It is shown that the presence of discrete symmetries in Floquet systems connected to metallic reservoirs imposes a definite parity on the charge and heat pumping as a function of the reservoir’s chemical potential, \( \mu \). In particular, when particle-hole symmetry (PHS) holds, the pumping of charge (heat) is an odd (even) function of \( \mu \). Whereas, if only the product of PHS and parity symmetry is present, pumping of charge (heat) is even (odd) in \( \mu \). Our results also extend to the presence of other unitary symmetries and provide a simple criterion for reversing (or maintaining) the direction of the flow. We illustrate our findings using two variants of the Su-Schrieffer-Heeger model under a time-periodic perturbation.

Quantum pumping consists of coherently transporting heat or charge between macroscopic reservoirs using a periodic drive. By exchanging energy with the drive, carriers can be transported across reservoirs even in the absence of any temperature or voltage bias.

The pumping of charge was first understood in the so-called adiabatic limit [1, 2], where the ratio between the driving period, \( T = 2\pi/\Omega \), and the time taken by carriers to traverse the sample, \( \tau \), is large, i.e. \( 2\pi/\Omega \tau \gg 1 \). As \( \tau \) is proportional to the linear sample size, \( L \), the adiabatic approximation eventually breaks down and one has to resort to a fully time dependent modeling using scattering Floquet theory [3, 4] or a non-equilibrium Green’s functions approach [4–9]. Since their introduction, quantum pumping processes have found applications in quantum computing Floquet theory [3, 4] or a non-equilibrium Green’s functions approach [4–9]. Since their introduction, quantum pumping processes have found applications in quantum information processing [14].

Charge and energy pumping. — We consider a typical transport setup consisting of two macroscopic metallic leads connected by a mesoscopic system, \( S \), to which the driving is applied. The total Hamiltonian is given by

\[
H(t) = H_S(t) + \sum_{l=R,L} (H_l + H_{l-S}),
\]

where the Hamiltonian of the system, \( H_S(t) = \sum_{\alpha\beta} c^\dagger_{\alpha}\mathbb{H}_S c_{\beta} \), is assumed to be quadratic, with \( c^\dagger_{\alpha} \) and \( c_{\alpha} \) the fermionic creation and annihilation operators, with a periodic single-particle Hamiltonian, \( \mathbb{H}_S(t) = \mathbb{H}_S(t + T) \). The Hamiltonians, \( H_l \), for the right and left (\( l = R, L \)) leads are time independent and non-interacting, and the same applies to the system-lead coupling term, \( H_{l-S} \). Under these conditions, the retarded Green’s function of the system verifies Dyson’s equation, \( [i\partial_t - \mathbb{H}_S(t)] G^R_S = \sum_l \Sigma^R_l G^R_{l-S} \), where \( \Sigma^R_l(t, t') = \int \frac{d\omega}{2\pi} e^{-i\omega(t-t')} \Sigma^R_l(\omega) \) is the time-translational invariant retarded self-energy induced by lead \( l \).

Under periodic driving, it is convenient to define the Floquet Green’s function [15]:

\[
\mathcal{G}_{(m)}(\epsilon) = \frac{1}{T} \int_0^T dt \int_{-\infty}^{+\infty} d\tau e^{i\epsilon(m\Omega t - c\tau)} G^R_S(t, t + \tau).
\]

Assuming there are no bound-states, at large times after the periodic drive has been turned on, a recurrent state is attained and observables become periodic with driving period \( \tau \). Here, we are concerned with the average charge \( J_T^c \), and energy, \( J_T^e \), currents leaving lead \( l \) over one driving cycle, defined as \( J_T^{c/e} = \lim_{T\to\infty} \int_T^{T+T} dt J_T^{c/e}(t) \).

In terms of the Floquet Green’s function, average cur-
The second term is the energy lost by

\[ J^c_l = -\frac{|e|}{h} \sum_{m \in \mathbb{Z}} \int de \left\{ T^{(m)}_{ll} (c) f_l (c) - T^{(m)}_{ll} (c) f_l (c) \right\}, \tag{3} \]

where \( T^{(m)}_{ll} (c) = \text{tr} \left[ G^{(m)}_{(l)} (c) \Gamma_l (c) G^{(m)}_{(l)} (c) \Gamma_l (c + m \hbar \Omega) \right] \)

is the transmission probability for a fermion leaving \( l' \) with energy \( c \) and arriving at \( l \) after absorbing \( m \) energy quanta (photons) from the driving field. \( \Gamma_l (c) = i \left( \Sigma^R_l (c) - \Sigma^A_l (c) \right) \)

is the hybridization matrix of lead \( l \), and we introduced the notation \( R = \text{L} \) and \( L = \text{R} \). \( f_l (c) \) denotes de Fermi-Dirac distribution function at lead \( l \) at temperature \( 1/\beta \). The first term of Eq. (4) describes the energy absorbed by \( l \) when an electron leaves \( l' \) with energy \( c \) and absorbs \( m \) photons; the second term is the energy lost by \( l \) when a photon with energy \( c \) is transmitted to \( l' \); and the last term is the energy gained when an electron is reflected back to \( l' \) having absorbed \( m \) photons.

