We compute bounds on the GUP parameters for two versions of GUP using gravitational wave data from the events GW150914 and GW190521. The speed of the graviton and photon are calculated in a curved spacetime modified by GUP, assuming that these particles have a small mass. The observational bound on the difference in their speeds translates to bounds on the GUP parameters. These bounds are some of the best obtained so far in the context of quantum gravity phenomenology.

I. INTRODUCTION

A completely consistent quantization of the gravitational field has remained as one of the main problems of Theoretical Physics for decades. In this search, there are many promising candidates such as String Theory, Loop Quantum Gravity, Causal Dynamical Triangulations, Doubly Special Relativity (DSR). It is expected that a theory of quantum gravity (QG) will lead us to the unification of the fundamental forces of nature. However, there has not been any experimental or observational support for any theory of QG so far. Efforts to obtain signatures of QG constitute QG Phenomenology [1, 2].

QG theories on the other hand, predict the existence of a minimum measurable length scale $\mathcal{O}(\ell_{Pl})$ [3–5], which constrains the measuring device from probing an arbitrarily small length scale. This in turn implies the modification of the Heisenberg Uncertainty Principle (HUP) to the Generalized Uncertainty Principle (GUP), which has played an important role in the development of QG phenomenology [6–9]. Its implications have been explored in the context of Hawking radiation from a black hole (BH) spacetime [10–12], BH thermodynamics [13–15], Friedman-Robertson-Walker (FRW) cosmology, FRW thermodynamics [16, 17], condensed matter systems [18], Neutrino oscillation probabilities [19], and other quantum mechanical systems [20] etc. In a separate context, studying solutions of the GUP-modified Schrödinger, Klein-Gordon, and Dirac equations in a one, two, and three dimensional box, the authors of Refs. [21–24] have shown that a measured length must be quantized in units of ℓ_{Pl} .

In this paper, we focus on two specific GUPs. The first, proposed by Kempf *et al.* in Ref. [5], consists of the following commutator and the corresponding resulting GUP

$$[\mathbf{x}, \mathbf{p}] = i\hbar(1 + \beta \mathbf{p}^2) \quad (1a)$$

$$\Delta x \Delta p \geq \frac{\hbar}{2} \left[1 + \beta(\Delta p)^2 \right] \quad (1b)$$

where (\mathbf{x}, \mathbf{p}) are the 3-position and 3-momentum operators and Δx and Δp are their uncertainties, respectively. The parameter β is given as $\beta = \frac{\beta_0 \ell_{Pl}^2}{\hbar^2} = \frac{\beta_0}{M_{Pl}^2 c^2} > 0$ and is independent of Δx , Δp while β_0 is the dimensionless GUP parameter. In the above, M_{Pl} is the Planck mass, such that $M_{Pl} c^2 \sim 10^{16}$ TeV. As is well known, Eqs.(1a) and (1b) imply a minimum position uncertainty: $\Delta x_0 = \hbar\sqrt{\beta} = \sqrt{\beta_0} \ell_{Pl}$.

Next, we consider the generalization proposed in Refs. [21, 25–28]

$$[x_i, p_j] = i\hbar \left[\delta_{ij} - \alpha \left(p \delta_{ij} + \frac{p_i p_j}{p} \right) + \alpha^2 \left(p^2 \delta_{ij} + 3 p_i p_j \right) \right]. \quad (2)$$

† saurya.das@uleth.ca

‡ noor.mansour@grad.ku.edu.kw

§ elias.vagenas@ku.edu.kw

In the above, $i, j = 1, 2, 3$, $p^2 = \sum_{j=1}^3 p_j p_j$, and $\alpha = \alpha_0/M_{Pl}c = \alpha_0 \ell_{Pl}/\hbar$. In this case, α_0 is a dimensionless parameter which will henceforth be referred to as the LQGUP parameter since in this version there are both linear and quadratic terms in momentum. Eq. (2) is consistent with DSR theories. In addition, it can also be proposed from a purely phenomenological point of view, and has also been shown to follow as an effective theory from very general grounds [29]. This gives rise to the following modified position-momentum uncertainty relation

$$\begin{aligned} \Delta x \Delta p &\geq \frac{\hbar}{2} \left[1 - 2\alpha \langle p \rangle + 4\alpha^2 \langle p^2 \rangle \right] \\ &\geq \frac{\hbar}{2} \left[1 + \left(\frac{\alpha}{\sqrt{\langle p^2 \rangle}} + 4\alpha^2 \right) \Delta p^2 + 4\alpha^2 \langle p \rangle^2 - 2\alpha \sqrt{\langle p^2 \rangle} \right]. \end{aligned} \quad (3)$$

The modified commutation relation, namely Eq. (2), and the modified uncertainty principle, namely Eq. (3), imply a minimum measurable length and a maximum measurable momentum of the form

$$\Delta x \geq (\Delta x)_{\min} \approx \alpha_0 \ell_{Pl}, \quad \Delta p \leq (\Delta p)_{\max} \approx \frac{M_{Pl} c}{\alpha_0}. \quad (4)$$

Note that for both GUPs under consideration, one assumes $[p_i, p_j] = [x_i, x_j] = 0$. A couple of comments are in order here. First, GUP gives rise to a modified energy momentum dispersion relation $E(p)$ which has potential observational consequences, as shown by a number of authors [30–36]. Second, the dimensionless GUP parameters β_0 and α_0 are sometimes assumed to be $\mathcal{O}(1)$ ¹. However, in this work, we will *not* make this assumption *a priori*. We keep them arbitrary, examine the consequences, and let experiments and observations decide on their values. We note however, that the above parameters give rise to the length scales $\alpha_0 \ell_{Pl}$ and $\sqrt{\beta_0} \ell_{Pl}$. Assuming that the length scales are no smaller than the Planck length $\ell_{Pl} \approx 10^{-35}$ m (as the physics beyond that scale is completely unknown) and do not exceed the electroweak scale, which is about 10^{-18} m, one gets a set of natural bounds $1 \leq \alpha_0 \leq 10^{17}$ and $1 \leq \beta_0 \leq 10^{34}$. The work of various authors, e.g. Ref. [20], and their exploration of low energy effects on GUP set stricter bounds on the parameters, and lend further credence to the possible existence of an intermediate scale between the Planck and electroweak scales.

Returning to the issue of modified dispersion relations (MDR), the authors in Refs.[39–41] have shown that this results in the difference between the speed of gravitational waves (GW) and electromagnetic waves from the same astrophysical event. This is compatible with data from the GW event GW150914, as reported by the Laser Interferometer Gravitational-Wave Observatory (LIGO) Scientific and Virgo Collaborations [42, 43]. Ref. [40] also reported an observationally compatible version of MDR. These potential departures from the standard dispersion relation show that it is important to pursue the search for the QG signatures in GW data, which may shed important light on QG theories. For example, the authors in Refs. [44, 45] have constrained the parametric space of several GUPs and obtained the upper bounds on the corresponding GUP parameters. In particular, in Ref. [44] the observational data of GW150914 were used while in Ref. [45] the observational data of GW170814 were used. Both groups have followed a similar approach to constrain the GUP parameters by calculating the difference between the speed of GWs, i.e., gravitons, and that of the light waves, i.e., photons.

