# LOCAL COMMUTANTS AND ULTRAINVARIANT SUBSPACES 

JANKO BRAČIČ

#### Abstract

For an operator $A$ on a complex Banach space $X$ and a closed subspace $\mathcal{M} \subseteq \mathcal{X}$, the local commutant of $A$ at $\mathcal{N}$ is the set $\mathcal{C}(A ; \mathcal{N})$ of all operators $T$ on $\mathcal{X}$ such that $T A x=A T x$ for every $x \in \mathcal{M}$. It is clear that $\mathcal{C}(A ; \mathcal{M})$ is a closed linear space of operators, however it is not an algebra, in general. For a given $A$, we show that $\mathcal{C}(A ; \mathcal{M})$ is an algebra if and only if the largest subspace $\mathcal{M}_{A}$ such that $\mathcal{C}(A ; \mathcal{M})=\mathcal{C}\left(A ; \mathcal{M}_{A}\right)$ is invariant for every operator in $\mathcal{C}(A ; \mathcal{M})$. We say that these are ultrainvariant subspaces of $A$. For several types of operators we prove that there exist non-trivial ultrainvariant subspaces. For a normal operator on a Hilbert space, every hyperinvariant subspace is ultrainvariant. On the other hand, the lattice of all ultrainvariant subspaces of a non-zero nilpotent operator can be strictly smaller than the lattice of all hyperinvariant subspaces.

## 1. Introduction

Let $\mathcal{X}$ be a complex Banach space and let $B(\mathcal{X})$ be the Banach algebra of all bounded linear operators on $\mathcal{X}$. The dual space of $\mathcal{X}$ will be denoted by $\mathcal{X}^{*}$. For $A \in B(\mathcal{X})$ and a closed subspace $\mathcal{M} \subseteq \mathcal{X}$, the local commutant of $A$ at $\mathcal{M}$ is $\mathcal{C}(A ; \mathcal{N})=\{T \in B(\mathcal{X}) ; T A x=$ ATx for all $x \in \mathcal{M}\}$. It is clear that $(A)^{\prime}$, the commutant of $A$, is a subset of $\mathcal{C}(A ; \mathcal{N})$. Of course, $\mathcal{C}(A ; \mathcal{X})=(A)^{\prime}$ and $\mathcal{C}(A ;\{0\})=B(X)$.

Local commutants were introduced by Larson [13, 6] more than twenty years ago, however there are only a few results related to them (see [4], for instance) although that there are some interesting open problems related to them. One among these problems is the question when is $\mathcal{C}(A ; \mathcal{M})$ an algebra. Of course, for an arbitrary $A$ and $\mathcal{M}$ which is equal either to $\{0\}$ or $\mathcal{X}$ the local commutant is an algebra. However, for $A$ which is not a scalar multiple of $I_{x}$, the identity operator on $\mathcal{X}$, there exists a closed subspace $\mathcal{M} \subseteq X$ such that $\mathcal{C}(A ; \mathcal{N})$ is not a subalgebra of $B(\mathcal{X})$ but just a linear subspace.

[^0]Recall that a closed subspace $\mathcal{M} \subseteq \mathcal{X}$ is said to be invariant for $A \in B(X)$ if $A \mathcal{M} \subseteq \mathcal{M}$. It is well-known that the family of all closed subspaces which are invariant for $A$ form a lattice; the lattice operations are the intersection and the closed linear span. As usual, we will denote this lattice by $\operatorname{Lat}(A)$. A sublattice of $\operatorname{Lat}(A)$ is $\operatorname{Lat}_{h}(A)$, the lattice of all hyperinvariant subspaces of $A$ : a subspace $\mathcal{M} \in \operatorname{Lat}(A)$ belongs to $\operatorname{Lat}_{h}(A)$ if and only if $T \mathcal{M} \subseteq \mathcal{N}$ for every $T \in(A)^{\prime}$. It is obvious that the trivial lattice $\{\{0\}, \mathcal{X}\}$ is a sublattice of $\operatorname{Lat}_{h}(A)$ and therefore of $\operatorname{Lat}(A)$. In 1970s, Enflo showed that there exists a Banach space $X$ and a bounded operator $A$ on it such that $\operatorname{Lat}(A)$ is trivial. The result was published much later in [9] and meanwhile Read published his example of an operator without a non-trivial invariant subspace, see [17]. Nowadays several examples of Banach spaces (including $l_{1}$ ) with operators whose lattice of invariant subspaces is trivial are known. On the other hand, Lomonosov [15] proved that an operator has a non-trivial invariant subspace if it commutes with an operator which is not a scalar multiple of $I_{x}$ and commutes with a non-zero compact operator. It follows that for some infinite dimensional Banach spaces $\mathcal{X}$ (see example given by Argyros and Haydon [2]) every operator in $B(X)$ has a non-trivial invariant subspaces.

However for many Banach spaces (for instance, for the infinite dimensional separable Hilbert space) it is not known if $\operatorname{Lat}(A)$ is non-trivial for every operator $A$. Similarly, for more or less the same class of Banach spaces, it is not known if $\operatorname{Lat}_{h}(A)$ can be trivial for an operator $A$ which is not a scalar multiple of $I_{x}$. Work on these problems is still very active, see [20] and references therein. The reader is referred to [5] and [16] for more details about the problem of invariant subspaces.

It turns out that our problem about the algebraic structure of $\mathcal{C}(A ; \mathcal{M})$ is connected with hyperinvariant subspaces of $A$. Our main observation is the following. Let $A \in B(X)$ and let $\mathcal{M} \subseteq \mathcal{X}$ be a closed subspace. Denote by $\mathcal{M}_{A} \subseteq \mathcal{X}$ the set of all vectors $x \in \mathcal{X}$ such that $T A x=A T x$ for every $T \in \mathcal{C}(A ; \mathcal{M})$. Then $\mathcal{M}_{A}$ is a closed subspace of $\mathcal{X}$ such that $\mathcal{M} \subseteq \mathcal{M}_{A}$ and $\mathcal{C}(A ; \mathcal{N})=\mathcal{C}\left(A ; \mathcal{M}_{A}\right)$. The local commutant $\mathcal{C}(A ; \mathcal{N})$ is an algebra if and only if $\mathcal{M}_{A}$ is invariant for every operator in $\mathcal{C}(A ; \mathcal{M})$; we say that $\mathcal{N}_{A}$ is an ultrainvariant subspace of $A$. Since $(A)^{\prime} \subseteq \mathcal{C}(A ; \mathcal{M})$ an ultrainvariant subspace is a hyperinvariant subspace, as well. The opposite is not true, in general.

Ultrainvariant subspaces are the main theme of the second part of this paper. Denote by $\operatorname{Lat}_{u}(A)$ the family of all ultrainvariant subspaces of $A$. It is a sublattice of $\operatorname{Lat}_{h}(A)$.

For several types of operators $A$ we show that $\operatorname{Lat}_{u}(A)$ is not trivial. There are classes of operators for which we are able to characterize the lattice of ultrainvariant subspaces completely. For instance, for algebraic operators, in particular, for operators on a finite dimensional Banach space, and for normal operators on a Hilbert space. If $A$ is a unicellular operator on a Hilbert space, then $\operatorname{Lat}_{u}(A)=\operatorname{Lat}_{h}(A)=\operatorname{Lat}_{u}(A)$. This holds, for instance, for the Volterra operator and Donoghue operators.

Several questions about ultrainvariant subspaces remain open. For instance, we do not know if every compact operator has a non-trivial ultrainvariant subspace. Actually we believe that it is hard to find an operator which has a non-trivial hyperinvariant subspace but does not have a non-trivial ultrainvariant subspace.

In the end of this section, let us say a few words about the terminology. Sz.-Nagy and Foiaş initiated the study of hyperinvariant subspaces in their book Analyse harmonique des opérateurs de l'espace Hilbert however they called them ultrainvariant subspaces. In this paper we use their terminology (see Definition4.1) for a special type of hyperinvariant subspaces. Another new term which we use is girder. The girder of $\mathcal{C}(A ; \mathcal{M})$ is the largest subspace $\mathcal{M}_{A} \subseteq \mathcal{X}$ such that $\mathcal{C}(A ; \mathcal{M})=\mathcal{C}\left(A ; \mathcal{M}_{A}\right)$. In our opinion the term girder is suitable as $\mathcal{M}_{A}$ "carries" the whole space $\mathcal{C}(A ; \mathcal{M})$ in the sense that $\mathcal{M}_{A}$ is the largest subspace whose vectors give the information whether $T$ belongs to $\mathcal{C}(A ; \mathcal{M})$ or not.

## 2. Local commutants

Although that we are mainly interested in local commutants we begin our study by considering a slightly more general objects. Let $X$ and $y$ be complex Banach spaces and let $B(X, y)$ be the space of all bounded linear operators from $X$ to $y$. For $A \in B(X)$ and $B \in B(y)$, let $\mathcal{J}(A, B)$ be the set of all operators $S \in B(X, y)$ which intertwine $A$ and $B$, that is, $\mathcal{J}(A, B)=\{S \in B(X, y) ; S A=B S\}$. Of course, if $X=y$ and $A=B$, then $\mathcal{J}(A, A)=(A)^{\prime}$. Let $\mathcal{M} \subseteq \mathcal{X}$ be a closed subspace. The space of operators which intertwine $A$ and $B$ locally at $\mathcal{M}$ is $\mathcal{J}(A, B ; \mathcal{N})=\{S \in B(\mathcal{X}, \mathcal{y}) ; S A x=B S x$ for every $x \in \mathcal{M}\}$. In particular, $\mathcal{J}(A, A ; \mathcal{M})=\mathcal{C}(A ; \mathcal{M})$ is the local commutant of $A$ at $\mathcal{M}$.

It is easily seen that $\mathcal{J}(A, B ; \mathcal{M})$ is closed in the strong operator topology and that $\mathcal{J}(A, B ; \mathcal{M})=\mathcal{J}\left(A-\lambda I_{x}, B-\lambda I_{y} ; \mathcal{M}\right)$, for every $\lambda \in \mathbb{C}$. For arbitrary invertible operators $U \in B(X)$ and $V \in B(y)$, we have

$$
\begin{equation*}
\mathcal{J}(A, B ; \mathcal{M})=V^{-1} \mathcal{J}\left(U A U^{-1}, V B V^{-1} ; U \mathcal{M}\right) U . \tag{1}
\end{equation*}
$$

If $\mathcal{M}_{1}, \mathcal{M}_{2}$ are closed subspaces of $\mathcal{X}$ such that $\mathcal{M}_{2} \subseteq \mathcal{M}_{1}$, then $\mathcal{J}\left(A, B ; \mathcal{M}_{1}\right) \subseteq \mathcal{J}\left(A, B ; \mathcal{M}_{2}\right)$.
In particular, $\mathcal{J}(A, B)=\mathcal{J}(A, B ; \mathcal{X}) \subseteq \mathcal{J}(A, B ; \mathcal{N}) \subseteq \mathcal{J}(A, B ;\{0\})=B(\mathcal{X}, \mathcal{y})$.
Let $\left\{\mathcal{M}_{j} ; j \in J\right\}$ be a non-empty family of closed subspaces of $\mathcal{X}$. It is not hard to see that

$$
\bigvee_{j \in J}\left\{\mathcal{J}\left(A, B ; \mathcal{M}_{j}\right) ; j \in J\right\} \subseteq \mathcal{J}\left(A, B ; \bigcap_{j \in J} \mathcal{M}_{j}\right)
$$

On the other hand,

$$
\begin{equation*}
\mathcal{I}\left(A, B ; \bigvee_{j \in J} \mathcal{M}_{j}\right)=\bigcap_{j \in J} \mathcal{J}\left(A, B ; \mathcal{M}_{j}\right) \tag{2}
\end{equation*}
$$

Here we denoted by $\bigvee_{j \in J}$ the closed linear span of the involved sets.
To verify (2亿), note that $\mathcal{J}\left(A, B ; \bigvee_{j \in J} \mathcal{M}_{j}\right) \subseteq \bigcap_{j \in J} \mathcal{J}\left(A, B ; \mathcal{M}_{j}\right)$ holds since $\mathcal{M}_{i} \subseteq \bigvee_{j \in J} \mathcal{M}_{j}$ and therefore $\mathcal{J}\left(A, B ; \bigvee_{j \in J} \mathcal{M}_{j}\right) \subseteq \mathcal{J}\left(A, B ; \mathcal{M}_{i}\right)$, for every $i \in J$. For the opposite inclusion, observe that $B S x_{j}=S A x_{j}$ for every $x_{j} \in \mathcal{N}_{j}$ and every $j \in J$ if $S \in \bigcap_{j \in J} \mathcal{J}\left(A, B ; \mathcal{N}_{j}\right)$. Hence $S \in \mathcal{J}\left(A, B ; \bigvee_{j \in J} \mathcal{M}_{j}\right.$ ). (Here we used a simple fact that $B S x=S A x$ holds for every $x \in \bigvee \mathcal{U}$ if it holds for every $x \in \mathcal{U} \subseteq \mathcal{X}$.)

Let $A \in B(\mathcal{X}), B \in B(\mathcal{y})$ and let $\mathcal{M} \subseteq \mathcal{X}$ be a complemented closed subspace, that is, there exists a closed subspace $\mathcal{N} \subseteq \mathcal{X}$ such that $\mathcal{X}=\mathcal{M} \oplus \mathcal{N}$. Let $\left[\begin{array}{ccc}A_{11} & A_{12} \\ A_{21} & A_{22}\end{array}\right]$ be the operator matrix of $A$ with respect to this decomposition. For arbitrary operators $S \in B(\mathcal{X}, \boldsymbol{y})$ and $T \in B(X)$, let $\left[S_{1} S_{2}\right]$, respectively $\left[\begin{array}{c}T_{11} \\ T_{21} \\ T_{22}\end{array}\right]$, be their operator matrices with respect to the decomposition $\mathcal{X}=\mathcal{M} \oplus \mathcal{N}$. These assumptions and notation will be used throughout this section.

A straightforward computation shows that $S \in \mathcal{J}(A, B)$ if and only if

$$
\begin{equation*}
B S_{1}=S_{1} A_{11}+S_{2} A_{21} \tag{3}
\end{equation*}
$$

and

$$
\begin{equation*}
B S_{2}=S_{1} A_{12}+S_{2} A_{22} \tag{4}
\end{equation*}
$$

Similarly, $T \in(A)^{\prime}$ if and only if

$$
\begin{equation*}
T_{11} A_{11}+T_{12} A_{21}=A_{11} T_{11}+A_{12} T_{21}, \quad T_{21} A_{11}+T_{22} A_{21}=A_{21} T_{11}+A_{22} T_{21} \tag{5}
\end{equation*}
$$

and

$$
\begin{equation*}
T_{11} A_{12}+T_{12} A_{22}=A_{11} T_{12}+A_{12} T_{22}, \quad T_{21} A_{12}+T_{22} A_{22}=A_{21} T_{12}+A_{22} T_{22} \tag{6}
\end{equation*}
$$

Lemma 2.1. Operator $S \in B(X, y)$ is in $\mathcal{J}(A, B ; \mathcal{N})$ if and only if (3) holds and $T \in B(X)$ is in $\mathcal{C}(A ; \mathcal{M})$ if and only if (5) holds.

Proof. Let $x \in \mathcal{X}$ be arbitrary and let $x=x_{1} \oplus x_{2}$, where $x_{1} \in \mathcal{M}$ and $x_{2} \in \mathcal{N}$. Then $S A x=\left(S_{1} A_{11}+S_{2} A_{21}\right) x_{1}+\left(S_{1} A_{12}+S_{2} A_{22}\right) x_{2}$ and $B S x=B S_{1} x_{1}+B S_{2} x_{2}$. Hence, if $S \in \mathcal{J}(A, B ; \mathcal{N})$, that is, $B S\left(x_{1} \oplus 0\right)=S A\left(x_{1} \oplus 0\right)$ for every $x_{1} \in \mathcal{M}$, then $B S_{1} x_{1}=\left(S_{1} A_{11}+\right.$ $\left.S_{2} A_{21}\right) x_{1}$ for every $x_{1} \in \mathcal{M}$ which gives (3). It is clear that the opposite implication holds, as well. The second part of the assertion follows by the first one if we put $B=\left[\begin{array}{ccc}A_{11} & A_{12} \\ A_{21} & A_{22}\end{array}\right]$, $S_{1}=\left[\begin{array}{l}T_{11} \\ T_{21}\end{array}\right]$ and $S_{2}=\left[\begin{array}{l}T_{12} \\ T_{22}\end{array}\right]$ in (3) .