In the following, we set the reservoirs to the same chemical potential, \( \mu_l = \mu \), and consider the total charge transferred in one cycle between the leads, \( Q = \frac{2\pi}{\hbar} J^c_l \). Charge conservation ensures that \( J^c_l = -J^c_r \). We also consider the total energy generated in one cycle, \( E^c_l = \frac{\beta}{2} (J^c_l + J^c_r) \), and the heat pumped between leads, \( E^\Delta = \frac{\beta}{2} (J^c_l - J^c_r) \), as functions of the leads’ chemical potential. For convenience, we study the derivatives of these quantities with respect to \( \mu \),

\[ Q^l (\mu) = \int \frac{\beta d\epsilon}{4 \cosh^2 \left( \frac{\beta (\epsilon - \mu)}{2} \right)} Q^{00} (\epsilon), \tag{5} \]

\[ \mathcal{E}^l_1 / \Delta (\mu) = \int \frac{\beta d\epsilon}{4 \cosh^2 \left( \frac{\beta (\epsilon - \mu)}{2} \right)} \mathcal{E}^{00} (\epsilon), \tag{6} \]

where the corresponding zero-temperature expressions read

\[ Q^{00} (\epsilon) = \frac{|e|}{\Omega h} \sum_{m \in \mathbb{Z}} \left[ T^{(m)}_{ll} (\epsilon) - T^{(m)}_{rl} (\epsilon) \right], \tag{7} \]

\[ \mathcal{E}^{00} (\epsilon) = \frac{1}{\hbar} \sum_{m \in \mathbb{Z}} \left\{ \sum_l \left[ T^{(m)}_{ll} (\epsilon) \pm T^{(m)}_{rl} (\epsilon) \right] m + (1 \mp 1) \frac{\epsilon}{\hbar \Omega} \left[ T^{(m)}_{ll} (\epsilon) \pm T^{(m)}_{rl} (\epsilon) \right] \right\}. \tag{8} \]

The heat current follows from (4) as the transport of \( \epsilon - \mu \) instead of \( \epsilon \),

\[ J^h_l = J^c_l - \frac{\mu}{|e|} J^c_l. \tag{9} \]

So, the heat transported per cycle is given by \( Q_t = \mathcal{E}_t \) and \( \mathcal{Q}_t = \mathcal{E}_\Delta - \frac{|e|}{\hbar} 2Q_t \).

Symmetries. — To study the implications of symmetry for pumping, we analyze the properties of the Green’s functions under symmetry transformations, which follow from those of the Hamiltonian [18–23]. We consider a generic transformation, \( H(t) \to H_X(t) \), of the full Hamiltonian (of \( S \) and leads), under the symmetry transformation, \( X \). Specifically, time-reversal and particle-hole transformations read \( H_X (t) = U_T^\dagger H^* (\tau) U_T \) and \( H_X (t) = -U_L T U_L^\dagger \), respectively, where \( U_X \) are suitable unitary matrices. We also consider \( x \)-axis inversion, \( x \in R \to x' = \|x\| R \), \( -x \in R \to -x' = \|x\| R \), where \( x \) is the coordinate along the propagation direction of the current. As in one dimension, \( x \)-axis inversion coincides with parity symmetry (PS), we denote this transformation as \( P \). However, the arguments below are valid for any symmetry transformation that inverts the \( x \)-axis [15, 24, 25].

Since the total total system evolves unitarily, the transformed Green’s function is given by \( G^R_X (t, t') = -i \Theta (t - t') T e^{-i \int_0^T d\tau H_X (\tau)} \), with \( T \) the time ordering operator. Using the definition of \( H_X \), the transformed Green’s functions read [26]

\[ G^R_X (t, t') = U_T^\dagger \left[ G^R (-t', -t) \right]^\dagger U_T, \tag{10} \]

\[ G^R_X (t, t') = -U_L^\dagger \left[ G^R (t, t') \right]^\dagger U_L, \tag{11} \]

\[ \langle x | G^R_X (t, t') | x' \rangle = \langle -x | U_P G^R (t, t') U_P^\dagger | -x' \rangle . \tag{12} \]

Note that the equalities \( H = \mathbb{H} \) and \( G^R_X (t, t') = G^R (t, t') \) hold whenever the symmetry \( X \) is present [27].

For transport, we are interested in the Green’s functions restricted to degrees of freedom solely within the system, \( G^R_S = \sum_{a,\beta \in S} \langle a | G^R (a) | \beta \rangle \). If the unitary matrices, \( U_X \), do not mix degrees of freedom of the system with those of the leads, \( G^R_S \) follows the same transformation rules (10-12) [26] and obeys

\[ [i \partial_t - H_{X,s} (t)] G^R_{X,S} (t, t') = \int dt' \sum_{l=R,L} \Sigma^R_{X,l} (t, \tau) G^R_{X,S} (\tau, t'), \tag{13} \]

where \( \Sigma^R_{X,l} \) is the transformed self-energy of lead \( l \), that also conforms with Eq. (10-12).

We note that when \( \Sigma^R (t, t') = \delta (t - t') \Sigma^R (t) \), the Green’s function can be written as \( G^R_S (t, t') = -i \Theta (t - t') T e^{-i \int_0^T d\tau Z (\tau)} \), where \( Z (t) = H_{X,S} (t) + \sum_l \Sigma^R_l (t) \) can be identified with an effective nonhermitian Hamiltonian, which transforms as \( Z_T (t) = U_P Z^T (\tau) U_T \) and \( Z_e (t) = -U_L^\dagger Z^* (\tau) U_L \). These transformation properties also found in systems with Markovian environments [28], and were recently studied under the nomenclature TRS [1] and PHS [1], respectively; in Ref. [29].
Using Eq. (2) and the transformation rules (10-12) it is straightforward to show that
\[
G_{T;\ell}(m) (\epsilon) = U_T^\dagger \left[ G_{\ell}(m) (\epsilon + m\hbar\Omega) \right]^\dagger U_T, \tag{14}
\]
\[
G_{C;\ell}(m) (\epsilon) = -U_C^\dagger \left[ G_{\ell}(m) (-\epsilon) \right]^* U_C, \tag{15}
\]
\[
\langle \chi | G_{T;\ell}(m) (\epsilon) | \chi' \rangle = U_p^\dagger \langle \chi | G_{\ell}(m) (-\epsilon) | \chi' \rangle U_p. \tag{16}
\]
In turn, Eqs. (14-16) can be used to deduce the transformation properties of the transmission probabilities:
\[
T_{T;\ell}^{(m)} (\epsilon) = T_{T;\ell}^{(m)} (\epsilon + m\hbar\Omega), \tag{17}
\]
\[
T_{C;\ell}^{(m)} (\epsilon) = T_{C;\ell}^{(m)} (-\epsilon), \quad T_{p;\ell}^{(m)} (\epsilon) = T_{p;\ell}^{(m)} (-\epsilon). \tag{18}
\]
The details of the derivation are given in [26] where it is also shown that Eqs. (17-18) can alternatively be obtained in the Floquet scattering matrix approach [3, 30].