In the aforementioned papers there are two limitations. The first limitation is due to the fact that the photon speed is considered unmodified (constant). However, the speed of the photon can be modified due to QG effects when it has a small mass. The second limitation of the aforementioned papers is that their analysis was done in flat spacetimes, although the GWs from the events GW150914 and GW170814 originated in a spacetime region of high curvature, from the merging of the two stellar mass BHs [42, 43, 46]. Although spacetime is almost flat at the site of the detectors and, hence, their results, e.g. those of Refs. [44, 45], should be valid at least approximately. Strictly speaking, the analysis should be carried out in a curved background spacetime, if at least to simply establish the limits of validity of the earlier results. Moreover, curvature effects may indeed be important for future events (those from regions of even higher curvatures) and for future detectors, with even higher accuracies.

Motivated by the above, in the present manuscript, we consider a curved spacetime, reasonably approximated by the Schwarzschild black hole metric at large distances, and obtain the modifications in the velocity² of the gravitons and photons due to the GUP effects. Our goal is to study the parametric space of the two well-known GUP versions, as described above, in the background of the specific curved spacetime.

The remainder of this paper is organised as follows. In Section II, we calculate the difference in the speed of gravitons and photons in the Schwarzschild background without GUP effects. The effect of the curved background

¹ Recently, in Ref. [37] and utilizing the GUP version, a numerical value of the dimensionless GUP parameter, namely β_0 , was obtained, namely $82\pi/5$. Furthermore, in Ref. [38] and utilizing the LQGUP version, the dimensionless GUP parameter, namely α_0 , was shown to be proportional to powers of the dimensionless ratio (M_{Pl}/M) .

² In this work, we use the terms “velocity” and “speed” interchangeably.

is expressed through the dependence of the difference in the speed of gravitons and photons on the metric element $g_{00}(r)$ of the Schwarzschild black hole spacetime. In the limit of $r \rightarrow \infty$, our result reproduces the ones for flat spacetime, as expected. Moreover, utilizing the data from GW150914, we get the upper bound for the difference in the speed of the gravitons and photons. This upper bound will be the reference point in the next sections in which the QG effects will be taken into consideration. In Section III, we obtain the difference in the speed of gravitons and photons in a Schwarzschild black hole background including the GUP effects, which are expressed through the terms involving the dimensionless GUP parameter β_0 . Utilizing the data from GW150914, we bound the difference in speeds and, thus, we get an upper bound for the GUP parameter β_0 . In addition, we consider the case in which the photon speed is GUP-modified as is the graviton speed. In this case, in order to get an upper bound, we use the data from GW190521 [47], since for this GW event, we have apart from the data from LIGO Scientific and Virgo Collaborations, its electromagnetic counterpart from the data of the Zwicky Transient Facility (ZTF) [48]. In Sections IV, we follow exactly the same analysis with that in Section III, but for the case of the LQGUP version and, thus, we obtain the upper bound on the dimensionless LQGUP parameter α_0 which is the lowest in the literature. In Section V, we conclude and present our results obtained here. Finally, we provide three appendices in which we have reconsidered all the previous three sections, namely II-IV, when the very speculative case of massive photons and gravitons is included without using the small mass approximation.

II. SPEED OF GRAVITON AND PHOTON IN THE SCHWARZSCHILD BACKGROUND

As mentioned in the introduction, we model a generic curved spacetime at large distances from the source by a 4-dimensional Schwarzschild metric

$$ds^2 = -f(r)c^2 dt^2 + \frac{1}{f(r)} dr^2 + r^2 d\Omega^2 \quad (5)$$

where $f(r) = \left(1 - \frac{2GM}{c^2 r}\right)$ and $d\Omega^2 = r^2 d\theta^2 + r^2 \sin^2\theta d\phi^2$. We write the squared 4-momentum of a particle of mass m in the aforesaid background as

$$p_\mu p^\mu = g_{00}(p^0)^2 + \underbrace{g_{ij}p^i p^j}_{p^2} \quad (6)$$

The standard dispersion relation dictates that $p_\mu p^\mu = -m^2 c^2$ and, therefore, the above equation becomes

$$(p^0)^2 = \frac{1}{g_{00}} \left(-p^2 - m^2 c^2 \right). \quad (7)$$

As usual, one defines the energy of a particle in this background using the timelike Killing vector field ξ_0 in the Schwarzschild background

$$\frac{E}{c} = -\xi_a p^a = -g_{ab} \xi^a p^b \quad (8)$$

where $\xi^a = (1, 0, 0, 0)$ is the timelike Killing vector. Therefore, from Eq. (8) we get

$$E = -g_{00} c p^0. \quad (9)$$

We now specify the particle as graviton with its rest mass and energy to be $m = m_g$ and $E = E_g$, respectively. From Eq. (7), we get the energy of the graviton to be

$$E_g = \sqrt{-g_{00}} (p^2 c^2 + m_g^2 c^4)^{1/2}. \quad (10)$$

It may be noted that extreme cosmic phenomena cause the fluctuations in spacetime, which in turn produce gravitons. These can then propagate as a GW and hit the GW detectors such as the LIGO and Virgo detectors. The speed of gravitons can be calculated by using the group velocity of the wave front

$$v_g = \frac{1}{\sqrt{-g_{00}}} \frac{\partial E_g}{\partial p}. \quad (11)$$

Using Eq. (10), we obtain

$$v_g = c \left[1 - \frac{m_g^2 c^4}{E_g^2} \left(1 - \frac{2GM}{r c^2} \right) \right]^{1/2}. \quad (12)$$

Expanding the term within the square brackets in Eq. (12) yields

$$v_g = c \left[1 - \frac{m_g^2 c^4}{2E_g^2} \left(1 - \frac{2GM}{r c^2} \right) - \frac{1}{8} \frac{m_g^4 c^8}{E_g^4} \left(1 - \frac{4GM}{r c^2} \right) - \mathcal{O}(G^2) \right]. \quad (13)$$

Since $\ell_{Pl} = \sqrt{G\hbar/c^3}$ and, thus, $\mathcal{O}(G^2) \sim \mathcal{O}(\ell_{Pl}^4)$, neglecting these higher order terms, the graviton speed reads

$$v_g = c \left[1 - \frac{m_g^2 c^4}{2E_g^2} \left(1 + \frac{m_g^2 c^4}{4E_g^2} \right) + \frac{m_g^2 c^4}{2E_g^2} \frac{2GM}{r c^2} \left(1 + \frac{m_g^2 c^4}{2E_g^2} \right) \right]. \quad (14)$$

