Stability of a class of entropies based on fractional calculus

Rui A. C. Ferreira

Abstract. In this work we argue about the Lesche stability of some systems, that are motivated by the use of fractional derivatives.

Mathematics Subject Classification (2010). 82A05, 94A17.

Keywords. Fractional derivatives, stability, entropy.

1. Preamble

This text is primarily motivated by the work of Ubriaco [5], namely, with the proof of the Lesche stability of a certain entropic functional presented therein. Specifically, based on the concept of the Liouville–fractional derivative, the author defined the following entropy (see [5, Section 3])

$$S(p) = \sum_{i=1}^{n} p_i (-\ln(p_i))^{\alpha}, \quad 0 < \alpha \le 1.$$
 (1.1)

In 1982, B. Lesche [4] introduced a way of measuring the stability of a system (see also [1]). Concretely, a system S over a probability distribution $P = \{p_1, \ldots, p_n\}$ with $n \geq 2$ is said to be Lesche stable iff

$$\forall \varepsilon > 0 \ \exists \delta > 0 \ s.t. \ \forall n, \ \forall p, p' \in P: \|p - p'\|_1 \le \delta \Rightarrow \frac{|S(p) - S(p')|}{S_{\max}} < \varepsilon.$$

In [5, Section 4.1] the author *showed* that (1.1) is Lesche stable, using the main result of [2]. However his proof has an inconsistency, as we shall now explain: having in mind the notation of [2], Ubriaco defined in [5, formula (30)] the following function,

$$f^{-1}(t) = (-\ln(t))^{\alpha} - \alpha(-\ln(t))^{\alpha-1}, \quad \alpha \in (0,1], \ t \in (0,1),$$

The author was supported by the "Fundação para a Ciência e a Tecnologia (FCT)" through the program "Stimulus of Scientific Employment, Individual Support-2017 Call" with reference CEECIND/00640/2017.

which is nothing else but the derivative of $t(-\ln(t))^{\alpha}$. We see that $f^{-1}(1) = \lim_{t\to 1^-} f^{-1}(t) = -\infty$. Now, the departure formula for the general entropic expression in [2] is

$$S(p) = \sum_{i=1}^{n} \left[p_i f^{-1}(p_i) - \int_{f^{-1}(0)}^{f^{-1}(p_i)} f(t) dt \right] + \int_{f^{-1}(0)}^{f^{-1}(1)} f(t) dt - f^{-1}(1),$$

where f is a monotonically decreasing function with range (0,1). Therefore, for $p_i < 1$, we see that $S(p) \ge +\infty$ which is just nonsense. We also note that the authors assumed differentiability of f^{-1} in order to obtain [2, formula (6)], which will be used somewhere after in their analysis. Summing up, we cannot conclude from the reasoning in [5, Section 4.1] that (1.1) is Lesche stable. However, we can conclude it from the results in [3]. Indeed, from [3, Example 3] we know that, defining $g(x) = x^{\alpha}$ for $x \in [0, \infty)$, then g(0) = 0 and the function $xg(-\ln(x))$ is concave. Therefore, the entropy (1.1) is Lesche stable.

In the next section we will introduce a function that generalizes the entropy given by (1.1). Some properties of it are presented as well.

2. A novel entropic function

We use the same motivation as in [5] to define a new entropy, but now by considering the tempered fractional derivative.

Let us start by introducing the concept (see e.g. [6]). For $0 < \sigma < 1$ and $\lambda \ge 0$, the Liouville tempered fractional derivative of order σ is defined by

$$D^{\sigma,\lambda}u(t) = \frac{e^{-\lambda t}}{\Gamma(1-\sigma)} \frac{d}{dt} \int_{-\infty}^{t} (t-s)^{-\sigma} e^{\lambda s} u(s) ds.$$
 (2.1)