Implications for transport. — We now derive the implications of the above symmetries for transport. It has long been known that charge, energy, or heat pumping requires inversion symmetry breaking [3, 15]. If the x-axis inversion leaves the full Hamiltonian, $\mathbb{H}$, invariant, then the Green’s function remains invariant, $G_{T;\ell}(m) (\epsilon) = G_{\ell}(m) (\epsilon)$, whereas the hybridizations are interchanged, $\Gamma_{\ell}(\epsilon) = \Gamma_{\ell}(\epsilon)$. In this case $T_{p;\ell}^{(m)} (\epsilon) = T_{p;\ell}^{(m)} (-\epsilon)$, yielding $Q'(\mu) = Q'_{-\mu} (\mu) = 0$, so no transport of charge or heat occurs.

However, if the system plus reservoirs are invariant under PHS, then $G_{C;\ell}(m) (\epsilon) = G_{\ell}(m) (\epsilon)$ and $\Gamma_{\ell}(\epsilon) = \Gamma_{\ell}(\epsilon)$, which implies $T_{p;\ell}^{(m)} (\epsilon) = T_{p;\ell}^{(m)} (-\epsilon)$. From Eqs. (5)-(8), we now obtain
\[
Q'(\mu) = Q'(-\mu), \quad Q'_{\ell\Delta} (\mu) = -Q'_{\ell\Delta} (-\mu). \tag{19}
\]
Then, $Q(\mu)$ is an odd function and $Q'_{\ell\Delta}(\mu)$ are even. $Q'(\mu)$ even implies $Q(\mu)$ odd plus a constant. That this constant is zero can be seen by considering either the limit $\mu \to -\infty$, where no available particles exist, or the opposite limit $\mu \to \infty$, where the fermionic states are all occupied and, therefore, Pauli blocked.

Composition of symmetries. — It may happen that both x-axis inversion and PHS are broken while their product, PC, still holds as a symmetry. In that case, $T_{p;\ell}^{(m)} (\epsilon) = T_{p;\ell}^{(m)} (-\epsilon)$, and from Eqs. (5)-(8),
\[
Q'(\mu) = -Q'(\mu), \tag{20}
\]
\[
Q'_{\ell\Delta} (\mu) = -Q'_{\ell\Delta} (-\mu). \tag{21}
\]
In this case the pumped charge (heat) is an even (odd) function of $\mu$ and the total heat absorbed is even.

Composition with other unitary symmetry leads to the same dependence on $\mu$. Consider, for instance, the half-period time translation [18, 19], $\mathbb{H}_\Pi (t) = U^\dagger_\Pi \mathbb{H} (t + T/2) U_\Pi$, and a generic unitary symmetry, $U$, implemented by an unitary operator, $U$, that acts locally on the unit cells, $\mathbb{H}_x(t) = U^\dagger_\Pi \mathbb{H} (t) U$. Under the composition II, we have $\mathbb{H}_{\Pi C}(m) (\epsilon) = (-1)^m U^\dagger_\Pi G_{\ell}(m) (\epsilon) U_\Pi$ and $\Gamma_{\Pi C} (\epsilon) = U^\dagger_{\Pi} \Gamma_{\ell}(\epsilon) U_\Pi$, implying $T_{\Pi C;\ell}^{(m)} (\epsilon) = T_{\Pi C;\ell}^{(m)} (-\epsilon)$.

From Eqs. (5)-(8), we now obtain
\[
Q'(\mu) = Q'(-\mu), \quad Q'_{\ell\Delta} (\mu) = -Q'_{\ell\Delta} (-\mu). \tag{19}
\]
Then, $Q(\mu)$ is an odd function and $Q'_{\ell\Delta}(\mu)$ are even. $Q'(\mu)$ even implies $Q(\mu)$ odd plus a constant. That this constant is zero can be seen by considering either the limit $\mu \to -\infty$, where no available particles exist, or the opposite limit $\mu \to \infty$, where the fermionic states are all occupied and, therefore, Pauli blocked.

Examples. — To illustrate the results above, we consider two versions of the SSH model for spinless fermions, illuminated by monochromatic radiation with angular frequency $\Omega$. In momentum space, the models read
\[
\mathbb{H}_{x}(k,t) = \left[ \cos k + \nu + A \cos(\Omega t), \sin k, 0 \right] \cdot \sigma, \tag{22}
\]
\[
\mathbb{H}_{xz}(k,t) = \left[ \sin k, 0, \cos k + \nu + A \cos(\Omega t) \right] \cdot \sigma, \tag{23}
\]
where the three Pauli matrices $\sigma$ act on sublattice space and $k$ is the Bloch wave vector over lattice cells [31]. Note that, for an infinite chain, both Hamiltonians obey PS as $U_p \mathbb{H}_{\Pi}(k,t) U^\dagger_p = \mathbb{H}(k,t)$, with $U_p = \sigma_1$ for $\mathbb{H}_{xy}$, and $U_p = \sigma_3$ for $\mathbb{H}_{xz}$. Here, we consider a finite chain with

TABLE I. Model symmetries and parity of charge and heat pumping. PS denotes x-axis inversion, and PC the composition of PHS and PS. Examples are included where PHS is implemented by a transformation $XC$ with $X = UII$ [See Eqs. (28)-(29)].
two-atom lattice cells, coupled to two infinite wide-band leads. In the wide-band approximation, the real part of the self-energy vanishes and the imaginary part becomes energy-independent [15]. The total self-energy then reads

$$\Sigma = -\frac{i}{2} \gamma L |1\rangle\langle 1| - \frac{i}{2} \gamma R |N\rangle\langle N|,$$

where $|j\rangle$ denotes the state at site $j$. We note that $|1\rangle$ is the first site of the cell at $x = 1$ and $|N\rangle$ is the second site of the cell at $x = N/2$. In the following we take $\gamma L = \gamma R = \gamma$.