It is clear that $\mathcal{J}(A, B ;\{0\})=B(\mathcal{X}, \mathcal{y})$ for arbitrary operators $A$ and $B$. Let $\mathcal{M} \neq\{0\}$. The following corollary characterizes those pairs of operators $A \in B(\mathcal{X})$ and $B \in B(y)$ for which $\mathcal{J}(A, B ; \mathcal{M})=B(\mathcal{X}, \mathfrak{y})$.

Proposition 2.2. Let $\mathcal{M} \neq\{0\}$. Then $\mathcal{J}(A, B ; \mathcal{M})=B(\mathcal{X}, \mathcal{y})$ if and only if $A_{11}=\lambda I_{\mathcal{M}}$, $B=\lambda I_{y}$, for some $\lambda \in \mathbb{C}$, and $A_{21}=0$. In particular, $\mathcal{C}(A ; \mathcal{M})=B(X)$ if and only if $A$ is a scalar multiple of $I_{x}$.

Proof. Assume that $\mathcal{J}(A, B ; \mathcal{M})=B(\mathcal{X}, y)$. Let $S=\left[S_{1} 0\right]$, where $S_{1} \in B(\mathcal{M}, y)$ is arbitrary. By Lemma 2.1, $B S_{1}=S_{1} A_{11}$. Let $y \in \mathcal{y}$ and $0 \neq \xi \in \mathcal{N}^{*}$ be arbitrary. Then $y \otimes \xi \in B(\mathcal{M}, \mathcal{y})$ and therefore $B(y \otimes \xi)=(y \otimes \xi) A_{11}$. If $x \in \mathcal{M}$ is such that $\langle x, \xi\rangle=1$, then $B y=B(y \otimes \xi) x=(y \otimes \xi) A_{11} x=\left\langle A_{11} x, \xi\right\rangle y$. Hence, $B \in B(y)$ is an operator such that every $0 \neq y \in y$ is its eigenvector. It follows that there exists $\lambda \in \mathbb{C}$ such that $B=\lambda I_{\mathrm{y}}$. Now we have $\lambda S_{1}=S_{1} A_{11}$ for every $S_{1} \in B(\mathcal{M}, y)$ which gives $A_{11}=\lambda I_{\mathcal{M}}$. Since every $S=\left[S_{1} S_{2}\right] \in B(\mathcal{X}, \boldsymbol{y})$ satisfies (3) we have $S_{2} A_{21}=0$ for every $S_{2} \in B(\mathcal{N}, y)$. Hence, $A_{21}=0$. The opposite implication is simple: if $A_{11}=\lambda I_{\mathcal{M}}, B=\lambda I_{y}$ and $A_{21}=0$, then (3) holds for every $S=\left[S_{1} S_{2}\right]$.

It follows from the first part of this corollary that in the case when $X=y$ and $A=B$ we have $\mathcal{C}(A ; \mathcal{M})=B(X)$ if and only if $A=\lambda I_{x}$ for some $\lambda \in \mathbb{C}$.

Equality $\mathcal{J}(A, B ; \mathcal{M})=\mathcal{J}(A, B)$ holds if and only if every pair of operators $S_{1} \in B(\mathcal{M}, y)$ and $S_{2} \in B(\mathcal{N}, y)$ which satisfies (3) satisfies (4), as well. In the following proposition we determine those pairs $A \in B(\mathcal{X})$ and $B \in B(y)$ for which $\mathcal{J}(A, B ; \mathcal{N})=\mathcal{J}(A, B)$ holds for a given subspace $\mathcal{M} \in \operatorname{Lat}(A), \mathcal{M} \neq \mathcal{X}$. We will use the following notation. For $S \in B(X, y)$, the kernel of $S$ is denoted by $\operatorname{ker}(S)$ and the range (image) of $S$ by $\operatorname{im}(S)$.

If $\mathbb{Z}$ is a non-empty set of vectors in $X$, then by $Z^{\perp}$ we denote its annihilator in $X^{*}$, that is, $Z^{\perp}=\left\{\xi \in \mathcal{X}^{*} ;\langle x, \xi\rangle=0\right.$ for all $\left.x \in \mathcal{Z}\right\}$.

Proposition 2.3. Let $\mathcal{M} \neq \mathcal{X}$. Then $\mathcal{J}(A, B ; \mathcal{M})=\mathcal{J}(A, B)$ and $\mathcal{M} \in \operatorname{Lat}(A)$ if and only if there exists $\lambda \in \mathbb{C}$ such that $A=\left[\begin{array}{cc}A_{11} & A_{12} \\ 0 & \lambda I_{\mathcal{N}}\end{array}\right], B=\lambda I_{y}$ and $\overline{\operatorname{im}\left(A_{12}\right)} \subseteq \overline{\operatorname{im}\left(\lambda I_{\mathcal{M}}-A_{11}\right)}$. In this case, $\mathcal{J}(A, B ; \mathcal{M})=\left\{\left[S_{1} S_{2}\right] \in B(\mathcal{X}, y) ; \overline{\operatorname{im}\left(\lambda I_{\mathcal{M}}-A_{11}\right)} \subseteq \operatorname{ker}\left(S_{1}\right), S_{2} \in B(\mathcal{N}, y)\right\}$.

Proof. Assume that $\mathcal{J}(A, B ; \mathcal{N})=\mathcal{J}(A, B)$, where $\mathcal{X} \neq \mathcal{M} \in \operatorname{Lat}(A)$. Then the operator matrix of $A$ with respect to the decomposition $\mathcal{X}=\mathcal{M} \oplus \mathcal{N}$ is $A=\left[\begin{array}{cc}A_{11} & A_{12} \\ 0 & A_{22}\end{array}\right]$. Hence, by Lemma 2.1, an operator $S=\left[S_{1} S_{2}\right] \in B(\mathcal{X}, \mathcal{y})$ intertwines $A$ and $B$ at $\mathcal{M}$ if and only if it satisfies (3) which in our case means

$$
\begin{equation*}
B S_{1}=S_{1} A_{11} \tag{7}
\end{equation*}
$$

It follows that $\left[0 S_{2}\right] \in \mathcal{J}(A, B ; \mathcal{N})$, and therefore $\left[0 S_{2}\right] \in \mathcal{J}(A, B)$, for every $S_{2} \in B(\mathcal{N}, \mathcal{y})$. Thus, $\left[0 S_{2}\right]$ satisfies (4), that is, $B S_{2}=S_{2} A_{22}$ holds for every $S_{2} \in B(\mathcal{N}, y)$. By Proposition 2.2, there exists $\lambda \in \mathbb{C}$ such that $A_{22}=\lambda I_{\mathcal{N}}$ and $B=\lambda I_{y}$. Now (77) reads as

$$
\begin{equation*}
S_{1}\left(\lambda I_{\mathfrak{M}}-A_{11}\right)=0 \tag{8}
\end{equation*}
$$

Hence, if $\left[S_{1} S_{2}\right]$ is an operator in $\mathcal{J}\left(A, \lambda I_{y} ; \mathcal{M}\right)$, then $\overline{\operatorname{im}\left(\lambda I_{\mathcal{M}}-A_{11}\right)} \subseteq \operatorname{ker}\left(S_{1}\right)$ and $S_{2}$ is arbitrary. Note that $\left[S_{1} S_{2}\right]$ is in $\mathcal{J}\left(A, \lambda I_{y}\right)$ if and only if it satisfies (4) which reads as

$$
\begin{equation*}
S_{1} A_{11}=0 \tag{9}
\end{equation*}
$$

in our case. Since $\mathcal{J}\left(A, \lambda I_{y} ; \mathcal{N}\right)=\mathcal{J}\left(A, \lambda I_{y}\right)$ every $S_{1}$ which satisfies (8) has to satisfy (97), as well. Suppose towards a contradiction that there exists $x=A_{12} u \in \operatorname{im}\left(A_{12}\right)$ such that $x \notin \overline{\operatorname{im}\left(\lambda I_{\mathcal{M}}-A_{11}\right)}$. Let $\xi \in \mathcal{M}^{*}$ be such that $\xi \in \overline{\operatorname{im}\left(\lambda I_{\mathcal{M}}-A_{11}\right)}{ }^{\perp}$ and $\langle x, \xi\rangle=1$. For any $0 \neq y \in y$, the rank one operator $y \otimes \xi \in B(\mathcal{M}, y)$ satisfies $(y \otimes \xi)\left(\lambda I_{\mathcal{M}}-A_{11}\right)=0$, which means $y \otimes \xi \in \mathcal{J}\left(A, \lambda I_{y} ; \mathcal{M}\right)$, however $(y \otimes \xi) A_{12} \neq 0$ since $(y \otimes \xi) A_{12} u=\langle x, \xi\rangle y \neq 0$. This proves that $\overline{\operatorname{im}\left(A_{12}\right)} \subseteq \overline{\operatorname{im}\left(\lambda I_{\mathcal{M}}-A_{11}\right)}$.

The opposite implication is easily checked and one gets that $\mathcal{J}(A, B ; \mathcal{M})=\left\{\left[S_{1} S_{2}\right] \in\right.$ $\left.B(\mathcal{X}, \mathrm{y}) ; \overline{\operatorname{im}\left(\lambda I_{\mathfrak{M}}-A_{11}\right)} \subseteq \operatorname{ker}\left(S_{1}\right), S_{2} \in B(\mathcal{N}, y)\right\}$.

Corollary 2.4. If $\mathcal{M} \in \operatorname{Lat}(A), \mathcal{M} \neq \mathcal{X}$, and $A$ is not a scalar multiple of $I_{x}$, then $(A)^{\prime} \subsetneq \mathcal{C}(A ; \mathcal{M})$.

Theorem 2.5. Let $A \in B(X)$ and assume that $A$ is not a scalar multiple of $I_{x}$. Let $\mathcal{M} \in \operatorname{Lat}(A),\{0\} \neq \mathcal{M} \neq \mathcal{X}$. The local commutant $\mathcal{C}(A ; \mathcal{M})$ is an algebra if and only if $\mathcal{C}(A ; \mathcal{M})=\left\{T \in B(X) ; T_{11} \in\left(A_{11}\right)^{\prime}\right.$ and $\left.T_{21}=0\right\}$.

Proof. We begin the proof with the following simple observation.
Claim. Let $x_{1}, x_{2}, x_{3}$ and $x_{4}$ be Banach spaces. If $T \in B\left(x_{1}, x_{2}\right)$ and $R \in B\left(x_{3}, x_{4}\right)$ are such that $R(u \otimes \xi) T=0$ for all $u \in X_{3}$ and $\xi \in X_{2}^{*}$, then either $R=0$ or $T=0$.
Indeed! Assume that $T \neq 0$. Then there exists $x \in X_{1}$ such that $T x \neq 0$. Let $\xi \in X_{2}^{*}$ be such that $\langle T x, \xi\rangle=1$. For an arbitrary $u \in X_{3}$ we have, by the assumption, $R(u \otimes \xi) T=0$ and therefore $R(u \otimes \xi) T x=R u=0$. This shows that $R=0$.

Assume that $\mathcal{C}(A ; \mathcal{M})$ is an algebra. Since $\mathcal{M} \in \operatorname{Lat}(A)$ the operator matrix of $A$ is of the form $\left[\begin{array}{cc}A_{11} & A_{12} \\ 0 & A_{22}\end{array}\right]$. Hence, by Lemma 2.1, an operator $T=\left[\begin{array}{cc}T_{11} & T_{12} \\ T_{21} & T_{22}\end{array}\right]$ is in $\mathcal{C}(A ; \mathcal{M})$ if and only if

$$
\begin{equation*}
T_{11} A_{11}-A_{11} T_{11}=A_{12} T_{21}, \quad T_{21} A_{11}-A_{22} T_{21}=0 \tag{10}
\end{equation*}
$$

and $T_{12} \in B(\mathcal{N}, \mathcal{M}), T_{22} \in B(\mathcal{N})$ are arbitrary. In particular, the projection $P$ onto $\mathcal{M}$ along $\mathcal{N}$ is in $\mathcal{C}(A ; \mathcal{N})$. Since $\mathcal{C}(A ; \mathcal{N})$ is assumed to be an algebra we see that operators PTP and $\left(I_{x}-P\right) T P$ are in $\mathcal{C}(A ; \mathcal{N})$ for every $T \in \mathcal{C}(A ; \mathcal{M})$. Note that the operator matrices of PTP and $\left(I_{x}-P\right) T P$ are $\left[\begin{array}{cc}T_{11} & 0 \\ 0 & 0\end{array}\right]$ and $\left[\begin{array}{cc}0 & 0 \\ T_{21} & 0\end{array}\right]$, respectively. Hence, if $T \in$ $\mathcal{C}(A ; \mathcal{M})$, then the entries of its operator matrix have to satisfy

$$
\begin{equation*}
T_{11} A_{11}-A_{11} T_{11}=0, \quad A_{12} T_{21}=0, \quad T_{21} A_{11}-A_{22} T_{21}=0 \tag{11}
\end{equation*}
$$

Suppose that $A_{12} \neq 0$. Let $u \in \mathcal{N}$ and $\xi \in \mathcal{N}^{*}$ be arbitrary. Then $U$ whose operator matrix is $\left[\begin{array}{cc}0 & 0 \\ 0 & u \otimes \xi\end{array}\right]$ satisfies (10) and therefore $U \in \mathcal{C}(A ; \mathcal{M})$ which gives $U\left(I_{x}-P\right) T P \in$ $\mathcal{C}(A ; \mathcal{M})$. The operator matrix of $U\left(I_{x}-P\right) T P$ is $\left[\begin{array}{cc}(u \otimes \xi) T_{21} & 0 \\ 0\end{array}\right]$ and the entries of this matrix satisfy (11); in particular, $A_{12}(u \otimes \xi) T_{21}=0$. Since $u \otimes \xi \in B(\mathcal{N})$ is an arbitrary operator of rank at most 1 and $A_{12} \neq 0$ we conclude, by Claim, that $T_{21}=0$.
Now we may assume that $A_{12}=0$. If $A_{11}=\lambda I_{\mathfrak{N}}$ and $A_{22}=\mu I_{\mathfrak{N}}$, then $\lambda \neq \mu$ as $A$ is not a scalar multiple of $I_{x}$. It follows, by the third equality in (11), that $T_{21}=0$. Thus, it remains to consider the case when either $A_{11}$ is not a scalar multiple of $I_{\mathfrak{m}}$ or $A_{22}$ is not a scalar multiple of $I_{\mathcal{N}}$. Suppose that this holds. Let $Q \in B(\mathcal{N}, \mathcal{N})$ be arbitrary and let $V \in B(X)$ be the operator whose operator matrix is $\left[\begin{array}{cc}0 & Q \\ 0 & 0\end{array}\right]$. Then $V \in \mathcal{C}(A ; \mathcal{M})$ and therefore $V\left(I_{x}-P(T P \in \mathcal{C}(A ; \mathcal{M})\right.$ for every $T \in \mathcal{C}(A ; \mathcal{M})$. The
operator matrix of $V\left(I_{x}-P\left(T P \in \mathcal{C}(A ; \mathcal{M})\right.\right.$ is $\left[\begin{array}{cc}Q T_{21} & 0 \\ 0 & 0\end{array}\right]$. Hence, $Q T_{21} \in\left(A_{11}\right)^{\prime}$. Since $T_{21}$ satisfies the third equality in (11) we have $A_{11} Q T_{21}=Q T_{21} A_{11}=Q A_{22} T_{21}$ which gives $\left(A_{11} Q-Q A_{22}\right) T_{21}=0$. We have supposed that either $A_{11}$ is not a scalar multiple of $I_{\mathcal{M}}$ or $A_{22}$ is not a scalar multiple of $I_{\mathcal{N}}$. Hence, by Proposition [2.2, there exists $Q_{0} \in B(\mathcal{N}, \mathcal{M})$ such that $R=A_{11} Q_{0}-Q_{0} A_{22} \neq 0$. Thus, $R T_{21}=0$ for every $T \in \mathcal{C}(A ; \mathcal{M})$. Let $T$ be fixed now. As in the previous paragraph, let $u \in \mathcal{N}$ and $\xi \in \mathcal{N}^{*}$ be arbitrary and let $U \in \mathcal{C}(A ; \mathcal{N})$ be the operator whose operator matrix is $\left[\begin{array}{cc}0 & 0 \\ 0 & u \otimes \xi\end{array}\right]$. Then $U\left(I_{x}-P\right) T P \in$ $\mathcal{C}(A ; \mathcal{M})$ and therefore $R(u \otimes \xi) T_{21}=0$. Since $u \otimes \xi \in B(\mathcal{N})$ is an arbitrary operator of rank at most 1 and $R \neq 0$ we conclude, by Claim, that $T_{21}=0$. This proves that $\mathcal{C}(A ; \mathcal{M})=\left\{T \in B(\mathcal{X}) ; T_{11} \in\left(A_{11}\right)^{\prime}\right.$ and $\left.T_{21}=0\right\}$ if $\mathcal{C}(A ; \mathcal{M})$ is assumed to be an algebra. The opposite implication is obvious.

