(Dated: December 29, 2021)

We propose a general theory of microwave absorption spectroscopy for symmetry-breaking synthetic antiferromagnets (SAFs). Generally, inhomogeneity or different thickness of the two ferromagnetic sublayers of a SAF results in the intrinsic symmetry breaking, while out-of-plane components of dc magnetic fields lead to the extrinsic one. The broken symmetry of SAFs excludes the original symmetry-protected crossing between pure in-phase and out-of-phase resonance modes with opposite parity. Alternatively, new frequency branches become hybridization of original bare modes in terms of symmetry-breaking-induced magnon-magnon coupling, which results in an indirect gap in ferromagnetic resonance frequencies. Also, the dependence of gap width on the degree of symmetry breaking for several typical cases are presented and compared with existing experiments. Our theory provides a simple but physical understanding on the rich structure of ferromagnetic resonance spectra for asymmetric SAFs.

Synthetic antiferromagnets (SAFs) are magnetic multilayers with two ferromagnetic (FM) sublayers coupled antiferromagnetically through a nonmagnetic metallic spacer[1]. They have attracted tremendous interest in the past decades due to their potential for developing the “SAF spintronics” and wide range of applications in magnetic nanodevices [2–21]. Compared with the strong exchange coupling in genuine antiferromagnetic (AFM) materials with terahertz intrinsic frequencies[22, 23], the relatively weak interlayer coupling in SAFs mainly comes from the Ruderman-Kittel-Kasuya-Yosida (RKKY) interaction[24–26] and thus realizes gigahertz FM resonance (FMR) frequencies that mature microwave electronics can match. Similar behaviors have also been observed in layered crystals[27, 28] and compensated ferrimagnets[29] with AFM inter-layer and inter-sublattice couplings, respectively. More interestingly, for symmetrical NiFe/Ru/NiFe[2, 16] and FeCoB/Ru/FeCoB SAFs[18–21], or layered crystal CrCl<sub>3</sub>[27], symmetry-protected mode crossings between in-phase and out-of-phase branches of FMR spectra have been observed under in-plane external dc magnetic fields. This indicates the absence of coupling between magnons with opposite parity, which is, on the contrary, very common in yttrium iron garnet/ferromagnet bilayers[30–32].

In fact, this mode crossing can be eliminated in several ways. For symmetrical SAFs or layered crystals, extrinsically exerting an out-of-plane dc field will lift the system's rotation-symmetry axis away from the SAF plane, thus breaks the rotation symmetry of the hard axis (normal of SAF plane) from the magnetostatic interaction. This introduces a magnon-magnon coupling between the original uncoupled modes with opposite parity, hence hybridizes the two modes and generate an anti-crossing gap[20, 27]. Very recently, strong magnon-magnon coupling under in-plane dc fields is also proposed by the dynamic dipolar interaction (nonuniform precession) in symmetrical FeCoB/Ru/FeCoB SAFs[18, 19], which provides an alternative way of extrinsic symmetry breaking (SB). The other

strategy is to break the intrinsic symmetry between the two FM sublayers in SAFs. In most existing experiments the two sublayers are prepared from the same FM materials but with different thickness. A frequency gap can be observed even under in-plane dc fields[16, 17]. In addition, intrinsic asymmetry should also appear when the two sublayers are made from different FM materials. However, to our knowledge the corresponding FMR measurements are not yet in the press, which mainly comes from the difficulty in sample preparation.

A lot of theoretical work has been performed to understand the rich structure of FMR spectra in SAFs[4, 14–18, 20, 21, 27, 29]. Representatively, in 2014 a discrete-lattice approach has been raised for asymmetric NiFe/Ru/NiFe SAFs[17], where the RKKY interaction, biquadratic exchange couplings and the uniaxial anisotropy at the NiFe/Ru interfaces are all considered, however a clear and simple physical picture is still lacking. In 2019, based on “macrospin” assumption MacNeill *et al.* proposed a systematic analysis for the gap induction by extrinsic SB from out-of-plane dc fields in which only the bilinear RKKY interaction is included[27]. However, they did not consider the intrinsic SB since the sublayers of their system are always symmetrical. In this Letter, we demonstrate that intrinsic and extrinsic SB in SAFs can induce magnon-magnon couplings via different mechanisms, thus further lead to indirect gaps in their FMR spectra. In brief, a general theory including both intrinsic and extrinsic SB (from tilting dc fields) will be presented first and then followed by several examples that are easy to compare with experiments.