A finite chain described by $Z_{xy}(t) = \mathbb{H}_{xy}(t) + \Sigma$ still enjoys PS because $U_P = \sigma_1$ [32] and

$$U_P \Sigma(-x) U_P^\dagger = \frac{-i}{2} \sigma_1 \left[ |N - 1\rangle\langle N - 1| + |2\rangle\langle 2| \right] \sigma_1 = -\frac{i}{2} \gamma \left( |N\rangle\langle N| + |1\rangle\langle 1| \right) = \Sigma(x).$$

It also has PHS with $U_C = \sigma_3$. Therefore, charge pumping does not occur in an homogeneous $xy$ chain.

For the finite $zx$ chain, described by $Z_{zx}(t) = \mathbb{H}_{zx}(t) + \Sigma$, $\Sigma$ breaks both PS and PHS. This is because, although $\mathbb{H}_{zx}$ admits $U_P = \sigma_3$ and $U_C = \sigma_1$, we have

$$U_P \Sigma(-x) U_P^\dagger \neq \Sigma(x), \quad U_C \Sigma^* U_C^\dagger \neq -\Sigma.$$

Nevertheless, the product of PS and PHS holds:

$$U_P U_C \Sigma^*(-x) U_C^\dagger U_P^\dagger = -\Sigma(x).$$

This $\mathcal{P}\mathcal{C}$ symmetry then ensures that Eqs. (20)-(21) hold. So, $Q(\mu)$ and $Q_{\Delta}(\mu)$ are even, while $Q_\Delta(\mu)$ is odd.

We now consider the inhomogeneous system sketched in Fig.1-(upper-right panel), where two halves of the chain are illuminated with different amplitudes. Here, both parity and the $\mathcal{P}\mathcal{C}$ symmetry are explicitly broken by the non-uniform illumination of the chain. In the case of the $xy$ chain, PHS still holds, and $Q(\mu)$ is an odd function while $Q_{\Delta}(\mu)$ is even.

The inhomogeneous $zx$ chain is invariant under a $XC$ transformation when $\nu = 0$, with $X = U \Pi U$, where, in real space, $U|x\rangle = \sigma_3(\sigma(t)^x|x\rangle$. In momentum space, $U = \sigma_3 \otimes (k \rightarrow k + \pi)$. Setting $U_C = 1$, $XC$ transforms the Hamiltonian as

$$X \left[ \mathbb{H}_{zx}(k, t) \right] X^{-1} = - \left[ \mathbb{H}_{zx}(k, t) \right]_{-\nu},$$

$$X \Sigma^x X^{-1} = -\Sigma.$$  

Therefore, PHS, implemented by $XC$, holds for $\nu = 0$ and renders $Q(\mu)$ odd and $Q_{\Delta}(\mu)$ even. Because the homogeneous $zx$ chain, for $\nu = 0$, enjoys both the above $\mathcal{P}\mathcal{C}$ symmetry and the PHS of Eqs. (28) and (29), no charge or heat pumping occurs. We note, for the sake of completeness, that the inhomogeneous $xy$ chain also enjoys a similar PHS for $\nu = 0$, with $U|x\rangle = (-1)^x|x\rangle$.

Table I summarizes these results for the model systems considered. Some representative cases of charge and heat pumping are also illustrated in Figure 1, exhibiting the even/odd parity identified above. Note that for the inhomogeneous $zx$ chain with $\nu \neq 0$, neither the charge (black line in the second row right panel) or heat (bottom panels black line) pumping are odd or even, as none of the above discussed symmetries exist.

![Figure 1](image_url)

FIG. 1. Homogeneous (left upper panel) and inhomogeneous (right upper panel) setups, consisting of illuminated SSH chains coupled to wide-band leads. Second row: charge pumped in the homogeneous $zx$ chain (left panel) and inhomogeneous (right panel) setups. Third row: heat pumping in the inhomogeneous $zx$ setup. Bottom row: heat pumping in the inhomogeneous $zx$ setup. $\hbar \Omega = 2\pi/1.6$, $\gamma = 0.5$, $N = 10$.

In summary, we have discussed the role of discrete symmetries on the pumping of charge, energy or heat. PHS causes the charge (heat) pumping to be an odd (even) function of the chemical potential. On the other hand,
the composition of PS and PHS causes the charge (heat) pumping to be an even (odd) function, and the total heat absorbed to be even. These results provide simple practical criteria to control the direction of the charge or heat flows, following the symmetry properties of physical setups.

[26] See Supplementary Material.
[31] $\mathbb{H}_{xy}$ and $\mathbb{H}_{zx}$ only differ through a rotation in $\vec{\sigma}$ space, therefore, they belong in the same symmetry class BDI.
[32] If the cell $x = \{(1), (2)\}$ then the parity transformation means that we take the cell $-x = \{(N-1), (N)\}$.
Supplementary Materials for:
Symmetry-induced even/odd parity in charge and heat pumping

In this Supplementary Material, we provide additional details on the derivations in the main text. In particular, we discuss the transformation of the Green’s functions (Sec. S1), and transmission probabilities (Sec. S2). In Sec. S3, we discuss the role of time reversal in detail. We provide the explicit construction of the Green’s function for the examples used in the main text in Sec. S4. Finally, in Sec. S5 we present a discussion on the consequences of symmetry on transport, based on the Floquet scattering matrix approach.

