(Dated: February 24, 2021)

We investigate the quantum entanglement of three photons performing discrete-time quantum walk (DTQW) on a square lattice. A linear optical implementation of such a DTQW setup has already been proposed. Each lattice site corresponds to the sequential action of a half-wave plate and a polarizing beam splitter. Two-dimensional DTQW can be mapped to an effective one-dimensional DTQW with a four-sided coin that depends on the polarization and direction of motion of the photons. It is known that such a system is capable to spatially entangle two photons, prepared in a separable state initially. We generalize the result to the case of three photons to explore if distinct entanglement classes, namely W and GHZ states, can be produced by this setup by projective measurements. In addition to spatial entanglement, we analyze the possibility of polarization entanglement isolated by projective measurements. Effect of imperfect linear optical setup decoherence too. Our results can be significant for a simple and fast generation of multipartite entangled photonic states demanded by practical quantum technology applications.

I. INTRODUCTION

Entanglement is a quintessential quantum phenomenon that gives the distinguishing superiority of quantum systems over the classical ones when applied in computation and communication technologies [1–4]. Practical quantum technologies demand fast and robust production of large quantum entangled states with two-level systems (qubits) and photons to exploit their scaling benefits [5–8]. Discrete-time quantum walk (DTQW) [9], which is analog of classical random walk, has been proposed as a convenient platform to realize multiqubit [10, 11] and two-photon entangled states [12]. In particular, photonic DTQW can be readily implemented by simple linear optical elements, such as beam splitters and half-wave plates [12]. Scaling the optical setups can be challenging due to the difficulty of alignment of too many elements. We ask if higher dimensional entangled states can be generated without increasing the size of the DTQW setup. Specifically, we explore if distinct entanglement classes of three photons, namely W and GHZ states, in spatial or polarization bases, can be produced in the two-dimensional linear optics DTQW setup proposed in Ref. [12].

Bipartite entanglement has been well understood fundamentally and utilized in many quantum information processes [13–16]. While multipartite entangled states [17] have much more complex structure, they promise significant enhancement in computational power compared to the bipartite systems [11, 14]. To utilize multipartite entanglement however, it is necessary for us to find definite measures and efficient generation schemes.

It was shown that we could produce entanglement via quantum walks [12]. DTQW is introduced as the counterpart of the classical random walk [9]. Single and two-photon systems have attracted much theoretical attention to examine properties of DTQW [18–22], which can be tested by available experimental setups of linear optical elements [23]. To explore the genuine quantum character of DTQW, Ref. [12] study DTQW of two photons in various separable and entangled states. They found that even though the initial state is not entangled and only linear optical elements are included, entanglement can still emerge after several steps in DTQW. The mechanism is related to the beam-splitter route to quantum entanglement when the Fock number states are injected into the setup’s ports. In this article, we make a straightforward generalization by studying the case of injecting three photons into the setup. Despite the simplicity, the case of three-photon entanglement is strikingly different from the bipartite case. It allows us to explore how to produce distinct entanglement classes, namely W and GHZ states and path entangled states, starting with separable three-photon states in the same setup of Ref. [12].

This paper is organized as follows. Sec. II describes the setup and introduces the representation of the Hilbert states for photons. In Sec. III we start by using genuine multipartite entanglement (GME) measure to qualify the entanglement of very complex final states. After this part, we analyze the results for three different aspects. For the polarization degree of freedom, we calculate the final states analytically and determine the character of tripartite entanglement. Secondly, using Fock states, we reveal the possible entangled states and explore the entanglement production in spatial degrees of freedom. Then, we analyze the mixed states for another perspective and show that they are also path entangled. We conclude in Sec. IV. Explicit analytical expressions of single-photon quantum states are presented in Appendix.

II. MODEL

To search for the tripartite entanglement, we consider the optical quantum quincunx [23]. We present the review of the setup and introduce the notation given in Ref. [12], with generalization to three-photon entanglement here. The schematic arrangement of the optical elements is shown in Fig. 1. The optical elements, polarizing beam splitters (PBS), and half-wave plates (HWP) are placed successively at the square lattice sites to create the two-dimensional discrete walk in every lattice point. It can be described effectively as a one-dimensional
quantum walk with a four-sided coin.

