# MAPS OF DEGREE ONE, RELATIVE LS CATEGORY AND HIGHER TOPOLOGICAL COMPLEXITIES 

YULI B. RUDYAK AND SOUMEN SARKAR

#### Abstract

In this paper, we introduce relative LS category of a map and study some of its properties. Then we introduce 'higher topological complexity' of a map, a homotopy invariant. We give a cohomological lower bound and compare it with previously known 'topological complexity' of a map. Moreover, we study the relation between LusternikSchnirelmann category and topological complexity of two closed oriented manifolds connected by a degree one map.

## 1. Introduction

The concept of "sectional category" of a fibration $p: E \rightarrow B$ was introduced by Schwarz in Sch66 under the name "genus". James Jam78 proposes to replace the overworked term "genus" by "sectional category". This invariant $\operatorname{secat}(p)$ is one less than the Schwarz genus of $p$ in Sch66. In particular, $\operatorname{secat}(p)=0$ if and only if $p$ has a section. Sectional category of $p$ is the minimum cardinality of the open coverings of $B$ such that on each open set in the covering there is a homotopy section of $p$. If no such integer exists then it is convention that $\operatorname{secat}(p)=\infty$. If $E$ is contractible and $p$ is surjective then $\operatorname{secat}(p)$ is equal to the classical Lusternik-Schnirelmann category (in short LS category throughout this paper) of $B$. Several applications and properties of sectional category and LS-category can be found in [CLOT03. There is a generalization of LS category called category of a map $f: X \rightarrow Y$. We recall that LS category of $f$ is the minimum number cat $(f)$ such that $X$ can be covered by cat $(f)+1$ many open subsets and the restriction of $f$ on each of these open subsets is null-homotopic. In particular, $\operatorname{cat}(i)=\operatorname{cat}(X)$. It is a homotopy invariant and

$$
\begin{equation*}
\operatorname{cat}(f \times g) \leq \operatorname{cat}(f)+\operatorname{cat}(g) \tag{1.1}
\end{equation*}
$$

see CLOT03, Sta02. In this paper, we, in particular introduce relative LS category of a map on a pair of spaces and study some of its properties.

[^0]Another well known particular case of sectional category is Farber's topological complexity [Far03]. He introduced topological complexity of a configuration space to understand the navigational complexity of the motion of a robot. We denote the closed unit interval $[0,1]$ by $I$. Let $X$ be a path connected Hausdorff space and $X^{[0,1]}$ the free path space in $X$ equipped with compact-open topology and

$$
\pi: X^{I} \rightarrow X \times X
$$

the free path fibration defined by $\pi(\alpha)=(\alpha(0), \alpha(1))$ for $\alpha \in X^{I}$. Then $\operatorname{secat}(\pi)$ is equal to Farber's topological complexity, denoted by TC $(X)$.
So, we have close relatives: topologisal complexity and Lusternik-Schnirelmann category. Both are numerical invariants and are special cases of Schwarz genus (sectional category). Thus, since we work with the pair (LS category of spaces, LS category of maps) and in view of parallelism between LS and TC, it seems reasonable to loop the presentation and introduce TC of mappings.
A. Dranishnikov enquired an appropriate definition for topological complexity of a map in his talk at the CIEM, Castro Urdiales in 2014. Let $f: X \rightarrow Y$ be a map. Given $y_{1}, y_{2} \in \operatorname{Im} f$, find a continuous motion planner $\alpha$ in $X$ such that $f(\alpha(0))=y_{1}$ and $f(\alpha(1))=y_{2}$. To answer this, we introduce a definition of "(higher) topological complexity" of a map.
We note that there are several notions of topological complexity of a map, but most of them lacks topologist's basic demand namely homotopy invariance. The basic goal to define map from one state $X$ to another state $Y$ is to study properties of one from another. For example, if $f: X \rightarrow Y$ and $f$ is nice enough then the complexity of the state $X$ could be approximate by the complexity of the state $Y$, and this expectation is very natural. On the other hand, topologists expect that if $X$ and $Y$ are less complex then complexity of $f$ has be less. In particular, if $X$ and $Y$ are contractible, that is there is no obstruction in both the state, then from topological point of view, complexity of a map from $X$ to $Y$ should be trivial. But an Example in page 4 of [Pav19] contradicts this topological expectation. So, we believe our definition is more appropriate according to topological point of view.
Recently Murillo and Wu (MW19] gave a definition of 'topological complexity' of a (work) map which is a homotopy invariant. They gave a cohomological lower bound for this invariant. However, our approach is totally different to define 'topological complexity, of a map as well as we introduce higher topological complexity of a map.
The paper is organize as follows. In Section 2, we recall two versions of relative category and introduce the concept of relative LS category of a map which is denoted by relcat $(f)$. We also study several properties of this invariant which generalizes some of the properties of category of a map. We show that

$$
\operatorname{relcat}(f \times g) \leq \operatorname{relcat}(f)+\operatorname{relcat}(g)
$$

and give a cohomological lower bound of $\operatorname{relcat}(f)$ in Proposition 2.8 and Theorem [2.10 respectively. We ask the Question 2.9 following Ganea conjecture.
In Section 3, we introduce the concept of 'higher topological complexity', denoted by $\mathrm{TC}_{n}(f)$, of a map $f: X \rightarrow Y$. We show that it is a homotopy invariant and the following holds.

$$
\mathrm{TC}_{n}(f) \leq \min \left\{\mathrm{TC}_{n}(X), \mathrm{TC}_{n}(Y)\right\}
$$

and

$$
\operatorname{cat}(f) \leq \mathrm{TC}_{n}(f) \leq \mathrm{TC}_{n+1}(f) \leq \operatorname{cat}\left(f^{n+1}\right) \leq(n+1) \operatorname{cat}(f)
$$

for all $n \geq 2$. That is growth of $\mathrm{TC}_{n}(f)$ is linear. The works of Pav19, RD18] and MW19 study 'topological complexity' of a map. However, we discuss higher analogue of it. We compare our definition with the previous ones.
Section 4 is dedicated to answer the following open problem for a broader class of manifolds. This question was asked by Rudyak Rud99 and now it is consider as a conjecture, see Dra15, DS19.
1.1. Question. Given two closed connected orientable manifolds $M$ and $N$, assume that there exists a map $f: M \rightarrow N$ of degree $\pm 1$. Is it true that $\operatorname{cat}(M) \geq \operatorname{cat} N$ ?
1.2. Remark. Since we speak about the degree of a map $M \rightarrow N$, the manifolds $M$ and $N$ (like in 1.1, say) must be assumed to be oriented. So, in future we will not mention "oriented" in such situations

We replace cat by TC in Question 1.1 and ask a similar question in Section 5. We give affirmative answer to this question too for several category of manifolds and when the dimensions are less than 4.

Through the paper, the word "space" means "topological space" unless some other is said explicitly, and all maps of spaces are assumed to be continuous. The word 'smooth" means $C^{\infty}$ for spaces as well as for maps. Finally, all manifolds are assumed to be smooth and connected unless some other is said explicitly.

## 2. Two Versions of Relative Category

In this section, we introduce relative category of a map and study some of its properties. Let cat $X$ denote the LS category of a space $X$. Note that we use the normalized category, that is cat of the point is zero. Many topological constructions exploit relative version, informally saying to use an object "modulo subspaces". Here we use two following definitions.
2.1. Definition ([CLOT03, Definition 7.1]). Let $(X, A)$ be a pair of topological spaces. The relative category $\operatorname{cat}(X, A)$ is the least non-negative integer $k$ such that $X$ can be cover by open sets $V_{0}, V_{1}, \ldots, V_{k}$ with $A \subseteq V_{0}$ and such that, for $i \geq 1$, the sets $V_{i}$ are contractible in $X$, and there exists a
homotopy of pairs $H:\left(V_{0} \times[0,1], A \times[0,1]\right) \rightarrow(X, A)$ with $H(-, 1)$ is given by the inclusion map $V_{0} \hookrightarrow X$ and $H\left(V_{0}, 0\right) \subseteq A$.
2.2. Definition ([LM15, Definition 2.1, 2.2]).
(1) Let $(X, A)$ be a pair of topological spaces. An open subset $U$ of $X$ is called relative categorical if there is a homotopy $H: U \times[0,1] \rightarrow X$ such that $H(-, 1)$ is the inclusion $U \hookrightarrow X$ and $H(U, 0) \subseteq A$.
(2) Relative category of the pair $(X, A)$, denoted by relcat $(X, A)$ is the least integer $n$ such that $X$ can be cover by $n+1$ many relative categorical sets. Otherwise, we say this is infinity.