In the proof of Theorem 2.5 we have seen that the projection $P$ which maps onto $\mathcal{M}$ along $\mathcal{N}$ is in $\mathcal{C}(A ; \mathcal{M})$ if $\mathcal{M} \in \operatorname{Lat}(A)$. It is not hard to see that the opposite implication holds as well.

Corollary 2.6. Projection $P$ is in $\mathcal{C}(A ; \mathcal{N})$ if and only if $\mathcal{M}$ is invariant for $A$.
Let $\sigma(T)$ denote the spectrum of $T \in B(X)$. It follows from a well-known theorem proved by Rosenblum that $\mathcal{J}(A, B)=\{0\}$ if $\sigma(A) \cap \sigma(B)=\emptyset$, see [18, Corollary 3.3] and [10, Theorem I.4.1]. Note that the condition $\sigma(A) \cap \sigma(B)=\emptyset$ is not necessary for $\mathcal{J}(A, B)=\{0\}$. For instance, let $B=0$ and let $A \in B(\mathcal{X})$ be such that $\overline{\operatorname{im}(A)}=\mathcal{X}$ and $\operatorname{ker}(A) \neq\{0\}$. Then $0 \in \sigma(A) \cap \sigma(B)$, however $\mathcal{J}(A, 0)=\{0\}$ because $S A=0$ holds for $S \in B(X, y)$ if and only if $S=0$ as $\overline{\operatorname{im}(A)}=X$. On the other hand, note that $\mathcal{J}(0, A) \neq\{0\}$. Indeed, if $S \in B(\mathcal{y}, \mathcal{X})$ is such that $\operatorname{im}(S) \subseteq \operatorname{ker}(A)$, then $A S=0$.

Corollary 2.7. If $\mathcal{M} \in \operatorname{Lat}(A)$ and $\sigma\left(A_{11}\right) \cap \sigma\left(A_{22}\right)=\emptyset$, then $\mathcal{C}(A ; \mathcal{M})$ is an algebra.
Proof. By Lemma 2.1, $T \in \mathcal{C}(A ; \mathcal{M})$ if and only if (5) holds. Since $A_{21}=0$ the equalities in (5)) simplify to (10). Because of $\sigma\left(A_{11}\right) \cap \sigma\left(A_{22}\right)=\emptyset$, only $T_{21}=0$ satisfies the second equation in (10). Thus, $\mathcal{C}(A ; \mathcal{M})=\left\{T \in B(\mathcal{X}) ; T_{11} \in\left(A_{11}\right)^{\prime}\right.$ and $\left.T_{21}=0\right\}$ and therefore it is an algebra, by Theorem 2.5.

In the following example we will see that $\mathcal{C}(Q ; \mathcal{L})$ can be an algebra for $Q \in B(X)$ and a closed subspace $\mathcal{L} \subseteq X$ which is not invariant for $Q$.

Example 2.8. Let $x_{1}, x_{2}, x_{3}$ be closed subspaces such that $x_{1}, x_{2}$ are non-trivial. Let $X=X_{1} \oplus X_{2} \oplus X_{3}$ and suppose that there exists a surjective operator in $B\left(X_{1}, x_{2}\right)$. Let $Q \in B(X)$ be the projection onto $X_{1}$ along $X_{2} \oplus X_{3}$. Choose and fix a surjective operator $U \in B\left(X_{1}, X_{2}\right)$. Let $\mathcal{L} \subseteq X$ be the subspace of all vectors $x \in \mathcal{X}$ which are of the form $x=x_{1} \oplus U x_{1} \oplus x_{3}$, where $x_{1} \in X_{1}$ and $x_{3} \in X_{3}$ are arbitrary. Denote by $P_{j}: X \rightarrow X_{j}$ $(j=1,2,3)$ the operators given by $P_{j}\left(x_{1} \oplus x_{2} \oplus x_{3}\right)=x_{j}$. It is clear that $P_{1} \mathcal{L}=X_{1}$ and $P_{3} \mathcal{L}=X_{3}$. Since $U$ is surjective we have $P_{2} \mathcal{L}=X_{2}$, as well. Note that $\mathcal{L} \notin \operatorname{Lat}(Q)$. Namely, if $x=x_{1} \oplus U x_{1} \oplus x_{3} \in \mathcal{L}$ is such that $U x_{1} \neq 0$, then $Q x=x_{1} \oplus 0 \oplus 0 \notin \mathcal{L}$.

Assume that $T \in \mathcal{C}(Q ; \mathcal{L})$. Let $\left[T_{i j}\right]_{i, j=1}^{3}$ be its operator matrix with respect to the decomposition $\mathcal{X}=X_{1} \oplus \mathcal{X}_{2} \oplus X_{3}$. For an arbitrary $x=x_{1} \oplus U x_{1} \oplus x_{3} \in \mathcal{L}$, we have $T Q x=T_{11} x_{1} \oplus T_{21} x_{1} \oplus T_{31} x_{1}$ and $Q T x=\left(T_{11} x_{1}+T_{12} U x_{1}+T_{13} x_{3}\right) \oplus 0 \oplus 0$. Since $x_{1} \in X_{1}$ and $x_{3} \in X_{3}$ are arbitrary and $U$ is surjective it follows from $T Q x=Q T x$ that $T_{21}=0$, $T_{31}=0, T_{12}=0$ and $T_{13}=0$. Hence $T \in(Q)^{\prime}$, that is $\mathcal{C}(Q ; \mathcal{L})=(Q)^{\prime} ;$ in particular, $\mathcal{C}(Q ; \mathcal{L})$ is an algebra.

Note that this example shows that $\mathcal{C}(A ; \mathcal{M})$ and $(A)^{\prime}$ can be equal for an operator which is not a scalar multiple of $I_{x}$ and $\mathcal{M} \neq X$ which is not invariant for $A$ (cf. Corollary 2.4).

Although that the condition $\mathcal{M} \in \operatorname{Lat}(A)$ does not need to be fulfilled for $\mathcal{C}(A ; \mathcal{N})$ being an algebra the invariance is not far away as we shall see in the following section.

## 3. Multiplicative structure of the space of local intertwiners

Let $A \in B(\mathcal{X})$ and let $\mathcal{M} \subseteq \mathcal{X}$ be a closed subspace. We know that $\mathcal{C}(A ; \mathcal{M})$ is not an algebra in general. However it has some non-trivial multiplicative structure. For instance, let $T \in(A)^{\prime}$ be such that $\mathcal{M} \in \operatorname{Lat}(T)$. Then $A S T x=S A T x=S T A x$ for all $S \in \mathcal{C}(A ; \mathcal{M})$ and $x \in \mathcal{M}$. Hence, $\mathcal{C}(A ; \mathcal{M}) T \subseteq \mathcal{C}(A ; \mathcal{M})$. The following proposition is a generalization of this simple observation.

Proposition 3.1. Let $A \in B(\mathcal{X}), B \in B(y)$ and let $\mathcal{M} \subseteq X$ be a closed subspace. Inclusion $\mathcal{J}(A, B ; \overline{T \mathcal{M}}) T \subseteq \mathcal{J}(A, B ; \mathcal{M})$ holds for every $T \in \mathcal{C}(A ; \mathcal{M})$. If $T$ is invertible, then $\mathcal{J}(A, B ; \overline{T \mathcal{M}}) T=\mathcal{J}(A, B ; \mathcal{M})$.

Proof. Let $T \in \mathcal{C}(A ; \mathcal{N})$. For arbitrary $S \in \mathcal{J}(A, B ; \overline{T \mathcal{M}})$ and $x \in \mathcal{M}$, we have $S T A x=$ $S A T x=B S T x$ and therefore $S T \in \mathcal{J}(A, B ; \mathcal{M})$.

Assume now that $T \in \mathcal{C}(A ; \mathcal{M})$ is invertible. Let $S \in \mathcal{J}(A, B ; \mathcal{M})$ be arbitrary. Then for every $x \in \mathcal{M}$ we have $S T^{-1} A T x=S A x=B S x=B S T^{-1} T x$ which implies that $S T^{-1} \in \mathcal{J}(A, B ; \overline{T \mathcal{M}})$, that is, $S \in \mathcal{J}(A, B ; \overline{T \mathcal{M}}) T$.

For a non-empty set of operators $\mathcal{S} \subseteq B(\mathcal{X}, \mathcal{y})$ and a closed subspace $\mathcal{M} \subseteq X$, let $\mathcal{S M}$ denote the closed linear span in $y$ of all subspaces $S \mathcal{M}$, where $S \in \mathcal{S}$, that is, $\mathcal{S M}=\bigvee_{S \in \mathcal{S}} S \mathcal{M}$.

Theorem 3.2. Let $A \in B(X), B \in B(y)$ and let $\mathcal{M} \subseteq X$ be a closed subspace. Then $\mathcal{C}(B ; \mathcal{J}(A, B ; \mathcal{M}) \mathcal{M})$ is a subalgebra of $B(y)$ and it is the largest subalgebra of $B(y)$ such that $\mathcal{J}(A, B ; \mathcal{M})$ is a left module over it.

Proof. Let us show that $\mathcal{C}(B ; \mathcal{J}(A, B ; \mathcal{M}) \mathcal{M}) \cdot \mathcal{J}(A, B ; \mathcal{M}) \subseteq \mathcal{J}(A, B ; \mathcal{M})$. Assume that $T \in \mathcal{C}(B ; \mathcal{J}(A, B ; \mathcal{M}) \mathcal{M})$ and $S \in \mathcal{J}(A, B ; \mathcal{M})$. For every $x \in \mathcal{M}$, we have $B S x=S A x$ and therefore $B T S x=T B S x=T S A x$ because $S x \in \mathcal{J}(A, B ; \mathcal{M}) \mathcal{M}$. We conclude that $T S \in \mathcal{J}(A, B ; \mathcal{M})$.

Let $T_{1}, T_{2} \in \mathcal{C}(B ; \mathcal{J}(A, B ; \mathcal{M}) \mathcal{M})$. If $S \in \mathcal{J}(A, B ; \mathcal{M})$, then $T_{2} S \in \mathcal{J}(A, B ; \mathcal{M})$, by the inclusion from the previous paragraph, and, by the same reason, $T_{1} T_{2} S \in \mathcal{J}(A, B ; \mathcal{N})$. Hence, for every $S \in \mathcal{J}(A, B ; \mathcal{N})$ and every $x \in \mathcal{M}$, we have $B T_{1} T_{2} S x=T_{1} T_{2} S A x=$ $T_{1} T_{2} B S x$. Because of linearity and countinuity we may conclude that $T_{1} T_{2}$ commutes with $B$ on the subspace $\mathcal{J}(A, B ; \mathcal{N}) \mathcal{M}$ of $y$, that is, $T_{1} T_{2} \in \mathcal{C}(B ; \mathcal{J}(A, B ; \mathcal{N}) \mathcal{M})$. Thus, $\mathcal{C}(B ; \mathcal{J}(A, B ; \mathcal{M}) \mathcal{M})$ is a subalgebra of $\mathcal{B}(y)$ and $\mathcal{J}(A, B ; \mathcal{N})$ is a left module over it.

Assume that $T \in B(\mathcal{y})$ is such that $T \mathcal{J}(A, B ; \mathcal{M}) \subseteq \mathcal{J}(A, B ; \mathcal{M})$. Let $S \in \mathcal{J}(A, B ; \mathcal{M})$ and $x \in \mathcal{M}$ be arbitrary. Then $B T S x=T S A x=T B S x$ which implies $T \in \mathcal{C}(B ; \mathcal{J}(A, B ; \mathcal{M}) \mathcal{M})$. This shows that $\mathcal{C}(B ; \mathcal{J}(A, B ; \mathcal{M}) \mathcal{M})$ is the largest subalgebra of $B(y)$ such that $\mathcal{J}(A, B ; \mathcal{N})$ is a left module over it.

Corollary 3.3. Let $A \in B(X)$ and let $\mathcal{N} \subseteq X$ be a closed subspace. Then $\mathcal{C}(A ; \mathcal{C}(A ; \mathcal{N}) \mathcal{M})$ is the largest algebra contained in $\mathcal{C}(A ; \mathcal{M})$. If $\mathcal{M} \in \operatorname{Lat}(\mathcal{C}(A ; \mathcal{M}))$, then $\mathcal{C}(A ; \mathcal{N})$ is an algebra.

Proof. By Theorem 3.2, $\mathcal{C}(A ; \mathcal{C}(A ; \mathcal{M}) \mathcal{M})$ is the largest algebra contained in $\mathcal{C}(A ; \mathcal{N})$. If $\mathcal{M} \in \operatorname{Lat}(\mathcal{C}(A ; \mathcal{N}))$, then $\mathcal{C}(A ; \mathcal{M}) \mathcal{M}=\mathcal{M}$ and therefore $\mathcal{C}(A ; \mathcal{N})$ is an algebra.

Now we consider the right module structure of $\mathcal{J}(A, B ; \mathcal{M})$. Let $A \in B(\mathcal{X}), B \in B(y)$ and let $\mathcal{S} \subseteq B(X, y)$ be an arbitrary set of operators. It is clear that every $S \in \mathcal{S}$
intertwines $A$ and $B$ at vector 0 , that is, $\mathcal{S} \subseteq \mathcal{J}(A, B ;\{0\})$. Hence, the family $\mathcal{F}$ of all closed subspaces $\mathcal{M} \subseteq \mathcal{X}$ such that $\mathcal{S} \subseteq \mathcal{J}(A, B ; \mathcal{N})$ is not empty. Let $\mathcal{M}_{\mathcal{S}}=\bigvee_{\mathcal{M} \in \mathcal{F}} \mathcal{M}$. By (2), $\mathcal{S} \subseteq \bigcap_{\mathcal{M} \in \mathcal{F}} \mathcal{J}(A, B ; \mathcal{M})=\mathcal{J}\left(A, B ; \mathcal{M}_{\mathcal{S}}\right)$, that is, $\mathcal{M}_{\mathcal{S}} \in \mathcal{F}$. Of course, $\mathcal{M}_{\mathcal{S}}$ is the largest subspace in $\mathcal{F}$. In particular, there exists the largest subspace $\mathcal{M}_{\mathcal{J}(A, B ; \mathcal{M})}$ of $\mathcal{X}$ on which all operators from $\mathcal{J}(A, B ; \mathcal{N})$ intertwine $A$ and $B$. We will simplify the notation to $\mathcal{M}_{A, B}$ instead of $\mathcal{M}_{\mathcal{J}(A, B ; \mathcal{M})}$ (and $\mathcal{M}_{A}$ instead of $\mathcal{M}_{A, A}$ if $\mathcal{X}=\mathcal{y}$ and $A=B$ ) and we will call this subspace a girder, more precisely, $\mathcal{M}_{A, B}$ is the girder of $\mathcal{J}(A, B ; \mathcal{M})$ (and $\mathcal{M}_{A}$ is the girder of $\mathcal{C}(A ; \mathcal{N}))$ induced by $\mathcal{M}$. Of course, $\mathcal{X}$ is the girder of $\mathcal{J}(A, B)$. On the other hand, $\{0\}$ is not necessary a girder - think about $I_{x}$. However, by Proposition 2.2, $\{0\}$ is the girder of $\mathcal{C}(A ;\{0\})=B(X)$ if $A$ is not a scalar multiple of $I_{x}$.

