Abstract

Magnon-polarons are coherently mixed quasiparticles that originate from the strong magnetoelastic coupling of lattice vibrations and spin waves in magnetic-ordered materials. Recently, magnon-polarons have attracted a lot of attention since they provide a powerful tool to manipulate magnons, which is essential for magnon-based spintronic devices. In this work, we report the experimental observation of facet-dependent magnon-polarons in epitaxial ferrimagnetic Fe₃O₄ thin films *via* spin Seebeck effect measurement. The critical magnetic fields for the

magnon-polarons in the (110)- and (100)-oriented Fe₃O₄ films are 1.5 T and 1.8 T, respectively, which arises from the different phonon velocities along the [110] and [100] directions. As the temperature decreases, the magnon-polarons-enhanced spin Seebeck voltage decreases in both (110)- and (100)-oriented Fe₃O₄ films, which could be attributed to the enhanced magnon-polarons scattering at elevated temperatures. This work demonstrates the crystal structure engineering in epitaxial magnetic films as a promising route to manipulate the magnon-polarons for future magnon spintronic applications.

I. INTRODUCTION

As the data carriers, the properties of magnons are crucial for magnon-based spintronic applications [1-5]. Magnon-polarons provide a powerful tool to improve the properties of magnons, such as increasing the lifetime and group velocity [6-10]. Magnon-polarons could be formed in magnetic-ordered materials due to the strong magnetoelastic coupling between spin waves and lattice vibrations. Recently, a magnon-polarons-induced anomaly has been discovered in the spin Seebeck effect (SSE) of yttrium iron garnet (Y₃Fe₃O₁₂: YIG) [7,8,11] and the spin Peltier effect of lutetium iron garnet [12]. Besides YIG, Fe₃O₄ is a ferrimagnetic insulator with strong magnon-phonon coupling [13,14], which makes it a potentially suitable platform to investigate magnon-polarons. More interestingly, neutron scattering studies have

shown the anisotropic properties of phonons in Fe₃O₄ [15]. Thus, Fe₃O₄ might reveal the anisotropic properties of magnon-polarons which are expected to exist theoretically [8], but have never been experimentally explored yet.

In this work, we report the magnon-polarons in high-quality (110)- and (100)-oriented epitaxial Fe₃O₄ thin films *via* SSE measurements. Interestingly, the critical magnetic fields of magnon-polarons are found to be strongly facet-dependent in the (110)- and (100)-oriented Fe₃O₄ films, which is due to the anisotropic phonon velocities along the Fe₃O₄ crystal's [110] and [100] directions. The magnon-polarons-enhanced SSE voltages decrease in both (110)- and (100)-oriented Fe₃O₄ films as temperature increases, which could be attributed to the enhanced magnon-polarons scattering at elevated temperatures.

II. EXPERIMENTAL

The Fe₃O₄ thin films were grown on (110)- and (100)-oriented MgO substrates (from Hefei Kejing Materials Technology) using oxide molecular-beam epitaxy system (MBE-Komponenten GmbH; Octoplus 400) with a base pressure lower than 1.0×10^{-10} mbar [16]. Prior to the Fe₃O₄ film growth, the MgO substrates were pre-cleaned by annealing at 600 °C for 2 hours. Then, the Fe₃O₄ thin films were grown by evaporating Fe from a thermal effusion cell with a deposition rate of 0.02 Å/s in the diluted ozone gas under the pressure of $\sim 5.2\times10^{-7}$ mbar. During the Fe₃O₄ film growth, *in situ* reflective high-energy electron diffraction (RHEED) was used to

monitor the growth and to characterize the crystalline properties. Figures 1(a) and 1(c) show the typical RHEED patterns of the (110)-oriented MgO substrates and 100 nm thick (110)-oriented Fe₃O₄ thin films viewed from the MgO crystal's [110] direction. The sharp RHEED pattern indicates the high-quality crystalline properties of (110)-oriented Fe₃O₄ thin films epitaxially grown on the MgO substrates. Following the same growth procedures, high quality (100)-oriented Fe₃O₄ thin films were achieved on (100)-oriented MgO substrates (Figs. 1(b) and 1(d)). Figures 1(e) and 1(f) show the X-ray diffraction (XRD) results of the Fe₃O₄ films, which clearly show the epitaxial features of the (110)- and (100)-oriented Fe₃O₄ films on the corresponding MgO substrates. Furthermore, the Verwey transitions are observed for (110)- and (100)-Fe₃O₄ thin films (Figs. 1(g) and 1(h)), which are consistent with the previous reports and further confirm the Fe₃O₄ phase of our samples [17-19].