S1. GREEN’S FUNCTION UNDER SYMMETRY

We first consider the total Hamiltonian, i.e. system + leads, $H(t) = \frac{1}{2} C \mathbb{H} (t) C$, with $\mathbb{H} (t) = \mathbb{H} (t)$, and obtain the transformation properties of the total Green’s function. In this case, the evolution of the operator $C$ under the transformed Hamiltonian, $H_X (t) = \frac{1}{2} C \mathbb{H}_X (t) C$, is

$$\partial_t C_X (t) = i [H_X (t), C (t)] = -i \mathbb{H}_X (t) C (t) , \quad (S1)$$

and thus

$$C_X (t) = U_X (t, 0) C , \quad (S2)$$

with

$$U_X (t, t') = \begin{cases} T e^{-i \int_{t'}^{t} dr \mathbb{H}_X (r)} & \text{for } t > t' \\ U_X (t', t) & \text{for } t' > t , \end{cases} \quad (S3)$$

yielding the retarded Green’s function

$$G^R_X (t, t') = -i \Theta (t - t') U_X (t, t') . \quad (S4)$$

Under time reversal,

$$\mathbb{H}_T (t) = U_T \mathbb{H}^* (-t) U_T , \quad (S5)$$

and therefore

$$G^R_T (t, t') = -i \Theta (t - t') T e^{-i \int_{t'}^{t} dr \mathbb{H}_T (r)} \quad (S6)$$

where $T$ and $\bar{T}$ are, respectively, the forward-time ordered and backward-time ordered operators.

Under charge conjugation,

$$\mathbb{H}_C (t) = - U_C^T \mathbb{H} (t) U_C^* , \quad (S7)$$

we get

$$G^R_C (t, t') = -i \Theta (t - t') T e^{-i \int_{t'}^{t} dr \mathbb{H}_C (r)} \quad (S8)$$

Under time translation by half a period we have,

$$\mathbb{H}_\Pi (t) = U_\Pi \mathbb{H} \left( t + \frac{T}{2} \right) U_\Pi , \quad (S9)$$
which yields

\[
G^R_{\Pi} (t, t') = -i \Theta (t - t') \mathcal{T} e^{-i \int_{t'}^{t} d\tau \, M_i (\tau)} = U^\dagger_{\Pi} \left[ -i \Theta (t - t') T \prod_{\tau = t'}^{t} e^{i \Xi (t+\frac{\tau}{2})} \Delta t \right] U_{\Pi} = U^\dagger_{\Pi} \left[ G^R \left( t + \frac{T}{2}, t' + \frac{T}{2} \right) \right] U_{\Pi}. \tag{S10}
\]

Finally, under x-coordinate inversion,

\[
\langle x | G^R_{K} (t, t') | x' \rangle = \langle -x | U^\dagger_{R} G^R_{K} (t, t') U_{R} | -x' \rangle. \tag{S11}
\]

If the unitary matrices, \( U_X \), do not mix degrees of freedom of the system with those of the leads, we may consider Green’s functions restricted to degrees of freedom solely within the system by defining \( G^R = \sum_{\alpha, \beta \in S} | \alpha \rangle \langle \alpha | G^R | \beta \rangle \langle \beta |. \) However, rather than respecting Eq.(S4), the Green’s function obeys

\[
[i \partial_t - \mathbb{H}_{X, S} (t)] G^R_{X, S} (t, t') = \int d\tau \sum_{l = R, L} \Sigma^R_{X, l} (t, \tau) G^R_{X, S} (\tau, t'), \tag{S12}
\]

where \( \Sigma^R_{X, l} \) is the transformed self-energy obeying the same \( G^R_{X, S}. \) In the following, as in the main text, we drop the the label S and refer to \( G^R \) as the Green’s function of the system.

For periodically driven systems, the Floquet retarded Green’s function is defined as

\[
G^R_{mm'} (\epsilon) = - \frac{1}{T} \int_0^T dt e^{i (\Omega_m - \Omega_{m'}) t} \int d\tau G^R (t, t + \tau) e^{-i (\epsilon + \Omega_m) \tau}, \tag{S13}
\]

where \( \Omega_m = m \Omega, \ m \in \mathbb{Z}. \) There is some redundancy in the definition of this quantity, since \( G^R_{m+k,m'+k} (\epsilon - \Omega_m) = G^R_{mm'} (\epsilon), \) which is lifted by defining the Floquet Green’s function given in the main text by

\[
\mathcal{G}_{(m)} (\epsilon) = G^R_{n0} (\epsilon). \tag{S14}
\]

Nevertheless, it is useful to consider \( G^R_{mm'} (\epsilon) \) for the derivations in the Supplemental Material.

Under the time reversal transformation we have

\[
G^R_{T:mm'} (\epsilon) = \frac{1}{T} \int_0^T dt e^{i (\Omega_m - \Omega_{m'}) t} \int d\tau G^R_T (t, t + \tau) e^{-i (\epsilon + \Omega_{m'}) \tau} = \frac{1}{T} \int_0^T dt e^{i (\Omega_m - \Omega_{m'}) t} \int d\tau U^\dagger_T \left[ G^R (-t - \tau, -t) \right]^\dagger U_T e^{-i (\epsilon + \Omega_{m'}) \tau} = \frac{1}{T} \int_0^T dt e^{-i (\Omega_m - \Omega_{m'}) t} \int d\tau U^\dagger_T \left[ G^R (t - \tau, t) \right]^\dagger U_T e^{-i (\epsilon + \Omega_{m'}) \tau} = \frac{1}{T} \int_0^T dt e^{-i (\Omega_m - \Omega_{m'}) t} \int d\tau U^\dagger_T \left[ G^R (t + nT, t' + \tau + nT) \right]^\dagger U_T e^{-i (\epsilon + \Omega_{m'}) \tau} = \frac{1}{T} \int_0^T dt e^{i (\Omega_m - \Omega_{m'}) t} \int d\tau U^\dagger_T \left[ G^R (t', t' + \tau) \right]^\dagger U_T e^{-i (\epsilon + \Omega_{m'}) \tau} = \quad \Upsilon^\dagger_T \left[ G^R_{mm'} (\epsilon) \right]^\dagger U_T, \tag{S15}
\]