Photons enter into the arrangement via the input ports at the origin 0. The HWP performs the Hadamard operation [12, 24] on the polarization state of a single photon.

\[
O_{\text{HWP}} \begin{bmatrix} |x \rangle \\ |y \rangle \end{bmatrix} = \frac{1}{\sqrt{2}} \begin{bmatrix} 1 & 1 \\ 1 & -1 \end{bmatrix} \begin{bmatrix} |x \rangle \\ |y \rangle \end{bmatrix}
\]
(1)

where \( |x \rangle \) and \( |y \rangle \) are the two orthogonal polarization states. PBS displaces the photons in the vertical (\( v \)) or horizontal (\( h \)) axis depending on their polarization states.

\[
O_{\text{PBS}} \begin{bmatrix} |h, x \rangle \\ |v, x \rangle \\ |v, y \rangle \\ |h, y \rangle \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} |h, x \rangle \\ |v, x \rangle \\ |v, y \rangle \\ |h, y \rangle \end{bmatrix}.
\]
(2)

Each step of the DTQW is defined by successive operations of \( O_{\text{HWP}} \) and \( O_{\text{PBS}} \).

An effective one-dimensional quantum walk description can be given along an axis \( q \) (cf. Fig. 1), by determining the position of the walker after projecting the triangular arrangement to a line such that

\[
\begin{bmatrix} n+1, q+1, h, x \\ n+1, q+1, h, y \\ n+1, q-1, v, x \\ n+1, q-1, v, y \end{bmatrix} = SC \begin{bmatrix} n, q, h, x \\ n, q, h, y \\ n, q, v, x \\ n, q, v, y \end{bmatrix}
\]
(3)

where \( n \) is the number of steps taken, \( C \) is the coin operator,

\[
C = \frac{1}{\sqrt{2}} \left( |h, x \rangle \langle h, x| + |v, y \rangle \langle h, x| + |h, x \rangle \langle h, y| - |v, y \rangle \langle h, y| + |v, x \rangle \langle v, x| + |h, y \rangle \langle v, x| + |v, x \rangle \langle v, y| - |h, y \rangle \langle v, y| \right),
\]
(4)

and \( S \) is the shift operator [12],

\[
S = |h, x \rangle \langle h, x| \otimes |n+1 \rangle \langle n| + |h, y \rangle \langle h, y| \otimes |n+1 \rangle \langle n| + |v, x \rangle \langle v, x| \otimes |n-1 \rangle \langle n| + |v, y \rangle \langle v, y| \otimes |n-1 \rangle \langle n|.
\]
(5)

By applying the operator, \( SC \), \( n \) times, we obtain the \( n \)-step walk of a single photon. Additionally, approximate analytical results can be derived for a large number of steps by using discrete Fourier analysis [22, 25].

To show the emergence of entanglement, Ref. [12] calculates the correlation function of the final states of two photons (Eq. 6), and it is shown that photon-photon correlation is non-zero almost everywhere.

\[
\sigma_{q_1 q_2} = P_n(q_1, q_2) - P_n(q_1)P_n(q_2),
\]
(6)

where

\[
P_n(q_1) = \sum_{q=-n}^{n} P_n(q_1, q).
\]
(7)

Here, two photon spatial state is denoted by

\[
|q_1, q_2 \rangle = \sum_{i,j} |n_1, q_1, h_1, x_i \rangle \otimes |n_2, q_2, h_2, x_j \rangle.
\]
(8)

We examine the three photon case in the same optical setup. In order to obtain the probability distribution of tripartite states we evolve the initial states by applying \( (SC)^n := (SC \otimes SC) \). After \( n \) steps, we express the evolved states as

\[
|\psi^{(n)} \rangle_{\alpha} = \sum_{q=-n}^{n} |\psi^{(n)}(q) \rangle,
\]
(9)

where

\[
|\psi^{(n)}(q) \rangle = 2|q \rangle \sum_{c} g_{c} |c \rangle.
\]
(10)