The SAF system under consideration is sketched in Fig. 1 (a). The saturation magnetization and thickness of the upper (lower) FM sublayer are  $M_s^{A,0}$  and  $d_A$  ( $M_s^{B,0}$  and  $d_B$ ), respectively. The crystalline anisotropy in both sublayers are neglected for simplicity. In typical SAFs, the FM intralayer nearest-neighbor exchange is much stronger than the interlayer AFM coupling. Therefore the “macrospin” approximation generally provides enough information about spin-wave

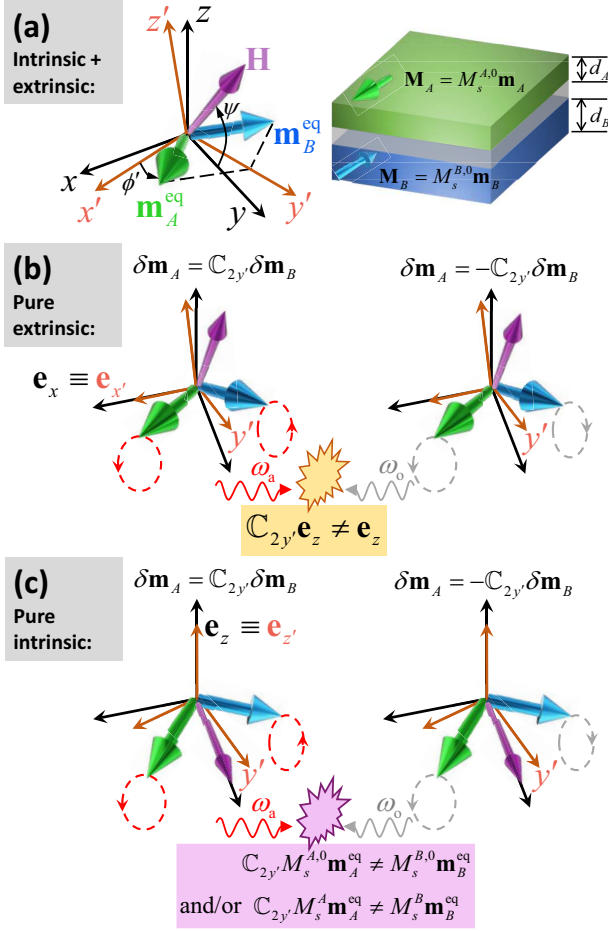

FIG. 1. (a) Sketch of a typical SAF with saturation magnetization  $M_s^{A(B),0}$  and thickness  $d_{A(B)}$  in its two FM sublayers. The macrospins ( $\mathbf{m}_A$  and  $\mathbf{m}_B$ ) of the two sublayers are coupled antiferromagnetically and tilted at equilibrium ( $\mathbf{m}_A^{\text{eq}}$  and  $\mathbf{m}_B^{\text{eq}}$ ) under both extrinsic and intrinsic SB. Generally, the new  $x'y'z'$  coordinate system (see definition in the main text) is totally different with the initial  $xyz$  one. The deviation of  $z'$  ( $x', y'$ ) from the  $z$  ( $x, y$ ) axis comes from the extrinsic (intrinsic) SB. (b) Sketch of magnon-magnon coupling between the in-phase ( $\delta \mathbf{m}_A = \mathcal{C}_{2y'} \delta \mathbf{m}_B$ ) and out-of-phase ( $\delta \mathbf{m}_A = -\mathcal{C}_{2y'} \delta \mathbf{m}_B$ ) modes with opposite parity under pure extrinsic SB with  $\mathbf{e}_x \equiv \mathbf{e}_{x'}$ . This coupling comes from the breaking rotation symmetry of magnetostatics under  $\mathcal{C}_{2y'}$  ( $\mathcal{C}_{2y'} \mathbf{e}_z \neq \mathbf{e}_z$ ). (c) Sketch of magnon-magnon coupling between in-phase and out-of-phase modes under pure intrinsic SB with  $\mathbf{e}_z \equiv \mathbf{e}_{z'}$ . This coupling comes from the breaking rotation symmetry of magnetostatics and/or magnetization under  $\mathcal{C}_{2y'}$  ( $\mathcal{C}_{2y'} M_s^{A,0} \mathbf{m}_A^{\text{eq}} \neq M_s^{B,0} \mathbf{m}_B^{\text{eq}}$  and/or  $\mathcal{C}_{2y'} M_s^A \mathbf{m}_A^{\text{eq}} \neq M_s^B \mathbf{m}_B^{\text{eq}}$ ).

