\kappa, j \neq k \). Thus for \( r \geq 3 \), we proceed as in the former of (6.12), and
\[ \int_0^T e^{i(k_2 - k_2)x} B^{(0,2)}(x; \sigma) \phi_2(\sigma) \, dx = 0, \]
whereas for \( r = 2 \), we proceed as in the latter of (6.12) and the integral does not vanish. When \( j = k \), so that \( k_{2j} - k_{2j} = 0 \), those terms of \( B^{(0,2)}(x; \sigma) \phi_2(\sigma) \) with a factor of \( \sin(\kappa x)^2 \) or \( \cos(\kappa x)^2 \) do not necessarily vanish after the integration over one period for any \( r \geq 2, \in \mathbb{Z} \).

It remains to show that if (6.1) holds for some \( r \geq 3, \in \mathbb{Z} \) then the second term on the right side of (6.16) vanishes when \( j \neq k \). Multiplying (6.15) by \( e^{-ik_{21}x} \), we arrive at
\[ e^{-ik_{21}x} a_{11}^{(0,1)}(x) = c_{11,1} e^{i(r+1)\kappa x} + c_{11,2} e^{i(r-1)\kappa x} - (c_{11,1} + c_{11,2}) e^{ir\kappa x}, \]
while we deduce from (12.2) and (3.3) that \( B^{(0,1)}(x; \sigma) \phi_2(\sigma) \) depends linearly on \( \sin(\kappa x) \) or \( \cos(\kappa x) \). Thus we proceed as in the former of (6.12), and
\[ \int_0^T B^{(0,1)}(x; \sigma)e^{-ik_{21}x} a_{11}^{(0,1)}(x) \, dx = 0. \]
Likewise,
\[ e^{-ik_{21}x} a_{21}^{(0,1)}(x) = c_{21,1} e^{i(r+1)\kappa x} + c_{21,2} e^{i(r-1)\kappa x} - (c_{21,1} + c_{21,2}), \]
and $B^{(0,1)}(x; \sigma)$ depends linearly on $\sin(\kappa x)$ or $\cos(\kappa x)$. Thus it becomes zero after the integration over one period. Also, we verify that
\[
\int_0^T B^{(0,1)}(x; \sigma)e^{-ik\sigma x}(a_{12}^{(0,1)}(x)\phi_2(\sigma) + a_{22}^{(0,1)}(x)\phi_4(\sigma)) \, dx = 0.
\]
Lastly, since each term of $w_k^{(0,1)}(x; \sigma)$ is made up of terms each having the factor of $e^{ik\sigma x}$ (see (6.2)),
\[
\int_0^T B^{(0,1)}(x; \sigma)e^{-ik\sigma x}w_k^{(0,1)}(x; \sigma) \, dx = 0.
\]
This completes the proof. □

6.2. Spectral instability indices. Let
\[
\sigma > \sigma_c \quad \text{and} \quad k_2(\sigma) - k_4(\sigma) = r\kappa \quad \text{for some} \ r \geq 2, \in \mathbb{Z},
\]
where $\kappa > 0$ is the wave number of a Stokes wave. Recall (6.2). Let
\[
\lambda = i\sigma + \delta, \ \delta \in \mathbb{C} \quad \text{and} \quad |\delta| < 1, \quad k = k_j(\sigma) + pk + \gamma, \ j = 2, 4, \ p \in \mathbb{Z}, \ \gamma \in \mathbb{R} \quad \text{and} \quad |\gamma| < 1,
\]
$\varepsilon \in \mathbb{R}$ and $|\varepsilon| < 1$, and we recall the result of Lemma 6.1 and Lemma 6.2 to arrive at
(6.17)
\[
\Delta(i\sigma + \delta, k_j(\sigma) + pk + \gamma; \varepsilon) = a_{11}^{(1,0)}a_{22}^{(1,0)}\delta^2 - T^2e^{2ik\sigma T}\gamma^2 + \det(a^{(0,2)}(T))\varepsilon^4
\]
\[
- iTe^{ik\sigma T}(a_{11}^{(1,0)} + a_{22}^{(1,0)})\varepsilon^2
\]
\[
+ (a_{12}^{(0,2)}a_{22}^{(0,2)} + a_{22}^{(0,2)}a_{11}^{(0,2)})\varepsilon^2 - iTe^{ik\sigma T}(a_{11}^{(0,2)} + a_{22}^{(0,2)})\gamma\varepsilon^2
\]
\[
- iTe^{ik\sigma T}(a_{11}^{(1,1)} + a_{22}^{(1,1)})\gamma\varepsilon
\]
\[
+ o(|\varepsilon|^2 + |\delta|^2 + |\varepsilon|^4 + |\delta|\varepsilon^2 + |\gamma|\varepsilon^2 + |\delta\varepsilon||\varepsilon|)
\]
as $\delta, \gamma, \varepsilon \to 0$, where $a_{jk}^{(m,n)}(T)$, $j, k = 1, 2$ and $m, n = 0, 1, 2, \ldots$ are in the previous subsection. We suppress $T$ for the simplicity of notation. See also (6.13). The formulae of $a_{jk}^{(0,2)}$, $j, k = 1, 2$, are too bulky to include here. □ We pause to remark that if $k_2(\sigma) - k_4(\sigma) \neq r\kappa$ for any $r \geq 2, \in \mathbb{Z}$, then
\[
\Delta(i\sigma + \delta, k_j(\sigma) + pk + \gamma; \varepsilon) = O(|\delta| + |\gamma| + |\varepsilon|^2) \quad \text{as} \ \delta, \gamma, \varepsilon \to 0,
\]
instead. We seek $\lambda_2(j, k_j(\sigma) + \gamma; \varepsilon)$, $j = 1, 2$, such that
\[
\lambda_2(j, k_j(\sigma) + \gamma; \varepsilon) = i\sigma \quad \text{and} \quad \Delta(\lambda_2(j, k_j(\sigma) + \gamma; \varepsilon), k_j(\sigma) + \gamma; \varepsilon) = 0
\]
as $\gamma, \varepsilon \to 0$. We proceed as in Section 5.2 and let
(6.18)
\[
\lambda_2(j, k_j(\sigma) + \gamma; \varepsilon) = i\sigma + \alpha^{(1,0)}_2(\gamma) + \alpha^{(0,2)}_2(\varepsilon)^2 + o(|\gamma| + |\varepsilon|^2), \quad j = 1, 2,
\]
as $\gamma, \varepsilon \to 0$, where $\alpha^{(1,0)}_2$ and $\alpha^{(0,2)}_2$, $j = 1, 2$, are to be determined in terms of $a_{jk}^{(m,n)}$, $j, k = 1, 2$ and $m, n = 0, 1, 2, \ldots$.

**Theorem 6.3** (Spectral stability and instability away from $0 \in \mathbb{C}$). A $2\pi/\kappa$ periodic Stokes wave of sufficiently small amplitude is spectrally unstable near $i\sigma \in \mathbb{C}$, $\sigma \in \mathbb{R}$, for which $k_2(\sigma) - k_4(\sigma) = 2\kappa$ (see (6.1)), provided that
(6.19)
\[
\text{ind}_2(\mu_0) := \left(\frac{a_{11}^{(0,2)}a_{22}^{(1,0)} - a_{11}^{(1,0)}a_{22}^{(0,2)}}{a_{11}^{(1,0)}a_{22}^{(1,0)}}\right)^2 + 4a_{12}^{(0,2)}a_{21}^{(0,2)}a_{11}^{(1,0)}a_{22}^{(1,0)}(a_{11}^{(1,0)}a_{22}^{(1,0)})^2(T) > 0,
\]
\[\text{It takes more than 500kB to save the Matlab data for the formulae of a}_{jk}^{(0,2)} while it takes about 17kB for } \theta_1^{(0,1)} \text{ and } \theta_1^{(0,1)} \text{ (see Appendix F), for instance.}
where \( a_{jk}^{(m,n)}(T) \) is in (6.7) and (6.10). Recall \( T = 2\pi/\kappa \).