Note that $\operatorname{cat}\left(X, x_{0}\right)=\operatorname{cat} X=\operatorname{relcat}\left(X, x_{0}\right)$ where $x_{0} \in X$. The following example shows that Definition 2.1 and Definition 2.2 are not equivalent, in general.
2.3. Example. Let $X=D^{n}$ be the unit closed $n$-ball in $\mathbb{R}^{n}$ and $A=\partial D^{n}$ its boundary. We prove that $\operatorname{relcat}(X, A)=0$ and $\operatorname{cat}(X, A)=1$.
First, note that $\operatorname{cat}(X, A) \geq 1$, since the open subset $V_{0}=X$ of $X$ does not satisfy the homotopy condition in Definition 2.1. Now, let $V_{0}=X-\{0\}$ be he punctured $n$-ball and $V_{1}=X-A$. Then $\left\{V_{0}, V_{1}\right\}$ is an open covering of $X$. Observe that this covering satisfy the conditions in Definition 2.1, Therefore, $\operatorname{cat}(X, A)=1$.
On the other hand, the open set $V_{0}=X$ is contractile to a point in $A$, and thus relcat $(X, A)=0$.

Now we are in a position to introduce the concept of relative category of a map. Then we study their several properties in the remaining of this section.
2.4. Definition. Let $g:(B, C) \rightarrow(X, A)$ be a map of pairs ( $C$ could be empty subset). Then $g$ is called relatively inessential map if there is a homotopy $H: B \times[0,1] \rightarrow X$ such that $H(-, 1)$ is $g, H(B, 0) \subseteq A, H(C, t) \subseteq$ $A$ for all $t \in[0,1]$.
2.5. Definition. Let $f:(B, C) \rightarrow(X, A)$ be a map of pairs. Then relcat $(f) \leq$ $\ell$ if $B$ has an open cover by $B_{0}, \ldots, B_{\ell}$ such that $\left.f\right|_{\left(B_{i}, B_{i} \cap C\right)}$ is relatively inessential. Minimum $\ell$ with this property is called relative-category of $f$. Otherwise we say it is infinity.
Clearly, if $C=\emptyset$ or $C=\{p t\}$ and $A=\{p t\}$ then relcat $(f)$ turns into known invariant $\operatorname{cat}(f)$ for $f: B \rightarrow X$, see CLOT03, Exercise 1.16].
2.6. Theorem. The number relcat $(f)$ is a homotopy invariant.

Proof. Let $f, g:(B, C) \rightarrow(X, A)$ be homotopic maps relative to $C$. Then there is a homotopy $H: B \times[0,1] \rightarrow X$ such that $H(b, 0)=f(b), H(b, 1)=$ $g(b)$ for all $b \in B$, and $H(C, t) \subseteq A$ for all $t \in[0,1]$. Let $B_{i}$ be an open subset of $B$ such that the map

$$
\left.g\right|_{\left(B_{i}, B_{i} \cap C\right)}:\left(B_{i}, B_{i} \cap C\right) \rightarrow(X, A)
$$

is relatively inessential. Now we use the homotopy $H$ to concude that

$$
\left.f\right|_{\left(B_{i}, B_{i} \cap C\right)}:\left(B_{i}, B_{i} \cap C\right) \rightarrow(X, A)
$$

is relatively inessential. Therefore, $\operatorname{relcat}(f) \leq \operatorname{relcat}(g)$. Similarly, the opposite inequality holds.
Note that for identity map, id: $(X, A) \rightarrow(X, A)$, $\operatorname{relcat}(i d)=\operatorname{relcat}(X, A)$. Moreover, we have the following from Definition 2.2 and 2.5.
2.7. Proposition. Let $f:(B, C) \rightarrow(X, A)$ and $g:(Y, D) \rightarrow(B, C)$ be two maps. Then
(i) $\operatorname{relcat}(f) \leq \min \{\operatorname{relcat}(B, C)$, $\operatorname{relcat}(X, A)\}$.
(ii) $\operatorname{relcat}(f \circ g) \leq \min \{\operatorname{relcat}(f)$, $\operatorname{relcat}(g)\}$.
2.8. Proposition. Let $f:(B, C) \rightarrow(X, A)$ and $g:(E, F) \rightarrow(Y, D)$ be two maps. Then $\operatorname{relcat}(f \times g) \leq \operatorname{relcat}(f)+\operatorname{relcat}(g)$.
Proof. The proof is similar to the proof of $\operatorname{cat}(X \times Y) \leq \operatorname{cat}(X)+\operatorname{cat}(Y)$ [CLOT03, Theorem 1.37] with some modification.
We can ask the following question generalizing Ganea conjecture Gan71.
2.9. Question. Let pt be a point in $S^{n}$. What are the pair of spaces $(X, Y)$ so that

$$
\operatorname{relcat}\left(X \times S^{n}, Y \times\{p t\}\right)=\operatorname{relcat}(X, Y)+1 ?
$$

We note that when $Y$ is a point in $X$, then Question 2.9 is known as Ganea conjecture, and counter example of this conjecture was first given by Iwase [Iwa98].
In the rest of this section we give a cohomological lower bound of relcat $(f)$. If $R$ be a commutative ring, then the nilpotency index of $R$ is the non-negative integer $n$ such that $R^{n} \neq 0$ but $R^{n+1}=0$ and it is denoted by nil $R$. Let $f:(B, C) \rightarrow(X, A)$ be a map of pairs, and let $f^{*}: H^{*}(X, A) \rightarrow H^{*}(B, C)$ be the induced homomorphism.
2.10. Theorem. $\operatorname{nilIIm}\left(f^{*}\right) \leq \operatorname{relcat}(f)$.

Proof. Let relcat $(f)=k$ and $g_{i}:\left(B_{i}, B_{i} \cap C\right) \rightarrow(X, A)$ relatively inessential map for $i=0,1, \ldots, k$ such that $g_{i}$ is a restriction of $f$ and $B_{0}, B_{1}, \ldots, B_{k}$ covers $B$. For the triple ( $B, B_{i}, B_{i} \cap C$ ), we have the following long exact sequence

$$
\cdots \rightarrow H^{*}\left(B, B_{i}\right) \xrightarrow{q_{i}^{*}} H^{*}\left(B, B_{i} \cap C\right) \xrightarrow{\iota_{i}^{*}} H^{*}\left(B_{i}, B_{i} \cap C\right) \rightarrow \cdots .
$$

Also we have the following commutative diagrams induced from natural inclusions and some restrictions of $f$.

and

Suppose $\beta_{0}, \beta_{1}, \ldots, \beta_{k}$ belong to $\operatorname{Im}(f)$. Then $\beta_{i}=f^{*}\left(\alpha_{i}\right)$ for some $\alpha_{i} \in$ $H^{*}(X, A)$ and $i \in\{0, \ldots, k\}$. Since $g_{i}$ is inessential, then $g^{*}$ is trivial. So $\iota_{i}^{*}\left(\bar{f}_{i}^{*}\left(\alpha_{i}\right)\right)=0 \in H^{*}\left(B_{i}, B_{i} \cap C\right)$. Thus $\bar{f}_{i}^{*}\left(\alpha_{i}\right)=q_{i}^{*}\left(\gamma_{i}\right)$ for some $\gamma_{i} \in$ $H^{*}\left(B, B_{i}\right)$ and $i \in\{0, \ldots, k\}$. By relative cohomology product rule, we get $\gamma_{0} \cup \gamma_{1} \cup \cdots \cup \gamma_{k} \in H^{*}(B, B)=0$, and $\bar{f}_{0}^{*}\left(\alpha_{0}\right) \cup \bar{f}_{1}^{*}\left(\alpha_{1}\right) \cup \ldots \cup \bar{f}_{k}^{*}\left(\alpha_{k}\right) \in$ $H^{*}(B, C)$. So using [Pav19, Proposition 3.19] and the map $q:(B, C) \rightarrow$ ( $B, B$ ) we can get

$$
\begin{aligned}
\beta_{0} \cup \beta_{1} \cup \cdots \cup \beta_{k} & =f^{*}\left(\alpha_{0}\right) \cup f^{*}\left(\alpha_{1}\right) \cup \cdots \cup f^{*}\left(\alpha_{k}\right) \\
& =\bar{f}^{*}\left(\alpha_{0}\right) \cup \bar{f}^{*}\left(\alpha_{1}\right) \cup \cdots \cup \bar{f}^{*}\left(\alpha_{k}\right) \\
& =q_{0}^{*}\left(\gamma_{0}\right) \cup q_{1}^{*}\left(\gamma_{1}\right) \cup \cdots \cup q_{k}^{*}\left(\gamma_{k}\right) \\
& =q^{*}\left(\gamma_{0} \cup \gamma_{1} \cup \cdots \cup \gamma_{k}\right) \\
& =0 .
\end{aligned}
$$

This proves the conclusion.