At this point a number of comments are in order. First, it is evident that $\Delta v_g = v_g - c \neq 0$ only when the gravitons are massive, i.e., $m_g \neq 0$. Second, by the same token, the speed of light remains intact as long as the photon is considered massless. Third, in Refs. [42, 43] the signal of the event GW 150914 is peaked at $\nu = 150$ Hz, which leads to the maximum energy of gravitons to be $E_g = h\nu \approx 6.21 \times 10^{-13}$ eV. In addition, we know that if the dispersion relation for the GW is modified, the upper bound on the Compton wavelength is constrained to be $\lambda_g > 10^{16}$ m and, thus, one obtains an upper bound for the mass of gravitons to be $m_g \leq 1.24 \times 10^{-22}$ eV/ c^2 [49]³. With these values, the term $\frac{m_g^2 c^5}{2E_g^2}$ in Eq. (14) becomes $\frac{m_g^2 c^5}{2E_g^2} = 5.98 \times 10^{-12}$ m/sec [44]. Therefore, one can neglect terms of higher order in $\frac{m_g^2 c^5}{2E_g^2}$ and the speed of graviton from Eq. (14) is

$$v_g = c \left[1 - \frac{m_g^2 c^4}{2E_g^2} \left(1 - \frac{2GM}{r c^2} \right) \right]. \quad (15)$$

Furthermore, if one considers the spacetime under consideration to be practically flat and ignores the curvature terms, then from Eq. (15), the difference between the speed of graviton and photon becomes

$$\Delta v_g = c - v_g = \frac{m_g^2 c^5}{2E_g^2} \quad (16)$$

which agrees with the bound obtained in Ref. [44] in which a flat spacetime was considered. Finally, utilizing the bound on the graviton mass, one gets the bound on the difference between the graviton and photon as

$$\Delta v_g \leq 5.98 \times 10^{-12} \text{m/sec} . \quad (17)$$

III. BOUND ON THE GUP PARAMETER FROM GW150914

In this section, we will study the modifications in the difference between the speed of graviton and photon, i.e., Δv_g , in Schwarzschild spacetime while incorporating the GUP defined by Eqs. (1a) and (1b). For this reason, the following variables are defined

$$x_i = x_{0i}, \quad p_0 = k_0 \quad (18a)$$

$$p_i = k_i (1 + \beta k^2) \quad (18b)$$

where x and p are the physical position and momenta, while x_0 and k are auxiliary ‘‘canonical variables’’, such that $[x_{0i}, k_j] = i\hbar \delta_{ij}$. Next, we expand the squared 4-momentum, using Eq. (18b) as follows

$$\begin{aligned} p_\alpha p^\alpha &= g_{00}(p^0)^2 + p^2 \\ &= g_{00}(p^0)^2 + k^2 [1 + 2\beta k^2 + \mathcal{O}(\beta^2)] . \end{aligned} \quad (19)$$

It is easily seen that the last term is of $\mathcal{O}(\ell_{Pl}^4)$ and, thus, it can be ignored compared to the linear term in β . In addition, the physical 4-momentum does not satisfy the standard dispersion relation, namely $p_\alpha p^\alpha \neq -m^2 c^2$, while the non-GUP-modified 4-momentum satisfies the standard dispersion relation, namely $k_\alpha k^\alpha = -m_g^2 c^2$. Therefore, employing the above equation, one ends up with

$$g_{00}(p^0)^2 = -m_g^2 c^2 - p^2 + 2\beta k^2 k^2 . \quad (20)$$

³ In different contexts, one can propose even smaller bounds on the graviton mass, e.g. $m_g \leq 10^{-32}$ eV/ c^2 [50].

Now one can take the inverse transformation of Eq. (18b) and write k as a function of p in the form

$$k^2 = p^2 (1 - 2\beta p^2). \quad (21)$$

Next we substitute Eq. (21) into Eq. (20) and we expand in terms of the GUP parameter. Then, due to the smallness of the QG corrections, we ignore the higher order terms in β , and, thus, we get

$$(p^0)^2 = \frac{(-1)}{g_{00}} \left[m_g^2 c^2 + p^2 (1 - 2\beta p^2) \right]. \quad (22)$$

Employing Eq. (9), the energy of the graviton becomes of the form

$$E_g = \sqrt{-g_{00}} \left[m_g^2 c^4 + p^2 c^2 (1 - 2\beta p^2) \right]^{1/2}. \quad (23)$$

The above equation now implies the following GUP-modified group velocity of the graviton

$$\tilde{v}_g = \frac{1}{\sqrt{-g_{00}}} \frac{\partial E_g}{\partial p} = \left[m_g^2 c^4 + p^2 c^2 (1 - 2\beta p^2) \right]^{-1/2} \left[p c^2 (1 - 2\beta p^2) - 2\beta p p^2 c^2 \right]. \quad (24)$$

Recalling the graviton mass bound $m_g \leq 1.24 \times 10^{-22} \text{ eV}/c^2$, we neglect the graviton mass term in comparison with the remaining terms in Eq. (24) and obtain

$$\tilde{v}_g = c (1 - 3\beta p^2). \quad (25)$$

At this point, we need to express the speed of the graviton, i.e., \tilde{v}_g , in terms of E_g , thus we implement the iteration method. First, we get the zeroth order solution for p by setting $\beta = 0$ in Eq. (23) which leads to $p = \left[\frac{E_g^2}{(-g_{00})c^2} - m_g^2 c^2 \right]^{1/2}$. Then, substituting the zeroth order solution in Eq. (23), employing $g_{00} = -\left(1 - \frac{2GM}{r c^2}\right)$, and adopting the small m_g approximation⁴, we finally obtain p as a function of E_g ⁵. So the speed of the graviton will read

$$\begin{aligned} \tilde{v}_g &= c \left[1 - \frac{3\beta E_g^2}{c^2} \left(1 - \frac{2GM}{r c^2} \right)^{-1} \right] \\ &= c \left[1 - \frac{3\beta E_g^2}{c^2} \left(1 + \frac{2GM}{r c^2} + \mathcal{O}(\ell_{Pl}^4) \right) \right] \\ &= c \left[1 - \frac{3\beta E_g^2}{c^2} \left(1 + \frac{2GM}{r c^2} \right) \right]. \end{aligned} \quad (26)$$

Therefore, for the GUP under consideration, the difference between the speed of the graviton and photon, i.e., $\Delta\tilde{v}_g$, is given by

$$\Delta\tilde{v}_g = c - \tilde{v}_g = \frac{3\beta E_g^2}{c} \left(1 + \frac{2GM}{r c^2} \right). \quad (27)$$

In Section II, we derived a bound (see Eq. (17)) for the difference in the speed of photon and graviton, which yields

$$\begin{aligned} \Delta\tilde{v}_g &= \frac{3\beta E^2}{c} \left(1 + \frac{2GM}{r c^2} \right) \leq \Delta v_g \\ \implies \beta_0 &\leq \frac{\Delta v_g M_{Pl}^2 c^3}{3 E_g^2} \left(1 - \frac{2GM}{r c^2} \right). \end{aligned} \quad (28)$$

At this point, we note a couple of comments. First, taking the $r \rightarrow \infty$ limit in Eq. (27), one reproduces the flat space result, i.e., $\Delta\tilde{v}_g = \frac{3\beta_0 E_g^2}{M_{Pl}^2 c^3}$, as expected [44]. Second, for the event GW150914, we take the final black hole mass to be $M = 62 M_\odot$ and the luminosity distance to be $r = 410 \text{ Mpc}$. Substituting the aforesaid values in Eq. (28) and using the upper bound from Eq. (17), i.e. $\Delta v_g = 5.98 \times 10^{-12} \text{ m/sec}$, we obtain

$$\beta_0 \leq 2.56 \times 10^{60}. \quad (29)$$

It should be noted that this bound is in agreement with the corresponding one obtained in Ref. [44]. In addition, it is one of lowest bounds among those obtained from observations in the sky [45, 51] and expected to improve significantly over time with increasing accuracies of GW observations.