It is spectrally unstable near \( i\sigma \in \mathbb{C} \), for which \( k_2(\sigma) - k_4(\sigma) = r\kappa \) for \( r \geq 3, \in \mathbb{Z} \), provided that

\[
(6.20) \quad \text{ind}_3(\mu_0) := f_3^2 > 0, \quad \text{where} \quad f_3 := \left( \frac{a_{12}^{(1,0)} a_{11}^{(1,0)} - a_{11}^{(0,2)} a_{22}^{(0,2)}}{a_{11}^{(1,0)} a_{22}^{(1,0)}} \right)(T),
\]

and spectrally stable at the order of \( \varepsilon^2 \) as \( \varepsilon \to 0 \) otherwise, where \( \varepsilon \) is the dimensionless amplitude parameter.

**Proof.** We suppress \( T \) for the simplicity of notation.

Substituting (6.18) into (6.17), after straightforward calculations, we arrive at

\[
(6.21) \quad (a_{11}^{(1,0)} a_{22}^{(1,0)}) (a_{2j}^{(0,2)})^2 + (a_{11}^{(0,2)} a_{22}^{(1,0)} + a_{11}^{(1,0)} a_{22}^{(0,2)}) a_{2j}^{(0,2)} + (a_{12}^{(0,2)} - a_{21}^{(0,2)})(a_{2j}^{(0,2)}) = 0,
\]

whence

\[
(6.22) \quad a_{2j}^{(0,2)} = -\frac{a_{12}^{(0,2)} a_{22}^{(1,0)} + a_{11}^{(1,0)} a_{22}^{(0,2)}}{2 a_{11}^{(1,0)} a_{22}^{(1,0)}} \pm \frac{1}{2} \sqrt{\text{ind}_2},
\]

where \( \text{ind}_2 \) is in (6.19). After straightforward calculations, we verify that if \( k_2(\sigma) - k_4(\sigma) = 2\kappa \) then the first term on the right side of (6.22) is purely imaginary while \( \text{ind}_2 \) is real, and \( \text{ind}_2 > 0 \) implies spectral instability.

If \( k_2(\sigma) - k_4(\sigma) = r\kappa \) for some \( r \geq 3, \in \mathbb{Z} \) then \( a_{12}^{(0,2)} = a_{21}^{(0,2)} = 0 \) by Lemma 6.2 whence (6.19) becomes (6.20). This completes the proof.

---

**Figure 3.** Left: A plot of \( \text{ind}_2 \) versus \( \mu_0 \); \( \text{ind}_2(\mu_0) > 0 \) if \( \mu_L < \mu_0 < \mu_R \). Middle: A plot of the index \( \text{ind}_3 \) versus \( \mu_0 \); \( \text{ind}_3(\mu_0) \leq 0 \) for all \( \mu_0 \). Right: \( \text{Im} f_3 \) versus \( \mu_0 \).

Numerical evaluation reveals that \( \text{ind}_2(\mu_0) > 0 \) if \( \mu_L < \mu_0 < \mu_U \), where \( \mu_L \approx 1.23743 \) and \( \mu_U \approx 1.31779 \), or, equivalently, \( \kappa_L < \kappa < \kappa_U \), \( \mu_0 = \kappa \coth(\kappa) \), where \( \kappa_L \approx 0.86430 \) and \( \kappa_U \approx 1.00804 \). See the left panel of Figure 3 for a plot of \( \text{ind}_2 \) versus \( \mu_0 \). Also, \( \text{ind}_2(F) > 0 \) if \( F_L < F < F_U \), \( F = 1/\sqrt{\mu_0} \), where \( F_L \approx 0.87112 \) and \( F_U \approx 0.89896 \).

A straightforward calculation reveals that \( f_3 \) is purely imaginary and, hence, \( \text{ind}_3(\mu_0) \leq 0 \) for all \( \mu_0 > 1 \). The middle panel of Figure 3 shows \( \text{ind}_3 \) versus \( \mu_0 \) when \( k_2(\sigma) - k_4(\sigma) = 3\kappa \). Notice that \( \text{ind}_3(\mu_*) = 0 \), where \( \mu_* \approx 1.221726 \). The right panel of Figure 3 shows that \( \text{Im} f_3 \) changes its sign at \( \mu_* \).

**Corollary 6.4.** A \( 2\pi/\kappa \) periodic Stokes wave of sufficiently small amplitude is spectrally unstable if \( \kappa_L < \kappa < \kappa_U \), where \( \kappa_L \approx 0.86430 \) and \( \kappa_U \approx 1.00804 \) are the roots of (6.19).

Any Stokes wave of sufficiently small amplitude is spectrally stable near \( i\sigma \in \mathbb{C}, \sigma \in \mathbb{R} \), for which \( k_2(\sigma) - k_4(\sigma) = r\kappa \) for \( r \geq 3, \in \mathbb{Z} \), at the order of \( \varepsilon^2 \) as \( \varepsilon \to 0 \), where \( \varepsilon \) is the dimensionless amplitude parameter.
Recall from Corollary 5.4 that the Benjamin–Feir instability sets in at \( \kappa = \kappa_c \approx 1.3628 \). Therefore, Corollary 6.4 says that there are Stokes waves spectrally unstable away from 0 \( \in \mathbb{C} \) although they are insusceptible to the Benjamin–Feir instability near 0 \( \in \mathbb{C} \). We remark that a necessary condition of spectral instability away from 0 \( \in \mathbb{C} \) is that \( a^{(0,1)}(T) = 0 \), so that \( a^{(0,2)} \) solves a quadratic equation (see (5.21)), and \( a^{(0,2)}_{jk}(T) \neq 0, j, k = 1, 2 \) and \( j \neq k \).

McLean [28] (see also [27,29]) in the infinite depth numerically investigated the spectral stability and instability of a Stokes wave, for a range of \( \varepsilon \) for \( \kappa \) smaller and greater than \( \kappa_c \) (permitting transversal perturbations), and reported instability in the vicinity of \( i\sigma \in \mathbb{C} \), \( \sigma \in \mathbb{R} \), whenever \( k_2(\sigma) - k_4(\sigma) = r\kappa \) for some \( r \geq 2, \in \mathbb{Z} \). See [28] Figures 2,3,4, for instance. See also [7,9], among others, for further numerical investigations. Theorem 6.3 and Corollary 6.4 explain some of the numerical findings, but not all. Particularly, when \( k_2(\sigma) - k_4(\sigma) = 2\kappa \), Corollary 6.4 gives the interval of unstable wave number \( (\kappa_L, \kappa_U) \), where \( \kappa_L \approx 0.86430 \) and \( \kappa_U \approx 1.00804 \), whereas numerical computations suggest instability for all \( \kappa \). Perhaps, this is because Theorem 6.3 and Corollary 6.4 are for arbitrarily small amplitude as \( \varepsilon \to 0 \) whereas numerical computations for small but finite amplitude. For instance, \( \varepsilon = 0.1 \) in [28]. We expect that the interval of unstable wave number will increase as \( \varepsilon \) increases.