behaviors. Now the magnetization within each sublayer can be viewed as uniform and denoted as  $\mathbf{m}_A$  and  $\mathbf{m}_B$ , respectively. The interlayer exchange energy is then modeled as  $\mu_0 \lambda_E S (d_A + d_B) M_s^{A,0} M_s^{B,0} \mathbf{m}_A \cdot \mathbf{m}_B / 2$ , where  $\lambda_E > 0$  is a dimensionless coefficient and  $S$  is the SAF cross-section area. In literatures, this term is also expressed as the “interlayer exchange energy per unit area”  $J_{\text{IEC}}$  [6, 7, 10, 12, 15, 18, 19, 21]. Hence  $\lambda_E = 2J_{\text{IEC}} / [\mu_0 M_s^{A,0} M_s^{B,0} (d_A + d_B)]$ . By neglecting the Gilbert damping, a coupled Landau-Lifshitz-Gilbert (LLG)

equation reads

$$\begin{aligned} \dot{\mathbf{m}}_A &= -\gamma \mathbf{m}_A \times [\mathbf{H} - \lambda_E M_s^B \mathbf{m}_B - M_s^{A,0} (\mathbf{m}_A \cdot \mathbf{n}) \mathbf{n}] + \boldsymbol{\tau}_A, \\ \dot{\mathbf{m}}_B &= -\gamma \mathbf{m}_B \times [\mathbf{H} - \lambda_E M_s^A \mathbf{m}_A - M_s^{B,0} (\mathbf{m}_B \cdot \mathbf{n}) \mathbf{n}] + \boldsymbol{\tau}_B, \end{aligned} \quad (1)$$

where an overdot means  $d/dt$ ,  $\mathbf{n}$  is the sublayer normal and

$$M_s^A = \frac{d_A + d_B}{2d_B} M_s^{A,0}, \quad M_s^B = \frac{d_A + d_B}{2d_A} M_s^{B,0} \quad (2)$$

are the “thickness-modified saturation magnetization” of the respective sublayers.  $\gamma = \mu_0 \gamma_e$  with  $\mu_0$  and  $\gamma_e$  being the vacuum permeability and electron gyromagnetic ratio, respectively. At last,  $\boldsymbol{\tau}_{A(B)}$  is the torque on  $\mathbf{m}_{A(B)}$  which arises from the rf excitation field of coplanar waveguides.

In the following we present a general theory describing the combining effects of intrinsic and extrinsic SB on FMR spectroscopy. As preparation, we calculate the equilibrium magnetization orientations under a general dc magnetic field  $\mathbf{H}$  with strength  $H$  and tilting angle  $\psi$  ( $0 \leq \psi < \pi/2$ ). First we construct the Cartesian coordinate system ( $\mathbf{e}_x, \mathbf{e}_y, \mathbf{e}_z$ ):  $\mathbf{e}_z \equiv \mathbf{n}$  thus the out-of-plane field component is  $H \sin \psi$ ,  $\mathbf{e}_y$  is parallel to the in-plane field component  $\mathbf{H} - H \sin \psi \mathbf{e}_z$ , and  $\mathbf{e}_x = \mathbf{e}_y \times \mathbf{e}_z$ . Due to the AFM interlayer coupling, without  $\mathbf{H}$  the unit magnetization vectors in the two sublayers orients oppositely in a certain in-plane direction in the absence of crystalline anisotropy. When  $\mathbf{H}$  is applied, in principle they are pulled out of  $xy$  plane and their final equilibrium states are denoted as  $\mathbf{m}_A^{\text{eq}}$  and  $\mathbf{m}_B^{\text{eq}}$ , respectively. We then set  $\theta_{A(B)}$  as their respective polar angles, and  $\phi_A$  ( $\phi_B$ ) being the angle that the in-plane component of  $\mathbf{m}_A^{\text{eq}}$  ( $\mathbf{m}_B^{\text{eq}}$ ) rotates anticlockwise (clockwise) with respect to  $\mathbf{e}_x$  ( $-\mathbf{e}_x$ ). These four angles can be explicitly solved from the static LLG equation (see Supplement Material).