⁴ A full analysis, with no small m_g approximation, is given in Appendix B.

⁵ For a more detailed derivation see Appendix B.

A. $\Delta\tilde{v}_g$ with the GUP-modified speed of photon and GW190521

One now considers the case in which the velocity of the photon is also GUP-modified similar to the velocity of the graviton. Therefore, adopting the previous analysis for the velocity of the graviton with the small mass approximation, the velocity of the photon takes the form (see Eq. (26))

$$\tilde{v}_\gamma = c \left[1 - \frac{3\beta E_\gamma^2}{c^2} \left(1 + \frac{2GM}{r c^2} \right) \right] \quad (30)$$

where \tilde{v}_γ is the GUP-modified velocity of the photon and E_γ is the energy of the photon. Hence, the difference in the speeds, i.e., $\Delta\tilde{v}_g$, reads now

$$\Delta\tilde{v}_g = |\tilde{v}_\gamma - \tilde{v}_g| = \frac{3\beta}{c} |(E_g^2 - E_\gamma^2)| \left(1 + \frac{2GM}{r c^2} \right). \quad (31)$$

At this point, it should be stressed that since the speed of the photon may vary due to the curvature and QG effects, the speed of the graviton may become larger than the modified speed of photon. Therefore, from now on, we will take the absolute value of the difference between the speed of the graviton and the speed of the photon in order to define the quantity $\Delta\tilde{v}_g$. Finally, employing the bound on the graviton mass in Eq. (31), we obtain a bound on the GUP parameter β_0

$$\beta_0 \leq \frac{\Delta v_g M_{Pl}^2 c^3}{3 |(E_g^2 - E_\gamma^2)|} \left(1 - \frac{2GM}{r c^2} \right). \quad (32)$$

A number of comments are now in order. First, in order to compute the bound given in Eq. (32), one needs to use data from a GW event for which the GW signal and its EM counterpart have both been detected. Until now, the only such GW event is the GW190521, a result from the merger of two black holes [47]. Second, for the event GW190521, we take the final black hole mass to be $M = 142 M_\odot$ and the luminosity distance to be $r = 5.3$ Gpc. In addition, the detected graviton frequency has now a peak at 60 Hz and, thus, the energy of the graviton is $E_g = 2.48 \times 10^{-13}$ eV. Therefore for the previously mentioned upper bound on the graviton mass, namely 1.24×10^{-22} eV/ c^2 , the difference between the speed of the photon and graviton becomes: $\Delta v_g = c - v_g = \frac{m_g^2 c^5}{2E_g^2} \leq 3.75 \times 10^{-11}$ m/sec. Third, the EM counterpart of GW190521 was detected by the ZTF [48]. In particular, the ZTF “sees” two frequency bands and specifically for the GW190521, in the g-band the observed wavelength is $\lambda_{\gamma g} = 4686 \times 10^{-10}$ m while in the r-band the observed wavelength is $\lambda_{\gamma r} = 6166 \times 10^{-10}$ m. Therefore, the energies corresponding to these observed photon wavelengths are $E_{\gamma g} = 2.65$ eV and $E_{\gamma r} = 2.01$ eV. Finally, substituting the above numerical values in Eq. (32), the upper bounds on the GUP parameter using the data for the r- and g- band read, respectively,

$$\beta_0 \leq \frac{\Delta v_g M_{Pl}^2 c^3}{3 |(E_g^2 - E_{\gamma r}^2)|} \left(1 - \frac{2GM}{r c^2} \right) = 1.54 \times 10^{36} \quad (33)$$

$$\beta_0 \leq \frac{\Delta v_g M_{Pl}^2 c^3}{3 |(E_g^2 - E_{\gamma g}^2)|} \left(1 - \frac{2GM}{r c^2} \right) = 8.83 \times 10^{35} \quad (34)$$

where we have used the upper bound, obtained above, i.e. $\Delta v_g = 3.75 \times 10^{-11}$ m/sec.

In the above, the curvature term $\frac{2GM}{r c^2}$ is approximately equal to 0.025×10^{-19} and, therefore, it was neglected in obtaining the numerical values in Eqs. (33) and (34).

IV. BOUND ON THE LQGUP PARAMETER FROM GW150914

In this section, we will study the modifications in the difference between the speed of graviton and photon, i.e., Δv_g , in Schwarzschild spacetime while incorporating the LQGUP version. We define the physical position and momenta in terms of the canonical auxiliary variables as follows

$$x_i = x_{0i}, \quad p_0 = k_0 \quad (35a)$$

$$p_i = k_i (1 - \alpha k + 2\alpha^2 k^2). \quad (35b)$$

We follow a procedure similar to Section III and allow terms up to the quadratic order of the parameter α , as well as of the LQGUP parameter α_0 . Employing the expression for the GUP-modified squared 4-momentum and substituting Eq. (35b), we obtain

$$g_{00} (p^0)^2 = -m_g^2 c^2 - p^2 - 2\alpha k k^2 + 5\alpha^2 k^2 k^2 . \quad (36)$$

We perform an inverse transformation of Eq. (35b) and write k as a function of p in the form

$$k^2 = p^2 (1 + 2\alpha k - \alpha^2 k^2) . \quad (37)$$

Solving the above quadratic equation, we get

$$k = \frac{\alpha p^2 \pm \left[2\alpha^2 p^2 p^2 + p^2 \right]^{1/2}}{(1 + \alpha^2 p^2)} \quad (38)$$

which upon simplifying yields

$$k = \alpha p^2 \pm p . \quad (39)$$

The above, substituted in Eq. (36), gives

$$(p^0)^2 = \frac{1}{g_{00}} \left[-m_g^2 c^2 - p^2 \mp 2\alpha p p^2 - \alpha^2 p^2 p^2 \right] . \quad (40)$$

Following the analysis in Section III, we obtain the energy of the graviton to be

$$E_g = \sqrt{-g_{00}} \left[m_g^2 c^4 + p^2 c^2 (1 \pm \alpha p)^2 \right]^{1/2} \quad (41)$$

which is the modified dispersion relation for the LQGUP under consideration. At this point, we follow the analysis as similar to Section III for the iteration method (see below Eq. (25)), and the group velocity of the graviton becomes ⁶

$$\tilde{v}_g = \frac{1}{\sqrt{-g_{00}}} \frac{\partial E_g}{\partial p} = c \left[1 \pm \frac{2\alpha E_g}{c} \left(1 + \frac{GM}{rc^2} \right) \right] . \quad (42)$$

Let us now consider separately the two cases in Eq. (42)

$$\text{Case 1 : } \quad \tilde{v}_g^{(1)} = c \left[1 + \frac{2\alpha E_g}{c} \left(1 + \frac{GM}{rc^2} \right) \right] \quad (43)$$

$$\text{Case 2 : } \quad \tilde{v}_g^{(2)} = c \left[1 - \frac{2\alpha E_g}{c} \left(1 + \frac{GM}{rc^2} \right) \right] . \quad (44)$$

Eq. (43) gives the speed of the graviton to be greater than c which is the speed of photon in vacuum. We ignore such superluminal propagation and, thus, we proceed with Case 2 associated with a subluminal graviton.