The Fe₃O₄ longitudinal SSE devices were fabricated using standard E-beam lithography and lift-off processes. The first step was to define a Pt electrode (width: 200 nm) on the Fe₃O₄ films *via* electron-beam lithography. The 10 nm thick Pt was deposited in a magneton sputtering system with a base pressure lower than 8.0×10⁻⁷ mbar. Then a heater electrode consisting of 100 nm thick Al₂O₃ and 20 nm thick Ti was grown *via* E-beam evaporation. Figure 2(a) shows the schematic of the fabricated longitudinal SSE device with the measurement geometry, where the Ti layer was used to generate the heat flow from Joule heating, the Pt electrode was used to detect the SSE voltage and the Al₂O₃ layer was used to accomplish electric insulation between

the Ti and Pt electrodes.

The magnon-polarons and SSE in Fe₃O₄ thin films were measured using on-chip local heating via standard low frequency lock-in technique in a Physical Properties Measurement System (PPMS, Quantum Design). A current source (K6221, Keithley) was used to provide the AC current (frequency: 7 Hz) in the Ti electrode to generate temperature gradient (∇T) perpendicular to the Fe₃O₄ films. The heating power was kept constant at 0.087 mW across the temperature range of measurement (2 K to 12.5 K). Additionally, the local temperature change in this study was a minor effect based on the analysis of the heating effect on the Fe₃O₄ films. The bottom surface of the SSE device was attached to the Cu sample holder using thermal conducting paste, where the Cu holder acted as a thermal sink. An in-plane magnetic field ($\mu_0 H$) was applied perpendicular to the Pt strip as shown in the right inset of Fig. 2(b). The SSE signals were measured via the second harmonic voltages using lock-in amplifiers (SR830, Stanford Research). During the measurement, a low noise voltage preamplifier (SR560, Stanford Research) was used to enhance the signal-to-noise ratio.

III. RESULTS AND DISCUSSION

Figure 2(b) shows the representative SSE voltage curves of (110)-oriented Fe₃O₄ films as a function of magnetic field at T = 2 K. At low magnetic fields, a hysteresis behavior of the SSE signal is observed between \pm 0.3 T at T = 2 K (left inset of Fig.

2(b)). The hysteresis loop of the SSE voltages follows the magnetization curves of the Fe₃O₄ as a function of the magnetic field. Interestingly, two enhancement anomalies of the SSE signals (indicated by the orange triangles) are observed clearly at $\mu_0 H \sim \pm$ 1.5 T, which are the typical experimental signatures of magnon-polarons in a magnetic material [7-9,20]. At the critical magnetic fields of $\mu_0 H \sim \pm$ 1.5 T, magnon-polarons form and enhance the SSE voltage signals as a result of the tangential magnon and phonon dispersions [8,20]. Theoretically, the magnon dispersion of ferrimagnetic Fe₃O₄ can be described by the following expression [7,8]:

$$\omega_k = \sqrt{D_{\rm ex}k^2 + \gamma\mu_0 H} \sqrt{D_{\rm ex}k^2 + \gamma\mu_0 H + \gamma\mu_0 M_{\rm s} \sin^2\theta} \# (1)$$

where ω_k is the angular frequency of magnon, k is the wave vector, $D_{\rm ex}$ is the exchange stiffness coefficient, γ is the gyromagnetic ratio, $\mu_0 H$ is the external magnetic field, $\mu_0 M_{\rm s}$ is the saturation magnetization, and θ is the angle between the external magnetic field and the magnon propagation direction. The transverse-acoustic (TA) phonon dispersion can be described by the following expression [7,8]:

$$\omega_{\text{TA}} = c_{\perp} k \# (2)$$

where ω_{TA} is the angular frequency of TA-phonon, and c_{\perp} is the TA-phonon velocity. The magnon and phonon dispersion curves of (110)-oriented Fe₃O₄ are plotted in Figs. 2(c-e). At the critical magnetic field, $\mu_0 H = \mu_0 H_{TA}^{[110]}$, the magnon and phonon dispersion curves of (110)-oriented Fe₃O₄ are tangential to each other