## 3. Topological complexity of a map

In different context 'topological complexity of a map' has been studied in the work of Pav19], RD18] and [MW19]. In this section, we introduce the concept of 'higher topological complexity' of a map in a different way and show that it is a homotopy invariant. Then we compare it with the previous ones and study some properties of this new invariant. Consider the free path fibration

$$
\begin{equation*}
\pi: X^{I} \rightarrow X \times X, \quad \pi(\alpha)=(\alpha(0), \alpha(1)), \alpha: I \rightarrow X \tag{3.1}
\end{equation*}
$$

Fatber [Far03] defined the topological complexity $\mathrm{TC}(X)$ of a space $X$ as the sectional category of $\pi$, and showed a nice application of this notion to robot motion planning, Far08. Later Rudyak Rud10, see also [BGRT14] introduced the "higher analogues" of topological complexity (also related to robotics, by the way). Let us recall the definition.
Given a space $X$, consider the fibration

$$
\begin{align*}
& \pi_{n}: X^{I} \rightarrow X^{n} \\
& \pi_{n}(\alpha)=\left(\alpha(0), \alpha\left(\frac{1}{n-1}\right), \ldots, \alpha\left(\frac{n-2}{n-1}\right), \alpha(1)\right) \tag{3.2}
\end{align*}
$$

where $\alpha \in X^{I}$.
3.1. Definition. A higher, or sequential topological complexity of order $n$ of a space $X$ (denoted by $\mathrm{TC}_{n}(X)$ ) is the sectional category of $\pi_{n}$. So, $\mathrm{TC}_{n}(X)=\operatorname{secat}\left(\pi_{n}\right)$.

Note that $\mathrm{TC}_{2}$ coincides with the invariant TC introduces by Farber.
Recall that the LS category of a map $f$ have two important properties: $\operatorname{cat}(f)$ is a homotopy invariant of $f$, and $\operatorname{cat}\left(\operatorname{id}_{X}\right)=\operatorname{cat}(X)$.
Since cat is a closed relative of TC, it seems reasonable and useful to introduce topological complexity $\mathrm{TC}(f)$ of a map $f$ having, in particular, properties that are similar to two above mentioned ones.
Let $\Delta_{n}: X \rightarrow X^{n}$ be the diagonal of the product $X^{n}$ for $n \geq 2$.
3.2. Definition. Let $X$ and $Y$ be path connected spaces, and $f: X \rightarrow Y$ be a map. Let $\phi_{n}:=f \times \cdots \times f(n$-times) and

$$
\bar{\phi}_{n}:\left(X^{n}, \Delta_{n}(X)\right) \rightarrow\left(Y^{n}, \Delta_{n}(Y)\right)
$$

be the induced maps of pairs. We define the $n$-th (higher) topological complexity of $f$, denoted by $\mathrm{TC}_{n}(f)$, as $\mathrm{TC}_{n}(f):=\operatorname{relcat} \bar{\phi}_{n}$.

Now one can see thet $\mathrm{TC}_{n}$ turns out to be a functor on the category of topological spaces.

Previously we had three following version of 'topological complexity' of a map: the first one that is given by Pavešić, Pav19], we denote it by TC ${ }^{\text {Pav }}$, the second one that is given by Rami and Derfoufi, RD18, we denote it by $\mathrm{TC}^{\mathrm{RD}}$, and third one is by Murillo and Wu MW19, we denoted by $\mathrm{TC}^{\mathrm{MW}}$. Here we have the equalities

$$
\mathrm{TC}^{\mathrm{Pav}}\left(\mathrm{id}_{X}\right)=\mathrm{TC}(X)=\mathrm{TC}\left(\mathrm{id}_{X}\right)=\mathrm{TC}^{\mathrm{RD}}\left(\mathrm{id}_{X}\right)==\mathrm{TC}^{\mathrm{MW}}\left(\mathrm{id}_{X}\right) .
$$

But neither $\mathrm{TC}^{\mathrm{Pav}}$ nor $\mathrm{TC}^{\mathrm{RD}}$ are homotopy invariant, see Example 3.3 and 3.4. Next we compare them with our definition of $\mathrm{TC}_{2}(f)$.

First we recall the definition of topological complexity $\mathrm{TC}^{\mathrm{Pav}}(f)$ of a map $f$. Let $q: E \rightarrow B$ be a surjective map. The sectional number, denoted by $\sec (q)$, of $q$ is the smallest length $n$ of the filtrations

$$
\emptyset=V_{0} \subset V_{1} \subset \cdots \subset V_{n}=B
$$

such that there is a section of $q^{-1}\left(V_{i}-V_{i-1}\right) \rightarrow V_{i}-V_{i-1}$ for $i=1, \ldots, n$. If there is no such integer then $\sec (p)=\infty$. We note that sectional number and sectional category of $q$ are equal if $q$ is a fibration. Let $X, Y$ be path connected spaces and $f: X \rightarrow Y$ a surjective map. Consider the fibration $\pi: X^{I} \rightarrow X \times X$ as in (3.1). It induces a continuous map $\pi_{f}: X^{I} \rightarrow X \times Y$ by $\pi_{f}=(\mathrm{id} \times f) \circ \pi$. Now, the topological complexity $\mathrm{TC}^{\mathrm{Pav}}(f)$ of $f$ is defined as the sectional number of $\pi_{f}$, that is

$$
\begin{equation*}
\operatorname{TC}^{\operatorname{Pav}}(f):=\sec \left(\pi_{f}\right) \tag{3.3}
\end{equation*}
$$

We note that [Pav19, Corollary 3.9] says that $\mathrm{TC}^{\mathrm{Pav}}$ is a fiber homotopy invariant.
3.3. Example. Let $f, g:[0,3] \rightarrow[0,2]$ be two continuous functions defined by the following.

$$
f(x)= \begin{cases}x & \text { if } 0 \leq x \leq 1 \\ 1 & \text { if } 1 \leq x \leq 2 \\ x-1 & \text { if } 2 \leq x \leq 3\end{cases}
$$

and

$$
g(x)=\frac{2 x}{3} \quad \text { if } 0 \leq x \leq 3
$$

Hence $f$ has no continuous section, and $g$ has a section. So $\mathrm{TC}^{\mathrm{Pav}}(f)>0$ and $\mathrm{TC}^{\mathrm{Pav}}(g)=0$. But $f$ and $g$ are homotopic by $t f+(1-t) g, t \in[0,1]$. Therefore $\mathrm{TC}^{\mathrm{Pav}}$ is not a homotopy invariant. This is mentioned in [Pav19], but an explicit example was not given.