Next we define a new  $x'y'z'$  coordinate system based on  $\mathbf{m}_A^{\text{eq}}$  and  $\mathbf{m}_B^{\text{eq}}$ :  $\mathbf{e}_{x'} \parallel \mathbf{m}_A^{\text{eq}} - \mathbf{m}_B^{\text{eq}}$ ,  $\mathbf{e}_{y'} \parallel \mathbf{m}_A^{\text{eq}} + \mathbf{m}_B^{\text{eq}}$ , and  $\mathbf{e}_{z'} \parallel \mathbf{m}_A^{\text{eq}} \times \mathbf{m}_B^{\text{eq}}$ . Note that to ensure the noncollinearity of  $\mathbf{m}_A^{\text{eq}}$  and  $\mathbf{m}_B^{\text{eq}}$ , the dc field strength  $H$  should be limited within the range  $H_{\text{AFM}} < |H| < H_{\text{FM}}$  (see Supplement Material for their general definitions). For  $|H| \leq H_{\text{AFM}}$  ( $\geq H_{\text{FM}}$ ),  $\mathbf{m}_A^{\text{eq}}$  and  $\mathbf{m}_B^{\text{eq}}$  point in the opposite (same) direction thus the SAF falls into AFM (FM) state. Then we denote  $\mathcal{C}_{2y'}$  as the rotation operator which rotates vectors around the  $y'$  axis by  $180^\circ$ . Obviously,  $\mathcal{C}_{2y'}^2 = 1$  and  $\mathcal{C}_{2y'} \mathbf{m}_{A(B)}^{\text{eq}} = \mathbf{m}_{B(A)}^{\text{eq}}$ . However, since  $M_s^{A,0} \neq M_s^{B,0}$  and/or  $d_A \neq d_B$ , the joint operation of  $\mathcal{C}_{2y'}$  and A-B sublayer exchange is no longer a symmetric operation of the entire SAF. When a rf field with frequency  $f = \omega/2\pi$  is excited, the magnetization vectors deviate slightly from their equilibrium orientations and begin to vibrate. We then expand  $\mathbf{m}_{A(B)} = \mathbf{m}_{A(B)}^{\text{eq}} + \delta \mathbf{m}_{A(B)} e^{i\omega t}$  and  $\boldsymbol{\tau}_{A(B)} = \boldsymbol{\tau}_{A(B)}^0 e^{i\omega t}$ . In addition, we introduce  $\delta \mathbf{m}_{\pm} \equiv \delta \mathbf{m}_A \pm \mathcal{C}_{2y'} \delta \mathbf{m}_B$  as the magnetization responses with even and odd parity (under  $\mathcal{C}_{2y'}$ ) to the torque terms  $\boldsymbol{\tau}_{\pm} = \boldsymbol{\tau}_A^0 \pm \mathcal{C}_{2y'} \boldsymbol{\tau}_B^0$ . By putting them into Eq. (1) and keeping up to linear-order terms, we get our central vectorial equation for the magnetization excitations  $\delta \mathbf{m}_{\pm}$ ,

$$\begin{aligned}
i\Omega\delta\mathbf{m}_{\pm} = & \mathbf{m}_A^{\text{eq}} \times \left\{ \frac{\lambda_E}{2} (M_s^A + M_s^B) (\delta\mathbf{m}_{\pm} \pm \mathcal{C}_{2y'} \delta\mathbf{m}_{\pm}) + \frac{\lambda_E}{2} (M_s^A - M_s^B) (\delta\mathbf{m}_{\mp} \pm \mathcal{C}_{2y'} \delta\mathbf{m}_{\mp}) \right. \\
& + \frac{M_s^{A,0} \pm M_s^{B,0}}{4} [\mathbf{e}_z \mathbf{e}_z \cdot + \mathcal{C}_{2y'} \mathbf{e}_z (\mathcal{C}_{2y'} \mathbf{e}_z) \cdot] \delta\mathbf{m}_{+} + \frac{M_s^{A,0} \pm M_s^{B,0}}{4} [\mathbf{e}_z \mathbf{e}_z \cdot - \mathcal{C}_{2y'} \mathbf{e}_z (\mathcal{C}_{2y'} \mathbf{e}_z) \cdot] \delta\mathbf{m}_{-} \\
& \left. + \frac{M_s^{A,0} \mp M_s^{B,0}}{4} [\mathbf{e}_z \mathbf{e}_z \cdot + \mathcal{C}_{2y'} \mathbf{e}_z (\mathcal{C}_{2y'} \mathbf{e}_z) \cdot] \delta\mathbf{m}_{-} + \frac{M_s^{A,0} \mp M_s^{B,0}}{4} [\mathbf{e}_z \mathbf{e}_z \cdot - \mathcal{C}_{2y'} \mathbf{e}_z (\mathcal{C}_{2y'} \mathbf{e}_z) \cdot] \delta\mathbf{m}_{+} \right\} + \tau_{\pm},
\end{aligned} \quad (3)$$

where  $\Omega = \omega/\gamma$ . Now  $\delta\mathbf{m}_{+}$  and  $\delta\mathbf{m}_{-}$  are coupled by both intrinsic (proportional to  $M_s^A - M_s^B$  and  $M_s^{A,0} - M_s^{B,0}$ ) and extrinsic (proportional to  $\mathcal{C}_{2y'} \mathbf{e}_z$ ) SB terms, thus result in strong magnon-magnon interaction between the bare modes with even and odd parities.