It is clear that $\bigcap_{S \in \mathcal{J}(A, B ; \mathcal{M})} \operatorname{ker}(B S-S A)$ is a closed subspace of $\mathcal{X}$ such that $B S x=S A x$ for every $x$ in this subspace. Hence $\bigcap_{S \in \mathcal{J}(A, B ; \mathcal{M})} \operatorname{ker}(B S-S A) \subseteq \mathcal{M}_{A, B}$. On the other hand, if $x \in \mathcal{M}_{A, B}$, then $B S x=S A x$ for every $S \in \mathcal{J}(A, B ; \mathcal{M})$, by the definition of $\mathcal{M}_{A, B}$. Hence,

$$
\begin{equation*}
\mathcal{M}_{A, B}=\bigcap_{S \in \mathcal{J}(A, B ; \mathcal{M})} \operatorname{ker}(S A-B S) \tag{12}
\end{equation*}
$$

It follows that

$$
\begin{equation*}
\mathcal{J}\left(A, B ; \mathcal{M}_{A, B}\right)=\mathcal{J}(A, B ; \mathcal{M}) \quad \text { and } \quad\left(\mathcal{M}_{A, B}\right)_{A, B}=\mathcal{M}_{A, B} \tag{13}
\end{equation*}
$$

Indeed, since $\mathcal{N} \subseteq \mathcal{M}_{A, B}$ we have $\mathcal{J}\left(A, B ; \mathcal{M}_{A, B}\right) \subseteq \mathcal{J}(A, B ; \mathcal{M})$. On the other hand, the opposite inclusion follows by (12). Thus, $\mathcal{J}\left(A, B ; \mathcal{M}_{A, B}\right)=\mathcal{J}(A, B ; \mathcal{M})$ and therefore $\left(\mathcal{M}_{A, B}\right)_{A, B}=\mathcal{M}_{A, B}$, by (12).

Proposition 3.4. Let $A \in B(\mathcal{X}), B \in B(y)$ and let $\mathcal{K}, \mathcal{N} \subseteq X$ be closed subspaces. If $\mathcal{M} \subseteq \mathcal{K}$, then $\mathcal{M}_{A, B} \subseteq \mathcal{K}_{A, B}$. In particular, if $\mathcal{M} \subseteq \mathcal{K} \subseteq \mathcal{M}_{A, B}$, then $\mathcal{M}_{A, B}=\mathcal{K}_{A, B}$ and therefore $\mathcal{J}\left(A, B ; \mathcal{M}_{A, B}\right)=\mathcal{J}(A, B ; \mathcal{K})$.

Proof. Assume that $\mathcal{M} \subseteq \mathcal{K}$. Then $\mathcal{J}(A, B ; \mathcal{M}) \supseteq \mathcal{J}(A, B ; \mathcal{K})$. Hence, if $x \in \mathcal{M}_{A, B}$, then $S A x=B S x$ for every $S \in \mathcal{J}(A, B ; \mathcal{K})$ and therefore $x \in \mathcal{K}_{A, B}$.

If $\mathcal{M} \subseteq \mathcal{K} \subseteq \mathcal{M}_{A, B}$, then $\mathcal{J}(A, B ; \mathcal{M}) \supseteq \mathcal{J}(A, B ; \mathcal{K}) \supseteq \mathcal{J}\left(A, B ; \mathcal{M}_{A, B}\right)=\mathcal{J}(A, B ; \mathcal{M})$, that is, $\mathcal{J}\left(A, B ; \mathcal{M}_{A, B}\right)=\mathcal{J}(A, B ; \mathcal{K})$. It follows from this and the definition of $\mathcal{K}_{A, B}$ that $\mathcal{K}_{A, B}=\mathcal{M}_{A, B}$.

For a closed subspace $\mathcal{M} \subseteq \mathcal{X}$, we denote by $\operatorname{Alg}(\mathcal{M})$ the algebra of all operators $T \in B(\mathcal{X})$ such that $\mathcal{M} \in \operatorname{Lat}(T)$.

Theorem 3.5. Let $A \in B(\mathcal{X}), B \in B(\mathcal{Y})$ and let $\mathcal{M} \subseteq \mathcal{X}$ be a closed subspace. Then $\mathcal{C}\left(A ; \mathcal{M}_{A, B}\right) \cap \operatorname{Alg}\left(\mathcal{M}_{A, B}\right)$ is a subalgebra of $B(\mathcal{X})$ and $\mathcal{J}(A, B ; \mathcal{M})$ is a right module over it. If $\mathcal{X}=\mathcal{y}$ and $A=B$, then $\mathcal{C}\left(A ; \mathcal{M}_{A}\right) \cap \operatorname{Alg}\left(\mathcal{M}_{A}\right)$ is the largest subalgebra of $B(\mathcal{X})$ such that $\mathcal{E}(A ; \mathcal{M})$ is a right module over it.

Proof. Recall that $\mathcal{M} \subseteq \mathcal{M}_{A, B}$, by the definition of $\mathcal{M}_{A, B}$, and $\mathcal{J}(A, B ; \mathcal{M})=\mathcal{J}\left(A, B ; \mathcal{M}_{A, B}\right)$, by (13). Let $S \in \mathcal{J}(A, B ; \mathcal{M})$ and $T \in \mathcal{C}\left(A ; \mathcal{M}_{A, B}\right) \cap \operatorname{Alg}\left(\mathcal{N}_{A, B}\right)$ be arbitrary. If $x \in \mathcal{M}$, then $S T A x=S A T x=B S T x$. The first equality holds because of $T \in \mathcal{C}\left(A ; \mathcal{M}_{A, B}\right)$ and the second because of $T x \in \mathcal{M}_{A, B}$ and $S \in \mathcal{J}\left(A, B ; \mathcal{M}_{A, B}\right)$. We have proved that

$$
\mathcal{J}(A, B ; \mathcal{M}) \cdot\left(\mathcal{C}\left(A ; \mathcal{M}_{A, B}\right) \cap \operatorname{Alg}\left(\mathcal{M}_{A, B}\right)\right) \subseteq \mathcal{J}(A, B ; \mathcal{M})
$$

If $T_{1}, T_{2} \in \mathcal{C}\left(A ; \mathcal{M}_{A, B}\right) \cap \operatorname{Alg}\left(\mathcal{M}_{A, B}\right)$, then, of course, $T_{1} T_{2} \in \operatorname{Alg}\left(\mathcal{M}_{A, B}\right)$. Let $x \in \mathcal{M}_{A, B}$ be arbitrary. Since $T_{2} \in \mathcal{C}\left(A ; \mathcal{M}_{A, B}\right)$ we have $T_{1} T_{2} A x=T_{1} A T_{2} x$. Because of $T_{2} x \in \mathcal{M}_{A, B}$ we have $A T_{1} T_{2} x=T_{1} A T_{2} x$, as well. Hence, $T_{1} T_{2} A x=A T_{1} T_{2} x$ for every $x \in \mathcal{M}_{A, B}$, that is, $T_{1} T_{2} \in \mathcal{C}\left(A ; \mathcal{M}_{A, B}\right)$. We have proved that $\mathcal{C}\left(A ; \mathcal{M}_{A, B}\right) \cap \operatorname{Alg}\left(\mathcal{M}_{A, B}\right)$ is a subalgebra of $B(\mathcal{X})$ and $\mathcal{J}(A, B ; \mathcal{N})$ is a right module over it.

Assume now that $x=y$ and $A=B$. By the first part of the proof we already know that $\mathcal{C}\left(A ; \mathcal{M}_{A}\right) \cap \operatorname{Alg}\left(\mathcal{M}_{A}\right)$ is a subalgebra of $B(\mathcal{X})$ and $\mathcal{C}\left(A ; \mathcal{M}_{A}\right)$ is a right module over it. Let $T \in B(\mathcal{X})$ be an arbitrary operator such that $\mathcal{E}\left(A ; \mathcal{M}_{A}\right) T \subseteq \mathcal{C}\left(A ; \mathcal{M}_{A}\right)$. Since $(A)^{\prime} \subseteq$ $\mathcal{C}\left(A ; \mathcal{M}_{A}\right)$ and $(A)^{\prime}$ contains the identity operator $I$ we see that $T \in \mathcal{C}\left(A ; \mathcal{M}_{A}\right)$. Let $x \in \mathcal{M}_{A}$ and $S \in \mathcal{C}\left(A ; \mathcal{M}_{A}\right)$ be arbitrary. Then $S A T x=S T A x$. Because of $S T \in \mathcal{C}\left(A ; \mathcal{M}_{A}\right)$ we also have $A S T x=S T A x$. Hence $(S A-A S) T x=0$ for all $S \in \mathcal{C}\left(A ; \mathcal{M}_{A}\right)$ which means, see (121), that $T x \in \mathcal{M}_{A}$. This proves that $T \in \operatorname{Alg}\left(\mathcal{M}_{A}\right)$. Thus, $\mathcal{C}\left(A ; \mathcal{M}_{A}\right) \cap \operatorname{Alg}\left(\mathcal{M}_{A}\right)$ is the largest subalgebra of $B(\mathcal{X})$ such that $\mathcal{C}(A ; \mathcal{N})$ is a right module over it.

In the following theorem we list equivalent conditions for $\mathcal{C}(A ; \mathcal{N})$ being an algebra.

Theorem 3.6. Let $A \in B(\mathcal{X}), A \neq \lambda I_{x}$ for every $\lambda \in \mathbb{C}$, and let $\mathcal{M} \subseteq \mathcal{X}$ be a closed subspace. The following assertions are equivalent:
(i) $\mathcal{C}(A ; \mathcal{N})$ is an algebra;
(ii) $\mathcal{C}(A ; \mathcal{N}) \mathcal{M} \subseteq \mathcal{M}_{A}$;
(iii) $\mathcal{E}(A ; \mathcal{N}) \mathcal{M}=\mathcal{M}_{A}$;
(iv) $\mathcal{M}_{A} \in \operatorname{Lat}(\mathcal{C}(A ; \mathcal{M}))$.

Proof. (i) $\Rightarrow$ (ii). Let $S, T \in \mathcal{C}(A ; \mathcal{N})$ be arbitrary. Since $S T \in \mathcal{C}(A ; \mathcal{N})$ we have $(S A-A S) T x=S T A x-S T A x=0$ for every $x \in \mathcal{M}$. Hence, $T x \in \operatorname{ker}(S A-A S)$. Since $S \in \mathcal{C}(A ; \mathcal{N})$ is arbitrary we have $T x \in \mathcal{M}_{A}$ which means that $T \mathcal{M} \subseteq \mathcal{M}_{A}$. Now we may conclude that $\mathcal{E}(A ; \mathcal{M}) \mathcal{M} \subseteq \mathcal{M}_{A}$.
(ii) $\Rightarrow$ (iii). If $\mathcal{C}(A ; \mathcal{M}) \mathcal{M}=\mathcal{X}$, then $\mathcal{C}(A ; \mathcal{M}) \mathcal{M}=\mathcal{M}_{A}$, of course. Assume therefore that $\mathcal{C}(A ; \mathcal{M}) \mathcal{M} \neq \mathcal{X}$. Then there exist $z \in \mathcal{X} \backslash \mathcal{C}(A ; \mathcal{M}) \mathcal{M}$ and $\xi \in(\mathcal{C}(A ; \mathcal{M}) \mathcal{M})^{\perp}$ such that $\langle z, \xi\rangle=1$. Since $A$ is not a scalar multiple of $I_{x}$ there exists $0 \neq y \in X$ which is not an eigenvector of $A$. Since $A x \in \mathcal{C}(A ; \mathcal{H}) \mathcal{M}$ whenever $x \in \mathcal{C}(A ; \mathcal{M}) \mathcal{M}$ we have $A(y \otimes \xi) x=0=(y \otimes \xi) A x$ for every $x \in \mathcal{C}(A ; \mathcal{M}) \mathcal{M}$. Hence, $y \otimes \xi \in \mathcal{C}(A ; \mathcal{M})$. It follows from $A(y \otimes \xi) z=A y$ and $(y \otimes \xi) A z=\langle A z, \xi\rangle y$ and the assumption that $y$ is not an eigenvector of $A$ that $A(y \otimes \xi) z \neq(y \otimes \xi) A z$ which implies $z \notin \mathcal{M}_{A}$.
(iii) $\Rightarrow$ (i). Let $S, T \in \mathcal{C}(A ; \mathcal{N})$ be arbitrary. Then, for every $x \in \mathcal{M}$, we have $(S T A-A S T) x=S A T x-S A T x=0$ since it follows by the assumption that $T x \in \mathcal{M}_{A}$ and we already know, see (13), that $\mathcal{C}(A ; \mathcal{M})=\mathcal{C}\left(A ; \mathcal{M}_{A}\right)$. Hence, $S T \in \mathcal{C}(A ; \mathcal{M})$.
(i) $\Rightarrow(i v)$. Since $\mathcal{C}(A ; \mathcal{M})=\mathcal{C}\left(A ; \mathcal{M}_{A}\right)$ we have $\mathcal{C}\left(A ; \mathcal{M}_{A}\right) \mathcal{M}_{A} \subseteq\left(\mathcal{M}_{A}\right)_{A}=\mathcal{M}_{A}$, by the equivalence of assertions (i) and (ii). Hence, $\mathcal{M}_{A} \in \operatorname{Lat}(\mathcal{C}(A ; \mathcal{M}))$.
(iv) $\Rightarrow(i)$. If $\mathcal{M}_{A} \in \operatorname{Lat}(\mathcal{C}(A ; \mathcal{M}))$, then $\mathcal{C}(A ; \mathcal{M}) \mathcal{M} \subseteq \mathcal{C}(A ; \mathcal{M}) \mathcal{M}_{A} \subseteq \mathcal{M}_{A}$ and therefore $\mathcal{C}(A ; \mathcal{M})$ is an algebra, by equivalence of assertions (i) and (ii).

## 4. Ultrainvariant subspaces

We begin this section with a definition.
Definition 4.1. A closed subspace $\mathcal{M} \subseteq \mathcal{X}$ is ultrainvariant for $A \in B(X)$ if it is invariant for every operator in $\mathcal{C}(A ; \mathcal{M})$.

Hence, every ultrainvariant subspace of $A$ is a hyperinvariant subspace, as well. We will see that the opposite implication does not hold in general. For instance, if $A \neq 0$ is a nilpotent operator, then $\overline{\operatorname{im}\left(A^{k}\right)}$ is a hyperinvariant subspace of $A$ for every $k \in \mathbb{N}$, however it is not necessary an ultrainvariant subspace (see Theorem 5.11).

Proposition 4.2. Let $A \in B(X), A \neq \lambda I_{x}$ for every $\lambda \in \mathbb{C}$. A closed subspace $\mathcal{M} \subseteq X$ is ultrainvariant for $A$ if and only if $\mathcal{C}(A ; \mathcal{M})$ is an algebra and $\mathcal{M}$ is its girder.