Here, \( c \) is coin state labels, and \( \alpha \) marks the initial coin state such that \( \alpha \in \{(h, x), (h, y), (v, x), (v, y)\} \). In this notation, \( g_{c} \) operates on \( |c \rangle \) such that if there exists a \( |q, c \rangle \) state with respect to \( |q \rangle \) it produces \( |c \rangle \), itself. Otherwise, \( g_{c} \) produces 0. In terms of this representation of the single-photon states, for three photons, the exchange symmetrization form is given in the following way,

\[
|\psi^{(n)}_{\alpha_1 \alpha_2 \alpha_3} \rangle = \frac{1}{\sqrt{6}} \sum_{q_1, q_2, q_3=-n}^{n} \sum_{\sigma \in \mathbb{P}_3} \sigma(i, j, k) |\psi^{(n)}_{\alpha_1}(q_1) \rangle \otimes |\psi^{(n)}_{\alpha_2}(q_2) \rangle \otimes |\psi^{(n)}_{\alpha_3}(q_3) \rangle,
\]
(11)

for \( \alpha_1, \alpha_2, \alpha_3 \in \{(h, x), (h, y), (v, x), (v, y)\} \) which denotes the initial state of the photons in polarization basis. Since, we are dealing with indistinguishable bosons, we always consider the exchange symmetrized version of the final states. We present our explicit...
III. RESULTS

After reviewing the setup in Ref. [12] introducing the generalized notation of orthogonal states, we present our results on various forms of three-photon entanglement in the following subsections.

A. GME measure for final states of DTQW

To characterize the entanglement in the final state, we start by using the GME measure, which is designed to detect a multipartite state that is not separable in any bi-partition basis. These states are called genuinely entangled states, which offer significant advantages for quantum computation tasks [\cite{citation missing}. GME measure for three-photon states is defined as [26]

\[ C_{\text{GME}}(\psi) = \sqrt{\min(1 - \text{Tr}(\rho_1^2), 1 - \text{Tr}(\rho_2^2), 1 - \text{Tr}(\rho_3^2))}, \]

(13)

where \( \rho_i \) is the reduced density matrix of \( i \)th particle which differs by the initial states of the photons.

By calculating \( C_{\text{GME}} \), as we present in Fig. 2, we conclude that there is GME entanglement in the final states. However, the explicit state structure is too complex and involves correlations between different spatial and polarization degrees of freedom. Therefore, it is impossible to characterize the entanglement observed by GME measure for particular GHZ and W states by using hyper-determinant calculations. By examining the entanglement in different bases in detail and presenting analytical calculations, we reveal the possibility of the production of tripartite entangled states via post-selection of projective measurements on specific states.

B. W and GHZ polarization entangled states

Three photons injected from the input ports with coin states \( |hx\rangle, |hy\rangle \) and \( |vx\rangle \) evolve into \( |\Psi(5)\rangle_{hx,hy,vx} \). In order to distinguish entanglement in polarization basis we project the state, \( |\Psi(5)\rangle_{hx,hy,vx} \) to \( \langle q_i | q_j | q_k | \Psi(5) \rangle_{hx,hy,vx} \), which gives

\[ \langle -3, v | (-1, h) | 1, h | \Psi(5) \rangle_{hx,hy,vx} = \frac{1}{\sqrt{3}} (|xxy\rangle - |xyx\rangle - |xxx\rangle) \]

(14)

\[ \langle -3, v | (-1, v) | 1, v | \Psi(5) \rangle_{hx,hy,vx} = \frac{1}{\sqrt{2}} (-|xxx\rangle + |yyy\rangle) \]

(15)

We see that both W and GHZ states can be obtained from \( |\Psi(5)\rangle_{hx,hy,vx} \). After \( n = 5 \), we get the same W and GHZ state for every odd step number. We found very similar results for other initial conditions, as long as at least one photon is sent in a different direction than the other two. We report above our results for a typical initial state to avoid repetition.