Now we recall the topological complexity $\mathrm{TC}^{\mathrm{RD}}(g)$ of a map $g$. Let $Z$ be a path connected space and $g: Z \rightarrow W$ be a map. Then the fiber space $Z \times{ }_{W} Z:=(g \times g)^{-1}(\Delta W)$ is a subset of $Z \times Z$. Let

$$
\pi^{g}: \pi^{-1}\left(Z \times_{W} Z\right) \rightarrow Z \times_{W} Z .
$$

be the fibration induced from $\pi: Z^{I} \rightarrow Z \times Z$ by the inclusion

$$
Z \times_{W} Z \rightarrow Z \times Z .
$$

Then $\operatorname{TC}^{\mathrm{RD}}(g)$ is the sectional category of $\pi^{g}$, that is

$$
\begin{equation*}
\mathrm{TC}^{\mathrm{RD}}(g):=\operatorname{secat}\left(\pi^{g}\right) \tag{3.4}
\end{equation*}
$$

It turns out that $\mathrm{TC}^{\mathrm{RD}}$ is also a fiber homotopy invariant RD18, Corollary 7]. We also note that this definition is a particular case of "relative topological complexity" studied in [Far08.
3.4. Example. In this example we show that $\mathrm{TC}^{\mathrm{RD}}$, "topological complexity of a map" defined in RD18] is not a homotopy invariant. Let $X$ be a path connected topological space and $C X$ the cone on $X$ with apex $a$. Write $C X=X \times[0,1] / X \times\{1\}$. Define $\iota, \mathfrak{c}: X \rightarrow C X$ where $\iota$ is the inclusion $\iota(x)=(x, 0)$ and $\mathfrak{c}(X)=a$. Then $\mathrm{TC}^{\mathrm{RD}}(\mathfrak{c})=\mathrm{TC}(X)$ (Farber's topological complexity).
For the map $\iota$, we have $X \times_{C X} X=\Delta X$. Then $\pi^{-1}(\Delta X)$ is the free loop space on $X$. So constant maps induce a section of $\pi^{\iota}$. Therefore $\mathrm{TC}^{\mathrm{RD}}(\iota)=1 \neq \mathrm{TC}(X)=\mathrm{TC}^{\mathrm{RD}}(\mathfrak{c})$ in general. It remain to note that $\iota$ and $\mathfrak{c}$ are homotopic.

In contrast to both definitions $\mathrm{TC}^{\mathrm{Pav}}$ and $\mathrm{TC}^{\mathrm{RD}}$ of the "topological complexity of a map", it is clear that our definition is a homotopy invariant, a topologist primary interest.

Now we show that $\mathrm{TC}^{\mathrm{Pav}} \neq \mathrm{TC} \neq \mathrm{TC}^{\mathrm{RD}}$ explicitly. Let $X$ be a contractible space and $Y$ a non-contractible space. Let $f: X \rightarrow Y$ be a surjective fibration, for example exp: $[0,1] \rightarrow S^{1}$. Then by Pav19, Proposition 3.2] $\mathrm{TC}^{\mathrm{Pav}}(f) \geq \operatorname{cat}(Y) \geq 1$. But our definition gives $\mathrm{TC}(f)=0$. Therefore these two are different.
On the other hand, if $g$ is a constant map then $\mathrm{TC}^{\mathrm{RD}}(g)$ is the topological complexity $\mathrm{TC}(X)$ of $X$ which is strictly greater than $\operatorname{cat}(X)$ in general.
Now we recall the definition of topological complexity $\mathrm{TC}^{\mathrm{MW}}(f)$ of (work) map. Let $f: X \rightarrow Y$ be a continuous map. Then $\operatorname{TC}^{\mathrm{MW}}(f)$ is the least integer $n \leq \infty$ such that there exist open subsets $U_{0}, \ldots, U_{n}$ of $X \times X$ on each of which there is a map $s_{i}: U_{i} \rightarrow X$ satisfying $(f \times f) \circ \Delta_{2} \circ s_{i} \simeq f \times\left. f\right|_{U_{i}}$ for $i=0, \ldots, n$. We also note that Scott defines topological complexity $\mathrm{TC}^{\mathrm{S}}(f)$ of a map in Sco20, Definition 3.1], and he shows that these two definitions are equivalent.
Let $(a, b) \in U_{i}$. So $s_{i}(a, b) \in X$. Then $(f \times f) \circ \Delta_{2} \circ s_{i}(a, b) \in \Delta_{2}(Y)$. Yet, we cannot conclude that $f \times\left. f\right|_{U_{i}}:\left(U, U \cap \Delta_{2}(X)\right) \rightarrow\left(Y, \Delta_{2}(Y)\right)$ is inessential in the sense of Definition 2.4. However, if we assume $f \times\left. f\right|_{U_{i}}$ is inessential, then it is homotopict to a map $U_{i} \rightarrow \Delta_{2}(Y)$. Thus by [Sco20, Theorem 3.4] we get the following.

$$
\begin{equation*}
\mathrm{TC}^{\mathrm{MW}}(f)=\mathrm{TC}^{\mathrm{S}}(f) \leq \mathrm{TC}_{2}(f) \tag{3.5}
\end{equation*}
$$

We do not know yet if $\mathrm{TC}_{2}(f)=\mathrm{TC}^{\mathrm{MW}}(f)$. Nevertheless, we give higher analogue of the topological complexity of a map which generalizes higher topological complexity of a space.

In the remaining we study some properties, lower bound and upper bound of $\mathrm{TC}_{n}(f)$.
3.5. Proposition. We have $\mathrm{TC}_{n}(f) \leq \min \left\{\mathrm{TC}_{n}(X), \mathrm{TC}_{n}(Y)\right\}$ for all maps $f: X \rightarrow Y$.

Proof. This follows from Proposition 2.7 and [BS18, Proposition 3.7].
We note that the sectional category of a map does not exceed the LScategory of the the codomain. Thus

$$
\mathrm{TC}_{n}(f) \leq \min \{n \operatorname{cat}(X), n \operatorname{cat}(Y)\}
$$

A part of the following result generalizes Rud10, Proposition 3.3].
3.6. Proposition. Let $f: X \rightarrow Y$ be a map. Then

$$
\operatorname{cat}(f) \leq \mathrm{TC}_{n}(f) \leq \mathrm{TC}_{n+1}(f) \leq \operatorname{cat}\left(f^{n+1}\right) \leq(n+1) \operatorname{cat}(f)
$$

for all $n$.
Proof. Let $x \in X$ and

$$
\left.\phi_{n+1}\right|_{\left(B, B \cap \Delta_{n+1}(X)\right)}:\left(B, B \cap \Delta_{n+1}(X)\right) \rightarrow\left(Y^{n+1}, \Delta_{n+1}(Y)\right)
$$

inessential for some open subset $B \subset X^{n+1}$. Let $A=X^{n} \times x, \phi_{n}^{\prime}$ be the restriction of $\phi_{n+1}$ on $A$, and $p r_{x}: Y^{n+1} \rightarrow Y^{n} \times f(x)$ the projection. Then $\phi_{n}^{\prime}$ is $\phi_{n}$ and the following composition

$$
p r_{x} \circ \phi_{n}^{\prime}:\left(A \cap B, A \cap B \cap\left(\Delta_{n}(X), x\right)\right) \rightarrow\left(Y^{n} \times f(x),\left(\Delta_{n}(Y), f(x)\right)\right)
$$

is inessential. This proves the second inequality. The first inequality follows from similar arguments. The third inequality follows from their definitions. The last inequality follows from (1.1).

We remark that (3.5), Proposition 3.5 and 3.6 imply Sco20, Proposition 3.8] in particular. Moreover, growth of $\mathrm{TC}_{n}(f)$ is linear like $\mathrm{TC}_{n}(X)$. Let $X, Y$ be a non-contractible space and $f: X \rightarrow Y$ constant map. Then $\mathrm{TC}_{n}(f)=1$, but cat $X \geq 2$ and $\operatorname{cat} Y \geq 2$. So we cannot say $\operatorname{cat} X$ or $\operatorname{cat}(Y)$ is a lower bound for $\mathrm{TC}_{n}(f)$ in general. However we can give the following cohomological lower bound by Theorem [2.10.
3.7. Proposition. Let $f: X \rightarrow Y$ and $\bar{\phi}_{n}$ be as in Definition 3.2. Then $\operatorname{nilIm}\left(\bar{\phi}_{n}^{*}\right) \leq \mathrm{TC}_{n}(f)$ for any $n$.
The map $\Delta_{2}: X \rightarrow X \times X$ induces a map $\cup: H^{*}(X) \otimes H^{*}(X) \rightarrow H^{*}(X)$ defined by the cup product. If $f: X \rightarrow Y$ is a map, then $\left.\operatorname{ker} \cup\right|_{\operatorname{Im}(f \times f)^{*}} \subseteq$ $\operatorname{Im}(f \times f)^{*}$. Therefore we get the following inequalities.
3.8. Corollary. nil $\left.\operatorname{ker} U\right|_{\operatorname{Im}(f \times f)^{*}} \leq \operatorname{nilIm}(f \times f)^{*}, \mathrm{TC}^{\mathrm{MW}}(f) \leq \mathrm{TC}_{2}(f)$.
3.9. Example. Let $L\left(p ; q_{1}, \ldots, q_{n}\right)$ be the generalized lens space and $S^{2 n+1} \xrightarrow{f}$ $L\left(p ; q_{1}, \ldots, q_{n}\right)$ be the corresponding orbit map. So $\operatorname{deg}(f)=p$. That is $f$ is essential. Thus $1 \leq \mathrm{TC}_{2}(f)$. On the other hand $\mathrm{TC}_{2}(f) \leq \mathrm{TC}\left(S^{2 n+1}\right)=1$ by Proposition [3.5 and [Far03, Theorem 8]. So $\mathrm{TC}_{2}(f)=1$ and it does not depend on the degree of $f$.
3.10. Example. Let $n \geq 3$ be odd and $\mathbb{R} P^{n} \xrightarrow{g} \mathbb{R} P^{n} / \mathbb{R} P^{n-1} \cong S^{n}$ the natural quotient map. So $g$ is essential which implies that $1 \leq \mathrm{TC}_{2}(f)$. On the other hand, $\mathrm{TC}_{2}(g) \leq \mathrm{TC}\left(S^{n}\right)$ by Proposition 3.5. Thus $\mathrm{TC}_{2}(g)=1$. Whereas the results in [MW19] cannot determine $\mathrm{TC}^{\mathrm{MW}}(\mathrm{g})$. However, we can have