Proof. Assume that $\mathcal{M}$ is an ultrainvariant subspace of $A$. Let $T_{1}, T_{2} \in \mathcal{C}(A ; \mathcal{N})$ be arbitrary. Then $T_{1} T_{2} A x=T_{1} A T_{2} x=A T_{1} T_{2} x$ for every $x \in \mathcal{M}$ because $T_{2} x \in \mathcal{M}$. Thus,
$\mathcal{C}(A ; \mathcal{M})$ is an algebra. By Theorem 3.6, $\mathcal{C}(A ; \mathcal{M}) \mathcal{M}=\mathcal{M}_{A}$. However, $\mathcal{C}(A ; \mathcal{M}) \mathcal{M}=\mathcal{M}$ as $\mathcal{M}$ is invariant for every operator in $\mathcal{C}(A ; \mathcal{M})$, that is, $\mathcal{M}=\mathcal{M}_{A}$. The opposite implication follows by Theorem 3.6.

Subspaces $\{0\}$ and $X$ are trivial ultrainvariant subspaces of every $A \in B(X)$. If $A$ is a scalar multiple of $I_{x}$, then it is obvious that $A$ has only trivial ultrainvariant subspaces as it has only trivial hyperinvariant subspaces.

In this section we will prove a few general results about ultrainvariant subspaces. Examples of ultrainvariant subspaces for some classes of operators will be given in sections that follow.

Proposition 4.3. Let $A \in B(X)$ and let $U \in B(X)$ be an invertible operator. A closed subspace $\mathcal{M} \subseteq \mathcal{X}$ is an ultrainvariant subspace of $A$ if and only if $U \mathcal{M}$ is an ultrainvariant subspace of $U A U^{-1}$.

Proof. Assume that $\mathcal{N}$ is ultrainvariant. By (11), every operator in $\mathcal{C}\left(U A U^{-1} ; U \mathcal{N}\right)$ is of the form $U T U^{-1}$ for some $T \in \mathcal{C}(A ; \mathcal{N})$. Hence, for every $x \in \mathcal{M}$, we have $\left(U T U^{-1}\right)(U x)=$ $U T x \in U \mathcal{M}$, that is, $U \mathcal{M}$ is invariant for every operator from $\mathcal{C}\left(U A U^{-1} ; U \mathcal{M}\right)$ and is therefore ultrainvariant. It is clear that the opposite implication holds, as well.

Recall that a closed subspace $X_{1} \subseteq X$ is reducing for $A \in B(X)$ if $X_{1} \in \operatorname{Lat}(A)$ and there exists $X_{2} \in \operatorname{Lat}(A)$ such that $X=X_{1} \oplus X_{2}$. In this case we will say that $\left(\mathcal{X}_{1}, X_{2}\right)$ is a reducing pair for $A$. Note that $A=A_{1} \oplus A_{2}$ with respect to the decomposition $\mathcal{X}=X_{1} \oplus X_{2}$. Let $P_{j}: \mathcal{X} \rightarrow X_{j}(j=1,2)$ be given by $P_{1}\left(x_{1} \oplus x_{2}\right)=x_{1}$ and $P_{2}\left(x_{1} \oplus x_{2}\right)=x_{2}$.

Proposition 4.4. Let $A \in B(\mathcal{X})$ and let $\left(\mathcal{X}_{1}, \mathcal{X}_{2}\right)$ be a reducing pair for $A$. If $\mathcal{M}$ is an ultrainvariant subspace of $A$, then $\mathcal{N}_{j}=P_{j} \mathcal{M}$ is an ultrainvariant subspace of $A_{j}$ ( $j=1,2$ ).

Proof. Assume that $\mathcal{M}=\mathcal{M}_{1} \oplus \mathcal{M}_{2}$ is ultrainvariant. Let $T_{1} \in \mathcal{C}\left(A_{1} ; \mathcal{M}_{1}\right)$ be arbitrary and let $T \in B(X)$ be such that $T=T_{1} \oplus 0$ with respect to the decomposition $X=X_{1} \oplus X_{2}$. For an arbitrary $x=x_{1} \oplus x_{2} \in \mathcal{N}$, we have $T A x=T_{1} A_{1} x_{1} \oplus 0=A_{1} T_{1} x_{1} \oplus 0=A T x$ which means that $T \in \mathcal{C}(A ; \mathcal{M})$. Since $\mathcal{M}$ is ultrainvariant it is invariant for $T$. In particular, for every $x_{1} \in \mathcal{M}_{1}$ we have $T\left(x_{1} \oplus 0\right)=T_{1} x_{1} \oplus 0 \in \mathcal{M}_{1} \oplus \mathcal{M}_{2}$, that is, $\mathcal{M}_{1}$ is invariant for $T_{1} \in \mathcal{C}\left(A_{1} ; \mathcal{M}_{1}\right)$. We have seen that $\mathcal{M}_{1}$ is an ultrainvariant subspace of $A_{1}$ and a similar proof shows that $\mathcal{M}_{2}$ is an ultrainvariant subspace of $A_{2}$.

Let $n \geq 2$ be an integer. For every $j \in\{1, \ldots, n\}$, let $X_{j}$ be a Banach space and $A_{j} \in B\left(X_{j}\right)$. Denote $X=X_{1} \oplus \cdots \oplus X_{n}$ and $A=A_{1} \oplus \cdots \oplus A_{n}$. Let $\mathcal{M}_{j} \subseteq X_{j}$ be a complemented closed subspace and let $\mathcal{N}_{j} \subseteq X_{j}$ be a closed subspace such that $X_{j}=$ $\mathcal{M}_{j} \oplus \mathcal{N}_{j}$. Let $\left[\begin{array}{ll}A_{11}^{(j)} & A_{1}^{(j)} \\ A_{21}^{(j)} & A_{22}^{(j)}\end{array}\right]$ be the operator matrix of $A_{j}$ with respect to the decomposition $X_{j}=\mathcal{M}_{j} \oplus \mathcal{N}_{j}$.

Proposition 4.5. If, for every $j \in\{1, \ldots, n\}, \mathcal{N}_{j}$ is an ultrainvariant subspace of $A_{j}$ and $\sigma\left(A_{11}^{(i)}\right) \cap \sigma\left(A_{j}\right)=\emptyset$ whenever $i \neq j$, then $\mathcal{M}:=\mathcal{M}_{1} \oplus \cdots \oplus \mathcal{M}_{n}$ is an ultrainvariant subspace of $A$.

Proof. It is enough to consider the case $n=2$. We will identify $X$ with $\mathcal{M}_{1} \oplus \mathcal{N}_{1} \oplus \mathcal{M}_{2} \oplus \mathcal{N}_{2}$. Then $\mathcal{M}=\mathcal{M}_{1} \oplus\{0\} \oplus \mathcal{M}_{2} \oplus\{0\}$. With respect to the decomposition $\mathcal{X}=\mathcal{M}_{1} \oplus \mathcal{N}_{1} \oplus \mathcal{M}_{2} \oplus \mathcal{N}_{2}$, operator $A$ has operator matrix

$$
\left[\begin{array}{cccc}
A_{11}^{(1)} & A_{12}^{(1)} & 0 & 0 \\
0 & A_{22}^{(1)} & 0 & 0 \\
0 & 0 & A_{11}^{(2)} & A_{12}^{(2)} \\
0 & 0 & 0 & A_{22}^{(2)}
\end{array}\right] .
$$

Let $T \in \mathcal{C}(A ; \mathcal{M})$ be arbitrary and let $\left[T_{i j}\right]_{i, j=1}^{4}$ be its operator matrix with respect to the decomposition $\mathcal{X}=\mathcal{M}_{1} \oplus \mathcal{N}_{1} \oplus \mathcal{M}_{2} \oplus \mathcal{N}_{2}$. Hence, $T A x=A T x$ for every $x=x_{1} \oplus 0 \oplus x_{2} \oplus 0 \in$ $\mathcal{M}$. If $x=x_{1} \oplus 0 \oplus 0 \oplus 0$, where $x_{1} \in \mathcal{M}_{1}$ is arbitrary, then it follows from $T A x=A T x$ that

$$
\begin{align*}
& T_{11} A_{11}^{(1)}=A_{11}^{(1)} T_{11}+A_{12}^{(1)} T_{21} \\
& T_{21} A_{11}^{(1)}=A_{22}^{(1)} T_{21} \\
& T_{31} A_{11}^{(1)}=A_{11}^{(2)} T_{31}+A_{12}^{(2)} T_{41}  \tag{14}\\
& T_{41} A_{11}^{(1)}=A_{22}^{(2)} T_{41} .
\end{align*}
$$

Let $W_{11} \in B\left(\mathcal{X}_{1}\right)$ be the operator whose operator matrix with respect to the decomposition $\mathcal{X}_{1}=\mathcal{M}_{1} \oplus \mathcal{N}_{1}$ is $\left[\begin{array}{cc}T_{11} & T_{12} \\ T_{21} & T_{22}\end{array}\right]$. The first two equalities in (14) give $W_{11} \in \mathcal{C}\left(A_{1} ; \mathcal{M}_{1}\right)$. Since $\mathcal{M}_{1}$ is an ultrainvariant subspace of $A_{1}$ it is invariant for $W_{11}$ and therefore $T_{21}=0$. Hence, by the first equality in (14), $T_{11} \in\left(A_{11}^{(1)}\right)^{\prime}$. Denote by $W_{21}$ the operator in $B\left(\mathcal{X}_{1}, \mathcal{X}_{2}\right)$ whose operator matrix with respect to the decompositions $X_{1}=\mathcal{N}_{1} \oplus \mathcal{N}_{1}$ and $X_{2}=\mathcal{N}_{2} \oplus \mathcal{N}_{2}$ is $\left[\begin{array}{ll}T_{31} & T_{32} \\ T_{41} & T_{42}\end{array}\right]$. It follows from the last two equalities in (14) that column $\left[\begin{array}{c}T_{31} \\ T_{41}\end{array}\right]$ intertwines $A_{11}^{(1)}$ and $A_{2}$. Since, by the assumption, $\sigma\left(A_{11}^{(1)}\right) \cap \sigma\left(A_{2}\right)=\emptyset$ we conclude that $T_{31}=0$ and $T_{41}=0$.

Let now $x_{2} \in \mathcal{M}_{2}$ be arbitrary and $x=0 \oplus 0 \oplus x_{2} \oplus 0$. A similar reasoning as in the previous paragraph shows that $T A x=A T x$ if and only if $T_{13}=0, T_{23}=0, T_{43}=0$ and $T_{33} \in\left(A_{11}^{(2)}\right)^{\prime}$. Hence, the operator matrix of $T$ with respect to the decomposition $X=\mathcal{M}_{1} \oplus \mathcal{N}_{1} \oplus \mathcal{M}_{2} \oplus \mathcal{N}_{2}$ is

$$
\left[\begin{array}{cccc}
T_{11} & T_{12} & 0 & T_{14} \\
0 & T_{22} & 0 & T_{24} \\
0 & T_{32} & T_{33} & T_{34} \\
0 & T_{42} & 0 & T_{44}
\end{array}\right]
$$

It is not hard to check now that $\mathcal{M}=\mathcal{M}_{1} \oplus\{0\} \oplus \mathcal{M}_{2} \oplus\{0\}$ is invariant for $T$. Since $T \in \mathcal{C}(A ; \mathcal{M})$ was arbitrary we conclude that $\mathcal{M}$ is an ultrainvariant subspace of $A$.

Proposition 4.6. Let $A \in B(\mathcal{X})$ and let $\mathcal{M} \subseteq \mathcal{X}$ be a closed subspace. Then

$$
\mathcal{C}(A ; \mathcal{C}(A ; \mathcal{M}) \mathcal{M}) \mathcal{C}(A ; \mathcal{M}) \mathcal{M}
$$

is the smallest ultrainvariant subspace of $A$ which contains $\mathcal{M}$.
Proof. By Corollary 3.3, $\mathcal{C}(A ; \mathcal{C}(A ; \mathcal{M}) \mathcal{M})$ is the largest algebra which is contained in $\mathcal{C}(A ; \mathcal{M})$. It follows, by Theorem 3.6, that $(\mathcal{C}(A ; \mathcal{M}) \mathcal{M})_{A}=\mathcal{C}(A ; \mathcal{C}(A ; \mathcal{M}) \mathcal{M}) \mathcal{C}(A ; \mathcal{M}) \mathcal{M}$ and $(\mathcal{C}(A ; \mathcal{M}) \mathcal{M})_{A}$ is an ultrainvariant subspace of $A$. It is clear that $\mathcal{M} \subseteq(\mathcal{C}(A ; \mathcal{M}) \mathcal{M})_{A}$.

Suppose that $\mathcal{K} \subseteq \mathcal{X}$ is an ultrainvariant subspace of $A$ such that $\mathcal{M} \subseteq \mathcal{K}$. Then $\mathcal{C}(A ; \mathcal{K})$ is an algebra and $\mathcal{C}(A ; \mathcal{M}) \supseteq \mathcal{C}(A ; \mathcal{K})$. Since $\mathcal{C}\left(A ;(\mathcal{C}(A ; \mathcal{M}) \mathcal{M})_{A}\right)=\mathcal{C}(A ; \mathcal{C}(A ; \mathcal{M}) \mathcal{M})$ is the largest algebra contained in $\mathcal{C}(A ; \mathcal{M})$ we have $\mathcal{C}(A ; \mathcal{K}) \subseteq \mathcal{C}(A ; \mathcal{C}(A ; \mathcal{M}) \mathcal{M})$. Hence, if $T \in \mathcal{C}(A ; \mathcal{K})$, then it commutes with $A$ at every vector from $\mathcal{C}(A ; \mathcal{M}) \mathcal{M}$ which means that $\mathcal{C}(A ; \mathcal{M}) \mathcal{M} \subseteq \mathcal{K}_{A}=\mathcal{K}$ and therefore $(\mathcal{C}(A ; \mathcal{M}) \mathcal{M})_{A} \subseteq \mathcal{K}$.

For $A \in B(X)$, let $\operatorname{Lat}_{u}(A)$ denote the family of all ultrainvariant subspaces of $A$.
Proposition 4.7. Let $A \in B(\mathcal{X})$ and let $\left\{\mathcal{N}_{j} ; j \in J\right\}$ be an arbitrary family of ultrainvariant subspaces of $A$. Then $\bigvee_{j \in J} \mathcal{M}_{j}$ and $\bigcap_{j \in J} \mathcal{M}_{j}$ are ultrainvariant subspaces of $A$. Hence, $\operatorname{Lat}_{u}(A)$ is a sublattice of $\operatorname{Lat}_{h}(A)$.

Proof. Denote $\mathcal{K}=\bigvee_{j \in J} \mathcal{M}_{j}$. By (2), we have $\mathcal{C}(A ; \mathcal{K})=\bigcap_{j \in J} \mathcal{C}\left(A ; \mathcal{M}_{j}\right)$. Hence, $\mathcal{M}_{j}(j \in J)$ is invariant for an arbitrary $T \in \mathcal{C}(A ; \mathcal{K})$. Assume that $x \in \mathcal{K}$ is such that $x=x_{1}+\cdots+x_{k}$, where $x_{i} \in \mathcal{M}_{j_{i}}(i=1, \ldots, k)$. Then $T x=T x_{1}+\cdots+T x_{k} \in \mathcal{M}_{j_{1}}+\cdots+\mathcal{M}_{j_{k}} \subseteq \mathcal{M}$. It follows that $T \mathcal{K} \subseteq \mathcal{K}$. Since $T \in \mathcal{C}(A ; \mathcal{K})$ is arbitrary we conclude that $\mathcal{K}$ is ultrainvariant.