7. Discussion on spectral stability

Theorem 5.3 gives a sufficient condition of spectral instability in the vicinity of 0 \( \in \mathbb{C} \) for a Stokes wave of sufficiently small amplitude, and Theorem 6.3 near \( i\sigma \in \mathbb{C} \), \( \sigma \in \mathbb{R} \), for which \( k_2(\sigma) - k_4(\sigma) = 2\kappa \), where \( \kappa \) is the wave number. An important question is whether a Stokes wave of sufficiently small amplitude is spectrally stable when \( \text{ind}_1, \text{ind}_2 \leq 0 \), where \( \text{ind}_1 \) and \( \text{ind}_2 \) are in (5.20) and (6.19). Recall that spectral stability follows near \( i\sigma \in \mathbb{C} \), \( \sigma \in \mathbb{R} \), if \( \Delta(\lambda(\gamma, \varepsilon), p\kappa + \gamma; \varepsilon) = 0 \) (see 4.26), where \( p \in \mathbb{Z} \), \( \lambda(0, 0) = i\sigma \) and \( \lambda(\gamma, \varepsilon) \) is purely imaginary for \( \gamma, \varepsilon \in \mathbb{R} \) and \( |\gamma|, |\varepsilon| \ll 1 \). For each \( \sigma \in \mathbb{R} \), not necessarily for which \( k_2(\sigma) - k_4(\sigma) = r\kappa \) for some \( r > 0, \in \mathbb{Z} \), we make a series expansion of \( \lambda(\gamma, \varepsilon) \) about \( i\sigma \) as \( \gamma, \varepsilon \to 0 \), and we proceed as in Section 5 and Section 4 to solve \( \Delta(\lambda(\gamma, \varepsilon), p\kappa + \gamma; \varepsilon) = 0 \), whereby determining the coefficients of the series expansion. Thus spectral stability follows if all the coefficients are purely imaginary for the series expansion. After straightforward calculations, we arrive at:

(i) When \( \text{ind}_1 \leq 0 \), where \( \text{ind}_1 \) is in (5.20), so that a Stokes wave of sufficiently small amplitude is insusceptible to the Benjamin–Feir instability, all the coefficients of (5.22) are purely imaginary;
(ii) When \( \text{ind}_2 \leq 0 \), where \( \text{ind}_2 \) is in (6.19), all the coefficients of (6.18) are purely imaginary;
(iii) When \( \lambda(\gamma, \varepsilon) \) is in the vicinity of \( i\sigma \in \mathbb{C} \), \( \sigma \in \mathbb{R} \), for which \( k_2(\sigma) - k_4(\sigma) = r\kappa \) for some \( r \geq 3, \in \mathbb{Z} \), the coefficients are purely imaginary for the series expansion of \( \lambda(\gamma, \varepsilon) \) about \( i\sigma \) as \( \gamma, \varepsilon \to 0 \) at all the orders we compute;
(iv) When \( k_2(\sigma) - k_4(\sigma) \neq r\kappa \) for any \( r \geq 2, \in \mathbb{Z} \), the coefficients are purely imaginary for the series expansion of \( \lambda(\gamma, \varepsilon) \) about \( i\sigma \) as \( \gamma, \varepsilon \to 0 \) at all the orders we compute.

Our computations suggest that a Stokes wave of sufficiently small amplitude is spectrally stable, provided that \( \text{ind}_1, \text{ind}_2 \leq 0 \). It is highly nontrivial, however, to prove that all the coefficient are purely imaginary for a series expansion of \( \lambda(\gamma, \varepsilon) \) as \( \gamma, \varepsilon \to 0 \), for which \( \Delta(\lambda(\gamma, \varepsilon), p\kappa + \gamma; \varepsilon) = 0 \). One difficulty is that such a series expansion may involve fractional powers. Suppose, for instance, that (5.20) converges for \( \lambda, \gamma, \varepsilon \in \mathbb{C} \) and \( |\lambda|, |\gamma|, |\varepsilon| \ll 1 \). The Weierstrass preparation theorem says that

\[
\Delta(\lambda, p\kappa + \gamma; \varepsilon) = W(\lambda, \gamma, \varepsilon)h(\lambda, \gamma, \varepsilon),
\]

where

\[
W(\lambda, \gamma, \varepsilon) = \lambda^4 + g_3(\gamma, \varepsilon)\lambda^3 + g_2(\gamma, \varepsilon)\lambda^2 + g_1(\gamma, \varepsilon)\lambda + g_0(\gamma, \varepsilon)
\]
is a Weierstrass polynomial, $g_j(\gamma, \varepsilon)$, $j = 0, 1, 2, 3$, are analytic and $g_j(0, 0) = 0$, and $h(\lambda, \gamma, \varepsilon)$ is analytic and $h(0, 0, 0) \neq 0$. Thus the roots of $\Delta(\lambda, pk + \gamma; \varepsilon)$ for $(\lambda, \gamma, \varepsilon)$ in the vicinity of $(0, 0, 0)$ are the four roots of $W(\lambda, \gamma, \varepsilon)$. One may wish to apply the Jung-Abhyankar theorem\(^{120}\), for instance, to show that (7.1) has all its roots in $\mathbb{C}[\gamma^{1/m}, \varepsilon^{1/n}]$ for some $m, n > 0, \varepsilon \in \mathbb{Z}$, which may help set up a proof by induction. Unfortunately, we are unable to verify the assumption of the Jung-Abhyankar theorem that the discriminant of (7.1) is the product of a monomial and a unit in $\mathbb{C}[\gamma, \varepsilon]$. Clearly, $W(0, 0, 0) = 0$ and, hence, $g_0(\gamma, \varepsilon) = \tilde{g}_0(\gamma, \varepsilon)$ for some $\tilde{g}_0$. But it is not obvious whether $g_1(\gamma, \varepsilon) = \gamma \tilde{g}_1(\gamma, \varepsilon)$ for some $\tilde{g}_1$.

A more feasible approach to locating the roots of (7.1) and, hence, $\Delta(\lambda, pk + \gamma; \varepsilon)$ is examining its discriminant. Let $\lambda = i\tilde{\lambda}$ and $\tilde{W}(\tilde{\lambda}, \gamma, \varepsilon) = W(\lambda, \gamma, \varepsilon)$. That is,

$$
\tilde{W}(\tilde{\lambda}, \gamma, \varepsilon) = (\tilde{\lambda}/i)^4 + g_3(\gamma, \varepsilon)(\tilde{\lambda}/i)^3 + g_2(\gamma, \varepsilon)(\tilde{\lambda}/i)^2 + g_1(\gamma, \varepsilon)(\tilde{\lambda}/i) + g_0(\gamma, \varepsilon)
= \tilde{\lambda}^4 + ig_3(\gamma, \varepsilon)\tilde{\lambda}^3 - g_2(\gamma, \varepsilon)\tilde{\lambda}^2 - ig_1(\gamma, \varepsilon)\tilde{\lambda} + g_0(\gamma, \varepsilon).
$$

Suppose that $ig_3(\gamma, \varepsilon)$, $-g_2(\gamma, \varepsilon)$, $-ig_1(\gamma, \varepsilon)$ and $g_0(\gamma, \varepsilon)$ are real. Let

- $\text{disc}^0(\gamma, \varepsilon) = \text{disc}(1, ig_3(\gamma, \varepsilon), -g_2(\gamma, \varepsilon), -ig_1(\gamma, \varepsilon), g_0(\gamma, \varepsilon))$,
- $\text{disc}^1(\gamma, \varepsilon) = -8g_2(\gamma, \varepsilon) + 3g_3(\gamma, \varepsilon)^2$,
- $\text{disc}^2(\gamma, \varepsilon) = 64g_0(\gamma, \varepsilon) - 16g_2(\gamma, \varepsilon)^2 + 16g_3(\gamma, \varepsilon)^2g_2(\gamma, \varepsilon) - 16g_3(\gamma, \varepsilon)g_1(\gamma, \varepsilon) - 3g_3(\gamma, \varepsilon)^4$,

where disc denotes the discriminant of a quartic polynomial. They classify the roots of (7.1):