C. W and GHZ spatial entangled states

It is convenient to use the Fock number creation and annihilation operators to write down the wave function such that

\[ a_{\alpha}^{(n,q)} |\phi\rangle = |n, q, \alpha\rangle, \]

(16)

where \( |\phi\rangle \) is the vacuum state and \( \alpha \in \{ (h, x), (h, y), (v, x), (v, y) \} \). Let us denote the transformed operators after \( n \)th step by \( b_{\alpha}^{(n,q)} \); they are expressed by

\[ b_{hx}^{(n,q)} = \frac{1}{\sqrt{2}} \left( a_{hx}^{(n+1,q+1)} + a_{vy}^{(n+1,q-1)} \right) \]

(17)

\[ b_{hy}^{(n,q)} = \frac{1}{\sqrt{2}} \left( a_{hx}^{(n+1,q+1)} - a_{vy}^{(n+1,q-1)} \right) \]

(18)

\[ b_{vx}^{(n,q)} = \frac{1}{\sqrt{2}} \left( a_{vx}^{(n+1,q+1)} + a_{hy}^{(n+1,q+1)} \right) \]

(19)

\[ b_{vy}^{(n,q)} = \frac{1}{\sqrt{2}} \left( a_{vx}^{(n+1,q+1)} - a_{hy}^{(n+1,q+1)} \right). \]

(20)

For example, let’s take the initial single photon state, \( |\psi(0)\rangle = |0, 0, h, x\rangle \). It can be represented as \( |\psi(0)\rangle = a_{hx}^{(0,0)} |\phi\rangle \), for the vacuum state \( |\phi\rangle \). After the first step we have,

\[ a_{hx}^{(0,0)} \rightarrow b_{hx}^{(0,0)} = \frac{1}{\sqrt{2}} \left( a_{hx}^{(1,1)} + a_{vy}^{(1,1)} \right). \]

(21)
After the second step,
\[
\hat{a}^{(0,0)}_{hx} \rightarrow \frac{1}{2} \left( \hat{a}^{(2,2)}_{hx} - \hat{a}^{(2,0)}_{hy} + \hat{a}^{(2,0)}_{vy} + \hat{a}^{(2,-2)}_{vx} \right). 
\tag{22}
\]

For the third step,
\[
\hat{a}^{(0,0)}_{hx} \rightarrow \frac{1}{2\sqrt{2}} \left( \hat{a}^{(3,3)}_{hx} - \hat{a}^{(3,1)}_{hx} - \hat{a}^{(3,1)}_{hy} + \hat{a}^{(3,0)}_{vy} + \hat{a}^{(3,-1)}_{vy} + \hat{a}^{(3,-1)}_{hx} + \hat{a}^{(3,-3)}_{vx} \right). 
\tag{23}
\]

Other states can be evolved similarly, and further details can be found in Eq. A21-A24.

We use the definition given in Eq. 16 and examine the photons initially in \(|0,0,h,x⟩ ⊗ |0,0,h,y⟩ ⊗ |0,0,v,x⟩ = \hat{a}^{(0,0)}_{hx} \hat{a}^{(0,0)}_{hy} \hat{a}^{(0,0)}_{vx} \hat{a}^{(0,0)}_{vy} \hat{0⟩} state where \(|0⟩\) is the vacuum state. After five steps by using Eq. A21-A24 we calculate the following state.
\[
|\Psi^{(5)}⟩_{hx,hy,vx} = \frac{1}{(4\sqrt{2})^3} \left( -3\hat{a}^{(5,5)}_{hx}\hat{a}^{(5,1)}_{hy}\hat{a}^{(5,1)}_{vy}\hat{a}^{(5,1)}_{hx} - \hat{a}^{(5,1)}_{hx}\hat{a}^{(5,1)}_{hy}\hat{a}^{(5,5)}_{vy}\hat{a}^{(5,5)}_{hx} \right. 
\]
\[
\left. \hat{a}^{(5,1)}_{hx}\hat{a}^{(5,1)}_{hy}\hat{a}^{(5,5)}_{vy}\hat{a}^{(5,5)}_{hx} \right) + \ldots . 
\tag{24}
\]