Denote $\mathcal{L}=\bigcap_{j \in J} \mathcal{M}_{j}$ and let $\mathcal{L}^{\prime} \subseteq X$ be the smallest ultrainvariant subspace of $A$ such that $\mathcal{L} \subseteq \mathcal{L}^{\prime}$ (see Proposition4.61). Since, for every $j \in J, \mathcal{L} \subseteq \mathcal{M}_{j}$ and $\mathcal{M}_{j}$ is ultrainvariant
we have $\mathcal{L}^{\prime} \subseteq \mathcal{M}_{j}$. Hence $\mathcal{L}^{\prime} \subseteq \bigcap_{j \in J} \mathcal{M}_{j}=\mathcal{L}$, that is, $\mathcal{L}=\mathcal{L}^{\prime}$, i.e., $\mathcal{L}$ is an ultrainvariant subspace of $A$.

The following example shows that even when $\mathcal{M} \in \operatorname{Lat}(A)$ is the girder of $\mathcal{C}(A ; \mathcal{N})$ it is not necessary an ultrainvariant subspace of $A$, that is, $\mathcal{C}(A ; \mathcal{M})$ is not necessary an algebra.

Example 4.8. Let $X=X_{1} \oplus X_{2} \oplus X_{3}$, where $X_{j}(j=1,2,3)$ are non-trivial subspaces of $X$. Let $A$ be the projection on $X_{1} \oplus X_{2}$ along $X_{3}$ and let $\mathcal{M}=X_{1} \oplus\{0\} \oplus X_{3}$, that is, in $\mathcal{M}$ are vectors of the form $x_{1} \oplus 0 \oplus x_{3}$, where $x_{1} \in \mathcal{X}_{1}$ and $x_{3} \in X_{3}$ are arbitrary. Hence, $\mathcal{M}$ is a non-trivial subspace of $\mathcal{X}$ and $\mathcal{M} \in \operatorname{Lat}(A)$.

Let $T \in \mathcal{C}(A ; \mathcal{M})$ be arbitrary and let $\left[T_{i j}\right]_{i, j=1}^{3}$ be its operator matrix with respect to the decomposition $\mathcal{X}=X_{1} \oplus X_{2} \oplus X_{3}$. For every $x=x_{1} \oplus 0 \oplus x_{3} \in \mathcal{M}$, we have $T A x=T_{11} x_{1} \oplus T_{21} x_{1} \oplus T_{31} x_{1}$ and $A T x=\left(T_{11} x_{1}+T_{13} x_{3}\right) \oplus\left(T_{21} x_{1}+T_{23} x_{3}\right) \oplus 0$. It follows from $T A x=A T x$ that $T_{11} x_{1}=T_{11} x_{1}+T_{13} x_{3}, T_{21} x_{1}=T_{21} x_{1}+T_{23} x_{3}$ and $T_{31} x_{1}=0$ for all $x_{1} \in \mathcal{X}_{1}$ and $x_{3} \in X_{3}$. Thus, $T_{13}=0, T_{23}=0$ and $T_{31}=0$. An operator $T$ is in $\mathcal{C}(A ; \mathcal{M})$ if and only if its operator matrix with respect to the decomposition $X=X_{1} \oplus X_{2} \oplus X_{3}$ is of the form $\left[\begin{array}{ccc}T_{11} & T_{12} & 0 \\ T_{21} & 1 & T_{22} \\ 0 & T_{32} & T_{33}\end{array}\right]$, where $T_{i j} \in B\left(X_{j}, X_{i}\right)$ are arbitrary. It follows that $\mathcal{C}(A ; \mathcal{N})$ is not an algebra.

To determine $\mathcal{M}_{A}$, let $x=x_{1} \oplus x_{2} \oplus x_{3} \in \mathcal{X}$ be such that $T A x=A T x$ for every $T \in \mathcal{C}(A ; \mathcal{M})$. Since $T A x=\left(T_{11} x_{1}+T_{12} x_{2}\right) \oplus\left(T_{21} x_{1}+T_{22} x_{2}\right) \oplus T_{32} x_{2}$ and $A T x=$ $\left(T_{11} x_{1}+T_{12} x_{2}\right) \oplus\left(T_{21} x_{1}+T_{22} x_{2}\right) \oplus 0$ we see that $T_{32} x_{2}=0$ for every $T_{32} \in B\left(X_{2}, X_{3}\right)$. As the involved subspaces are non-trivial we conclude that $x_{2}=0$. This proves that $\mathcal{N}_{A}=\mathcal{M}$. However, $\mathcal{M}$ is not an ultrainvariant subspace of $A$ because $\mathcal{C}(A ; \mathcal{N})$ is not an algebra. Moreover, $\mathcal{C}(A ; \mathcal{M}) \mathcal{M}=\mathcal{X}$. Namely, let $x=x_{1} \oplus x_{2} \oplus x_{3}$ be an arbitrary vector from $X$. Let $y=y_{1} \oplus 0 \oplus y_{3} \in \mathcal{M}$ be such that $y_{1} \neq 0$ and $y_{3} \neq 0$. Then there exist $T_{11} \in B\left(X_{1}\right), T_{21} \in B\left(X_{1}, X_{2}\right)$ and $T_{33} \in B\left(X_{3}\right)$ such that $T_{11} y_{1}=x_{1}, T_{21} y_{1}=x_{2}$ and $T_{33} y_{3}=x_{3}$. It is clear that $T$ whose operator matrix with respect to the decomposition $X=X_{1} \oplus X_{2} \oplus X_{3}$ is $\left[\begin{array}{ccc}T_{1} & 0 & 0 \\ T_{21} & 0 & 0 \\ 0 & 0 & T_{33}\end{array}\right]$ is in $\mathcal{C}(A ; \mathcal{M})$ and $T y=x$.

## 5. Operators with non-trivial ultrainvariant subspaces

Let $A \in B(X)$ and assume that $\mathcal{M} \in \operatorname{Lat}(A)$ is complemented, say $X=\mathcal{M} \oplus \mathcal{N}$. Let $\left[\begin{array}{cc}A_{11} & A_{12} \\ 0 & A_{22}\end{array}\right]$ be the operator matrix of $A$ with respect this decomposition. Next proposition is basically a reformulation of Corollary 2.7.

Proposition 5.1. If $\sigma\left(A_{11}\right) \cap \sigma\left(A_{22}\right)=\emptyset$, then $\mathcal{M}$ is an ultrainvariant subspace of $A$.
Proof. If $\mathcal{M}$ is trivial, then there is nothing to prove. Assume therefore that $\{0\} \neq \mathcal{M} \neq \mathcal{X}$. By Corollary [2.7, $\mathcal{C}(A ; \mathcal{N})$ is an algebra. Hence, if $\left[\begin{array}{c}T_{11} T_{12} \\ T_{21} T_{22}\end{array}\right]$ is the operator matrix of $T \in \mathcal{C}(A ; \mathcal{N})$ with respect to the decomposition $\mathcal{X}=\mathcal{M} \oplus \mathcal{N}$, then $T_{11} \in\left(A_{11}\right)^{\prime}$ and $T_{21}=0$ by Theorem 2.5. It follows that $\mathcal{M}$ is invariant for every $T \in \mathcal{C}(A ; \mathcal{N})$.

Recall that the ascent $\alpha(A)$ of $A \in B(X)$ is the smallest positive integer $k$ such that $\operatorname{ker}\left(A^{k}\right)=\operatorname{ker}\left(A^{k+1}\right)$. If there is no positive integer with this property, then $\alpha(A)=\infty$. The descent $\delta(A)$ of $A$ is the smallest positive integer $k$ such that $\operatorname{im}\left(A^{k}\right)=\operatorname{im}\left(A^{k+1}\right)$ and $\delta(A)=\infty$ if there is no $k$ with this property. Assume that $A$ has finite ascent and descent. Then $\alpha(A)=n=\delta(A)$ for a positive integer $n$ and, by [1, Lemma 2.21], $\operatorname{im}\left(A^{n}\right)$ is a closed complement of $\operatorname{ker}\left(A^{n}\right)$, that is $\mathcal{X}=\operatorname{ker}\left(A^{n}\right) \oplus \operatorname{im}\left(A^{n}\right)$. Hence, $\left(\operatorname{ker}\left(A^{n}\right), \operatorname{im}\left(A^{n}\right)\right)$ is a reducing pair of $A$ and therefore $A=A_{1} \oplus A_{2}$, where $A_{1} \in B\left(\operatorname{ker}\left(A^{n}\right)\right)$ and $A_{2} \in$ $B\left(\operatorname{im}\left(A^{n}\right)\right)$. By [1, Theorem 2.23], $A_{1}$ is nilpotent and $A_{2}$ is invertible which implies $\sigma\left(A_{1}\right) \cap \sigma\left(A_{2}\right)=\emptyset$. It is clear now that the following corollary is a simple consequence of Proposition 5.1

Corollary 5.2. If $A \in B(\mathcal{X})$ has finite ascent and descent $n$, then $\operatorname{ker}\left(A^{n}\right)$ and $\operatorname{im}\left(A^{n}\right)$ are ultrainvariant subspaces of $A$.

It is not hard to see that for every $\lambda \in \mathbb{C}$ the $\operatorname{kernel} \operatorname{ker}\left(A-\lambda I_{x}\right)$ is an ultrainvariant subspace of $A \in B(X)$. Namely, if $T \in \mathcal{C}\left(A ; \operatorname{ker}\left(A-\lambda I_{x}\right)\right)$, then $A T x=T A x=\lambda T x$ for every $x \in \operatorname{ker}\left(A-\lambda I_{x}\right)$, that is, $\operatorname{ker}\left(A-\lambda I_{x}\right)$ is invariant for every $T \in \mathcal{C}\left(A ; \operatorname{ker}\left(A-\lambda I_{x}\right)\right)$. Hence, if $A$ is not a scalar multiple of $I_{x}$ and the point spectrum $\sigma_{p}(A)$ is not empty, then $A$ has a non-trivial ultrainvariant subspace. More can be said. We need the following lemma.

Lemma 5.3. Let $A \in B(X)$ and let $\mathcal{A} \subseteq B(X)$ be the strongly closed subalgebra generated by $A$ and $I_{x}$. If $\mathcal{M} \in \operatorname{Lat}(A)$, then $\mathcal{C}(A ; \mathcal{M}) \subseteq \mathcal{C}(B ; \mathcal{M})$ for every $B \in \mathcal{A}$.

Proof. Assume first that $B=A-\lambda I_{x}$, where $\lambda \in \mathbb{C}$ is such that $B$ is an invertible operator. Hence, $B \mathcal{M}=\mathcal{M}$. It is clear that $C(A ; \mathcal{M})=\mathcal{C}(B ; \mathcal{M})$. Let us check that $\mathcal{C}(B ; \mathcal{M}) \subseteq \mathcal{C}\left(B^{k} ; \mathcal{M}\right)$ for every integer $k \geq 0$. If $k=0$ or $k=1$, then the assertion is trivial. Since $B$ is invertible and $B \mathcal{M}=\mathcal{M}$ we have $\mathcal{C}(B ; \mathcal{N})=\mathcal{C}(B ; \mathcal{M}) B$, by Proposition 3.1. Hence, if $T \in \mathcal{C}(B ; \mathcal{M})$, then $T B \in \mathcal{C}(B ; \mathcal{M})$ and, by induction, $T B^{j} \in \mathcal{C}(B ; \mathcal{M})$ for
every $j \geq 2$. Let $k \geq 2$ and assume that $T B^{j} x=B^{j} T x$ holds for every $0 \leq j \leq k-1$ and every $x \in \mathcal{M}$. Then $T B^{k} x=B^{k-1} T B x$ and $T B x=B T x$ for every $x \in \mathcal{M}$. It follows that $T B^{k} x=B^{k} T x$ for every $x \in \mathcal{M}$. Since $A=B+\lambda I_{x}$ we conclude that

$$
T A^{k} x=T \sum_{j=0}^{k}\binom{k}{j} \lambda^{j} B^{k-j} x=\sum_{j=0}^{k}\binom{k}{j} \lambda^{j} B^{k-j} T x=A^{k} T x \quad \text { for every } x \in \mathcal{M} .
$$

It follows that $T p(A) x=p(A) T x$ for every $x \in \mathcal{M}$ and every polynomial $p \in \mathbb{C}[z]$. Let $B \in \mathcal{A}$ be arbitrary. Let $T \in \mathcal{C}(A ; \mathcal{M})$ and $x \in \mathcal{M}$. For every $\varepsilon>0$, there exists a polynomial $p$ such that $\|B x-p(A) x\|<\varepsilon$ and $\|B T x-p(A) T x\|<\varepsilon$. Hence $\| T B x-$ $B T x\|\leq\| T\|\|B x-p(A) x\|+\| B T x-p(A) T x \|<\varepsilon(\|T\|+1)$, which gives $T B x=B T x$.

Proposition 5.4. Let $A \in B(X)$ and let $\mathcal{A} \subseteq B(X)$ be the strongly closed subalgebra generated by $A$ and $I_{x}$. If $B \in \mathcal{A}$ and $\mathcal{M} \in \operatorname{Lat}(A)$ is an ultrainvariant subspace of $B$, then $\mathcal{M}$ is an ultrainvariant subspace of $A$. In particular, every kernel $\operatorname{ker}\left(B-\lambda I_{x}\right)$ $(\lambda \in \mathbb{C})$ is an ultrainvariant subspace of $A$.

Proof. By Lemma 5.3, $\mathcal{C}(A ; \mathcal{M}) \mathcal{M} \subseteq \mathcal{C}(B ; \mathcal{M}) \mathcal{M}=\mathcal{M}$. Thus, $\mathcal{M}$ is invariant for every operator from $\mathcal{C}(A ; \mathcal{M})$, that is, it is an ultrainvariant subspace of $A$.

It follows from the following proposition that a reducing subspace does not need to be ultrainvariant.

Proposition 5.5. Let $A \in B(\mathcal{X})$. Assume that $(\mathcal{M}, \mathcal{N})$ is a pair of reducing subspaces for A. Let $A$ be equal to $A_{\mathcal{M}} \oplus A_{\mathcal{N}}$ with respect to the decomposition $\mathcal{X}=\mathcal{M} \oplus \mathcal{N}$. Then $\mathcal{M}$ is an ultrainvariant subspace of $A$ if and only if $\mathcal{J}\left(A_{\mathcal{M}}, A_{\mathfrak{N}}\right)=\{0\}$.

Proof. Suppose that $\mathcal{M}$ is ultrainvariant and let $S \in \mathcal{J}\left(A_{\mathfrak{N}}, A_{\mathfrak{N}}\right)$ be arbitrary. Then $T(x \oplus$ $y)=0 \oplus S x$, where $x \in \mathcal{M}, y \in \mathcal{N}$ are arbitrary, defines a bounded linear operator on X. Since $A T(x \oplus 0)=0 \oplus A_{\mathcal{N}} S x=0 \oplus S A_{\mathcal{M}} x=T A(x \oplus 0)$ for all $x \in \mathcal{M}$ we have $T \in \mathcal{C}(A ; \mathcal{M})$. It follows from $T \mathcal{M} \subseteq \mathcal{M}$ that $S x=0$ for every $x \in \mathcal{M}$, that is, $S=0$.

Assume now that $\mathcal{J}\left(A_{\mathcal{M}}, A_{\mathcal{N}}\right)=\{0\}$. Let $T \in \mathcal{C}(A ; \mathcal{M})$ be arbitrary and let $\left[\begin{array}{cc}T_{11} & T_{12} \\ T_{21} \\ T_{22}\end{array}\right]$ be its operator matrix with respect to the decomposition $\mathcal{X}=\mathcal{M} \oplus \mathcal{N}$. It follows from $T A(x \oplus 0)=A T(x \oplus 0)$, where $x \in \mathcal{M}$ is arbitrary, that $T_{21} \in \mathcal{J}\left(A_{\mathfrak{N}}, A_{\mathfrak{N}}\right)$, that is, $T_{21}=0$. Hence, $\mathcal{M}$ is an ultrainvariant subspace of $A$.