$$
1 \leq \mathrm{TC}^{\mathrm{MW}}(g) \leq \mathrm{TC}_{2}(g)=1
$$

## 4. Maps of Degree 1 and Lusternik-Schnirelmann category

In this section, we give affirmative answer of Question 1.1 in a broader category, other than the class of manifolds discussed in Rud17. Please, pay attention to Remark 1.2. For future references, we note the following 2 known facts.
4.1. Proposition. If $M$ be a closed manifold with cat $M=1$ then $M$ is a homotopy sphere.

Proof. Recall that $\pi_{1}(X)$ is free for all CW spaces (not necessarily manifold) $X$ with cat $X=1$ (i.e the so-called co- $H$-spaces), see [CLOT03, Ex.1.21] or Ark11, Prop. 2.4.3]. For simply connected closed manifold $M^{n}$ we claim that $H^{i}(M)=0$ for $i \neq 0, n$ (and hence $M$ is a homotopy sphere). Indeed, if $a \in H^{k}(M), a \neq 0$ for some $k \neq 0, n$ then there is a Poincaré dual class $b \in H^{n-k}(M)$ with $a \smile b \neq 0$. Hence cup-length of $M$ is at least 2 , and so cat $M \geq 2$, a contradiction. If $M$ is not simply connected then $\pi_{1}(M)$ is non-trivial free group, and so $H_{1}(M)$ is a non-zero free abelian group, and so $H^{1}(M) \neq 0$. Hence, asserting as above, we see that cuplength of $M$ is at least 2. Thus, cat $M \geq 2$, a contradiciton.
4.2. Proposition. Let $f: M \rightarrow N$ be a map of degree $\pm 1$. Then $f_{*}: H_{*}(M) \rightarrow$ $H_{*} N$ is an epimorphism and $f^{*}: H^{*}(N) \rightarrow H^{*}(M)$ is a monomorphism. Furtherbore, $f_{*}: \pi_{1}(M) \rightarrow \pi_{1} N$ is an epimorphism.

Proof. For $H_{*}, H^{*}$ see Rud98, Theorem V.2.13], cf. also Dyer69. For $\pi_{1}$ see DR09, Prop 5.1].
4.3. Corollary. Let $f: M \rightarrow N$ be a map of degree $\pm 1$. If $M$ is a homotopy sphere then $N$ is.

We recall the notion of category weight, see Rud96, Rud99, Str97.
4.4. Definition. Given a connected CW space $X$ and spectrum (cohomology theory) $E^{*}$, the category weight of $u \in E^{*}(X)$, denoted by wgt $u$ is defined by
wgt $u \geq k$ if and only if $\varphi^{*}(u)=0$ for all $\varphi: A \rightarrow X$ with cat $\varphi>k$.
Another definition looks as follows: wgt $u$ is the greater integer $k$ such that $p_{k-1}^{*}(u)=0$. Here $p_{k-1}: G_{k-1}(X) \rightarrow X$ is the $(k-1)$ th Ganea fibration, [CLOT03, Definition 1.51]. For the proof of equivalence of these two definitions, see Section 2.7 in [CLOT03, Lemma 8.21]
4.5. Remark. The origin of notion of category weght goes back to Fadell and Husseini [FH92]. However, their definition has a disadvantage that it is not a homotopy invariant.
4.6. Proposition. Category weight has the following properties.
(1) $\operatorname{wgt} u \leq \operatorname{cat} X \leq \operatorname{dim} X$ for all $u \in E^{*}(X)$;
(2) $\operatorname{wgt}\left(f^{*}(u) \geq \operatorname{wgt} u\right.$ for any $u \in E^{*}(X)$ and $f: Y \rightarrow X$ with $f^{*}(u) \neq$ 0);
(3) If $E^{*}$ is ring spectrum then $\operatorname{wgt}(u \smile v) \geq \operatorname{wgt} u+\operatorname{wgt} v$ for $u, v \in$ $E^{*}(X)$;
(4) If $u \in H^{s}(K(\pi, 1) ; R)$ then wgt $u \geq s$.

Proof. See [Rud99, Theorem 1.8] or [CLOT03, Prop. 8.22]
4.7. Definition ( Rud99). Let $X$ and $E$ be as in Definition4.4. An element $u \in E^{*}$ is a detecting element for $X$ is $\operatorname{wgt} u=\operatorname{cat}(X)$.
4.8. Proposition ([Rud17, Section 4]). Let $f: M \rightarrow N$ be a map of degree $\pm 1$. If dimension of $M, N$ is less than 5 , then $\operatorname{cat}(M) \geq \operatorname{cat}(N)$.
We note that if $f: M \rightarrow N$ is a degree one map and $\operatorname{cat}(N) \leq 2$, then $\operatorname{cat}(M) \geq \operatorname{cat}(N)$ in any dimension.
The following propositions give an effect of having detecting element after taking finite product with spheres.
4.9. Proposition. Let $g: M \rightarrow N \times S^{n_{1}} \times \cdots \times S^{n_{\ell}}$ be a map of degree $\pm 1$ for some $\ell \geq 0$.
(i) If $N$ possesses a detecting element in $H^{*}$ then

$$
\operatorname{cat}(M) \geq \operatorname{cat}\left(N \times S^{n_{1}} \times \cdots \times S^{n_{\ell}}\right)
$$

(ii) If $M$ and $N$ are stable parallelizable manifold and $N$ is a (q-1)connected manifold with $q \operatorname{cat}(N)=\operatorname{dim} N \geq 4$ then

$$
\operatorname{cat}(M) \geq \operatorname{cat}\left(N \times S^{n_{1}} \times \cdots \times S^{n_{\ell}}\right)
$$

Proof. For sake of simplicity, put $N^{*}:=N \times S^{n_{1}} \times \cdots \times S^{n_{\ell}}$.
(i) If $N$ possesses a detecting element in $H^{*}$, then by Rud99, Corollary 2.3] $N^{*}$ possesses a detecting element, say, $u$. Since $\operatorname{deg} g= \pm 1$ we conclude that $g^{*}: H^{*}\left(N^{*}\right) \rightarrow H^{*}(M)$ is a monomorphism by Rud17, Lemma 2.2]. Thus, by Prop. 4.6 we have

$$
\operatorname{cat}(M) \geq \operatorname{wgt} g^{*} u \geq \operatorname{wgt} u=\operatorname{cat}\left(N^{*}\right) .
$$