In these combinations we easily observe sample entangled states,
\[
|\text{GHZ-like}⟩ = \frac{1}{(4\sqrt{2})^3} \left( \hat{a}^{(5,1)}_{by}\hat{a}^{(5,1)}_{vx}\hat{a}^{(5,1)}_{vy} \right. 
\]
\[
\left. \hat{a}^{(5,1)}_{hx}\hat{a}^{(5,1)}_{hy}\hat{a}^{(5,1)}_{vy}\hat{a}^{(5,1)}_{hx} \right) + \ldots . 
\tag{25}
\]
\[
|\text{W-like}⟩ = \frac{1}{(4\sqrt{2})^3} \left( \hat{a}^{(5,1)}_{hx}\hat{a}^{(5,1)}_{by}\hat{a}^{(5,3)}_{vx}\hat{a}^{(5,3)}_{vy} \right. 
\]
\[
\left. \hat{a}^{(5,1)}_{hx}\hat{a}^{(5,1)}_{by}\hat{a}^{(5,3)}_{vx}\hat{a}^{(5,3)}_{vy} \right) + \ldots . 
\tag{26}
\]

Here, we view the first state as \(|-1,-1,-1⟩_{ABC} - |1,1,1⟩_{ABC} where A = hy, B = vx, C = vy and second state as \(|-3,-3,3⟩_{ABC} - |3,3,-3⟩_{ABC} where A = hy, B = vy, C = hx in the position basis.

For both polarization and position basis entanglement, we cannot use a general entanglement measure to show that one example of a GHZ/W state or GHZ-like/W-like state dominates the final state. Because final states of a DTQW have a very complex structure comprised of many distinct entangled states, we show several examples above. Since fidelity of a single tripartite entangled sub-state is always one after it emerges in the random walk by using post selection methods and the analytical calculations presented here, it is possible to produce entangled tripartite states from the quincunx setup.

D. N-photon two-mode path entangled states

For two photons initially in separable states, \(|\Psi^{(0)}⟩_{hx,hy} = |0,0,h,x⟩ ⊗ |0,0,h,y⟩\), we project the final state after three steps into the position basis as follows
\[
\langle hx| \langle hx|\Psi^{(0)}⟩ |hx|\Psi^{(0)}⟩_{hx,hy} = 
\frac{1}{2} \left( (|1⟩_3|0⟩_1 - |0⟩_3|1⟩_1)(|1⟩_3|0⟩_1 + |0⟩_3|1⟩_1) 
\right. 
\]
\[
\left. + (|1⟩_3|0⟩_1 + |0⟩_3|1⟩_1)(|1⟩_3|0⟩_1 - |0⟩_3|1⟩_1) \right) 
\tag{27}
\]
\[
= |2⟩_3|0⟩_1 - |0⟩_3|2⟩_1 . 
\tag{28}
\]

By examining the single photon states of DTQW in the lattice as Bell states depending on the localization between two lattice points we show that q = 3 and q = 1 are path-entangled for the final state, \(|\Psi^{(3)}⟩_{hx,hy,vx}\). From Eqs. (A13)-(A16) we can easily observe that this is not special for this particular lattice points.