using \( t - \tau = t' + nT, \ n \in \mathbb{Z}. \) Similarly, for charge conjugation

\[
G^R_{C:mm'} (\epsilon) = - U^\dagger_C \left[ G^R_{-m-m'} (-\epsilon) \right]^* U_C, \tag{S16}
\]

and for the time translation by half a period,

\[
G^R_{\Pi:mm'} (\epsilon) = (-1)^{m+m'} \Upsilon^\dagger_{\Pi} G^R_{mm'} (\epsilon) \Upsilon_{\Pi}. \tag{S17}
\]

Using the definition of the Floquet Green’s function, we obtain the transformations given in the main text.
S2. TRANSMISSION PROBABILITIES UNDER SYMMETRY TRANSFORMATIONS

S2.1. T, C and P

Using the transformation properties of $G_{(m)}(\epsilon)$ and $\Gamma_l(\epsilon)$, the transmission probabilities under $T$ transform as

$$T^{(m)}_{T;l'}(\epsilon) = \text{tr} \left[ G_{T;l'}(\epsilon) \Gamma_{T;l}(\epsilon + \Omega_m) \right]$$

$$= \text{tr} \left[ G_{T;l}^{-T}(\epsilon + \Omega_m) \Gamma_{T;l}(\epsilon) G_{T;l'}(\epsilon + \Omega_m) \right]$$

$$= \text{tr} \left[ G_{T;l}^{-T}(\epsilon + \Omega_m) \Gamma_{T;l}(\epsilon + m\Omega) G_{T;l'}(\epsilon + \Omega_m) \Gamma_{T;l}(\epsilon) \right]$$

$$= \text{tr} \left[ G_{(m)}(\epsilon + \Omega_m) \Gamma_l(\epsilon + m\Omega) G_{l'}(\epsilon + \Omega_m) \Gamma_l^\dagger(\epsilon) \right]$$

$$= T^{(m)}_{l;l'}(\epsilon + \Omega_m)^*, \quad (S18)$$

and, similarly, under $C$,

$$T^{(m)}_{C;l'}(\epsilon) = \text{tr} \left[ G_{C;l'}(\epsilon) \Gamma_{C;l}(\epsilon + \Omega_m) \right]$$

$$= \text{tr} \left[ G_{C;l}^{-\dagger}(\epsilon - \Omega_m) \Gamma_{C;l}(\epsilon) G_{C;l'}(\epsilon - \Omega_m) \right]$$

$$= \text{tr} \left[ G_{C;l}^{-\dagger}(\epsilon - \Omega_m) \Gamma_{C;l}(\epsilon - m\Omega) G_{C;l'}(\epsilon - \Omega_m) \Gamma_{C;l}(\epsilon) \right]$$

$$= T^{(m)}_{l;l'}(\epsilon - \Omega_m)^*. \quad (S19)$$

Invariance under $x$-axis inversion implies that the Green’s function is invariant but the hybridization matrices are mapped onto each other, i.e.,

$$G_{P;l}(\epsilon) = G_{(m)}(\epsilon), \quad \Gamma_{P;l}(\epsilon) = \Gamma_l(\epsilon). \quad (S20)$$

In this case,

$$T^{(m)}_{l;l'}(\epsilon) = \text{tr} \left[ G_{(m)}(\epsilon) \Gamma_{l'}(\epsilon) G_{(m)}^\dagger(\epsilon) \Gamma_l(\epsilon + m\Omega) \right]$$

$$= T^{(m)}_{l;l'}(\epsilon). \quad (S22)$$

S3. THE ROLE OF TIME REVERSAL

We here consider the role of time reversal symmetry on the charge and energy currents. Introducing the transformation of the transmission probability, given in the main text, into the expression for the particle current,

$$J_l^\tau = -\frac{|e|}{\hbar} \sum_{m \in \mathbb{Z}} \int d\epsilon \frac{1}{2} \left\{ T^{(m)}_{ll'}(\epsilon) f_l(\epsilon) - T^{(m)}_{ll'}(\epsilon + m\Omega) f_l(\epsilon) \right\}$$

$$= -\frac{|e|}{\hbar} \sum_{m \in \mathbb{Z}} \int d\epsilon \frac{1}{2} \left\{ T^{(m)}_{ll'}(\epsilon) \left[ f_l(\epsilon) - f_l(\epsilon + m\Omega) \right] \right\}. \quad (S23)$$

Similarly, for the energy current,

$$J_l^\e = \frac{1}{\hbar} \sum_{m \in \mathbb{Z}} \int d\epsilon \left\{ (m\Omega + \epsilon) T^{(m)}_{ll'}(\epsilon) \left[ f_l(\epsilon) - f_l(\epsilon + m\Omega + \epsilon) \right] \right\}$$

$$+ \frac{1}{2} m\Omega T^{(-m)}_{ll'}(\epsilon) \left[ f_l(\epsilon) - f_l(\epsilon + m\Omega) \right]. \quad (S24)$$

Therefore, for the pumping setup $f_l(\epsilon) = f(\epsilon)$, we find that only in the infinite temperature case can the time-reversed processes happen with the same probability. In that case $f_l(\epsilon) = \frac{1}{2}$ and $J_l^\tau = J_l^\e = 0$.