(ii) If $M, N$ are stable parallelizable manifold then $M, N$ is $S$-orientable with respect to the sphere spectrum $S$. Recall that $N$ is a $(q-1)$ connected manifold with $q \operatorname{cat}(N)=\operatorname{dim} N \geq 4$. Hence by Rud99, Theorem 3.1], $N$ possesses a detecting element $v \in E^{*}(N)$ for some spectrum $E$. So, $N^{*}$ has a detecting element for $E$ by Rud99, Lemma 2.2]. Since every spectrum is a module spectrum over $S$, we conclude that $g^{*}: E^{*}\left(N^{*}\right) \rightarrow E^{*}(M)$ is a monomorphism by Rud98, Theorem V.2.13]. Now the proof can be completed as the previous part.
4.10. Proposition. Let $f: M \rightarrow N$ be a map of degree $\pm 1$ and suppose that $\operatorname{cat}\left(M \times S^{m_{1}} \times \cdots \times S^{m_{k}}\right) \geq \operatorname{cat}\left(N \times S^{n_{1}} \times \cdots \times S^{n_{k}}\right), \quad k \geq 1$.
If either $N$ possesses a detecting element or $\operatorname{dim} N \leq 2 \operatorname{cat}(N)-3$ then $\operatorname{cat}(M) \geq \operatorname{cat}(N)$.
Proof. If $N$ possesses a detecting element, then by Rud99, Corollary 2.3] we have $\operatorname{cat}\left(N \times S^{n_{1}} \times \cdots \times S^{n_{k}}\right)=\operatorname{cat}(N)+k$.
Also, if $\operatorname{dim} N \leq 2 \operatorname{cat}(N)+3$, then by Rud99, Theorem 3.8], we have $\operatorname{cat}\left(N \times S^{n_{1}} \times \cdots \times S^{n_{k}}\right)=\operatorname{cat}(N)+k$.
Since $\operatorname{cat}(X \times Y) \leq \operatorname{cat}(X)+\operatorname{cat}(Y)$ for all $X, Y$, we have

$$
\operatorname{cat}\left(M \times S^{m_{1}} \times \cdots \times S^{n_{k}}\right) \leq \operatorname{cat}(M)+k
$$

This implies the conclusion.

Now, let $N=\left(N^{2 n}, \omega\right)$ be a closed symplectic manofold with the closed non-degenerate symplectic 2-form $\omega$. Let $[\omega] \in H^{2}(N ; \mathbb{R})$ be the de Rham cohomology class of $\omega$.
4.11. Proposition. Let $f: M \rightarrow N$ be a map of degree $\pm 1$ and $N$ is a symplectic manifold as above. In addition, assume that $N$ is simply connected . Then $\operatorname{cat}(M) \geq \operatorname{cat}(N)$.

Proof. By the cup-length theory for LS category, we have $\operatorname{cat}(N) \geq n$ as $[\omega]^{n} \neq 0$. Furthermore, $\operatorname{cat}(N) \leq n$ as $N$ is simply connected of dimension $2 n$. Hence, $\operatorname{cat}(N)=n$. Since $f^{*}: H^{*}(N ; \mathbb{R}) \rightarrow H^{*}(M ; \mathbb{R})$ is injective by Rud17, Lemma 2.2], we have $f^{*}([\omega])^{n} \neq 0$. Therefore, $\operatorname{cat}(M) \geq n$.

This results can be improved as follows.
4.12. Proposition. Let $f: M \rightarrow N$ be a map of degree $\pm 1$ and $\left(N^{2 n}, \omega\right)$ a symplectic manifold such that the de Rham cohomology class $0 \neq[\omega] \in$ $H^{*}(N ; \mathbb{R})$ vanishes on the image of $\psi_{N}: \pi_{2}(N) \rightarrow H_{2}(N)$ where $\psi$ is the Hurewicz homomorphism. Then $\operatorname{cat}(M)=\operatorname{cat}(N)=2 n$.

Proof. Since $[\omega]$ vanishes on $\psi$, there exist a map $g: N \rightarrow K\left(\pi_{1}(N) ; 1\right)$ and cohomology class $\omega_{\pi} \in H^{2}\left(K\left(\pi_{1}(N) ; 1\right)\right.$ such that $g^{*}\left(\omega_{\pi}\right)=[\omega]$, see [CLOT03, Lemma 8.18]. Note that $\operatorname{wgt}\left(\omega_{\pi}\right) \geq 2$, and so $\operatorname{wgt}[\omega] \geq 2$, by Propositions $4.6(2,4)$.
Since $\omega$ is a symplectic form, $\left[\omega^{n}\right] \neq 0$, and so $g^{*}\left(\omega_{\pi}^{n}\right) \neq 0$. Hence

$$
\operatorname{cat}(N) \geq \operatorname{wgt}\left(g^{*}\left(\omega_{\pi}^{n}\right)\right) \geq n \operatorname{wgt}\left(g^{*} \omega_{\pi}\right) \geq 2 n
$$

So, $\operatorname{cat}(N)=2 n$. Furthermore $\operatorname{wgt}\left(f^{*}\left[\omega^{n}\right]\right) \neq 0$ because $f^{*}$ is monic ( $\operatorname{deg} f= \pm 1$ ). Recall that $\operatorname{wgt}[\omega] \geq 2$. Thus, by Prop. 4.6

$$
\operatorname{cat}(M) \geq \operatorname{wgt} f^{*}\left[\omega^{n}\right] \geq \operatorname{wgt}\left[\omega^{n}\right]=n \operatorname{wgt}[\omega] \geq 2 n
$$

4.13. Proposition. Let $f: M \rightarrow N$ be a map of degree $\pm 1$. Suppose that $\operatorname{dim} M=5=\operatorname{dim} N$, and $\operatorname{cat}(N)=5$. Then $\operatorname{cat}(M) \geq \operatorname{cat}(N)$.

Proof. By Rud99, Corollary 3.3 (ii)], there is a detecting element for $N$. Now the result follows from [Rud99, Theorem 1.8 (iii)].
4.14. Proposition. Let $f: M \rightarrow N$ be a map of degree $\pm 1$. Assume that $N$ a simply connected manifold, and dimension of $M, N$ is equal to 5 or 6 . Then $\operatorname{cat}(M) \geq \operatorname{cat}(N)$.

Proof. First, suppose that $\operatorname{dim} N=5$. Then $\operatorname{cat}(N) \leq 2$ by CLOT03, Theorem 1.50]. The case $\operatorname{cat}(N)=1$ is obvious. Furthermore, if $\operatorname{cat}(N)=2$, then $\operatorname{cat}(M) \geq 2$. Indeed, by way of contradiction, suppose that $\operatorname{cat}(M)=$ 1. Then, by Prop.4.1, $M$ is homotopy equivalent to the sphere $S^{5}$. Now, the condition $\operatorname{deg} f= \pm 1$ implies that $N$ is a homotopy sphere by Corollary 4.3, and thus $\operatorname{cat}(N)=1$. This is a contradiction.

Let $\operatorname{dim} N=6$. Then $\operatorname{cat}(N) \leq 3$. If $\operatorname{cat}(N) \leq 2$, then argument is similar to the previous paragraph. Now suppose that $\operatorname{cat}(N)=3$, and so $2 \operatorname{cat}(N)=$ $6 \geq 4$. It follow from [Rud99, Corollary 3.1] that $N$ has a detecting element $u$. Moreover, we know that $f^{*}(u) \neq 0$ because $\operatorname{deg} f= \pm 1$. This implies that $\operatorname{wgt} f^{*}(u) \geq \operatorname{wgt} u=6$ by Prop. 4.6, and thus $\operatorname{cat}(M)=6$.
4.15. Proposition. Let $f: M \rightarrow L_{p}^{2 n+1}$ be a map of degree $\pm 1$ where $L_{p}^{2 n+1}$ is a lens space. Then $\operatorname{cat}(M) \geq \operatorname{cat}\left(L_{p}^{2 n+1}\right)$.
Proof. We know that

$$
H^{*}\left(L_{p}^{2 n+1} ; \mathbb{Z} / p\right)=\mathbb{Z} / p\left[u, \beta u \mid u^{2}=0,(\beta u)^{n+1}=0\right]
$$

where $\beta$ is the Bockstein homomorphism $\bmod p$. Furthermore, wgt $u=$ 2, [FH92, Rud99]. So, wgt $\left(u \smile(\beta u)^{n}\right) \geq 2 n+1$ by Prop. 4.6(3). Hence, $\operatorname{wgt}\left(u \smile(\beta u)^{n}\right)=2 n+1$ by Prop. 4.6(1). Therefore, $\left.f^{*}\left(u \smile(\beta u)^{n}\right)\right) \neq 0$ by Rud17, Lemma 2.2].
Thus, $\operatorname{cat}\left(L_{p}^{2 n+1}\right) \geq \operatorname{wgt}\left(f^{*}\left(u \smile(\beta u)^{n}\right)=2 n+1\right.$ by Prop. 4.6.
4.16. Proposition. Let $f: M \rightarrow N$ be a map of degree $\pm 1$ and $N$ a sphere bundle over sphere with a cross-section. Then $\operatorname{cat}(M) \geq \operatorname{cat}(N)$.
Proof. Let $q: N \rightarrow S^{n}$ be a sphere bundle with fiber $S^{m}$. So, by (3.3) in [JW54, $N$ has a cell complex structure given by $N=e^{0} \cup e^{m} \cup e^{n} \cup e^{m+n}$. Since $N$ has a cross-section, $e^{0} \cup e^{m} \cup e^{n}$ is homeomorphic to $S^{m} \vee S^{n}$, see discussion after (3.3) in [JW54. Thus $\operatorname{cat}(N) \leq 2$. So by the remark after Proposition 4.8 the conclusion follows.