1. If $\text{disc}^0(\gamma, \varepsilon) < 0$ then (7.1) has two distinct pure imaginary roots and two distinct complex roots, symmetric about the imaginary axis;
2. If $\text{disc}^0(\gamma, \varepsilon) > 0$ and $\text{disc}^1(\gamma, \varepsilon) > 0$ then (7.1) has two distinct pairs of complex roots, symmetric about the imaginary axis;
3. If $\text{disc}^0(\gamma, \varepsilon) > 0$, $\text{disc}^1(\gamma, \varepsilon) < 0$ and $\text{disc}^2(\gamma, \varepsilon) < 0$ then (7.1) has four distinct and purely imaginary roots;
4. If $\text{disc}^0(\gamma, \varepsilon) > 0$, $\text{disc}^1(\gamma, \varepsilon) < 0$ and $\text{disc}^2(\gamma, \varepsilon) > 0$ then (7.1) has two distinct pairs of complex roots, symmetric about the imaginary axis;
5. If $\text{disc}^0(\gamma, \varepsilon) = 0$ then at least two roots of (7.1) are equal.

Thus one can prove spectral stability near $0 \in \mathbb{C}$ for a Stokes wave of sufficiently small amplitude when it is insusceptible to the Benjamin–Feir instability, if one can show that $\text{disc}^0(\gamma, \varepsilon) > 0$, $\text{disc}^1(\gamma, \varepsilon), \text{disc}^2(\gamma, \varepsilon) < 0$ as $\gamma, \varepsilon \to 0$. We predict that the sign of $\text{disc}^0$ agrees with that of $-\text{ind}_1$ (see (5.20)), so that Theorem 5.3 corresponds to $\text{disc}^0(\gamma, \varepsilon) > 0$, and that $\text{disc}^1(\gamma, \varepsilon), \text{disc}^2(\gamma, \varepsilon) < 0$ when $\gamma$ and $\varepsilon$ are small.

Since $g_j(\gamma, \varepsilon)$, $j = 0, 1, 2, 3$, depend analytically on $\gamma$ and $\varepsilon$,

$$
g_j(\gamma, \varepsilon) = \sum_{m+n \geq 1} g_{j(m,n)}^{(m,n)} \gamma^m \varepsilon^n \quad \text{and} \quad h(\lambda, \gamma, \varepsilon) = \sum_{\ell+m+n \geq 0} h^{(\ell,m,n)}(\lambda) \gamma^\ell \gamma^m \varepsilon^n
$$
as $\gamma, \varepsilon \to 0$, where $g_{j(m,n)}^{(m,n)}$, $m + n \geq 1$, and $h^{(\ell,m,n)}$, $\ell + m + n \geq 0$, can be determined by $\Delta(\lambda, pk + \gamma; \varepsilon) = W(\lambda, \gamma, \varepsilon)h(\lambda, \gamma, \varepsilon)$ and (5.20). One can in turn make power series expansions of $\text{disc}^j(\gamma, \varepsilon)$, $j = 0, 1, 2, 3$, as $\gamma, \varepsilon \to 0$, and examine the signs of the lowest order terms. Also, one may prove by induction that $g_{j(m,n)}^{(m,n)}$, $m + n \geq 1$, are real or purely imaginary and, hence, $ig_3(\gamma, \varepsilon)$, $-g_2(\gamma, \varepsilon)$, $-ig_1(\gamma, \varepsilon)$ and $g_0(\gamma, \varepsilon)$ are all real. (For a large class of Hamiltonian systems in one

\[^{1}\text{For } a x^4 + b x^3 + c x^2 + d x + e, \]

$\text{disc}(a, b, c, d, e) = 256a^3 e^3 - 192a^2 b d e^2 - 128a^2 c^2 e^2 + 144a^2 c d e^2 - 27a^2 d^2 e - 144 a b^2 c e^2 - 6 a b^2 d e - 80 a b c^2 d e + 18 a b c d^2 + 16 a c^3 e - 4 a c^2 d e - 27 b^5 e^2 + 18 b^2 c d e - 4 b^2 c^3 e + b^2 c^2 d^2$.\[31]
dimension, permitting nonlocal operators, this follows from that the spectrum is symmetric about the imaginary axis \([15,16]\). One can proceed likewise to prove spectral stability near \(i\sigma \in \mathbb{C}, \sigma \in \mathbb{R}\), when \(k_2(\sigma) - k_4(\sigma) = 2\kappa\), for which the roots of the Weierstrass polynomial and, hence, the periodic Evans function will be classified via a discriminant of a quadratic polynomial. To recapitulate, one may examine the discriminant of the Weierstrass polynomial for the periodic Evans function to prove spectral stability of a Stokes wave of sufficiently small amplitude. This is a subject of future investigation.

Appendix A. Stokes Expansion

Substituting (3.3) into (3.2) and (3.1), at the order of $\varepsilon^2$, we gather

$$
\begin{align*}
\phi_{yy} + \phi_{xy} &= 2\eta_1 \phi_{yy} + y\eta_{1x} \phi_{1y} + 2y\eta_1 \phi_{1xy} & \text{for } 0 < y < 1, \\
\phi_{yy} &= 0 & \text{at } y = 0, \\
\eta_{xx} + \phi_{xy} &= \eta_1 \phi_{xx} + \eta_1 \phi_{1y} & \text{at } y = 1, \\
\phi_2 + \phi_{xx} - \mu_0 \eta_2 &= \eta_1 \phi_{xx} + \frac{1}{2}(\phi_{xx}^2 + \phi_{yy}^2) + \mu_1 \eta_1 & \text{at } y = 1,
\end{align*}
$$

(A.1)

where $\phi_1, \eta_1$, and $\mu_0$ are in (3.5) and (3.6). Recall that $\phi_2$ and $\eta_2$ are $2\pi/\kappa$ periodic functions of $x$, $\phi_2$ is an odd function of $x$, $\eta_2$ is an even function and of mean zero over one period, and $\bar{\phi}_2$ and $\mu_1$ are constants. We solve (A.1) by the method of undetermined coefficients, for instance, to obtain

$$
\bar{\phi}_2 = \frac{\mu_0^2}{4} \tanh(\kappa)^2,
$$

(A.2)

$$
\phi_2(x, y) = \frac{3\mu_0 \sin(2\kappa x) \cosh(2\kappa y)}{8 \sinh(\kappa) \cosh(\kappa)} + \frac{\mu_0 \sinh(\kappa)^2}{2 \cosh(\kappa)} y \sin(2\kappa x) \sinh(\kappa y),
$$

$$
\eta_2(x) = \frac{\mu_0}{4} (2 \sinh(\kappa)^2 + 3) \cos(2\kappa x),
$$

and $\mu_1 = 0$.