Next we calculate the FMR spectroscopy. After defining

the average bare and “thickness-modified” saturation magnetization as  $\bar{M}_s^0 = (M_s^{A,0} + M_s^{B,0})/2$  and  $\bar{M}_s = (M_s^A + M_s^B)/2$ , as well as their deviations  $\kappa_0 = (M_s^{A,0} - M_s^{B,0})/(M_s^{A,0} + M_s^{B,0})$  and  $\kappa = (M_s^A - M_s^B)/(M_s^A + M_s^B)$  describing the degree of asymmetry between the two FM sublayers, the secular equation for Eq. (3) is

$$\begin{vmatrix}
p_1 - i\Omega & p_2 & q_2 + 2\lambda_E \bar{M}_s \kappa \cos^2 \phi' & p_4 \\
q_1 + 2\lambda_E \bar{M}_s \cos^2 \phi' & -p_1 - i\Omega & p_1 - i\Omega & -p_3 \\
p_3 & p_4 - 2\lambda_E \bar{M}_s \kappa & p_1 - i\Omega & p_2 - 2\lambda_E \bar{M}_s \\
q_2 + 2\lambda_E \bar{M}_s \kappa \sin^2 \phi' & -p_3 & q_1 + 2\lambda_E \bar{M}_s \sin^2 \phi' & -p_1 - i\Omega
\end{vmatrix} = 0. \quad (4)$$

in which  $p_1 = \bar{M}_s^0 (\cos \alpha \sin \phi' - \kappa_0 \cos \beta \cos \phi') \cos \eta$ ,  $p_2 = -\bar{M}_s^0 \cos^2 \eta$ ,  $p_3 = \bar{M}_s^0 (\kappa_0 \cos \alpha \sin \phi' - \cos \beta \cos \phi') \cos \eta$ ,  $p_4 = -\bar{M}_s^0 \kappa_0 \cos^2 \eta$ ,  $q_1 = [(p_1 - p_3)^2 (p_4 + p_2) - (p_1 + p_3)^2 (p_4 - p_2)]/[2(p_4^2 - p_2^2)]$ , and  $q_2 = [-(p_1 - p_3)^2 (p_4 + p_2) - (p_1 + p_3)^2 (p_4 - p_2)]/[2(p_4^2 - p_2^2)]$ . In addition,  $\cos \alpha$ ,  $\cos \beta$  and  $\cos \eta$  are the three cosines of  $\mathbf{e}_z$  in the new  $x'y'z'$  coordinate system:  $\cos \alpha = (\cos \theta_A - \cos \theta_B)/(2 \cos \phi')$ ,  $\cos \beta = (\cos \theta_A + \cos \theta_B)/(2 \sin \phi')$ , and  $\cos \eta = \sqrt{\sin^2 \theta_A \sin^2 \theta_B - (\cos \theta_A \cos \theta_B + \cos 2\phi')^2 / \sin 2\phi'}$ . At last,  $\phi'$  is the angle between  $\mathbf{m}_A^{\text{eq}}$  and  $\mathbf{e}_z$  which satisfies  $\cos 2\phi' = -\cos \theta_A \cos \theta_B + [(M_s^A \sin \theta_A)^2 + (M_s^B \sin \theta_B)^2 - (H \cos \psi / \lambda_E)^2] / (2M_s^A M_s^B)$ .

In the most general case where intrinsic and extrinsic SB coexist ( $\kappa_0 \neq 0$ ,  $\kappa \neq 0$ ,  $\psi > 0$ ), Eq. (4) can hardly be solved analytically. However, based on the above results numerical calculation can always be performed once we have knowledge on  $M_s^{A(B),0}$ ,  $d_{A(B)}$ ,  $\lambda_E$  and  $\psi$ . By first fixing  $H$  and solving the above secular equation then further sweeping  $H$ , the entire FMR spectrum in the “ $\omega \sim H$ ” space can be obtained. In Fig. 2 the dimensionless FMR spectra under different configurations are provided based on Eqs. (3) and (4). In all calculations, saturation magnetizations and magnetic fields are in the unit of  $M_s^{A,0}$  and  $\omega$  is in the unit of  $\gamma M_s^{A,0}$ . In addition,  $\lambda_E = 0.1$ . In the absence of any SB, a mode crossing is clearly seen. When any single type of asymmetry appears, an anticrossing gap emerges. While all kinds of SB coexist, the gap width is greatly enlarged.