We recall the definition of toric manifold briefly following [DJ91]. A toric manifold is a $2 n$-dimensional smooth manifold equipped with an $n$-dimensional torus action such that the action is locally resemble the $T^{n}$-action on $\mathbb{C}^{n}$ and the orbit space has the structure of an $n$-dimensional simple polytope.
4.17. Proposition. Let $f: M \rightarrow N$ be a map of degree $\pm 1$ and $N$ a toric manifold. Then $\operatorname{cat}(M) \geq \operatorname{cat}(N)$.
Proof. Let $\mathfrak{q}: N \rightarrow P$ be the orbit map where $\operatorname{dim}(N)=2 n$ and $P$ is an $n$-dimensional polytope. Let $v$ be a vertex of $P$. So there is unique $n$ many codimension one faces $F_{1}, \ldots, F_{n}$ of $P$ such that $v=F_{1} \cap \cdots \cap F_{n}$. From the discussion just above [DJ91, Proposition 3.10], we get that the codimension2 submanifolds $\mathfrak{q}^{-1}\left(F_{1}\right), \ldots, \mathfrak{q}^{-1}\left(F_{n}\right)$ intersects transversely and $\mathfrak{q}^{-1}(v)=$ $\mathfrak{q}^{-1}\left(F_{1}\right) \cap \cdots \cap \mathfrak{q}^{-1}\left(F_{n}\right)$ is a point. Let $x_{i}$ be the Poincaré dual of $\mathfrak{q}^{-1}\left(F_{i}\right)$. So $x_{1}, x_{2}, \ldots, x_{n} \in H^{2}(N ; \mathbb{Z})$ such that $x_{1} \smile \cdots \smile x_{n}$ is nonzero in $H^{*}(N ; \mathbb{Z})$. This implies that cup-length of $N$ is at least $n$. Also $N$ is simply connected by [DJ91, Cor. 3.9]. Now, the proposition follows from [Rud17, Proposition 3.3].

This result can be extended to the class of locally standard torus manifolds [MP06, Section 4] where the orbit space may not be a simple polytope always.
4.18. Proposition. Let $f: M \rightarrow N$ be a map of degree $\pm 1$ and $N$ is a $2 n$-dimensional locally standard torus manifold. If the orbit space $N / T^{n}$ is simply connected and contains a boundary of a simple polytope, then $\operatorname{cat}(M) \geq \operatorname{cat}(N)$.

Proof. In the proof of BS15, Lemma 4.2], the authors show that there are cohomology classes $x_{1}, x_{2}, \ldots, x_{n} \in H^{2}(N ; \mathbb{Z})$ such that $x_{1} \smile \cdots \smile x_{n}$ is nonzero in $H^{*}(N ; \mathbb{Z})$. Also, $\operatorname{cat}(N)=n$ by BS15, Theorem 4.3]. Then the result follows from [Rud17, Proposition 3.3].
4.19. Remark. Dranishnikov and Scott [DS19] proved the inequality cat $M \geq$ cat $N$ in case of the existence of a normal map $M \rightarrow N$ of degree 1, provided that $\operatorname{dim} N \leq 2 r$ cat $N-3$. Here $M$ and $N$ are closed manifolds and the $N$ is $(r-1)$-connected, $r \geq 1$.

## 5. Maps of Degree 1 and Topological Complexity

In this section, we compare the topological complexity of two orientable manifolds when there is a degree one map between them. We recall that $\mathrm{TC}_{2}(X)$ of Definition 3.1 is Farber's $\mathrm{TC}(X)$. The following proposition is proved in LM15.
5.1. Proposition. Let $\Delta X$ be the diagonal space of the product $X \times X$. Then $\mathrm{TC}(X)=\operatorname{relcat}(X \times X, \Delta X)$ if $\mathrm{TC}(X)$ is finite.

Analogously to the Question 1.1, one may ask the following.
5.2. Question. Let $n \geq 2$ and $M, N$ two closed orientable manifolds such that there exists a map $f: M \rightarrow N$ of degree $\pm 1$. Is it true that $\mathrm{TC}_{n}(M) \geq$ $\mathrm{TC}_{n}(N)$ ?

If $\operatorname{dim} M, N=1$ then it is clear. In the remaining, we show that this question has affirmative answer when dimension of $M, N$ are 2 and 3 . Note that if the degree of the map in Question 5.2 is more than one then the question has negative answer, for example one can take degree $k$ map from 3 -sphere to lens space. We also analyse this question on several types of oriented manifolds.
5.3. Definition. Given a space $X$, a commutative ring $R$, and a positive integer $n$, we say that $u \in H^{*}\left(X^{n} ; R\right)$ is a zero-divisor class of grade $n$ if $d_{n}^{*} u=0$. Here $d_{n}: X \rightarrow X^{n}$ is the diagonal map. A zero-divisors-cup-length of grade $n$ of $H^{*}(X ; R)$, denoted by $\operatorname{zcl}_{n}(X)=\operatorname{zcl}_{n}^{R}(X)$ is the maximal $k$ such that $u_{1} \smile \cdots \smile u_{k} \neq 0$ provided each $u_{i}$ is a zero-divisor class of grade $n$.

We note that the cup product in $H^{*}(X ; R)$ yields a homomorphiam

$$
\left(H^{*}(X ; R)\right)^{\otimes n} \longrightarrow H^{*}\left(X^{n} ; R\right) \xrightarrow{d_{n}^{*}} H^{*}(X ; R) .
$$

We also denote the above composition by $d_{n}^{*}$.
5.4. Theorem. For any commutative ring $R$ we have the inequality $\mathrm{TC}_{n}(X) \geq$ $\mathrm{zcl}_{n}^{R}(X)$.
Proof. This theorem follows from [Sch66, Theorem 4] if we replace the fibration $p: E \rightarrow B$ in the Sch66, Theorem 4] by the fibration $\pi_{n}: X^{I} \rightarrow X^{n}$ in (3.2).
5.5. Proposition. Let $f: M \rightarrow N$ is a map of degree $\pm 1$. Then for any commutative ring $R$ we have $\operatorname{zcl}_{n}(M) \geq \operatorname{zcl}_{n}(N)$. In particular, if $\mathrm{TC}_{n}(N)=$ $\operatorname{zcl}_{n}(N)$ then $\mathrm{TC}_{n}(M) \geq \mathrm{TC}_{n}(N)$.
Proof. Let $\operatorname{zcl}_{n}(N)=k$. Consider elements $u_{1}, \ldots, u_{k} \in H^{*}\left(N^{n} ; R\right)$ with $d_{n}^{*}\left(u_{i}\right)=0$ for $i=1, \ldots, k$ and such that $u_{1} \smile \cdots \smile u_{k} \neq 0$. Now we have $f^{*}\left(u_{1}\right) \smile \cdots \smile f^{*}\left(u_{k}\right) \neq 0$ by [Rud17, Lemma 2.2]. So the result follows.
5.6. Proposition. Let $M \rightarrow S^{k_{1}} \times S^{k_{2}} \times \cdots \times S^{k_{m}}, k_{i}>0$ be a map degree $\pm 1$. Then

$$
\mathrm{TC}_{n}(M) \geq \mathrm{TC}_{n}\left(S^{k_{1}} \times S^{k_{2}} \times \cdots \times S^{k_{m}}\right)
$$