To proceed, at the order of $\varepsilon^3$, we gather

$$
\begin{align*}
\phi_{yy} + \phi_{xy} &= 2y\eta_{1x} \phi_{2xy} + 2\eta_1 \phi_{2yy} + y\eta_{1xx} \phi_{2y} \\
&+ 2y(\eta_2 - \eta_1 \phi_{2yy} + (2\eta_2 - 3\eta_1^2 - y^2 \eta_{1x}^2) \phi_{1yy} + y(\eta_{1xx} - 2\eta_{1x}^2 - \eta_1 \phi_{xx}) \phi_{1y})
\end{align*}
$$

for $0 < y < 1$, $\phi_3 = 0$ at $y = 0$, and

$$
\begin{align*}
\eta_{xx} + \phi_{xy} &= \eta_1 \phi_{xx} + \eta_2 + (\eta_2 - \eta_1^2 - \eta_1^2) \phi_{1y} \\
\phi_3 + \eta_3 &= \eta_1 \phi_{xx} + \eta_2 + (\eta_2 - \eta_1^2 - \eta_1^2) \phi_{1y} \\
&+ (\eta_1 \eta_{1x} + \phi_{xx} \eta_{1x}) \phi_{1y} - \eta_1 \phi_{1y}^2 + \mu_2 \eta_1
\end{align*}
$$

at $y = 1$, where $\phi_1, \eta_1, \eta_0$ are in (3.5) and (3.6), $\bar{\phi}_2, \phi_2, \eta_2$ are in (A.2). We likewise solve this by the method of undetermined coefficients to obtain $\tilde{\phi}_3 = 0$,

$$
\begin{align*}
\phi_3(x, y) &= -\frac{\mu_0^2 (4s^2 - 9)}{16s(2)^2} \sin(3\kappa x) \cosh(3\kappa y) + \frac{3\mu_0^2 s}{8(s^2 + 1)} y \sin(3\kappa x) \sinh(2\kappa y) \\
&+ \frac{\mu_0^2 s (2s^2 + 3)}{8c} y \sin(3\kappa x) \sinh(\kappa y) + \frac{\mu_0^2 s^4}{8(s^2 + 1)} y^2 \sin(3\kappa x) \cosh(\kappa y) \\
&+ \frac{3\mu_0^2 s}{8(s^2 + 1)} y \sin(\kappa x) \sin(2\kappa y) - \frac{\mu_0^2 s (2s^2 + 3)}{8c} y \sin(\kappa x) \sinh(\kappa y) \\
&+ \frac{\mu_0^2 s^4}{8(s^2 + 1)} y^2 \sin(\kappa x) \cosh(\kappa y),
\end{align*}
$$

(A.3a)

$$
\eta_3(x) = \frac{\mu_0^2 (24s^6 + 72s^4 + 72s^2 + 27)}{64(s^3 + s)} \cos(3\kappa x) + \frac{\mu_0^2 s (5s^4 + 13s^2 + 6)}{8(s^2 + 1)} \cos(\kappa x),
$$

(A.3b)

and

$$
\mu_2 = -\frac{\mu_0^3 (8s^4 + 12s^2 + 9)}{8(s^2 + 1)},
$$

(A.3c)
where
\[ c = \cosh(\kappa), \quad s = \sinh(\kappa) \quad \text{and} \quad s(2) = \sinh(2\kappa). \]

We do not include the formulae of \( \phi_4, \phi_4, \phi_5, \phi_5, \ldots, \eta_4, \eta_5, \ldots, \mu_3, \mu_4, \ldots \).

**APPENDIX B. PROOF OF LEMMA 4.3**

Let \( \lambda \in \text{spec}(\mathcal{L}(\varepsilon)) \), and suppose that \( u = \begin{pmatrix} \phi \\ v \\ \eta \end{pmatrix} \in L^\infty(\mathbb{R}; Y) \), by abuse of notation, is a nontrivial solution of (4.2) satisfying \( u(x + T) = e^{i\kappa T}u(x) \) for all \( x \in \mathbb{R} \) for some \( k \in \mathbb{R} \). Notice that (4.2) remains invariant under
\[ \lambda \mapsto \lambda^* \quad \text{and} \quad u \mapsto u^*, \]
and \( u^*(x + T) = e^{-i\kappa T}u^*(x) \) for all \( x \in \mathbb{R} \), where the asterisk denotes complex conjugation. Thus \( \lambda^* \in \text{spec}(\mathcal{L}(\varepsilon)) \). Also, notice that (4.2) remains invariant under
\[ \lambda \mapsto -\lambda \quad \text{and} \quad \begin{pmatrix} \phi(x) \\ v(x) \\ \eta(x) \end{pmatrix} \mapsto \begin{pmatrix} -\phi(-x) \\ v(-x) \\ \eta(-x) \end{pmatrix} =: u_-(x), \]
and \( u_-(x + T) = e^{-i\kappa T}u_-(x) \) for all \( x \in \mathbb{R} \). Thus \( -\lambda \in \text{spec}(\mathcal{L}(\varepsilon)) \). This completes the proof.

**APPENDIX C. PROOF OF LEMMA 4.4**

The proof of (4.17), (4.18) and (4.19) is rudimentary. When \( \sigma = \sigma_c \), clearly,
\[ (\mathbf{L}(i\sigma_c) - ik_c)\phi_3(\sigma_c) = (\mathbf{L}(i\sigma_c) - ik_c) \begin{pmatrix} \mu_0 \cosh(k_c y) \\ i(k_c - \sigma_c) \cosh(k_c y) \\ i(k_c - \sigma_c) \cosh(k_c) \end{pmatrix} = 0. \]

It remains to solve
\[ (\mathbf{L}(i\sigma_c) - ik_c)u := (\mathbf{L}(i\sigma_c) - ik_c) \begin{pmatrix} \phi \\ v \\ \eta \end{pmatrix} = \begin{pmatrix} \mu_0 \cosh(k_c y) \\ i(k_c - \sigma_c) \cosh(k_c y) \\ i(k_c - \sigma_c) \cosh(k_c) \end{pmatrix}, \]
where \( u \in \text{dom}(\mathbf{L}) \). Solving the first and second equations, subject to \( \phi_y(0) = 0 \) (see (4.11)), we obtain
\[ \phi(y) = c\mu_0 \cosh(k_c y) - i\mu_0 y \sinh(k_c y) \quad \text{and} \quad v(y) = (1 + ic(k_c - \sigma_c)) \cosh(k_c y) + (k_c - \sigma_c) y \sinh(k_c y) \]
for some constant \( c \), whence \( \eta = (1 + ic(k_c - \sigma_c)) \cosh(k_c) + (k_c - \sigma_c) \sinh(k_c) \) by (4.11). Substituting into the third equation, we arrive at
\[ c((\sigma - k_c)^2 - \mu_0 k_c \tanh(k_c)) + i((\mu_0 - (\sigma - k_c)^2) \tanh(k_c) + 2\sigma - 2k_c + \mu_0 k_c) = 0. \]

In view of (3.15), this is solvable, provided that the second term on the left side vanishes. Differentiating (3.15) and evaluating \( k = k_c \), we learn that
\[ 2\sigma_+(k_c) - 2k_c + \mu_0 k_c = \mu_0 k_c \tanh(k_c)^2 - \mu_0 \tanh(k_c), \]
whence
\[ (\mu_0 - (\sigma_+(k_c) - k_c)^2) \tanh(k_c) + 2\sigma_+(k_c) - 2k_c + \mu_0 k_c \]
\[ = (\mu_0 - (\sigma_+(k_c) - k_c)^2) \tanh(k_c) + \mu_0 k_c \tanh(k_c)^2 - \mu_0 \tanh(k_c) = 0. \]

Therefore \( c \) is arbitrary. Also, we verify that
\[ \ker((\mathbf{L}(i\sigma_c) - ik_c)^3) = \ker((\mathbf{L}(i\sigma_c) - ik_c)^2), \]
where \( \mathbf{1} \) is the identity operator. This completes the proof.
APPENDIX D. EXPANSION OF $B(x; \sigma, \delta, \epsilon)$

Throughout the section, let $u = \begin{pmatrix} \phi \\ \nu \\ \eta \end{pmatrix}$. Recalling (5.7) and (6.6), we use (1.2), (1.3), (1.5), (1.6), (4.7), (4.9), (3.5), (A.2), (A.3), and make straightforward calculations to show that

\begin{equation}
\mathbf{B}^{(1,0)}(x; \sigma)u = \begin{pmatrix} -\nu - 2i\sigma \mu_0^{-1} \phi \\ \phi \\ \eta \end{pmatrix}
\quad \text{and} \quad
\mathbf{B}^{(2,0)}(x; \sigma)u = \begin{pmatrix} 0 \\ 0 \\ -\mu_0^{-1} \phi \end{pmatrix}.
\end{equation}

Notice that $\mathbf{B}^{(m,0)}$, $m \geq 1$, do not involve $x$.