For this case, the difference between the speed of the graviton and the speed of the photon is now of the form

$$\Delta \tilde{v}_g = |c - \tilde{v}_g| = 2\alpha E_g \left(1 + \frac{GM}{rc^2} \right) . \quad (45)$$

As in Section III, the difference in the speed of graviton and photon is bounded from above by Δv_g , and this sets a bound on the LQGUP parameters as follows

$$\begin{aligned} \alpha &\leq \frac{\Delta v_g}{2E_g} \left(1 + \frac{GM}{rc^2} \right)^{-1} \\ \alpha_0 &\leq \frac{\Delta v_g M_{Pl} c}{2E_g} \left(1 - \frac{GM}{rc^2} \right) \end{aligned} \quad (46)$$

where we have neglected terms of $O(\ell_{Pl}^4)$. Finally, if we use the data set from the event GW150914 [42, 43], as we did in Section III, we obtain an upper bound on the LQGUP parameter

$$\alpha_0 \leq 1.96 \times 10^{20} . \quad (47)$$

At this point, it is worth mentioning that this bound agrees with the corresponding ones obtained in Ref. [44, 45]. In addition, it is expected to improve significantly over time with increasing accuracies of GW observations.

⁶ A full analysis, with no small m_g approximation, is given in Appendix C.

A. $\Delta\tilde{v}_g$ with the LQGUP-modified speed of photon and GW190521

As in Subsection IIIA, we now consider the case that the velocity of the photon is also LQGUP-modified similar to the velocity of the graviton. Therefore, adopting the previous analysis for the velocity of the graviton with small mass approximation (see Eq. (42)), we get

$$\tilde{v}_\gamma = c \left[1 \pm \frac{2\alpha E_\gamma}{c} \left(1 + \frac{GM}{rc^2} \right) \right]. \quad (48)$$

We now explore all possible cases of \tilde{v}_γ and \tilde{v}_g .

$$\begin{aligned} \text{Case 1 :} \quad \tilde{v}_g^{(1)} &= c \left[1 + \frac{2\alpha E_g}{c} \left(1 + \frac{GM}{rc^2} \right) \right] \\ \tilde{v}_\gamma^{(1)} &= c \left[1 + \frac{2\alpha E_\gamma}{c} \left(1 + \frac{GM}{rc^2} \right) \right]. \end{aligned} \quad (49)$$

Since the above equation gives the speed of the graviton to be greater than c , i.e., it is superluminal, we drop this case from future considerations and proceed to the remaining Cases.

$$\begin{aligned} \text{Case 2 :} \quad \tilde{v}_g^{(2)} &= c \left[1 + \frac{2\alpha E_g}{c} \left(1 + \frac{GM}{rc^2} \right) \right] \\ \tilde{v}_\gamma^{(2)} &= c \left[1 - \frac{2\alpha E_\gamma}{c} \left(1 + \frac{GM}{rc^2} \right) \right]. \end{aligned} \quad (50)$$

As in Case 1, Case 2 also introduces a superluminal and hence unphysical graviton. Thus, we drop Case 2 as well.

$$\begin{aligned} \text{Case 3 :} \quad \tilde{v}_g^{(3)} &= c \left[1 - \frac{2\alpha E_g}{c} \left(1 + \frac{GM}{rc^2} \right) \right] \\ \tilde{v}_\gamma^{(3)} &= c \left[1 + \frac{2\alpha E_\gamma}{c} \left(1 + \frac{GM}{rc^2} \right) \right]. \end{aligned} \quad (51)$$

In this case, the GUP-modified speed of photon is greater than c , i.e., it is superluminal, thus we drop this case from future considerations.

$$\begin{aligned} \text{Case 4 :} \quad \tilde{v}_g^{(4)} &= c \left[1 - \frac{2\alpha E_g}{c} \left(1 + \frac{GM}{rc^2} \right) \right] \\ \tilde{v}_\gamma^{(4)} &= c \left[1 - \frac{2\alpha E_\gamma}{c} \left(1 + \frac{GM}{rc^2} \right) \right]. \end{aligned} \quad (52)$$

The above equations gives us a difference between the speed of the graviton and photon of the form

$$\Delta\tilde{v}_g^{(4)} = 2\alpha |[E_g - E_\gamma]| \left(1 + \frac{GM}{rc^2} \right) \quad (53)$$

which leads to the bound on the LQGUP parameter of the form

$$\alpha_0 \leq \frac{\Delta v_g M_{Pl} c}{2 |(E_g - E_\gamma)|} \left(1 - \frac{GM}{rc^2} \right). \quad (54)$$

Finally, we utilize the data for the event GW190521 as given by LIGO Scientific and Virgo Collaborations [47] and by ZTF [48]. Using the data for the r- and g- bands, we obtain the upper bound on the LQGUP parameter, respectively, as follows

$$\alpha_0 \leq \frac{\Delta v_g M_{Pl} c}{2 |(E_g - E_{\gamma r})|} \left(1 - \frac{GM}{rc^2} \right) = 3.79 \times 10^8 \quad (55)$$

and

$$\alpha_0 \leq \frac{\Delta v_g M_{Pl} c}{2 |(E_g - E_{\gamma g})|} \left(1 - \frac{GM}{rc^2} \right) = 2.88 \times 10^8 \quad (56)$$

where we use the upper bound $\Delta v_g = 3.75 \times 10^{-11}$ m/sec.

V. CONCLUSION

The existence of a minimum measurable length has been predicted by candidate theories of QG as well as from other considerations such as from the physics of black holes. This necessitates the modification of HUP to GUP. An implication of GUP is the modification of the standard dispersion relation and, consequently, of the speed of particles. From theoretical studies on GWs, one can bound the mass of the graviton and, thus, the speed of the graviton. In our analysis here, we consider two versions of GUP: one with a quadratic term in momentum (GUP) and the other with linear and quadratic terms in momentum (LQGUP). It should be noted that we employed LQGUP, since it can be viewed as an “effective theory” from a Lorentz covariant theory, e.g. as described in Ref. [52].

In the current work, we consider a curved spacetime background and employing GUP, we obtain upper bounds for the GUP parameters. Using the data from GW150914, the GUP parameter is bounded as $\beta_0 < 2.56 \times 10^{60}$ while the LQGUP parameter is bounded as $\alpha_0 < 1.96 \times 10^{20}$. From these results, it is evident that the effects of the curved background are negligible since our results are the same with the existing ones in the literature, which were derived for a flat background. However, one can consider the speed of the photon to be modified as well, along with the speed of the graviton. In this case, one can use the data from GW190821, since this is the only gravitational event between two black holes which has electromagnetic part that was detected by ZTF. So taking into consideration the observed energies of the photons, the GUP parameter is bounded as $\beta_0 < 1.54 \times 10^{36}$ for the r-band observed by ZTF, and $\beta_0 < 8.83 \times 10^{35}$ for the g-band observed by ZTF. The LQGUP parameter is bounded as $\alpha_0 < 3.79 \times 10^8$ for the r-band observed by ZTF, and $\alpha_0 < 2.88 \times 10^8$ for the g-band observed by ZTF. These bounds are among the best compared to the ones existing in the literature, and specifically the bounds on the dimensionless LQGUP parameter α_0 are the tightest. Therefore, GW observations give strict bounds on the GUP parameters, especially when employing data from different “messenger” signals which describe the same gravitational event. This underscores the need for more and further advanced gravitational wave detectors and, that of multimessenger observations. We note that in our analysis, we have assumed small but non-zero masses for the graviton and photon, consistent with observational bounds on these masses.