If we pursue the same calculations for three photons, after 3 steps we observe a similar situation.
\[
\langle hx| \langle hx|\Psi^{(3)}⟩ |hx|\Psi^{(3)}⟩_{hx,hy} = 
\frac{1}{6} \left( |6⟩_3|3⟩_1 - 2|1⟩_3|2⟩_1 + 2|2⟩_3|1⟩_1 - 6|0⟩_3|3⟩_1 
\right. 
\]
\[
\left. - 2|3⟩_3|2⟩_1 - 2|1⟩_2|2⟩_1 + 2|2⟩_3|1⟩_1 + 2|2⟩_3|1⟩_1 \right) 
\tag{29}
\]
\[
= (|3⟩_3|0⟩_1 - |0⟩_3|3⟩_1) + (|2⟩_3|1⟩_1 - |1⟩_3|2⟩_1) . 
\tag{30}
\]

By projecting the final states into the position basis, we observe that they are Bell states, such that \(|1⟩_q|0⟩_p\), denotes the probability of being in the qth lattice point and not being in the pth lattice point in the position basis, which is consistent with the beam splitter route to the entanglement of Fock states in our linear optical system.

Path entanglement is directly linked to quantum metrology, which is one of the most promising fields of quantum technologies [27]. The presented results suggest that the linear optics DTQW setup can produce bilinear path entangled states for one or two photons [28–30].

IV. CONCLUSION

In conclusion, the setup introduced in Ref. [12] can be used to generate W and GHZ states both in polarization and spatial degree of freedom after post-selection. Besides, We can identify W or GHZ states separately in the polarization basis by analytical calculations and determine the required post-selections for their emergence. In addition, N-photon 2-mode path entangled states can be produced after a few steps for the specific application of projective measurements. Our analysis suggests that the setup in Ref. [12] can be a versatile and fast generator of significant multipartite quantum entangled states demanded by quantum technology applications.

ACKNOWLEDGEMENTS

We would like to thank Utku Sağlam for fruitful discussions.
Appendix A: DTQW of Single Photon

Here we present, DTQW of a single walker for several steps, explicitly and for simplicity we omit the number of steps degree of freedom which is obvious from the $\psi^{(n)}$ notation. For the initial state $\psi^{(0)}(h, x) = \ket{0, 0, h, x}$,

$$\psi^{(1)}(h, x) = \frac{1}{\sqrt{2}} \left[ (1, h, x) + |-1, v, y) \right]$$  \hspace{1cm} (A1)

$$\psi^{(2)}(h, x) = \frac{1}{2} \left[ (2, h, x) + |0, v, y) + |-2, v, x) - |0, h, y) \right]$$ \hspace{1cm} (A2)

$$\psi^{(3)}(h, x) = \frac{1}{2\sqrt{2}} \left[ (3, h, x) + |1, v, y) + |-1, v, x) - |1, h, y) - |1, h, x) + |-1, v, y) \right]$$ \hspace{1cm} (A3)

For the initial state $\psi^{(0)}(h, y) = \ket{0, 0, h, y}$,

$$\psi^{(1)}(h, y) = \frac{1}{\sqrt{2}} \left[ (1, h, x) - |-1, v, y) \right]$$  \hspace{1cm} (A4)

$$\psi^{(2)}(h, y) = \frac{1}{2} \left[ (2, h, x) + |0, v, y) - |-2, v, x) + |0, h, y) \right]$$ \hspace{1cm} (A5)

$$\psi^{(3)}(h, y) = \frac{1}{2\sqrt{2}} \left[ (3, h, x) + |1, v, y) + |-1, v, x) - |1, h, y) + |1, h, x) - |-1, v, y) \right]$$ \hspace{1cm} (A6)

For the initial state $\psi^{(0)}(v, x) = \ket{0, 0, v, x}$,

$$\psi^{(1)}(v, x) = \frac{1}{\sqrt{2}} \left[ |-1, v, x) + |1, h, y) \right]$$  \hspace{1cm} (A7)

$$\psi^{(2)}(v, x) = \frac{1}{2} \left[ |-2, v, x) + |0, h, y) + |2, h, x) - |0, v, y) \right]$$ \hspace{1cm} (A8)

$$\psi^{(3)}(v, x) = \frac{1}{2\sqrt{2}} \left[ |-3, v, x) + |-1, h, y) + |1, h, x) - |-1, v, y) + |3, h, x) + |1, v, y) - |-1, v, x) + |1, h, y) \right]$$ \hspace{1cm} (A9)