Let $\mathbf{B}^{(0,1)}(x; \sigma)u = \begin{pmatrix} \mathbf{B}^{(0,1)}(x; \sigma)u_1 \\ \mathbf{B}^{(0,1)}(x; \sigma)u_2 \\ \mathbf{B}^{(0,1)}(x; \sigma)u_3 \end{pmatrix}$, and we make straightforward calculations to show that

\begin{equation}
\mathbf{B}^{(0,1)}(x; \sigma)u_1 = i\sigma \phi_1 x(1) \phi + (y\eta_1 + \phi_1 y(1)) \phi_y - y\phi_1 y(1)
+ \mu_0 \phi_1 x(1) - i\sigma \phi_1 y(1) \nu + i\sigma \phi_1 y \eta,
\end{equation}

\begin{equation}
\mathbf{B}^{(0,1)}(x; \sigma)u_2 = (i\sigma^2 \phi_1 y(1) + \mu_0^2 \phi_1 x(1) - i\mu_0 \sigma \phi_1 x(1)) \mu_0^{-2} \phi - (\phi_1 y(1) + 2i\sigma \phi_1 y(1)) \mu_0^{-1} \phi_y
+ (\mu_0 \phi_1 x(1) + 2\mu_0 \eta_1 - i\sigma \phi_1 y(1)) \mu_0^{-2} \phi_y
+ (i\sigma \phi_1 y(1) + \mu_0 \phi_1 x(1) - i\mu_0 \sigma \phi_1 x(1)) \mu_0^{-1} \nu + (y\eta_1 - \phi_1 y(1)) \nu_y
+ (2\phi_1 \eta_1 + \sigma^2 \phi_1 y + i\sigma \phi_1 y) \mu_0^{-1} \eta,
\end{equation}

\begin{equation}
\mathbf{B}^{(0,1)}(x; \sigma)u_3 = i\sigma \eta_1 \phi(1) + (\eta_1 - \phi_1 x(1)) \phi_y(1) + \mu_0 \eta_1 u(1) + (\phi_1 y(1) + i\sigma \phi_1 x(1)) \eta,
\end{equation}

where $\phi_1$ and $\eta_1$ are in (3.5), and, likewise,

\begin{equation}
\mathbf{B}^{(1,1)}(x; \sigma)u_1 = \phi_1 x(1) \phi - \phi_1 y(1) \nu + y\phi_1 y \eta,
\end{equation}

\begin{equation}
\mathbf{B}^{(1,1)}(x; \sigma)u_2 = (3\sigma^2 \phi_1 y(1) - \mu_0 \phi_1 x(1) - 2i\mu_0 \sigma \phi_1 x(1)) \mu_0^{-2} \phi - 2\phi_1 y(1) \mu_0^{-1} \phi_y
- \phi_1 y(1) \mu_0^{-2} \phi_y + y\phi_1 y \mu_0^{-1} \phi_y(1)
+ (\phi_1 y(1) - \mu_0 \phi_1 x(1)) \mu_0^{-1} \nu + (y \phi_1 y - 2i\sigma y \phi_1 y) \mu_0^{-1} \eta,
\end{equation}

\begin{equation}
\mathbf{B}^{(1,1)}(x; \sigma)u_3 = \eta_1 x \phi(1) + \phi_1 x(1) \eta.
\end{equation}

Additionally, we calculate that

\begin{equation}
\mathbf{B}^{(0,2)}(x; \sigma)u_1
= i\sigma \left( \phi_1 x(1)^2 + \tilde{\phi}_2 + \phi_2 x(1) - \phi_1 y(1) \eta_1 x \right) \phi
+ \left( \phi_2 y(1) + \phi_1 x(1) \phi_1 y(1) - 2 \phi_1 y(1) \eta_1 + y\eta_2 - y \eta_1 \eta_1 \right) \phi_y
+ i\sigma y \phi_1 y \eta_1 x \phi(1) + (2y \eta_1 \phi_1 y - y \phi_1 x(1) \phi_1 y - y \phi_2 y) \phi_y(1)
+ \left( \mu_2 + \mu_0 \phi_1 x(1)^2 + \tilde{\phi}_2 \mu_0 - \phi_1 y(1)^2 + \mu_0 \phi_2 x(1)ight)
- i\sigma \phi_2 y(1) - \mu_0 \phi_1 y(1) \eta_1 x - i\sigma \phi_1 x(1) \phi_1 y(1) + i\sigma \phi_1 y(1) \eta_1 \nu(1)
+ (i\sigma y \phi_2 y - y \phi_1 y \eta_1 x + y \phi_1 y(1) \phi_1 y + i\sigma y \phi_1 x(1) \phi_1 y - i\sigma y \eta_1 \phi_1 y) \eta,
\end{equation}

36
\( (B^{(0,2)}(x; \sigma) u)_2 \)

\[
= \left( \mu_0^2 \sigma^2 \phi_{1x}(1) - \mu_0 \mu_0 \sigma^2 - \sigma^4 \phi_{1y}(1)^2 + \bar{\phi}_2 \mu_0^2 \sigma^2 - i \mu_0 \sigma^3 \phi_{2x}(1) + i \mu_0 \sigma^3 \phi_{2y}(1) \\
+ \mu_0 \sigma^2 \phi_{1y}(1)^2 + \mu_0 \sigma^2 \phi_{2x}(1) + i \mu_0 \sigma^2 \phi_{1xy}(1) \eta_{ix} - i \mu_0 \sigma^2 \phi_{1x}(1) \phi_{1xx}(1) + \mu_0 \sigma^2 \phi_{1y}(1) \phi_{1xx}(1) \\

\]

where \( \phi_2 \) and \( \eta_2 \) are in (A.2).

We do not include the formulae of \( B^{(m,n)}(\sigma) \), \( m + n \geq 3 \).
Appendix E. Expansion of $w_{k}^{(m,n)}(x;0)$