S4. CALCULATION OF THE FLOQUET GREEN’S FUNCTION IN THE WIDE-BAND LIMIT

In the wide-band limit, the self-energy induced by the leads becomes frequency-independent. Recalling the definition of the effective Hamiltonian, we obtain $Z(t) = \mathbb{H}(t) - \frac{i}{\hbar} (\Gamma_L + \Gamma_R)$, where $\mathbb{H}(t)$ is the time-periodic single-particle Hamiltonian. The eigenstates of this operator obey the Floquet equation,

$$i\hbar \partial_t |\phi_n(t)\rangle = [Z(t) - \epsilon] |\phi_n(t)\rangle, \quad (S25)$$

with $\epsilon$ the quasi-energy. The time Fourier series for the Floquet state reads

$$|\phi_n(t)\rangle = \sum_{n \in \mathbb{Z}} e^{-i\Omega t} |\Phi_n(\epsilon)\rangle. \quad (S26)$$

Expanding the effective Hamiltonian as $Z(t) = \sum_n Z_n e^{i\Omega t}$, the Fourier components of the Floquet state, $|\Phi_n(\epsilon)\rangle$, satisfy the equation

$$\sum_{n \in \mathbb{Z}} \left( Z_{n-m} - n\hbar \Omega \delta_{n,m} \right) |\Phi_n(\epsilon)\rangle = \epsilon |\Phi_m(\epsilon)\rangle. \quad (S27)$$

Because $Z(t)$ is not hermitian, the quasi-energies are, in general, complex-valued. The Floquet states with $\epsilon + \hbar \Omega$ are physically the same, so it is assumed that $-\hbar\Omega/2 < \Re(\epsilon) \leq \hbar\Omega/2$. One must also consider the left eigenstates, $\phi_n^+(t)$, satisfying the Floquet equation

$$-i\hbar \partial_t |\phi_n^+(t)\rangle = |\phi_n^+(t)\rangle [Z(t) - \epsilon], \quad (S28)$$

whose Fourier time components obey

$$\sum_{n \in \mathbb{Z}} \langle \Phi_n^+(\epsilon) \langle Z_{m-n} - n\hbar \Omega \delta_{n,m} \rangle = \epsilon \langle \Phi_m^+(\epsilon) \rangle, \quad (S29)$$
and we rewrite \((S34)\) as
\[ S \]
Probability conservation implies the right- and left- eigenvector basis works out for the lattice sites \( |i \rangle \) as
\[ \sum_{\epsilon} \sum_{m \in \mathbb{Z}} | \Phi_{m}^{+}(\epsilon) \rangle \langle \Phi_{m}(\epsilon) | = 1. \] (S30)
Using this relations, we obtain the Green’s function for Floquet systems as
\[ G_{(m)}(E) = \sum_{\epsilon} \sum_{n} \frac{| \Phi_{m+n}^{+}(\epsilon) \rangle \langle \Phi_{n}(\epsilon) |}{E - \epsilon - \hbar \Omega}. \] (S31)

5. SYMMETRIES OF THE FLOQUET SCATTERING MATRIX

As already stated in the main text, the even/odd behavior of the transport properties can also be obtained from the Floquet scattering matrix approach. Here, we present a discussion of the symmetry properties of the Floquet scattering matrix in general terms, where the asymptotic form of the wave function far from a scatterer assumes a plane-wave form.

We view the Floquet function
\[ \psi(x,t) = \sum_{n} \phi_{n}(x) e^{-\frac{i}{\hbar} E_{n}t} e^{-i n \Omega t}, \]
with quasi-energy \( E \), as a superposition of states with energies \( E + n \hbar \Omega \). For a scattering state, the spatial part of the Floquet functions, \( \phi_{n}(x) \), takes the form of plane waves far from the scatterer:
\[ \phi_{n}(x \rightarrow -\infty) = A_{n} e^{i k_{n} x} + C_{n} e^{-i k_{n} x} \]
\[ \phi_{n}(x \rightarrow +\infty) = D_{n} e^{i k_{n} x} + B_{n} e^{-i k_{n} x}. \]

The Floquet scattering matrix, \( S(E + n' \hbar \Omega, E + n \hbar \Omega) \), relates the Fourier amplitudes of the incoming waves with the outgoing ones:
\[ \begin{bmatrix} C_{n'} \\ D_{n'} \end{bmatrix} = S(E + n' \hbar \Omega, E + n \hbar \Omega) \begin{bmatrix} A_{n} \\ B_{n} \end{bmatrix}. \] (S34)
We may think of the column vectors as having all entries \( n \in \mathbb{Z} \). Then, the \( S \) matrix has four blocks:
\[ S = \begin{bmatrix} S_{LL}(n',n) & S_{LR}(n',n) \\ S_{RL}(n',n) & S_{RR}(n',n) \end{bmatrix}, \] (S35)
and we rewrite (S34) as
\[ \begin{bmatrix} C^{*} \\ D^{*} \end{bmatrix} = S^{T} \begin{bmatrix} A^{*} \\ B^{*} \end{bmatrix}. \] (S36)
Probability conservation implies \( S S^{T} = 1 \). The relation between the \( S \) matrix and the above transmission probabilities is
\[ T_{ll}^{(m)}(\epsilon) = |S_{ll}(\epsilon + m \hbar \Omega, \epsilon)|^{2}. \] (S37)
We now consider the role of symmetries.