Let $A \in B(X)$. A subset $\emptyset \subsetneq \sigma \subsetneq \sigma(A)$ is an isolated part of $\sigma(A)$ if both $\sigma$ and $\sigma(A) \backslash \sigma$ are closed sets. It is well-known, see [10, §I.2], that for an isolated part $\sigma$ of $\sigma(A)$ there
exists an idempotent $P_{\sigma} \in B(\mathcal{X})$, the Riesz projection of $A$ corresponding to $\sigma$, such that $\mathcal{M}=\operatorname{im}\left(P_{\sigma}\right)$ and $\mathcal{N}=\operatorname{im}\left(I-P_{\sigma}\right)$ are in $\operatorname{Lat}(A)$ and $\sigma\left(\left.A\right|_{\mathcal{M}}\right)=\sigma, \sigma\left(\left.A\right|_{\mathcal{N}}\right)=\sigma(A) \backslash \sigma$. Hence, the following result is an immediate consequence of Proposition 5.5.

Corollary 5.6. Let $A \in B(X)$. If $\sigma$ is an isolated part of $\sigma(A)$, then $\operatorname{im}\left(P_{\sigma}\right)$ is an ultrainvariant subspace of $A$.

Corollary 5.6 is a special case of the next result for which we need some notions from the local spectral theory. Let $A \in B(X)$ and $x \in \mathcal{X}$. The local resolvent set $\rho_{A}(x)$ of $A$ at $x$ is the union of all open subsets $U \subseteq \mathbb{C}$ for which there exists an analytic function $f: U \rightarrow X$ such that $\left(A-\lambda I_{x}\right) f(\lambda)=x$ for all $\lambda \in U$. The local spectrum of $A$ at $x$ is then defined as $\sigma_{A}(x)=\mathbb{C} \backslash \rho_{A}(x)$. It is obvious that $\sigma_{A}(x)$ is a closed subset of the spectrum $\sigma(A)$. For an arbitrary $F \subseteq \mathbb{C}$, the local spectral subspace of $A$ corresponding to $F$ is $X_{A}(F)=\left\{x \in X ; \sigma_{A}(x) \subseteq F\right\}$. By [14, Proposition 1.2.16 (a)], $\overline{X_{A}(F)}$ is a hyperinvariant subspace of $A$.

Proposition 5.7. $\overline{X_{A}(F)}$ is an ultrainvariant subspace of $A$.
Proof. Let $T \in \mathcal{C}\left(A ; \overline{X_{A}(F)}\right)$ be arbitrary. Let $x \in X_{A}(F)$ and let $\lambda_{0} \in \rho_{A}(x)$. Then there is an open neighborhood $U \subseteq \rho_{A}(x)$ of $\lambda_{0}$ and an analytic function $f: U \rightarrow X$ such that $\left(A-\lambda I_{x}\right) f(\lambda)=x$ for all $\lambda \in U$. By [14, Lemma 1.2.14 ], $\sigma_{A}(f(\lambda))=\sigma_{A}(x)$ for every $\lambda \in U$. Hence, $f(\lambda) \in X_{A}(F)$ for all $\lambda \in U$. It follows that $\left(A-\lambda I_{x}\right) T f(\lambda)=$ $T\left(A-\lambda I_{x}\right) f(\lambda)=T x$ for all $\lambda \in U$. Since $\lambda \mapsto T f(\lambda)$ is an analytic function on $U$ we conclude that $\lambda_{0} \in \sigma_{A}(T x)$ and therefore $\sigma_{A}(T x) \subseteq \sigma_{A}(x) \subseteq F$. Thus, $\overline{X_{A}(F)}$ is invariant for $T$.

Recall that $A \in B(X)$ is a decomposable operator if for every open cover $\mathbb{C}=U \cup V$ there exist spaces $\mathcal{M}, \mathcal{N} \in \operatorname{Lat}(A)$ such that $\mathcal{X}=\mathcal{M}+\mathcal{N}$ and $\sigma\left(\left.A\right|_{\mathcal{M}}\right) \subseteq U, \sigma\left(\left.A\right|_{\mathcal{N}}\right) \subseteq V$ (see Definition 1.1 .1 in [14]). If $A$ is decomposable, then the local spectral subspace $X_{A}(F)$ is closed whenever $F$ is a closed subset of $\mathbb{C}$ (see Definition 1.2.18 and Theorem 1.2.29 in [14]) and $\sigma(A)=\cup\left\{\sigma_{A}(x) ; x \in X\right\}$ (see Proposition 1.3.2 in [14]).

Corollary 5.8. If $A \in B(X)$ is a decomposable operator such that the spectrum $\sigma(A)$ contains at least two points, then $A$ has a proper non-trivial ultrainvariant subspace.

Proof. Let $\lambda_{1} \neq \lambda_{2}$ be points in $\sigma(A)$ and let $\mathbb{C}=U \cup V$ be an open cover such that $\lambda_{1} \in U$ and $\lambda_{2} \notin \bar{U}$. Then $X_{A}(\bar{U})$ and $X_{A}(\bar{V})$ are non-trivial and proper closed subspaces of $\mathcal{X}$.

Indeed, by [14, Theorem 1.2.23], $X=X_{A}(\bar{U})+X_{A}(\bar{V})$. Since $\sigma_{A}(x) \subseteq \bar{U} \cap \sigma(A) \subsetneq \sigma(A)$ and $\sigma(A)=\cup\left\{\sigma_{A}(x) ; x \in \mathcal{X}\right\}$ there are vectors which are not in $X_{A}(\bar{U})$. Similarly, there are vectors which are not in $\mathcal{X}_{A}(\bar{V})$. Hence, $\mathcal{X}_{A}(\bar{U})$ and $X_{A}(\bar{V})$ are proper and non-trivial. By Proposition 5.7, these subspaces are ultrainvariant.

Assume that $A \in B(X)$ is a nilpotent operator of order $n \geq 2$, that is, $A^{n}=0$ and $A^{n-1} \neq 0$. It is well-known that

$$
\{0\}=\operatorname{ker}\left(A^{0}\right) \subseteq \operatorname{ker}(A) \subseteq \operatorname{ker}\left(A^{2}\right) \subseteq \cdots \subseteq \operatorname{ker}\left(A^{n-1}\right) \subseteq \operatorname{ker}\left(A^{n}\right)=X
$$

and

$$
\{0\}=\operatorname{im}\left(A^{n}\right) \subseteq \overline{\operatorname{im}\left(A^{n-1}\right)} \subseteq \overline{\operatorname{im}\left(A^{n-2}\right)} \subseteq \cdots \subseteq \overline{\operatorname{im}(A)} \subseteq \operatorname{im}\left(A^{0}\right)=X
$$

are two chains of hyperinvariant subspaces of $A$. By [3, Remarque p. 317], subspaces $\overline{\operatorname{im}\left(A^{n-1}\right)}$ and $\operatorname{ker}\left(N^{n-1}\right)$ are the smallest, respectively the largest, non-trivial hyperinvariant subspaces of $A$. For every $j=0,1, \ldots, n-1$, we have $\overline{\operatorname{im}\left(A^{n-j}\right)} \subsetneq \operatorname{im}\left(A^{n-j-1}\right)$ and $\operatorname{ker}\left(A^{j}\right) \subsetneq \operatorname{ker}\left(A^{j+1}\right)$. Of course, $\overline{\operatorname{im}\left(A^{n-j}\right)} \subseteq \operatorname{ker}\left(A^{j}\right)$. Later we will need the following simple facts.

Lemma 5.9. (i) For every $j=1, \ldots, n-1$, there exists $u \in \operatorname{im}\left(A^{n-j}\right)$ such that $u \notin$ $\operatorname{ker}\left(A^{j-1}\right)$.
(ii) Let $e \in X$ be such that $A^{k} e \neq 0$ for an integer $k \in\{0,1, \ldots, n-1\}$. Then $A^{k} e \notin \bigvee\left\{e, A e, \ldots, A^{k-1} e\right\}$, that is, $e, A e, \ldots, A^{k} e$ are linearly independent.

Proof. (i) If $\operatorname{im}\left(A^{n-j}\right) \subseteq \operatorname{ker}\left(A^{j-1}\right)$, then we would have $A^{j-1}\left(N^{n-j} x\right)=0$ for every $x \in \mathcal{X}$, that is, it would be $A^{n-1}=0$.
(ii) Towards a contradiction assume that there exist numbers $\alpha_{0}, \ldots, \alpha_{k-1}$ such that

$$
A^{k} e=\alpha_{0} e+\alpha_{1} A e+\cdots+\alpha_{k-1} A^{k-1} e
$$

Since $A^{k} e \neq 0$ there exists the smallest index $0 \leq j \leq k-1$ such that $\alpha_{j} \neq 0$. Hence,

$$
A^{k} e=\alpha_{j} A^{j} e+\alpha_{j+1} A^{j+1} e+\cdots+\alpha_{k-1} A^{k-1} e
$$

Let $m$ be the integer such that $A^{m} e \neq 0$ and $A^{m+1} e=0$. Multiply the above equality by $A^{m-j}$. Since $j<k$ we have

$$
0=A^{m-j+k} e=\alpha_{j} A^{m} e+\alpha_{j+1} A^{m+1}+\cdots+\alpha_{k-1} A^{m-j+k-1} e=\alpha_{j} A^{m} e
$$

It follows that $\alpha_{j}=0$ as $A^{m} e \neq 0$. This is a contradiction.

Lemma 5.10. Let $j \in\{1, \ldots, n\}$. If $e \in \operatorname{ker}\left(A^{j}\right)$ and $\xi \in X^{*}$, then

$$
(e \otimes \xi) A^{j-1}+A(e \otimes \xi) A^{j-2}+\cdots+A^{j-1}(e \otimes \xi) \in \mathcal{C}\left(A ; \overline{\operatorname{im}\left(A^{n-j}\right)}\right)
$$

Proof. It is not hard to check that $(e \otimes \xi) A^{j-1}+A(e \otimes \xi) A^{j-2}+\cdots+A^{j-1}(e \otimes \xi)$ and $A$ commute locally at every vector $A^{n-j} x \in \operatorname{im}\left(A^{n-j}\right)$, where $x \in \mathcal{X}$ is arbitrary.

Theorem 5.11. Let $A \in B(X)$ be a nilpotent operator of order $n \geq 2$. A closed subspace $\mathcal{M} \subseteq \mathcal{X}$ is ultrainvariant for $A$ if and only if $\mathcal{M}=\operatorname{ker}\left(A^{j}\right)$ for some $j \in\{0,1, \ldots, n\}$.

Proof. By Proposition 5.4, every kernel $\operatorname{ker}\left(A^{j}\right)(j=0,1, \ldots, n)$ is an ultrainvariant subspace of $A$. For the opposite implication, suppose that $\mathcal{M}$ is an ultrainvariant subspace for $A$. Then $\mathcal{M}$ is hyperinvariant for $A$ and therefore, by [3, Lemma 5], there exists a unique $j \in\{0,1, \ldots, n\}$ such that $\overline{\operatorname{im}\left(A^{n-j}\right)} \subseteq \mathcal{M} \subseteq \operatorname{ker}\left(A^{j}\right)$.

We claim that $\mathcal{C}\left(A, \overline{\operatorname{im}\left(A^{n-j}\right)}\right) \overline{\operatorname{im}\left(A^{n-j}\right)}=\operatorname{ker}\left(A^{j}\right)$, for every $j \in\{0,1, \ldots, n\}$. If $j=0$ or $j=n$, then the assertion is trivial. Assume therefore that $1 \leq j \leq n-1$. Let $T \in \mathcal{C}\left(A, \overline{\operatorname{im}\left(A^{n-j}\right)}\right)$ and $x \in \operatorname{im}\left(A^{n-j}\right)$ be arbitrary. Let $z \in \mathcal{X}$ be such that $x=A^{n-j} z$. By Lemma 5.3, $A^{j} T x=T A^{j} x=T A^{n} z=0$. This proves that $\mathcal{C}\left(A, \overline{\operatorname{im}\left(A^{n-j}\right)} \overline{\operatorname{im}\left(A^{n-j}\right)} \subseteq\right.$ $\operatorname{ker}\left(A^{j}\right)$. For the opposite inclusion, assume that $x \in \operatorname{ker}\left(A^{j}\right)$. Let $e \in \operatorname{im}\left(A^{n-j}\right)$ be such that $A^{j-1} e \neq 0$ (it exists by Lemma 5.9 (i)). Since, by Lemma 5.9 (ii), vectors $e, A e, \ldots, A^{j-1} e$ are linearly independent there exists $\xi \in X^{*}$ such that $\left\langle A^{j-1} e, \xi\right\rangle=1$ and $\left\langle A^{i} e, \xi\right\rangle=0$ for $i=0, \ldots, j-2$. Denote $T=(x \otimes \xi) A^{j-1}+A(x \otimes \xi) A^{j-2}+$ $\cdots+A^{j-1}(x \otimes \xi)$. By Lemma 5.10, $T \in \mathcal{C}\left(A, \overline{\operatorname{im}\left(A^{n-j}\right)}\right)$. Since $T e=x$ the equality $\mathcal{C}\left(A, \overline{\operatorname{im}\left(A^{n-j}\right)}\right) \overline{\operatorname{im}\left(A^{n-j}\right)}=\operatorname{ker}\left(A^{j}\right)$ is proved. By Proposition 4.6, $\mathcal{C}\left(A ; \mathcal{C}\left(A, \overline{\operatorname{im}\left(A^{n-j}\right)}\right) \overline{\operatorname{im}\left(A^{n-j}\right)}\right) \mathcal{C}\left(A, \overline{\operatorname{im}\left(A^{n-j}\right)}\right) \overline{\operatorname{im}\left(A^{n-j}\right)}=\mathcal{C}\left(A ; \operatorname{ker}\left(A^{j}\right)\right) \operatorname{ker}\left(A^{j}\right)=\operatorname{ker}\left(A^{j}\right)$ is the smallest ultrainvariant subspace of $A$ which contains $\overline{\operatorname{im}\left(A^{n-j}\right)}$. Hence, $\mathcal{M}=$ $\operatorname{ker}\left(A^{j}\right)$.

An operator $A \in B(X)$ is algebraic if there exists a non-zero polynomial $p$ such that $p(A)=0$. It is not hard to see that for an algebraic operator $A$ there exists a unique monic polynomial $q_{A}$ of the minimal degree, called the minimal polynomial of $A$, such that $q_{A}(A)=0$. Every operator on a finite dimensional Banach space is algebraic. Let $q_{A}(z)=\left(z-\lambda_{1}\right)^{n_{1}} \cdots\left(z-\lambda_{k}\right)^{n_{k}}$ with $\lambda_{1}, \ldots, \lambda_{k}$ distinct. For every $j=1, \ldots, k$, let $X_{j}=\operatorname{ker}\left(\left(A-\lambda_{j} I_{x}\right)^{n_{i}}\right)$. Then $X=X_{1} \oplus \cdots \oplus X_{k}$ and with respect to this decomposition $A=\left(\lambda_{1} I_{X_{1}}+A_{1}\right) \oplus \cdots \oplus\left(\lambda_{k} I_{X_{k}}+A_{k}\right)$, where $A_{j} \in B\left(X_{j}\right)$ is a nilpotent operator of order
$n_{j}\left(\right.$ if $n_{j}=1$, then $A_{j}=0$ ). The reader is referred to [19, §5.9] for details about algebraic operators on a complex Banach space.

Corollary 5.12. Let $A \in B(X)$ be algebraic and let $A=\left(\lambda_{1} I_{x_{1}}+A_{1}\right) \oplus \cdots \oplus\left(\lambda_{k} I_{x_{k}}+A_{k}\right)$ be its decomposition as described above. Then a closed subspace $\mathcal{N} \subseteq \mathcal{X}$ is an ultrainvariant subspace of $A$ if and only if $\mathcal{M}=\operatorname{ker}\left(A_{1}^{m_{1}}\right) \oplus \cdots \oplus \operatorname{ker}\left(A_{k}^{m_{k}}\right)$ for some $0 \leq m_{j} \leq n_{j}$ $(j=1, \ldots, k)$.