Recalling (5.6), we solve (5.11) and (5.10), and make straightforward calculations to show that, to the lowest orders,

\[
\begin{align*}
    w_{1}^{(1,0)}(x;0) &= e^{-ix} \left( \begin{array}{c}
    b_{1,1}^{(1,0)} y \sinh(\kappa y) + b_{1,2}^{(1,0)} + b_{1,3}^{(1,0)} \cosh(\kappa y) \\
    -i \tanh(\kappa) (b_{1,1}^{(1,0)} y \sinh(\kappa y) + b_{1,2}^{(1,0)} + b_{1,3}^{(1,0)} \cosh(\kappa y)) \\
    -i \tanh(\kappa) (b_{1,1}^{(1,0)} \sinh(\kappa) + b_{1,2}^{(1,0)} + b_{1,3}^{(1,0)} \cosh(\kappa))
    \end{array} \right), \\
    w_{2}^{(1,0)}(x;0) &= e^{ix} \left( \begin{array}{c}
    -(b_{1,1}^{(1,0)} y \sinh(\kappa y) + b_{1,2}^{(1,0)} + b_{1,3}^{(1,0)} \cosh(\kappa y)) \\
    -i \tanh(\kappa) (b_{1,1}^{(1,0)} y \sinh(\kappa y) + b_{1,2}^{(1,0)} + b_{1,3}^{(1,0)} \cosh(\kappa y)) \\
    -i \tanh(\kappa) (b_{1,1}^{(1,0)} \sinh(\kappa) + b_{1,2}^{(1,0)} + b_{1,3}^{(1,0)} \cosh(\kappa))
    \end{array} \right),
\end{align*}
\]

and

\[
\begin{align*}
    w_{3}^{(1,0)}(x;0) &= \left( \begin{array}{c}
    -\frac{\kappa c}{s-\kappa c} y^2 + \frac{\kappa c(3s-\kappa c)}{3(s-\kappa c)^2} + \frac{4c}{\kappa (\kappa - cs)} \cosh(\kappa y) \\
    0 \\
    0
    \end{array} \right), \\
    w_{4}^{(1,0)}(x;0) &= \left( \begin{array}{c}
    0 \\
    0
    \end{array} \right),
\end{align*}
\]

where

\[
\begin{align*}
    b_{1,1}^{(1,0)} &= -\frac{2i\kappa c^2}{\kappa - cs}, & b_{1,2}^{(1,0)} &= -\frac{2i\kappa^2}{s-\kappa c} & \text{and} & b_{1,3}^{(1,0)} &= -\frac{i(2\kappa c^4 + c^3 s - 3\kappa c^2)}{(\kappa - cs)^2}.
\end{align*}
\]

Throughout the section, we employ the notation

\[
    s = \sinh(\kappa) \quad \text{and} \quad c = \cosh(\kappa)
\]

wherever it is convenient to do so.

Let $w_{k}^{(0,1)}(x;0) = \left( \begin{array}{c}
    (w_{k}^{(0,1)}(x;0))_1 \\
    (w_{k}^{(0,1)}(x;0))_2 \\
    (w_{k}^{(0,1)}(x;0))_3
    \end{array} \right)$, $k = 1, 2, 3, 4$, and we likewise make straightforward calculations to show that, to the lowest orders,

\[
\begin{align*}
    (w_{1}^{(0,1)}(x;0))_1 &= e^{-2i\kappa x} (b_{1,1}^{(0,1)} y \sinh(\kappa y) + b_{1,2}^{(0,1)} + b_{1,3}^{(0,1)} \cosh(\kappa y) + b_{1,4}^{(0,1)} \cosh(2\kappa y)), \\
    (w_{1}^{(0,1)}(x;0))_2 &= e^{-2i\kappa x} (b_{2,1}^{(0,1)} (y + \frac{1}{2}) \sinh(\kappa y) + b_{2,2}^{(0,1)} + b_{2,3}^{(0,1)} \cosh(\kappa y) + b_{2,4}^{(0,1)} \cosh(2\kappa y)) \\
    &\quad + b_{2,1}^{(0,1)} (y - \frac{1}{2}) \sinh(\kappa y) + b_{2,5}^{(0,1)} + b_{2,6}^{(0,1)} \cosh(\kappa y)), \\
    (w_{1}^{(0,1)}(x;0))_3 &= [(w_{1}^{(0,1)}(x;0))_2]_{y=1},
\end{align*}
\]

and

\[
\begin{align*}
    (w_{2}^{(0,1)}(x;0))_1 &= e^{-2i\kappa x} (b_{1,1}^{(0,1)} y \sinh(\kappa y) + b_{1,2}^{(0,1)} + b_{1,3}^{(0,1)} \cosh(\kappa y) + b_{1,4}^{(0,1)} \cosh(2\kappa y)), \\
    (w_{2}^{(0,1)}(x;0))_2 &= -e^{-2i\kappa x} (b_{2,1}^{(0,1)} (y + \frac{1}{2}) \sinh(\kappa y) + b_{2,2}^{(0,1)} + b_{2,3}^{(0,1)} \cosh(\kappa y) + b_{2,4}^{(0,1)} \cosh(2\kappa y)) \\
    &\quad - b_{2,1}^{(0,1)} (y - \frac{1}{2}) \sinh(\kappa y) - b_{2,5}^{(0,1)} - b_{2,6}^{(0,1)} \cosh(\kappa y)), \\
    (w_{2}^{(0,1)}(x;0))_3 &= [(w_{2}^{(0,1)}(x;0))_2]_{y=1},
\end{align*}
\]
where

\( b_{1,1}^{(0,1)} = \kappa^2 c, \)
\( b_{1,3}^{(0,1)} = \frac{2\kappa^2 c^3 + \kappa^2 c + \kappa c^2 s}{2(\kappa - cs)}, \)
\( b_{2,1}^{(0,1)} = -i\kappa^2 s, \)
\( b_{2,3}^{(0,1)} = \frac{i\kappa(4\kappa - 3\kappa^4 - \kappa c^2 + cs - c^3 s)}{2s(\kappa - cs)}, \)
\( b_{2,5}^{(0,1)} = \frac{i\kappa(\kappa c^2 + \kappa^3 - \kappa - kc + 2cs - 2c^3 s)}{2Kcs - 2c^2 + 2}, \)

\( b_{1,2}^{(0,1)} = -\kappa\frac{(4c^2 s - \kappa c)}{4s - 4Kc}, \)
\( b_{1,4}^{(0,1)} = \frac{3\kappa c}{4s^3}, \)
\( b_{2,2}^{(0,1)} = \frac{i\kappa(\kappa c - \kappa c^3 + 2cs - 2c^3 s)}{2Kcs - 2c^2 + 2}, \)
\( b_{2,4}^{(0,1)} = -\frac{3i\kappa^2}{2s^2}, \)

Additionally, we calculate that, to the lowest orders,

\( (w_3^{(0,1)}(x; 0))_1 = \sin(kx)(b_{3,1}^{(0,1)} y \sinh(ky) + b_{3,2}^{(0,1)} + b_{3,3}^{(0,1)} \cosh(ky)), \)
\( (w_3^{(0,1)}(x; 0))_2 = \tanh(k) \cos(kx)(b_{3,1}^{(0,1)} y \sinh(ky) + b_{3,2}^{(0,1)} + b_{3,3}^{(0,1)} \cosh(ky)), \)
\( (w_3^{(0,1)}(x; 0))_3 = [(w_3^{(0,1)}(x; 0))_2]_{y=1}, \)

where

\( b_{3,1}^{(0,1)} = \frac{-2\kappa^2 c^2 - kcs}{\kappa - cs}, \)
\( b_{3,2}^{(0,1)} = \frac{-c(s + 2kc)}{s - kc}, \)
\( b_{3,3}^{(0,1)} = \frac{c^2 - c^4 + 6\kappa^2 c^2 - 4\kappa^4 c^3 + 3Kcs - 4Kc^3 s}{2c^2 + 2c^2s^2 - 4Kcs}, \)

and \( w_4^{(0,1)}(x; 0) = 0. \)

We do not include the formulae of \( w_k^{(m,n)}(x; 0), k = 1, 2, 3, 4, \) and \( m + n \geq 2. \)