1. **TRS:** There exists a unitary matrix, \( U_{T} \), such that \( U_{T} \psi^{*}(x,-t) \) has the same quasi-energy, \( E \). Complex conjugation with \( t \rightarrow -t \) does not change the time-dependent exponentials, but the spatial part is modified as
\[ U_{T} \phi_{n}(x \rightarrow -\infty) = A_{n}^{*} U_{T} e^{-i k_{n} x} + C_{n}^{*} U_{T} e^{i k_{n} x}, \]
\[ U_{T} \phi_{n}(x \rightarrow +\infty) = D_{n}^{*} U_{T} e^{-i k_{n} x} + B_{n}^{*} U_{T} e^{i k_{n} x}. \] (S38)
(here it is assumed that \( U_{T} \) acts on the spinor form of the plane waves). This operation inverts the direction of propagation of the plane waves. We then write
\[ \begin{bmatrix} A_{n}^{*} \\ B_{n}^{*} \end{bmatrix} = S(E + n' \hbar \Omega, E + n \hbar \Omega) \begin{bmatrix} C_{n}^{*} \\ D_{n}^{*} \end{bmatrix}. \] (S40)
Then, from (S40) and (S34) we see that
\[ S^{T} = S. \]

2. **PHS:** There exists a unitary matrix, \( U_{C} \), such that the state \( U_{C} \psi^{*}(x,t) \) has quasi-energy \( -E \). Note that complex conjugation changes both the time and spatial dependence of the exponentials, therefore, the direction of propagation of the waves is not changed. The state \( U_{C} \psi^{*}(x,t) \) has the asymptotic behavior:
\[ \sum_{n} \left( A_{n}^{*} U_{C} e^{-i k_{n} x} + C_{n}^{*} U_{C} e^{i k_{n} x} \right) e^{\frac{i}{\hbar} E_{n}t} e^{i n \Omega t} \]
\[ \quad \quad \quad \quad \quad \quad \quad \text{as } x \rightarrow -\infty, \]
\[ \sum_{n} \left( D_{n}^{*} U_{C} e^{-i k_{n} x} + B_{n}^{*} U_{C} e^{i k_{n} x} \right) e^{\frac{i}{\hbar} E_{n}t} e^{i n \Omega t} \]
\[ \quad \quad \quad \quad \quad \quad \quad \text{as } x \rightarrow \infty. \] (S42)
The waves ‘\( n \)’ have energy \( -E - n \hbar \Omega \). Taking the energy labels into account and the definition of the \( S \) matrix, we write
\[ \begin{bmatrix} C_{n'}^{*} \\ D_{n'}^{*} \end{bmatrix} = S(-E - n' \hbar \Omega, -E - n \hbar \Omega) \begin{bmatrix} A_{n}^{*} \\ B_{n}^{*} \end{bmatrix}, \] (S43)
and comparing with (S34) we get
\[ S^{*} (E + n' \hbar \Omega, E + n \hbar \Omega) = \]
\[ S(-E - n' \hbar \Omega, -E - n \hbar \Omega). \]
In particular, for the case \( n = 0 \),

\[
S^* (E + n' \hbar \Omega, E) = S( -E - n' \hbar \Omega, -E) .
\]

(S44)

3. Symmetry under \( U \Pi C \) operator: this is the modified PHS for the model \( \mathbb{H}_{iz} \) at \( \nu = 0 \), as discussed in the main text.

The state \( U \Pi \phi^*_n (x, t) \) has quasi-energy \(-E\) in the Hamiltonian \( \mathbb{H}_{-\nu}(t) + \Sigma \). Its asymptotic behavior reads

\[
\sum_n \sigma_3 \left( A_n e^{-i(k+\pi)x} + C_n^* e^{i(k+\pi)x} \right) e^{\pm E t} e^{i\Omega t + i\pi} \\
\text{as } x \to -\infty , \\
\sum_n \sigma_3 \left( D_n e^{-i(k+\pi)x} + B_n^* e^{i(k+\pi)x} \right) e^{\pm E t} e^{i\Omega t + i\pi} \\
\text{as } x \to \infty .
\]

(S45)

Like in the case of PHS, we see that the waves \( n \) have energies \(-E - n \hbar \Omega\). We then can write

\[
(-1)^{n'} \begin{bmatrix} C_{n'}^* \\ D_{n'}^* \end{bmatrix} = \\
(-1)^n S^{(-\nu)}( -E - n' \hbar \Omega, -E - n \hbar \Omega) \begin{bmatrix} A_n^* \\ B_n^* \end{bmatrix} ,
\]

(S46)

which, compared with the definition (S34) yields

\[
S^{(\nu)^*}(E + n' \hbar \Omega, E + \hbar \Omega) = \\
S^{(-\nu)}( -E - n' \hbar \Omega, -E - n \hbar \Omega)( -1)^{n+n'} .
\]

(Taking \( n = 0 \), then

\[
S^{(\nu)^*}(E + n' \hbar \Omega, E) = \\
S^{(-\nu)}( -E - n' \hbar \Omega, -E)( -1)^{n'} .
\]

4. Parity: There exists a unitary matrix, \( U_P \), such that the function \( P\psi(-x, t) \) has the same quasi-energy, \( E \). The function \( P\psi(-x, t) \) then obeys

\[
U_P \phi_n (x \to -\infty) = D_n U_P e^{ikx} + B_n U_P e^{-ikx} \quad (S48) \\
U_P \phi_n (x \to +\infty) = A_n U_P e^{ikx} + C_n U_P e^{-ikx} \quad (S49)
\]

so, we write

\[
\begin{bmatrix} D \\ C \end{bmatrix} = S \begin{bmatrix} B \\ A \end{bmatrix} \quad (S50)
\]

\[
\Leftrightarrow \sigma_1 S \sigma_1 = S , \quad (S51)
\]

where \( \sigma_1 \) acts on the \((L, R)\) subspace. The blocks of the \( S \) matrix in (S35) then obey

\[
S_{LL}(n', n) = S_{RR}(n', n) , \quad (S52) \\
S_{LR}(n', n) = S_{RL}(n', n) . \quad (S53)
\]