Finally, it should be noted that recently, the LIGO Scientific and Virgo Collaborations have released their updated catalogue of GW detections, i.e., GWTC-2, in which the bound on the mass of the graviton is even stricter and, for the first time, based on observational data. The new upper bound on the graviton mass is $m_g \leq 1.76 \times 10^{-23}$ eV/ c^2 [53]. This bound is tighter by a factor of 10 which means that all the bounds derived in our work can be improved by a factor of 10.

ECV would like to thank E. Berti and M. Kasliwal for useful correspondences and fruitful comments. This work was supported by the Natural Sciences and Engineering Research Council of Canada.

Appendix A: Speed of photon and graviton in the Schwarzschild background with massive photon

We consider the photon with a small but non-zero mass. Then, following the analysis in Section II and employing Eq. (15), adapted to the massive photon, we obtain

$$v_\gamma = c \left[1 - \frac{m_\gamma^2 c^4}{2E_\gamma^2} \left(1 - \frac{2GM}{rc^2} \right) \right] \quad (\text{A1})$$

where m_γ is the mass of the photon and we have reasonably assumed $\frac{m_\gamma^2 c^4}{2E_\gamma^2} \ll 1$. Therefore, the difference in the speed of the graviton and photon assumes the form

$$\Delta v_g = \frac{c^5}{2} \left(1 - \frac{2GM}{rc^2} \right) \left(\frac{m_g^2}{E_g^2} - \frac{m_\gamma^2}{E_\gamma^2} \right). \quad (\text{A2})$$

Appendix B: Bound on GUP parameter with massive photon and graviton

One may now want to include QG effects due to the GUP version, as we did in Section III, when the photon and graviton are both massive. So, we get the zeroth order solution for p by setting $\beta = 0$ in Eq. (23) which leads to

$p = \pm \left[\frac{E_g^2}{(-g_{00})c^2} - m_g^2 c^2 \right]^{1/2}$ and consider only the positive root for the momentum. For our convenience, we define $\mathcal{E}_g = \left[\frac{E_g^2}{(-g_{00})c^2} - m_g^2 c^2 \right]$ and substitute it in Eq. (23) in order to get the momentum in the form $p = p(E_g)$. Finally, we substitute in the (LHS) of Eq. (23) the zeroth order expression $\frac{E_g}{\sqrt{-g_{00}}} = (m_g^2 c^4 + p^2 c^2)^{1/2}$ and get

$$(m_g^2 c^4 + p^2 c^2)^{1/2} = \left[m_g^2 c^4 + c^2 \mathcal{E}_g (1 - 2\beta \mathcal{E}_g) \right]^{1/2} \quad (\text{B1})$$

which yields

$$p^2 = \mathcal{E}_g (1 - 2\beta \mathcal{E}_g) \quad (\text{B2})$$

$$p = \mathcal{E}_g^{1/2} (1 - \beta \mathcal{E}_g + \mathcal{O}(\beta^2)) . \quad (\text{B3})$$

Since $\beta \sim \ell_{Pl}^2$, we neglect terms of higher order of β , so Eq. (B3) becomes $p(E_g) = \mathcal{E}_g^{1/2} (1 - \beta \mathcal{E}_g)$ and substituting it in Eq. (24), we get

$$\begin{aligned} \tilde{v}_g &= \frac{pc^2 (1 - 4\beta p^2)}{\left[m_g^2 c^4 + p^2 c^2 - 2\beta p^2 p^2 c^2 \right]^{1/2}} \\ &= c(1 - 4\beta p^2) \left[1 + \left(\frac{m_g^2 c^2}{p^2} - 2\beta p^2 \right) \right]^{-1/2} . \end{aligned} \quad (\text{B4})$$

Now, we expand, the last term in the (RHS) of Eq. (B4), which is in the square brackets with respect to the parameter β and neglecting the terms of higher order of β , we obtain

$$\begin{aligned} \tilde{v}_g &= c(1 - 4\beta p^2) \left[1 - \frac{m_g^2 c^2}{2p^2} + \beta p^2 + \frac{3m_g^4 c^4}{8p^4} - \frac{3\beta m_g^2 c^2}{2} \right] \\ &= c \left[1 - \frac{m_g^2 c^2}{2\mathcal{E}_g} - \frac{\beta m_g^2 c^2}{2} + \frac{3m_g^4 c^4}{8\mathcal{E}_g^2} - 3\beta \mathcal{E}_g \right] . \end{aligned} \quad (\text{B5})$$

We evaluate the second term in the (RHS) of Eq. (B5)

$$\frac{m_g^2 c^2}{2\mathcal{E}_g} = \frac{m_g^2 c^2}{2 \left[\frac{E_g^2}{c^2 (-g_{00})} - m_g^2 c^2 \right]} = \frac{m_g^2 c^2}{2 \left[\frac{E_g^2}{c^2 \left(1 - \frac{2GM}{rc^2} \right)} - m_g^2 c^2 \right]} = \frac{m_g^2 c^2}{2 \left[\frac{E_g^2}{c^2} \left(1 + \frac{2GM}{rc^2} \right) - m_g^2 c^2 \right]} \quad (\text{B6})$$

in which, using the data from GW190521, the terms below assume the values

$$\frac{2GM}{rc^2} \sim 0.025 \times 10^{-19}, \quad m_g \sim 1.24 \times 10^{-22} \text{eV}/c^2, \quad E_g = 2.49 \times 10^{-13} \text{eV} . \quad (\text{B7})$$

So, utilizing the above numerical values the second and fourth terms in the (RHS) of Eq. (B5) become $\frac{m_g^2 c^2}{2\mathcal{E}_g} \sim 1.24 \times 10^{-19}$ and $\frac{3m_g^4 c^4}{8\mathcal{E}_g^2} \sim 2.3 \times 10^{-38}$. Therefore, neglecting the terms $\frac{m_g^2 c^2}{2\mathcal{E}_g}$ and $\frac{3m_g^4 c^4}{8\mathcal{E}_g^2}$ with respect to unity in Eq. (B5), the speed of the graviton reads

$$\tilde{v}_g = c - \frac{\beta m_g^2 c^3}{2} - 3\beta \mathcal{E}_g c . \quad (\text{B8})$$

Following exactly the same analysis for the case of the massive photon, the speed of the photon will be of the form

$$\tilde{v}_\gamma = c - \frac{\beta m_\gamma^2 c^3}{2} - 3\beta \mathcal{E}_\gamma c . \quad (\text{B9})$$

At this point a number of comments are in order. First, we use the data for the event GW190521, and, specifically, for the photon energy, we employ the numerical values given by ZTF, thus $E_{\gamma g} = 2.65 \text{ eV}$ and $E_{\gamma r} = 2.02 \text{ eV}$. It is clear

that these numerical values are much higher than the energy of the graviton, i.e., E_g , and, thus, the corresponding quantity \mathcal{E}_γ is larger than \mathcal{E}_g . Second, taking the above-mentioned comments into consideration, similar to the massive graviton, we reasonably neglect the terms $\frac{m_\gamma^2 c^2}{2\mathcal{E}_\gamma}$ and $\frac{3m_g^4 c^4}{8\mathcal{E}_g^2}$ with respect to unity.