The mechanisms of inducing magnon-magnon coupling by extrinsic and intrinsic SB are different. We have already de-

FIG. 2. (Color online) Anticrossing gap opening when extrinsic and/or intrinsic symmetry breaking emerge. In all calculations based on Eqs. (3) and (4),  $\lambda_E = 0.1$  and  $M_s^{A,0}$  is taken as the unit of saturation magnetizations and magnetic fields.  $\omega$  is in the unit of  $\mu_0 \gamma M_s^{A,0}$ . The tilting angle ( $\psi$ ) of dc fields and the ratios of bare saturation magnetization ( $M_s^{B,0}/M_s^{A,0}$ ) as well as sublayer thickness ( $d_B/d_A$ ) are three sources of symmetry breaking. Each has been first independently shifted away from the symmetrical configuration (red, blue and magenta curves), and then together (green curve).

scribed that for extrinsic SB, the breaking rotation symmetry of hard axis  $\mathbf{n}$  (from magnetostatic interaction) with respect to the pulled up rotation-symmetry axis (due to out-of-plane dc fields) is the basic reason. While for intrinsic ones ( $\psi = 0$ ), the new rotation axis is still in the SAF plane but the entire mag-

netic layout (including magnetization and magnetostatics) is no longer unchanged under the two-fold rotation. The considerable entanglement between magnetization vibrations with opposite parity results in the strong magnon-magnon coupling thus greatly affects the FMR spectroscopy of SAFs.

To acquire clearer physics meantime provide more convenient fitting tools for experiments, in the following we focus on a few special cases and present more details about the anti-crossing gap. In the first class, only extrinsic SB is present so that  $M_s^{A,0} = M_s^{B,0}$ ,  $d_A = d_B$  and  $\psi > 0$  [see Fig. 1(b)]. This is just the case similar to layered crystal  $\text{CrCl}_3$  and have been systematically investigated already, so we won't repeat it here. The second class includes the cases where only intrinsic SB is involved, which means only in-plane dc fields are applied ( $\psi = 0$ ) as depicted in Fig. 1(c). As a result,  $\mathbf{e}_{z'} \equiv \mathbf{e}_z$  thus the new  $x'y'$  plane is identical to the old  $xy$  one. Now the AFM and FM critical fields take much simpler forms:  $H_{\text{AFM}} = \lambda_E |M_s^A - M_s^B|$  and  $H_{\text{FM}} = \lambda_E (M_s^A + M_s^B)$ . Consequently, the secular equation (4) is simplified to

$$\tilde{\omega}^4 - \left( \tilde{h}^2 + \mu \frac{1 + \kappa_0 \kappa}{2\lambda_E} \right) \tilde{\omega}^2 + \frac{2\lambda_E + \nu}{4\lambda_E^2} (1 - \tilde{h}^2) (\tilde{h}^2 - \kappa^2) = 0, \quad (5)$$

with  $\tilde{\omega} \equiv \Omega/H_{\text{FM}}$ ,  $\kappa < \tilde{h} \equiv H/H_{\text{FM}} < 1$ ,  $\mu = (M_s^{A,0} + M_s^{B,0})/(M_s^A + M_s^B)$  and  $\nu = (M_s^{A,0}/M_s^A) \cdot (M_s^{B,0}/M_s^B)$ . Generally, a gap appears as long as  $\kappa_0^2 + \kappa^2 \neq 0$ .

In particular, this gap can be further analyzed for two special cases. In the first case, the two FM sublayers have the same thickness ( $d_A = d_B$ ) but are made of different FM materials ( $M_s^{A,0} \neq M_s^{B,0}$ ). Then  $M_s^{A(B)} = M_s^{A(B),0}$ , thus  $\mu = \nu = 1$  and  $\kappa_0 = \kappa \neq 0$ . Similar to MacNeill *et al.* in 2019[27], Now the secular equation (5) can be rewritten into the eigenvalue problem of a  $2 \times 2$  matrix as

$$\begin{vmatrix} \tilde{\omega}_a^2(\tilde{h}) - \tilde{\omega}^2 & \tilde{\Delta}^2 \\ \tilde{\Delta}^2 & \tilde{\omega}_o^2(\tilde{h}) - \tilde{\omega}^2 \end{vmatrix} = 0. \quad (6)$$