(Fig. 2(d)), which results in the enhancement anomalies of the SSE signals (orange triangles in Fig. 2(a)). For a small magnetic field, $\mu_0 H < \mu_0 H_{\rm TA}^{[110]}$, the magnon and phonon dispersion curves are intersecting (Fig. 2(c)). For a large magnetic field, $\mu_0 H > \mu_0 H_{\mathrm{TA}}^{[110]}$, the magnon and phonon dispersion curves are detached (Fig. 2(e)). By using the typical experimental values of $D_{\rm ex} \sim 6.76 \times 10^{-6} \, {\rm m^2/s}$ [21], $\mu_0 M_{\rm s}$ of 364 emu/cm³ [22], and $c_{\perp} \sim 3240$ m/s for k // [110] direction [15], the critical magnetic field $(\mu_0 H_{\mathrm{TA}}^{[110]})$ is estimated to be ~2 T. The calculated $\mu_0 H_{\mathrm{TA}}^{[110]}$ is slightly higher than the experimental results, which might result from the slight modification of material parameters in our epitaxial thin films compared to their bulk values. Compared to the magnon-polarons-enhanced SSE signals observed in YIG [7,11], a much broader peak shape is observed in Fe₃O₄ thin films, which could be attributed to the large magnon-phonon coupling in Fe₃O₄ [8]. Notice that the high longitudinal-acoustic phonon velocity of 7600 m/s for Fe₃O₄[15] could lead to a large critical magnetic field of ~ 12.5 T for the magnon-polarons-enhanced SSE signal, which is above the maximum magnetic field of 9 T in our PPMS system.

Next, the anisotropic properties of magnon-polarons in the (110)- and (100)-oriented Fe₃O₄ thin films are investigated. Figure 3(a) shows the results of SSE signals in Fe₃O₄ thin films as a function of the magnetic field at T=2 K. The critical magnetic field of the magnon-polarons is ~1.8 T for (100)-oriented Fe₃O₄, which is larger than that of (110)-oriented Fe₃O₄ (~1.5 T). In the following, we discuss the physical mechanisms that account for the facet-dependent critical magnetic fields in

(110)- and (100)-oriented Fe₃O₄ thin films. The magnon dispersion curves have been shown to be isotropic in previous inelastic neutron scattering studies [14,23-25]. On the other hand, the TA-phonon velocities for k along [110] and [100] direction of Fe₃O₄ crystal are 3240 m/s and 3430 m/s, respectively [15]. Hence, the different phonon velocities could lead to the experimental observation of the smaller $\mu_0 H_{TA}^{[110]}$ and larger $\mu_0 H_{TA}^{[100]}$, as illustrated in Figs. 3(b-c).

Figures 4(a-b) show the magnetic field dependence of SSE voltages for (110)- and (100)-oriented Fe₃O₄ at T=2, 5, 7.5 and 10 K, respectively. Figure 4(c) summarizes the magnon-polarons-enhanced SSE voltages (V_{TA}) as a function of the temperature. As temperature increases, V_{TA} exhibits a strong suppression and disappears around 10 K. Since the magnon-polarons-enhanced SSE arises from the much longer phonon lifetimes than the magnon lifetimes ($\tau_{ph}/\tau_{mag} > 1$), this observation could be attributed to the smaller ratio of τ_{ph}/τ_{mag} as temperature increases. In other words, the enhancement of the magnon-polarons scattering rate at elevated temperatures leads to the reduction of the magnon-polarons-induced SSE anomaly [7-9]. The critical magnetic fields exhibit little variation as a function of the temperature, as shown in the inset of Fig. 4(c), which is expected in the small temperature range from 2 K to 10 K.

Based on these results, it can be concluded that the present study for the facet-dependent magnon-polarons in epitaxial ferrimagnetic Fe₃O₄ thin films is an interesting piece that complements the results for the magnon-polarons of YIG/Pt

heterostructures [7,12] as well as the spin caloritronics effects of Fe₃O₄/Pt heterostructures [26,27]. These results demonstrate that the crystalline structure plays an important role in the magnon-polarons-induced anomalies, which could provide a powerful method for magnon control. Hence, it might be useful for the research field of magnon spintronics that utilizes magnon for information carriers.

IV. CONCLUSIONS

In summary, the facet-dependent magnon-polarons in high-quality epitaxial Fe₃O₄ thin films are experimentally investigated. Different critical magnetic fields for the magnon-polarons are observed in (110)- and (100)-oriented Fe₃O₄ thin films, which can be well interpreted by the anisotropy of phonon velocities. Furthermore, the stronger magnon-polarons scattering at higher temperatures results in the decrease of magnon-polarons-enhanced SSE voltages. Our work emphasizes the function of crystal directions in the magnon-polarons-induced SSE anomalies, and enriches the field of the magnon-polarons-dominated spin caloritronics effects in magnetic insulators.