Proof. Put $N=S^{k_{1}} \times S^{k_{2}} \times \cdots \times S^{k_{m}}$. Then, by [BGRT14, Cor. 3.12], we have $\mathrm{TC}_{n}(N)=m(n-1)+\ell$ where $\ell$ is the number of even dimensional spheres. (Note that the invariant $\operatorname{cl}(X, n)$ in BGRT14] is exactly our invariant $\left.\mathrm{zcl}_{n}(X)=\operatorname{zcl}_{n}^{\mathbb{Z}}(X)\right)$. By [BGRT14, Theorem 3.10] we have $\operatorname{zcl}_{n}\left(S^{2 k+1}\right)=n-1$ and $\operatorname{zcl}_{n}\left(S^{2 k}\right)=n$, and, moreover, the same theorem yields the inequality $\operatorname{zcl}_{n}(N) \geq m(n-1)+\ell=\mathrm{TC}_{n}(N)$ by induction. So, $\mathrm{TC}_{n}(N)=\operatorname{zcl}_{n}(N)$ by Theorem 5.4. Thus, by Prop. 5.5 we have $\mathrm{TC}_{n}(M) \geq \operatorname{zcl}_{n}(M) \geq \operatorname{zcl}_{n}(N)=\mathrm{TC}_{n}(N)$.
5.7. Proposition. Let $M$ be a stably parallelizable 14-dimensional. Consider the exceptional Lie group $G_{2}$, see e.g. Ada96]. If $f: M \rightarrow G_{2}$ is a map of degree $\pm 1$ then $\mathrm{TC}_{n}(M) \geq \mathrm{TC}_{n}\left(G_{2}\right)$.
Proof. We have $\operatorname{cat}(M) \geq \operatorname{cat}\left(G_{2}\right)$ by Rud17, Prop. 5.4]. Furthermore, [BGRT14, Theorem 3.5] says that $\mathrm{TC}_{n}\left(G_{2}\right)=\left(\operatorname{cat}\left(G_{2}\right)\right)^{n-1}$. So proposition follows from the inequality $(\operatorname{cat}(X))^{n-1} \leq \mathrm{TC}_{n}(X)$ for all $X$, BGRT14, Cor. 3.3].
5.8. Proposition. Let $M$ be a closed connected smooth manifold and $f: M \rightarrow$ $S O(n)$ is a degree one map, then $\mathrm{TC}(M) \geq \mathrm{TC}(S O(n))$ if $n \leq 9$.
Proof. We have $\operatorname{cat}(M) \geq \operatorname{cat}(S O(n))$ if $n \leq 9$ by Rud17, Theorem 5.5]. Furthermore, [BGRT14, Theorem 3.5] says that $\mathrm{TC}(G)=\operatorname{cat}(G)$ for a connected Lie group. So proposition follows from the inequality $(\operatorname{cat}(X))^{n-1} \leq$ $\mathrm{TC}_{n}(X)$.
5.9. Proposition. If $f: M \rightarrow N$ is a map of degree $\pm 1$ and $\mathrm{TC}(N)=2$, then $\mathrm{TC}(M) \geq 2$.
Proof. If TC $(M)=1$ then $M$ must be an odd-dimensional homotopy sphere, see GLO13. Thus, $N$ must be an odd-dimensional homotopy sphere by Prop. 4.3 .
5.10. Proposition. If $f: M \rightarrow N$ is a map of degree $\pm 1$ and $\operatorname{dim} N=2$, then $\mathrm{TC}(M) \geq \mathrm{TC}(N)$.

Proof. Since $N$ is an oriented 2-dimensional manifold, it satisfies the hypothesis of Proposition 5.5. So we are done.
5.11. Theorem. Let $M$ be an odd-dimensional oriented manifold which is not a rational sphere. If $f: M \rightarrow N$ has degree $\pm 1$ and $\mathrm{TC}(N)=3$, then $\mathrm{TC}(M) \geq \mathrm{TC}(N)$.

Proof. Since $M$ is not a rational sphere, then there is a non-zero cohomology class $\alpha \in H^{i}(M ; \mathbb{R})$ for some $0<i<\operatorname{dim} M$. Then there is a Poincaré dual, denoted by $\alpha^{\prime}$, of $\alpha$ such that $\alpha \smile \alpha^{\prime} \neq 0$ in $H^{\operatorname{dim} M}(M ; \mathbb{R})$. Let $a:=1 \otimes \alpha-\alpha \otimes 1$ and $b:=1 \otimes \alpha^{\prime}-\alpha^{\prime} \otimes 1$. So $a, b \in \operatorname{zcl}_{2}(M)$.
If $\operatorname{dim} \alpha$ is even then

$$
a \smile a=-2 \alpha \otimes \alpha \neq 0 .
$$

Hence for $M \times M$ we have
$\left.a \smile a \smile b=(-2 \alpha \otimes \alpha) \otimes\left(\alpha^{\prime} \otimes 1-1 \otimes \alpha^{\prime}\right)=\left(-2 \alpha \smile \alpha^{\prime}\right) \otimes \alpha\right)+(2 \alpha \otimes \alpha) \smile \alpha^{\prime} ;$
here the cup-product $\smile$ in the right-hand side of the last equality appears as $M$, not $M \times M$. Since $a \smile a \smile b \neq 0$ is $\operatorname{zcl}_{2}(M)$, we conclude that $\mathrm{TC}(M) \geq 3=\mathrm{TC}(N)$.
If $\operatorname{dim} a$ is odd then $\operatorname{dim} b$ is even, and the same argument shows that $\mathrm{TC}(M) \geq 3=\mathrm{TC}(N)$.
5.12. Theorem. Let $M^{2 n}$ be a closed orientable manifold. Assume that there exists $k, 0<k<n$ such that $2 k$-th Betti number of $M$ is non-zero. Then $\mathrm{TC}(M) \geq 4$. In particular, if $f: M \rightarrow N$ has degree $\pm 1$ and $\mathrm{TC}(N) \leq 4$, then $\mathrm{TC}(M) \geq \mathrm{TC}(N)$.
Proof. There is a non-zero cohomology class $\alpha \in H^{2 k}(M ; \mathbb{R})$ for some $0<$ $2 k<\operatorname{dim} M$. Then there is a Poincaré dual, denoted by $\alpha^{\prime} \in H^{2 n-2 k}(M ; \mathbb{R})$, of $\alpha$ such that $\alpha \smile \alpha^{\prime} \neq 0$ in $H^{2 n}(M ; \mathbb{R})$. Let $a:=1 \otimes \alpha-\alpha \otimes 1$ and $b:=1 \otimes \alpha^{\prime}-\alpha^{\prime} \otimes 1$ in $H^{*}(M \times M ; \mathbb{R})$. Then $a \smile a=\alpha \otimes \alpha$, and similarly for $b$. So $a, b \in \operatorname{zcl}_{2}(M)$ and $a \smile a \smile b \smile b \neq 0$ in $\operatorname{zcl}(M)$. Thus $\mathrm{TC}(M) \geq 4$.
5.13. Proposition. Let $M, N$ be two 3-dimensional oriented manifolds. Suppose that $\mathrm{TC}(N)=3$. If $f: M \rightarrow N$ has degree $\pm 1$, then $\mathrm{TC}(M) \geq 3$.

Proof. This follows from Prop. 5.11, but give also an alternative proof. By way of contradiction, suppose that $\mathrm{TC}(M) \leq 2$, Than cat $M \leq 2$. If cat $M=$ 1 then $M$ is a homotopy sphere, and hence $N$ is a homotoopy sphere by Prop. 4.1. This contradicts the condition $\mathrm{TC}(N)=3$. If cat $M=2$ then $M$ has a free fundamental group, DKR08. Hence $M$ is a connected sum of copies of $S^{1} \times S^{2}$ (because $M$ is orientable), this is classical on 3-manifolds, [H76. Since TC $\left(S^{1} \times S^{2}\right)=3$ by BGRT14, Cor. 3.12], we conclude that $\mathrm{TC}(M)=3$ by [DS19]. .
5.14. Proposition. Let $f: M \rightarrow N$ be a map of degree $\pm 1$ and $(N, \omega)$ a simply connected symplectic manifold. Then $\mathrm{TC}(M) \geq \mathrm{TC}(N)$.

Proof. This follows from Proposition 4.2 and 5.5 ,