Here  $\tilde{\omega}_a = \sqrt{1 + (2\lambda_E)^{-1}} \tilde{h}$  and  $\tilde{\omega}_o = [(1 + \kappa^2)(1 - \tilde{h}^2)/(2\lambda_E) + (\kappa^2 \tilde{h}^2)/(2\lambda_E)]^{1/2}$  are the bare in-phase (acoustic) and out-of-phase (optical) mode frequencies, respectively. Meantime  $\tilde{\Delta} = [(2\lambda_E + 1)\kappa^2/(4\lambda_E^2)]^{1/4}$  describes the *dc-field-independent* magnon-magnon coupling strength. When  $|\kappa| \ll 1$  (nearly symmetric),  $\tilde{\Delta}$  is negligible thus the solution of Eq. (6) are approximately  $\tilde{\omega} \approx \tilde{\omega}_a$  and  $\tilde{\omega} \approx \tilde{\omega}_o$ . For finite  $\kappa$ , when  $\tilde{h}$  is close to  $\kappa$  or 1, the solutions of Eq. (6) only deviate slightly from  $\tilde{\omega}_a$  and  $\tilde{\omega}_o$ . When the optical and acoustic modes get closer in frequency, they will be hybridized by  $\tilde{\Delta}$  term and thus a gap is opened. Direct calculations yield that this gap is an indirect gap (see Supplement Material): the minimum  $\tilde{\omega}_{\text{up}}^{\min}$  (maximum  $\tilde{\omega}_{\text{down}}^{\max}$ ) of the “up (down)” branch takes place at  $\tilde{h}_{\text{up}}^{\min}$  ( $\tilde{h}_{\text{down}}^{\max}$ ), where  $\tilde{h}_{\text{up}}^{\min} \neq \tilde{h}_{\text{down}}^{\max}$  for nonzero  $\kappa$ . The corresponding dimensionless gap width reads  $\delta\tilde{\omega} = |\kappa| \sqrt{(2\lambda_E + 1)/[\lambda_E(\lambda_E + 1)]}$ . Interestingly, the real gap width  $\delta\tilde{\omega}$  is linear to  $|\kappa|$  (degree of asymmetry between the two FM sublayers), which is different from the square-root dependence of the coupling  $\tilde{\Delta}$  on  $\kappa$ . By recalling the defini-

tions of  $\tilde{\omega}$  and  $\kappa$ , we then get the dimensional gap width

$$\delta f = \sqrt{\frac{\lambda_E(2\lambda_E + 1)}{\lambda_E + 1}} \frac{\gamma}{2\pi} |M_s^{A,0} - M_s^{B,0}|, \quad (7)$$

which should be more useful for experimental physicists. Obviously, the AFM interlayer coupling and the inhomogeneity of sublayers are both crucial for the gap opening.

Another interesting case is that the two FM sublayers are made of the same material ( $M_s^{A,0} = M_s^{B,0}$ ) but have different thickness ( $d_A \neq d_B$ ), which is the most common choice in real experiments. Accordingly  $\kappa_0 = 0$ ,  $\kappa = (d_A - d_B)/(d_A + d_B)$  and  $\mu = \nu = 1 - \kappa^2$ . Now Eq. (5) can not be reorganized to the  $2 \times 2$  matrix form as that in Eq. (6) if we require the coupling term to be  $\tilde{h}$ -independent. However, similar calculus shows that now the gap is also indirect. The new extremum, extremum locations and the gap width become more complicated (see Supplement Material), and we then focus on the situation where  $|\kappa| \ll 1$ . After standard linearization operation, the gap width is approximated to another linear dependence on  $|\kappa|$  as  $|\kappa|[(2\lambda_E + 1)/(\lambda_E + 1)]^{3/2}/(2\sqrt{\lambda_E})$ . Back to dimensional form, we have

$$\delta f' \approx \frac{\sqrt{\lambda_E}}{2} \left( \frac{2\lambda_E + 1}{\lambda_E + 1} \right)^{\frac{3}{2}} \frac{|1 - (d_B/d_A)^2|}{2(d_B/d_A)} \frac{\gamma}{2\pi} M_s^{A,0}. \quad (8)$$

Eq. (8) can be directly compared with existing experimental measurements for asymmetrical NiFe/Ru/NiFe SAFs[16, 17]. For NiFe(13.6 nm)/Ru( $t_{\text{Ru}}$ )/NiFe(27.2 nm) SAFs in Ref. [16], we choose  $t_{\text{Ru}} = 4.7 \text{ \AA}$  as an example. By taking  $M_s^{A,0} = 860 \text{ kA m}^{-1}$  and  $J_{\text{IEC}} \approx |J_1| = 286 \text{ \mu J m}^{-2}$ , we get  $\lambda_E \approx 0.015$  and  $\delta f' \approx 1.4 \text{ GHz}$ . While for Ni<sub>80</sub>Fe<sub>20</sub>(200 \AA)/Ru( $t_{\text{Ru}}$ )/Ni<sub>80</sub>Fe<sub>20</sub>(100 \AA) SAFs in Ref. [17], the magnetic parameters for  $t_{\text{Ru}} = 3.3 \text{ \AA}$  are  $M_s^{A,0} = 720 \text{ kA m}^{-1}$  and  $J_{\text{IEC}} \approx 154 \text{ \mu J m}^{-2}$ . These lead to  $\lambda_E \approx 0.016$  and  $\delta f' \approx 1.2 \text{ GHz}$ . For other Ru thickness, similar calculations can be performed and all results show good agreement between analytics and experimental data.