For the initial state $\psi^{(0)}(v, y) = \ket{0, 0, v, y}$,

$$\psi^{(1)}(v, y) = \frac{1}{\sqrt{2}} \left[ |-1, v, x) - |1, h, y) \right]$$  \hspace{1cm} (A10)

$$\psi^{(2)}(v, y) = \frac{1}{2} \left[ |-2, v, x) + |0, h, y) - |2, h, x) + |0, v, y) \right]$$ \hspace{1cm} (A11)

$$\psi^{(3)}(v, y) = \frac{1}{2\sqrt{2}} \left[ |-3, v, x) + |-1, h, y) + |1, h, x) - |-1, v, y) - |3, h, x) - |1, v, y) + |-1, v, x) + |1, h, y) \right]$$ \hspace{1cm} (A12)

We take $\Psi^{(3)}$ states and examine the position basis entanglement for a single photon.

$$\psi^{(3)}(h, x) = \frac{1}{2\sqrt{2}} \left[ |0, v, y) (|1, h, x) + |0, h, y) \right]$$

$$+ |v, y) (|1, 0, h, x) - |0, 0, v, y) \right]$$

$$+ |v, x) (|1, 0, h, y) + |0, 0, v, x) \right]$$ \hspace{1cm} (A13)

$$\psi^{(3)}(h, y) = \frac{1}{2\sqrt{2}} \left[ |0, v, x) (|1, h, y) + |0, h, x) \right]$$

$$+ |h, y) (|1, 0, h, y) + |0, 0, v, y) \right]$$

$$+ |h, x) (|1, 0, h, x) - |0, 0, v, x) \right]$$ \hspace{1cm} (A14)

$$\psi^{(3)}(v, x) = \frac{1}{2\sqrt{2}} \left[ |0, v, y) (|1, h, x) + |0, h, y) \right]$$

$$+ |v, y) (|1, 0, h, x) - |0, 0, v, y) \right]$$

$$+ |v, x) (|1, 0, h, y) + |0, 0, v, x) \right]$$ \hspace{1cm} (A15)

$$\psi^{(3)}(v, y) = \frac{1}{2\sqrt{2}} \left[ |0, v, x) (|1, h, y) + |0, h, x) \right]$$

$$+ |h, y) (|1, 0, h, y) + |0, 0, v, y) \right]$$

$$+ |h, x) (|1, 0, h, x) - |0, 0, v, x) \right]$$ \hspace{1cm} (A16)

Another way to examine the same states is to keep all degrees of freedom in a certain way, as given in Eq. 10 and Eq. 11. For example,

$$\ket{\Psi^{(3)}(h, x)} = \frac{1}{2\sqrt{2}} \left[ |1, v, x) - |1, h, y) \right]$$

$$+ |v, y) + |1) \left( |v, y) - |h, x) \right) \left[ |3) \left| h, x) \right] \right)$$ \hspace{1cm} (A17)

$$\ket{\Psi^{(3)}(h, y)} = \frac{1}{2\sqrt{2}} \left[ |1, v, y) - |1, h, x) \right]$$

$$- |v, y) + |1) \left( |v, y) + |h, x) \right) \left[ |3) \left| h, x) \right] \right)$$ \hspace{1cm} (A18)

$$\ket{\Psi^{(3)}(v, x)} = \frac{1}{2\sqrt{2}} \left[ |1, v, x) - |1, h, y) \right]$$

$$- |v, y) + |1) \left( |v, y) - |h, x) \right) \left[ |3) \left| h, x) \right] \right)$$ \hspace{1cm} (A19)

$$\ket{\Psi^{(3)}(v, y)} = \frac{1}{2}\left[ |1, v, y) - |1, h, x) \right]$$

$$+ |v, y) + |1) \left( |v, y) + |h, x) \right) \left[ |3) \left| h, x) \right] \right)$$ \hspace{1cm} (A20)

We can obtain Bell state entanglement as presented in Eq. A13-A16 for $|\Psi^{(3)}(\alpha) \rangle \otimes |\Psi^{(3)}(\beta) \rangle$ or its symmetrized version. The entanglement shown here is in the joint Hilbert space of coin and spatial degrees of freedom. Vertices $-3,-1,1,3$ are quantum correlated. However due to the involvement of coin degrees of freedom, we distinguish this
from genuine, pure spatial entanglement. If we project the final state to any coin state, e.g. $|\hat{h}, \hat{x}\rangle$ the entanglement disappears. In order to discuss position basis entanglement analytically we will need the n=5 steps evolution of the photons.