Therefore, the difference in the speed of the graviton and photon now reads

$$\Delta\tilde{v}_g = |\tilde{v}_\gamma - \tilde{v}_g| = \beta \left[\frac{5c^3(m_\gamma^2 - m_g^2)}{2} + \frac{3}{c} \left(1 + \frac{2GM}{rc^2} \right) |(E_g^2 - E_\gamma^2)| \right]. \quad (\text{B10})$$

Therefore, as in Section III, the difference in the speed of the graviton and photon is bounded from above by Δv_g as given by Eq. (A2), and this sets a bound on the GUP parameter as follows

$$\begin{aligned} \beta \left[\frac{5c^3(m_\gamma^2 - m_g^2)}{2} + \frac{3}{c} \left(1 + \frac{2GM}{rc^2} \right) |(E_g^2 - E_\gamma^2)| \right] &\leq \Delta v_g \\ \implies \beta_0 &\leq \Delta v_g M_{Pl}^2 c^2 \left[\frac{5c^3(m_\gamma^2 - m_g^2)}{2} + \frac{3}{c} \left(1 + \frac{2GM}{rc^2} \right) |(E_g^2 - E_\gamma^2)| \right]^{-1}. \end{aligned} \quad (\text{B11})$$

A couple of comments are in order. First, if we had a bound for the mass of the photon in the context of GW observations, then from Eq. (B11) the upper bound on β_0 can be estimated. This is because all other quantities are known for the event GW190521 by the data given for the gravitons by the LIGO Scientific and Virgo Collaborations [47] and for the photons by ZTF [48]. Second, if the masses of graviton and photon are taken to be zero, i.e., $(m_\gamma, m_g) \rightarrow 0$, one obtains Eq. (31) from Eq.(B10), as expected.

Appendix C: Bound on LQGUP parameter with massive photon and graviton

One may now want to include QG effects due to LQGUP version, as we did in Section IV, when the photon and graviton are both massive. So, we get the zeroth order solution for the momentum p of Eq. (41) without the small mass approximation for the graviton. For our convenience, we use again the quantity $\mathcal{E}_g = \left[\frac{E_g^2}{(-g_{00})c^2} - m_g^2 c^2 \right]$ and substitute it in Eq. (41) in order to get the momentum in the form $p = p(E_g)$. Then, we follow a similar analysis as in Appendix B to get

$$p^2 = \mathcal{E}_g (1 \pm \alpha \mathcal{E}_g^{1/2})^2 \quad (\text{C1})$$

and the speed of the graviton now reads

$$\begin{aligned} \tilde{v}_g &= \frac{1}{\sqrt{-g_{00}}} \frac{\partial E_g}{\partial p} = \frac{\partial}{\partial p} \left[m_g^2 c^4 + p^2 c^2 (1 \pm \alpha p)^2 \right]^{1/2} \\ &= \frac{pc^2 + 2\alpha^2 c^2 pp^2 \pm 3\alpha c^2 p^2}{\left[m_g^2 c^4 + p^2 c^2 (1 \pm 2\alpha p + \alpha^2 p^2) \right]^{1/2}}. \end{aligned} \quad (\text{C2})$$

We now expand the denominator in the (RHS) of Eq. (C2) and keeping terms up to $\mathcal{O}(\alpha^2)$, we get

$$\left[m_g^2 c^4 + p^2 c^2 (1 \pm 2\alpha p + \alpha^2 p^2) \right]^{-1/2} = (pc)^{-1} \left[1 + \left(\frac{m_g^2 c^2}{p^2} \pm 2\alpha p + \alpha^2 p^2 \right) \right]^{-1/2} \quad (\text{C3})$$

$$= (pc)^{-1} \left[1 - \frac{1}{2} \left(\frac{m_g^2 c^2}{p^2} \pm 2\alpha p + \alpha^2 p^2 \right) + \frac{3}{8} \left(\frac{m_g^2 c^2}{p^2} \pm 2\alpha p + \alpha^2 p^2 \right)^2 + \dots \right] \quad (\text{C4})$$

$$= (pc)^{-1} \left[1 - \frac{m_g^2 c^2}{2p^2} + \frac{3m_g^4 c^4}{8p^4} \mp \alpha p \pm \frac{3\alpha m_g^2 c^2}{2p} + \alpha^2 p^2 + \frac{3\alpha^2 m_g^2 c^2}{4} \right]. \quad (\text{C5})$$

It is easily seen that there are two cases to be studied in Eq. (C2), one for each sign. Therefore, we take the first case and write the Eq. (C2) as follows

$$\tilde{v}_g = c \left[1 + 2\alpha^2 p^2 + 3\alpha p \right] \left[1 - \frac{m_g^2 c^2}{2p^2} + \frac{3m_g^4 c^4}{8p^4} - \alpha p + \frac{3\alpha m_g^2 c^2}{2p} + \alpha^2 p^2 + \frac{3\alpha^2 m_g^2 c^2}{4} \right] \quad (\text{C6})$$

$$= c \left[1 - \frac{m_g^2 c^2}{2p^2} + \frac{3m_g^4 c^4}{8p^4} + 2\alpha p + \frac{9\alpha m_g^4 c^4}{8p^3} + \frac{17\alpha^2 m_g^2 c^2}{4} + \frac{3\alpha^2 m_g^4 c^4}{4p^2} \right]. \quad (\text{C7})$$

Now, we write the above equation in terms of \mathcal{E}_g and utilize the same analysis as the one adopted in the previous Appendix. We neglect the terms $\frac{m_g^2 c^2}{2\mathcal{E}_g}$ and $\frac{3m_g^4 c^4}{8\mathcal{E}_g^2}$ with respect to unity and so the speed of the graviton becomes

$$\tilde{v}_g = c \left[1 + 2\alpha \mathcal{E}_g^{1/2} + \frac{\alpha m_g^2 c^2}{\mathcal{E}_g^{1/2}} - \frac{3\alpha m_g^4 c^4}{8 \mathcal{E}_g^{3/2}} + 2\alpha^2 \mathcal{E}_g + \frac{9\alpha^2 m_g^4 c^4}{8 \mathcal{E}_g} + \frac{11\alpha^2 m_g^2 c^2}{4} \right]. \quad (\text{C8})$$