**Appendix F. Expansion of \( w_k^{(m,n)}(x; \sigma) \)**

Throughout the section, \( \sigma > \sigma_c. \) Inserting \( 6.3, 6.5 \) and \( 6.6 \) into the latter equation of \( (4.22), \) at the order of \( \delta^m \varepsilon^n, m + n \geq 1, \) let \( w_k^{(m,n)}(x; \sigma) = \begin{pmatrix} \phi \\ \eta \end{pmatrix}, \) by abuse of notation, and we arrive at

\[
\begin{align*}
\phi_{xx} + \phi_{yy} = & i\sigma((1 - \Pi(\sigma))f_k^{(m,n)}(x; \sigma))_1 + ((1 - \Pi(\sigma))f_k^{(m,n)}(x; \sigma))_1x \\
+ & \mu_0((1 - \Pi(\sigma))f_k^{(m,n)}(x; \sigma))_2 \\
& \text{for } 0 < y < 1,
\end{align*}
\]

\( v = \mu_0^{-1}\phi_x - i\sigma\mu_0^{-1}\phi - \mu_0^{-1}((1 - \Pi(\sigma))f_k^{(m,n)}(x; \sigma))_1 \\
\eta_x = -\phi_y + i\sigma\eta + ((1 - \Pi(\sigma))f_k^{(m,n)}(x; \sigma))_3 \\
\eta = v \\
\phi_y = 0
\]

We solve the first and the last equations of \( (F.1) \) by the method of undetermined coefficients, for instance, subject to that \( w_k^{(m,n)}(x; \sigma) \in (1 - \Pi(\sigma))Y, \) so that \( \Pi(\sigma)w_k^{(m,n)}(x; \sigma) = 0, \) to determine \( \phi, \) and we determine \( v \) and \( \eta \) by the second and fourth equations of \( (F.1). \)
A straightforward calculation reveals that, to the lowest orders,

\[
(w_1^{(0,1)}(x; \sigma))_1 = e^{ikx} \left( (b_{1,1}^{(0,1)} \sin(\kappa x) + b_{1,2}^{(0,1)} \cos(\kappa x)) \cosh(k_2 y) + b_{1,3}^{(0,1)} \sin(\kappa x) y \sinh(\kappa y) + k_2 \kappa c \cos(\kappa x) y \sinh(k_2 y) + \left( b_{1,4}^{(0,1)} \sin(\kappa x) + b_{1,5}^{(0,1)} \cos(\kappa x) \right) \cosh(k_4 y) + b_{1,6}^{(0,1)} e^{-ix} \cosh((k_2 + \kappa) y) + b_{1,7}^{(0,1)} e^{-ix} \cosh((k_2 - \kappa) y) \right),
\]

\[
(w_1^{(0,1)}(x; \sigma))_2 = e^{ikx} \left( (b_{1,8}^{(0,1)} \sin(\kappa x) + b_{1,9}^{(0,1)} \cos(\kappa x)) \cosh(k_2 y) + \left( b_{1,10}^{(0,1)} \sin(\kappa x) + b_{1,11}^{(0,1)} \cos(\kappa x) \right) \cosh(k_4 y) \right),
\]

\[
(w_1^{(0,1)}(x; \sigma))_3 = \left[ (w_1^{(0,1)})_2 \right]_{y=1},
\]

where

\[
b_{1,1}^{(0,1)} = \frac{-4ik_2^3 (k_2^2 c_2 s + \sigma^2 c_2 s - k_2 \kappa c s_2 - 2k_2 \sigma c_2 s)}{\kappa s_2 (4k_2^2 - \kappa^2)}, \quad \quad b_{1,2}^{(0,1)} = \frac{2k_2 (k_2^2 c_2 s + \sigma^2 c_2 s - k_2 \kappa c s_2 - 2k_2 \sigma c_2 s)}{s_2 (4k_2^2 - \kappa^2)} + \frac{p_{1,1}^{(0,1)} c_2 (k_2 - \sigma)^2}{k_2 \kappa s_2},
\]

\[
b_{1,3}^{(0,1)} = i\kappa c_2 (k_2 - \sigma), \quad \quad b_{1,4}^{(0,1)} = \frac{i c_4 (k_4 - \sigma)^2 ((k_4 - k_2) p_{1,3}^{(0,1)} + ik p_{1,4}^{(0,1)})}{k_4 s_4 (2k_2 k_4 - k_2^2 - k_4^2 + \kappa^2)},
\]

\[
b_{1,5}^{(0,1)} = \frac{-ic_4 (k_4 - \sigma)^2 ((k_4 - k_2) p_{1,4}^{(0,1)} + ik p_{1,3}^{(0,1)})}{k_4 s_4 (2k_2 k_4 - k_2^2 - k_4^2 + \kappa^2)},
\]

and

\[
b_{1,8}^{(0,1)} = i(k_2 - \sigma) \mu_0^{-1} b_{1,1}^{(0,1)} - \kappa \mu_0^{-1} b_{1,2}^{(0,1)} + p_{1,1}^{(0,1)} - \sigma c^{-1}(c^2 - 1)(k_2 - \sigma), \quad \quad b_{1,9}^{(0,1)} = \kappa \mu_0^{-1} b_{1,1}^{(0,1)} + ik(k_2 - \sigma) \mu_0^{-1} b_{1,2}^{(0,1)} + p_{1,1}^{(0,1)} - \kappa k_2 c,
\]

\[
b_{1,10}^{(0,1)} = i(k_2 - \sigma) \mu_0^{-1} b_{1,4}^{(0,1)} - \kappa \mu_0^{-1} b_{1,5}^{(0,1)} + p_{1,1}^{(0,1)}, \quad \quad b_{1,11}^{(0,1)} = \kappa \mu_0^{-1} b_{1,4}^{(0,1)} + ik(k_2 - \sigma) \mu_0^{-1} b_{1,5}^{(0,1)} + p_{1,1}^{(0,1)}.
\]

Here and elsewhere, we employ the notation

\[
s = \sinh(\kappa), \quad s_2 = \sinh(k_2), \quad s_4 = \sinh(k_4), \quad s(1) = \sinh(1),
\]

\[
c = \cosh(\kappa), \quad c_2 = \cosh(k_2), \quad c_4 = \cosh(k_4), \quad s_2(2) = \sinh(2k_2).
\]
whenever it is convenient to do so. Also,

\[
b^{(0,1)}_{1,0} = \left( 2k^2 \kappa^2 c_2 s_2 + 6k^4 \kappa^2 c_2^2 s_2 - 4k^2 \delta^3 c_2^4 s_2 + 2k^2 \sigma^4 c_2^4 s_2 - 2k^3 \sigma^3 c_2^2 s_2 - 2k^3 \kappa^2 c_2^3 c^2 + 4k^2 \kappa c_2 c^2 \\
+ 4k^2 \kappa c_2^2 s_2 + 4k^2 \delta c_2 c_4 + 2k^2 \kappa^2 c_2^2 c_2 - 4k^1 \kappa c_2^2 c_2 + 10k^2 \kappa c_2 c_2 c_2 s_2 + 4k^2 \kappa c_2^2 c_2 s_2 - 16k^3 \kappa c_2 c_2^2 c_2 s_2 \\
- 16k^2 \kappa c_2 c_2 s_2 + 2k^3 \kappa c_2^2 c_2 s_2 + 8k^2 \kappa c_2^4 c_2^2 s_2 + 2k^2 \sigma^4 c_2^4 s_2 - 2k^2 \kappa^2 c_2^4 c_2^2 - 4k^2 \kappa^2 c_2^4 c_2^2 s_2 \\
+ 4k^2 \kappa^2 \sigma c_2^2 c_2 + 2k^3 \kappa^2 c_2 c_2 c_2 s_2 + 8k^2 \kappa^2 c_2^2 c_2 c_2 s_2 - 6k^2 \kappa^3 c_2 c_2 s_2 - 12k^2 \kappa^2 c_2^2 c_2 s_2 + 6k^2 \kappa^3 \sigma^2 c_2^2 s_2 \\