After 5 steps we have:

\[
\begin{align*}
    a_{hx}^{(0,0)} & \rightarrow \frac{1}{2\sqrt{2}} \left( a_{hx}^{(5,5)} - 3a_{hx}^{(5,3)} - a_{hy}^{(5,3)} + a_{vy}^{(5,3)} + a_{hx}^{(5,1)} \\
    & + a_{hy}^{(5,1)} + a_{vx}^{(5,1)} - a_{vy}^{(5,1)} + a_{hx}^{(5,-1)} + 3a_{hy}^{(5,-1)} \\
    & + a_{vx}^{(5,-1)} + a_{vy}^{(5,-1)} + a_{hy}^{(5,-3)} + a_{vx}^{(5,-3)} - a_{vy}^{(5,-3)} \\
    & + a_{vx}^{(5,-5)} \right) \\
    \text{(A21)}
\end{align*}
\]

\[
\begin{align*}
    a_{hy}^{(0,0)} & \rightarrow \frac{1}{2\sqrt{2}} \left( a_{hx}^{(5,5)} - a_{hx}^{(5,3)} - a_{hy}^{(5,3)} + a_{vy}^{(5,3)} + a_{hx}^{(5,1)} \\
    & - a_{hy}^{(5,1)} + a_{vx}^{(5,1)} + a_{vy}^{(5,1)} - a_{hy}^{(5,-1)} - a_{hx}^{(5,-1)} \\
    & + 3a_{vx}^{(5,-1)} - 3a_{vy}^{(5,-1)} - a_{hy}^{(5,-3)} + a_{vx}^{(5,-3)} + a_{vy}^{(5,-3)} \\
    & - a_{vx}^{(5,-5)} \right) \\
    \text{(A22)}
\end{align*}
\]

\[
\begin{align*}
    a_{vx}^{(0,0)} & \rightarrow \frac{1}{2\sqrt{2}} \left( a_{hx}^{(5,5)} + a_{hx}^{(5,3)} - a_{hx}^{(5,3)} + a_{vy}^{(5,3)} + a_{hx}^{(5,1)} \\
    & + a_{hy}^{(5,1)} + a_{vx}^{(5,1)} + 3a_{vy}^{(5,1)} + a_{hx}^{(5,-1)} - a_{hy}^{(5,-1)} \\
    & + a_{vx}^{(5,-1)} + a_{vy}^{(5,-1)} + a_{hy}^{(5,-3)} - 3a_{vx}^{(5,-3)} - a_{vy}^{(5,-3)} \right) \\
    \text{(A23)}
\end{align*}
\]

\[
\begin{align*}
    a_{vy}^{(0,0)} & \rightarrow \frac{1}{2\sqrt{2}} \left( a_{hx}^{(5,5)} + a_{hx}^{(5,3)} + a_{hy}^{(5,3)} - a_{hy}^{(5,3)} + 3a_{hx}^{(5,1)} \\
    & - 3a_{hy}^{(5,1)} - a_{vx}^{(5,1)} - a_{vy}^{(5,1)} + a_{hx}^{(5,-1)} + a_{hy}^{(5,-1)} \\
    & + a_{vx}^{(5,-1)} - a_{vy}^{(5,-1)} + a_{hy}^{(5,-3)} - a_{vx}^{(5,-3)} - a_{vy}^{(5,-3)} \right) \\
    \text{(A24)}
\end{align*}
\]