Similarly, the speed of photon becomes

$$\tilde{v}_\gamma = c \left[1 + 2\alpha \mathcal{E}_\gamma^{1/2} + \frac{\alpha m_\gamma^2 c^2}{\mathcal{E}_\gamma^{1/2}} - \frac{3\alpha m_\gamma^4 c^4}{8 \mathcal{E}_\gamma^{3/2}} + 2\alpha^2 \mathcal{E}_\gamma + \frac{9\alpha^2 m_\gamma^4 c^4}{8 \mathcal{E}_\gamma} + \frac{11\alpha^2 m_\gamma^2 c^2}{4} \right]. \quad (\text{C9})$$

Therefore, the difference between the speed of graviton and photon turns out to be

$$|\Delta \tilde{v}_g| = |\tilde{v}_\gamma - \tilde{v}_g| = \left| \left[2\alpha c (\mathcal{E}_\gamma^{1/2} - \mathcal{E}_g^{1/2}) + \alpha c^3 \left(\frac{m_\gamma^2}{\mathcal{E}_\gamma^{1/2}} - \frac{m_g^2}{\mathcal{E}_g^{1/2}} \right) - \frac{3\alpha c^5}{8} \left(\frac{m_\gamma^4}{\mathcal{E}_\gamma^{3/2}} - \frac{m_g^4}{\mathcal{E}_g^{3/2}} \right) + 2\alpha^2 c (\mathcal{E}_\gamma - \mathcal{E}_g) + \frac{9\alpha^2 c^5}{8} \left(\frac{m_\gamma^4}{\mathcal{E}_\gamma} - \frac{m_g^4}{\mathcal{E}_g} \right) + \frac{11\alpha^2 c^3}{4} (m_\gamma^2 - m_g^2) \right] \right|. \quad (\text{C10})$$

As in Section IV, the difference in the speed of graviton and photon is bounded from above by Δv_g as given by Eq. (A2), and this sets a bound on the LQGUP parameter as follows

$$\left[2\alpha c (\mathcal{E}_\gamma^{1/2} - \mathcal{E}_g^{1/2}) + \alpha c^3 \left(\frac{m_\gamma^2}{\mathcal{E}_\gamma^{1/2}} - \frac{m_g^2}{\mathcal{E}_g^{1/2}} \right) - \frac{3\alpha c^5}{8} \left(\frac{m_\gamma^4}{\mathcal{E}_\gamma^{3/2}} - \frac{m_g^4}{\mathcal{E}_g^{3/2}} \right) + 2\alpha^2 c (\mathcal{E}_\gamma - \mathcal{E}_g) + \frac{9\alpha^2 c^5}{8} \left(\frac{m_\gamma^4}{\mathcal{E}_\gamma} - \frac{m_g^4}{\mathcal{E}_g} \right) + \frac{11\alpha^2 c^3}{4} (m_\gamma^2 - m_g^2) \right] \leq \Delta v_g. \quad (\text{C11})$$

It should be noted that both particles, namely graviton and photon, in this case appear to be superluminal particles. Next, we take the second possible case of Eq. (C2) which leads to the speed of the graviton to be of the form

$$\tilde{v}_g = c \left[1 - 3\alpha p + 2\alpha^2 p^2 \right] \left[1 - \frac{m_g^2 c^2}{2p^2} + \frac{3m_g^4 c^4}{8p^4} + \alpha p - \frac{3\alpha m_g^2 c^2}{2p} + \alpha^2 p^2 + \frac{3\alpha^2 m_g^2 c^2}{4} \right] \quad (\text{C12})$$

$$= c \left[1 - \frac{m_g^2 c^2}{2p^2} + \frac{3m_g^4 c^4}{8p^4} - 2\alpha p - \frac{9\alpha m_g^4 c^4}{8p^3} + \frac{17\alpha^2 m_g^2 c^2}{4} + \frac{3\alpha^2 m_g^4 c^4}{4p^2} \right]. \quad (\text{C13})$$

Employing now $p^2 = \mathcal{E}_g (1 - \alpha \mathcal{E}_g^{1/2})^2$ in the above equation and proceeding as before, we obtain

$$\tilde{v}_g = c \left[1 - 2\alpha \mathcal{E}_g^{1/2} - \frac{\alpha m_g^2 c^2}{\mathcal{E}_g^{1/2}} + \frac{3\alpha m_g^4 c^4}{8 \mathcal{E}_g^{3/2}} + 2\alpha^2 \mathcal{E}_g + \frac{9\alpha^2 m_g^4 c^4}{8 \mathcal{E}_g} + \frac{11\alpha^2 m_g^2 c^2}{4} \right] \quad (\text{C14})$$

and

$$\tilde{v}_\gamma = c \left[1 - 2\alpha \mathcal{E}_\gamma^{1/2} - \frac{\alpha m_\gamma^2 c^2}{\mathcal{E}_\gamma^{1/2}} + \frac{3\alpha m_\gamma^4 c^4}{8 \mathcal{E}_\gamma^{3/2}} + 2\alpha^2 \mathcal{E}_\gamma + \frac{9\alpha^2 m_\gamma^4 c^4}{8 \mathcal{E}_\gamma} + \frac{11\alpha^2 m_\gamma^2 c^2}{4} \right]. \quad (\text{C15})$$

In this second case, the difference between the speed of graviton and photon reads

$$|\Delta \tilde{v}_g| = |\tilde{v}_\gamma - \tilde{v}_g| = \left| \left[\alpha c^3 \left(\frac{m_\gamma^2}{\mathcal{E}_\gamma^{1/2}} - \frac{m_g^2}{\mathcal{E}_g^{1/2}} \right) - 2\alpha c (\mathcal{E}_\gamma^{1/2} - \mathcal{E}_g^{1/2}) + \frac{3\alpha c^5}{8} \left(\frac{m_\gamma^4}{\mathcal{E}_\gamma^{3/2}} - \frac{m_g^4}{\mathcal{E}_g^{3/2}} \right) + 2\alpha^2 c (\mathcal{E}_\gamma - \mathcal{E}_g) + \frac{9\alpha^2 c^5}{8} \left(\frac{m_\gamma^4}{\mathcal{E}_\gamma} - \frac{m_g^4}{\mathcal{E}_g} \right) + \frac{11\alpha^2 c^3}{4} (m_\gamma^2 - m_g^2) \right] \right|. \quad (\text{C16})$$

As stated before, the difference in the speed of graviton and photon is bounded from above by Δv_g as given by Eq. (A2), and this sets a bound on the LQGUP parameter as follows

$$\left[\alpha c^3 \left(\frac{m_\gamma^2}{\mathcal{E}_\gamma^{1/2}} - \frac{m_g^2}{\mathcal{E}_g^{1/2}} \right) - 2\alpha c (\mathcal{E}_\gamma^{1/2} - \mathcal{E}_g^{1/2}) + \frac{3\alpha c^5}{8} \left(\frac{m_\gamma^4}{\mathcal{E}_\gamma^{3/2}} - \frac{m_g^4}{\mathcal{E}_g^{3/2}} \right) + 2\alpha^2 c (\mathcal{E}_\gamma - \mathcal{E}_g) + \frac{9\alpha^2 c^5}{8} \left(\frac{m_\gamma^4}{\mathcal{E}_\gamma} - \frac{m_g^4}{\mathcal{E}_g} \right) + \frac{11\alpha^2 c^3}{4} (m_\gamma^2 - m_g^2) \right] \leq \Delta v_g. \quad (\text{C17})$$