For $\lambda = 0$ the operator (2.1) is just the Liouville fractional derivative used in [5, formula (16)]. Now we wish to calculate (2.1) at t = -1 with $u(s) = e^{-s \ln(p_i)}$, $p_i < 1$ (see [5, Section 3]). We have,

$$\frac{d}{dt} \int_{-\infty}^{t} (t-s)^{-\sigma} e^{\lambda s} e^{-s \ln(p_i)} ds = \frac{d}{dt} e^{t(\lambda - \ln(p_i))} \int_{0}^{\infty} u^{-\sigma} e^{-u(\lambda - \ln(p_i))} du$$

$$= \frac{d}{dt} e^{t(\lambda - \ln(p_i))} (\lambda - \ln(p_i))^{\sigma - 1} \Gamma(1 - \sigma)$$

$$= e^{t(\lambda - \ln(p_i))} (\lambda - \ln(p_i))^{\sigma} \Gamma(1 - \sigma),$$

where we used the definition of the gamma function $\Gamma(t) = \int_0^\infty x^{t-1} e^{-x} dx$. Therefore,

$$D^{\sigma,\lambda}(s \to e^{-s\ln(p_i)})(-1) = \frac{e^{-\lambda(-1)}}{\Gamma(1-\sigma)} e^{-1(\lambda-\ln(p_i))} (\lambda - \ln(p_i))^{\sigma} \Gamma(1-\sigma)$$
$$= p_i(\lambda - \ln(p_i))^{\sigma}, \quad p_i < 1.$$

For a probability distribution $P = \{p_1, \dots, p_n\}$ with $n \ge 2$, we postulate the following two parameter entropy:

$$S_{\sigma,\lambda}(p) = \sum_{i=1}^{n} p_i \left[(\lambda - \ln(p_i))^{\sigma} - \lambda^{\sigma} \right], \quad \sigma \in (0,1], \ \lambda \ge 0.$$
 (2.2)

Note that, for $\sigma=1$, we are adopting the usual convention that $x \ln(x)|_{x=0}$. It is clear that $S_{\sigma,0}$ reduces to the entropy defined by Ubriaco in (1.1). The entropy defined above satisfies the following three Shannon–Khinchin axioms: let $\Delta_n = \{(p_1, ..., p_n) \in \mathbb{R}^n \mid p_i \geq 0, p_1 + ... + p_n = 1\}$. Then,

- 1. S_n is nonnegative and continuous on Δ_n .
- 2. For all $(p_1,...,p_n) \in \Delta_n$: $S_n(p_1,...,p_n) \leq S_n(1/n,...,1/n)$.
- 3. For all $(p_1,...,p_n) \in \Delta_n$: $S_{n+1}(p_1,...,p_n,0) = S_n(p_1,...,p_n)$.

Essentially that is due to the fact that the function defined by

$$f_{\sigma,\lambda}(x) = x \left[(\lambda - \ln(x))^{\sigma} - \lambda^{\sigma} \right], \quad x \in [0, 1],$$

where we understand for the value $f(0) = \lim_{x\to 0^+} x \left[(\lambda - \ln(x))^{\sigma} - \lambda^{\sigma} \right] = 0$, is concave. Moreover, defining $g(x) = (\lambda + x)^{\sigma} - \lambda^{\sigma}$, $x \ge 0$, we get that g(0) = 0 and g is concave. Therefore, using again [3, Example 3], we conclude that $S_{\sigma,\lambda}$ given by (2.2) is Lesche stable¹.

We would like to end this work remarking that $S_{\sigma,\lambda}(p) \leq S_{\sigma,0}(p)$. Indeed, this inequality follows from the elementary inequality $(x+y)^{\alpha} \leq x^{\alpha} + y^{\alpha}$ for $x, y \geq 0$ and $\alpha \in (0, 1)$.

¹We note that, for $\lambda > 0$, the function $f_{\sigma,\lambda}(x)$ is differentiable at x = 1. Therefore, if we define by $f^{-1}(x) = \frac{d}{dx}x\left[(\lambda - \ln(x))^{\sigma} - \lambda^{\sigma}\right]$, then we could actually use the results of [2] to conclude that (2.2) is Lesche stable.