Proof. Assume that $\mathcal{M}$ is an ultrainvariant subspace of $A$. Let $\mathcal{M}=\mathcal{M}_{1} \oplus \cdots \oplus \mathcal{M}_{k}$, where $\mathcal{M}_{j} \subseteq X_{j}(j=1, \ldots, k)$. Since every subspace $X_{j}$ is reducing subspace of $A$, it follows, by Proposition 4.4, that $\mathcal{N}_{j}$ is an ultrainvariant subspace of $\lambda_{1} I_{X_{j}}+A_{j}$. By Theorem 5.11, there exists $m_{j} \in\left\{0,1, \ldots, n_{j}\right\}$ such that $\mathcal{M}_{j}=\operatorname{ker}\left(A_{j}^{m_{j}}\right)$. The opposite implication follows by Proposition 4.5 because $\sigma\left(\lambda_{i} I_{x_{i}}+A_{i}\right) \cap \sigma\left(\lambda_{j} I_{x_{j}}+A_{j}\right)=\emptyset$ whenever $i \neq j$.

## 6. Ultrainvariant subspaces of operators on a Hilbert space

In this section, $\mathcal{H}$ is the infinite dimensional separable complex Hilbert space. The inner product of vectors $x, y \in \mathcal{H}$ is denoted by $(x, y)$. For a closed subspace $\mathcal{N} \subseteq \mathcal{H}$, let $\mathcal{M}^{\perp}$ be its orthogonal complement.

Our first result in this section is the complete description of the lattice of ultrainvariant subspaces of a normal operator. It turns out that $\operatorname{Lat}_{u}(A)=\operatorname{Lat}_{h}(A)$ whenever $A$ is normal.

Let $A$ be a normal operator on $\mathcal{H}$ and let $E$ be its spectral measure. For a Borel subset $\sigma \subseteq \sigma(A)$, operator $E(\sigma) \in B(\mathcal{H})$ is an orthogonal projection. Subspace $\mathcal{M}=\operatorname{im}(E(\sigma))$ is reducing for $A$ and $\mathcal{M}^{\perp}=\operatorname{im}(E(\sigma(A) \backslash \sigma))$ because $E(\sigma(A) \backslash \sigma)=I-E(\sigma)$ (see Section XXXI. 7 in [11] for details).

Theorem 6.1. Let $A \in B(\mathcal{H})$ be a normal operator and let $E$ be its spectral measure. $A$ subspace $\mathcal{M} \subseteq \mathcal{H}$ is an ultrainvariant subspace of $A$ if and only if $\mathcal{M}$ is a hyperinvariant subspace of $A$, that is, if and only if there exists a Borel subset $\sigma \subseteq \sigma(A)$ such that $\mathcal{M}=\operatorname{im}(E(\sigma))$.

Proof. By [7, Theorem 3], $\mathcal{M} \subseteq \mathcal{H}$ is a hyperinvariant subspace of $A$ if and only if there exists a Borel subset $\sigma \subseteq \sigma(A)$ such that $\mathcal{M}=\operatorname{im}(E(\sigma))$. Hence, it remains to prove that for every Borel subset $\sigma \subseteq \sigma(A)$ the subspace $\mathcal{M}=\operatorname{im}(E(\sigma))$ is ultrainvariant. We can write $A=A_{\mathfrak{N}} \oplus A_{\mathcal{M}^{\perp}}$ with respect to the decomposition $\mathcal{H}=\mathcal{M} \oplus \mathcal{M}^{\perp}$. We have
to see that $\mathcal{J}\left(A_{\mathcal{M}}, A_{\mathcal{M} \perp}\right)=\{0\}$ because then, by Proposition 5.5, $\mathcal{M}$ is an ultrainvariant subspace of $A$. There are a few ways how to see that $\mathcal{J}\left(A_{\mathcal{M}}, A_{\mathcal{M} \perp}\right)=\{0\}$. We will show it as follows. Assume that $S \in \mathcal{J}\left(A_{\mathfrak{M}}, A_{\mathcal{M}_{\perp}}\right)$. Then operator $T \in B(\mathcal{H})$ whose operator matrix with respect to the decomposition $\mathcal{H}=\mathcal{N} \oplus \mathcal{M}^{\perp}$ is $\left[\begin{array}{cc}0 & 0 \\ S & 0\end{array}\right]$ commutes with $A$. It follows, by The Fuglede-Putnam Theorem, that $T$ commutes with $E(\sigma)$ (see Theorems XXXI.7.4 and XXXI.7.9 in [11, for instance). It is easy to see now that $T E(\sigma)=E(\sigma) T$ gives $S=0$.

Let $1 \leq p<\infty$ and let $(X, \mu)$ be a measure space such that $L^{p}(X, \mu)$ is separable. For $\phi \in L^{\infty}(X, \mu)$, let $M_{\phi}$ be the multiplication by $\phi$ in $L^{p}(X, \mu)$. By [12, Theorem 1], a closed subspace $\mathcal{M} \subseteq L^{p}(X, \mu)$ is hyperinvariant for $M_{\phi}$ if and only if $\mathcal{M}=M_{\chi_{\sigma} \circ \phi}\left(L^{p}(X, \mu)\right)$ for some Borel set $\sigma \subseteq X$. Here $\chi_{\sigma}$ denotes the characteristic function of $\sigma$ and $M_{\chi_{\sigma} \circ \phi}$ is the multiplication operator induced by $\chi_{\sigma} \circ \phi$. Note that $M_{\chi_{\sigma} \circ \phi}$ is an idempotent. Hence $M_{\chi_{\sigma} \circ \phi}\left(L^{p}(X, \mu)\right)$ is complemented and its complement $M_{\chi_{X \backslash \sigma \phi}}\left(L^{p}(X, \mu)\right)$ is a hyperinvariant subspace of $M_{\phi}$. A similar reasoning as in the proof of Theorem 6.1 gives that every hyperinvariant subspace of $M_{\phi}$ is an ultrainvariant subspace.

For a closed subspace $\mathcal{M} \subseteq \mathcal{H}$, let $P_{\mathcal{M}}$ be the orthogonal projection onto $\mathcal{M}$. Let $A \in B(\mathcal{H})$. A distance on $\operatorname{Lat}(A)$ is the mapping $\theta$ which is given by $\theta(\mathcal{N}, \mathcal{N})=\left\|P_{\mathcal{M}}-P_{\mathcal{N}}\right\|$ $(\mathcal{M}, \mathcal{N} \in \operatorname{Lat}(A))$. A subspace $\mathcal{M} \in \operatorname{Lat}(A)$ is said to be inaccessible if the only continuous mapping $f:[0,1] \rightarrow \operatorname{Lat}(A)$ with $f(0)=\mathcal{M}$ is the constant map $f(t)=\mathcal{M}(t \in[0,1])$. A simple modification of the proof of [7, Theorem 1] gives the following result.

Theorem 6.2. Let $A \in B(\mathcal{H})$. If $\mathcal{M} \in \operatorname{Lat}(A)$ is inaccessible, then it is an ultrainvariant subspace of $A$.

Proof. Let $0 \neq T \in \mathcal{C}(A ; \mathcal{M})$ be an arbitrary operator. Denote $\Lambda=\{\lambda \in \mathbb{R} ; 0 \leq$ $\left.\lambda<\|T\|^{-1}\right\}$. Then for each $\lambda \in \Lambda$, the operator $I_{\mathcal{H}}-\lambda T$ is invertible and therefore $\mathcal{M}_{\lambda}=\left(I_{\mathcal{H}}-\lambda T\right) \mathcal{M}$ is a closed subspace of $\mathcal{H}$. If $y \in \mathcal{M}_{\lambda}$, then there exists $x \in \mathcal{N}$ such that $y=\left(I_{\mathcal{H}}-\lambda T\right) x$. Hence, $A y=A\left(I_{\mathcal{H}}-\lambda T\right) x=\left(I_{\mathcal{H}}-\lambda T\right) A x \in \mathcal{M}_{\lambda}$ because $A x \in \mathcal{M}$. This shows that $\mathcal{M}_{\lambda} \in \operatorname{Lat}(A)$ for every $\lambda \in \Lambda$. The map $\lambda \mapsto \mathcal{M}_{\lambda}$ is continuous (see the proof of Theorem 1 in [7]). Since $\mathcal{M}=\mathcal{M}_{0}$ and $\mathcal{M}$ is inaccessible we have $\mathcal{M}=\mathcal{M}_{\lambda}$ for each $\lambda \in \Lambda$. Thus, $\mathcal{M}=\left(I_{\mathcal{H}}-\lambda T\right) \mathcal{M}$ for a non-zero $\lambda$ which implies that $\mathcal{M}$ is invariant for $T$, that is, it is an ultrainvariant subspace of $A$.

It is clear that $\mathcal{M} \in \operatorname{Lat}(A)$ is inaccessible if it is an isolated point.

Corollary 6.3. Let $A \in B(\mathcal{H})$. If $\mathcal{M} \in \operatorname{Lat}(A)$ is such that $P_{\mathcal{N}}$ commutes with every $P_{\mathcal{N}}$ $(\mathcal{N} \in \operatorname{Lat}(A))$, then $\mathcal{M}$ is an ultrainvariant subspace of $A$.

Proof. Assume that $\mathcal{M} \in \operatorname{Lat}(A)$ is such that $P_{\mathcal{M}} P_{\mathcal{N}}=P_{\mathcal{N}} P_{\mathcal{M}}$ for every $\mathcal{N} \in \operatorname{Lat}(A)$. Then, for every $\mathcal{N} \in \operatorname{Lat}(A), P_{\mathcal{M}} P_{\mathfrak{N}}$ is an orthogonal projection such that $P_{\mathcal{M}} P_{\mathcal{N}} \leq P_{\mathcal{M}}$ and $P_{\mathcal{M}} P_{\mathcal{N}} \leq P_{\mathcal{N}}$. Suppose that $\mathcal{N} \neq \mathcal{M}$. Then either $P_{\mathcal{M}} P_{\mathcal{N}}<P_{\mathcal{N}}$ or $P_{\mathcal{M}} P_{\mathcal{N}}<P_{\mathcal{N}}$. If the former holds, then there exists $x \in \operatorname{im}\left(P_{\mathcal{M}}\right),\|x\|=1$, such that $P_{\mathcal{M}} P_{\mathfrak{N}} x=0$. Since $P_{\mathcal{M}} x=x$ it follows that $P_{\mathcal{N}} x=P_{\mathcal{N}} P_{\mathcal{M}} x=0$. Thus, $\left\|P_{\mathcal{M}}-P_{\mathcal{N}}\right\| \geq\left\|P_{\mathcal{M}} x-P_{\mathcal{N}} x\right\|=\|x\|=1$ which gives $\left\|P_{\mathcal{M}}-P_{\mathcal{N}}\right\|=1$. We get the same conclusion if $P_{\mathcal{M}} P_{\mathcal{N}}<P_{\mathcal{N}}$ holds. We conclude that $\mathcal{M}$ is an isolated point of $\operatorname{Lat}(A)$. Hence, it is inaccessible and therefore it is an ultrainvariant subspace of $A$, by Theorem 6.3.

Recall that $A \in B(\mathcal{H})$ is unicellular if $\operatorname{Lat}(A)$ is totally ordered, that is, for any two subspaces $\mathcal{M}, \mathcal{N} \in \operatorname{Lat}(A)$, either $\mathcal{M} \subseteq \mathcal{N}$ or $\mathcal{M} \supseteq \mathcal{N}$.

Corollary 6.4. If $A \in B(\mathcal{H})$ is unicellular, then every $\mathcal{N} \in \operatorname{Lat}(A)$ is an ultrainvariant subspace of $A$.

Proof. Assume that $A \in B(\mathcal{H})$ is unicellular and let $\mathcal{M} \in \operatorname{Lat}(A)$ be arbitrary. If $\mathcal{N} \in$ $\operatorname{Lat}(A)$, then either $\mathcal{M} \subseteq \mathcal{N}$ or $\mathcal{M} \supseteq \mathcal{N}$ which implies that $P_{\mathcal{M}}$ and $P_{\mathcal{N}}$ commute. By Corollary 6.3, $\mathcal{M}$ is an ultrainvariant subspace of $A$.

An example of a unicellular operator is the Volterra operator $V$ on $L^{2}[0,1]$. By [8, Example 3] (see also [16, Theorem 4.14]), Lat $(V)$ consists of subspaces $\mathcal{M}_{\alpha}=\{f \in$ $L^{2}[0,1] ; f=0$ a.e. on $\left.[0, \alpha]\right\}$, where $\alpha \in[0,1]$. Hence, by Corollary [6.4, every invariant subspace of $V$ is actually an ultrainvariant subspace.

Let $\left(e_{n}\right)_{n=0}^{\infty}$ be an orthonormal basis of $\mathcal{H}$ and let $w=\left(w_{n}\right)_{n=1}^{\infty}$ be a bounded sequence of complex numbers. Then $w$ determines an operator $W_{w} \in \mathcal{H}$ by $W_{w} e_{0}=0$ and $W_{w} e_{n}=$ $w_{n} e_{n-1}$ for $n \in \mathbb{N}$ (hence, $W_{w}$ is the weighted backward shift determined by $w$ ). For each $n \geq 0$, denote $\mathcal{M}_{n}=\bigvee\left\{e_{0}, \ldots, e_{n}\right\}$.

Proposition 6.5. Every $\mathcal{M}_{n} \subseteq \mathcal{H}(n \geq 0)$ is an ultrainvariant subspace of $W_{w}$.
Proof. Since $\mathcal{M}_{0}=\operatorname{ker}\left(W_{w}\right)$ and kernels are ultrainvariant (see the paragraph before Lemma (5.3) we may assume that $n \geq 1$. Observe that $W_{w} x \in \mathcal{M}_{k}$ for some $x \in \mathcal{H}$ and $k \geq 0$ if and only if $x \in \mathcal{M}_{k+1}$. Indeed, if $x=\sum_{j=0}^{\infty}\left(x, e_{j}\right) e_{j}$ and $\left(x, e_{j}\right) \neq 0$ for some $j>k+1$, then $W_{w} x=\sum_{j=1}^{\infty}\left(x, e_{j}\right) w_{j} e_{j-1} \notin \mathcal{M}_{k}$.

Let $T \in \mathcal{C}\left(W_{w} ; \mathcal{M}_{n}\right)$ be arbitrary. Then $W_{w} T e_{0}=T W_{w} e_{0}=0$ and therefore $T e_{0} \in \mathcal{M}_{0}$. Suppose that for $j<n$ we have $T e_{j} \in \mathcal{M}_{j}$. Then $W_{w} T e_{j+1}=T W_{w} e_{j+1}=w_{j} T e_{j} \in \mathcal{M}_{j}$ which gives $T e_{j+1} \in \mathcal{M}_{j+1}$. We conclude that $\mathcal{M}_{n}$ is invariant for every $T \in \mathcal{C}\left(W_{w} ; \mathcal{M}_{n}\right)$, that is, $\mathcal{M}_{n}$ is ultrainvariant.

If $w$ is a sequence of non-zero complex numbers such that $\left|w_{1}\right|>\left|w_{2}\right|>\cdots$ and $\sum_{n=1}^{\infty}\left|w_{n}\right|^{2}<\infty$, then $W_{w}$ is called the Donoghue operator with weight sequence $w$. By [16, Theorem 4.12] (a special case was considered by Donoghue [8, Example 1]), a closed subspace $\mathcal{M} \subseteq \mathcal{H}$ is a non-trivial invariant subspace of the Donoghue operator $W_{w}$ if and only if $\mathcal{N}=\mathcal{M}_{n}$ for some $n \geq 0$. Hence the Donoghue operator is unicellular and therefore every $\mathcal{M}_{n}$ is an ultrainvariant subspace of $W_{w}$.