Interestingly, in FeCoB/Ru/FeCoB SAFs we can acquire larger  $\lambda_E$ , although nearly all existing published experiments are performed in symmetrical cases[18–21]. For symmetrical FeCoB thickness being 15 nm[18, 19], 3 nm[20] and 5 nm[21], the respective  $\lambda_E$  are estimated to be 0.033, 0.093 and 0.119(0.141) (two samples therein). Combined with larger saturation magnetization of FeCoB, asymmetrical FeCoB/Ru/FeCoB SAFs are expected to open larger indirect gaps. In view of this, we have performed related measurements in asymmetrical CoFeB/Ir/CoFeB SAFs (experimental details will be published elsewhere). In the “CoFeB(10 nm)/Ir(0.6 nm)/CoFeB(12 nm)” SAF, direction measurements provide  $M_s^{A,0} = 1400 \text{ kA m}^{-1}$  and  $H_{\text{ex}} \equiv 2J_{\text{IEC}}/[\mu_0 M_s^{A,0}(d_A + d_B)] = 549 \text{ Oe}$ , thus  $\lambda_E \approx 0.0312$  and  $\delta f' \approx 0.80 \text{ GHz}$ , which is in good agreement with experimental observation of gap width (0.74 GHz). In addition, the gap is observed to take place around 760 Oe, which is also in accordance with theoretical prediction (770 Oe). We are looking forward to more

experimental measurements in the near future. In very recent symmetrical CoFeB/Ru/CoFeB SAFs[20], out-of-plane dc fields are needed to open gaps up to 1 GHz. Our results provide the possibility that by appropriately designing the thickness ratio of two CoFeB sublayers, greater gap can be opened which indicates stronger magnon-magnon coupling. On the other hand, we know that it is very difficult to prepare inhomogeneous SAFs ( $M_s^{A,0} \neq M_s^{B,0}$ ) experimentally, however this issue is indeed worth exploring further and Eq. (7) should help to reveal interesting physics.

At the end of this Letter, several points need to be clarified. First, in this work the crystalline anisotropy has been neglected because of two reasons: (i) in most existing experimental setups, the FM sublayers of SAFs are made from soft magnetic materials which can be viewed as isotropic; (ii) the explicit orientations of  $\mathbf{m}_A^{\text{eq}}$  and  $\mathbf{m}_B^{\text{eq}}$  can hardly be obtained analytically if the in-plane crystalline anisotropy is considered (even for the simplest uniaxial case), but they are crucial for obtaining the vectorial LLG equation and then the secular equations for FMR frequencies. For the above reasons, in this work we choose the isotropic case for simplicity, but it can cover the vast majority of experimental data. Note that our analytics also holds for perpendicular-magnetic-anisotropy case as long as we change  $M_s^{A(B),0}$  to  $M_s^{A(B),0} - H_K^{A(B)}$  in Eq. (1) where  $H_K^{A(B)}$  is the out-of-plane anisotropic field in the respective sublayer. Another neglected term is the Gilbert damping term. In most investigations of spin wave, the damping term is dropped off when only the resonance spectrum is under consideration. However when the linewidth is also of interest, then the damping process should be included in Eq. (3) by a respective term  $i\omega\alpha\mathbf{m}_A^{\text{eq}} \times \delta\mathbf{m}_{\pm}$  with  $\alpha$  being the Gilbert damping coefficient[27].

In summary, we have proposed a simple but revealing theory for understanding the rich structure of FMR spectroscopy in asymmetrical SAFs under tilting dc magnetic fields. Both intrinsic and extrinsic SB cause entanglement between magnetization vibrations with opposite parity, thus excite strong magnon-magnon coupling between the bare in-phase and out-of-phase modes, then eventually result in the anticrossing gap in microwave absorption spectroscopy. In addition, for pure intrinsic SB the two-fold rotation symmetry of both the magnetization and magnetostatics around  $\mathbf{m}_A^{\text{eq}} + \mathbf{m}_B^{\text{eq}}$  fails. While for pure extrinsic SB, only that of magnetostatics fails. This new picture helps to understand the rich experimental data of FMR spectra for existing SAFs and future measurements on other SAF or SAF-like systems.
