(Received 2018)

We study the Darboux integrability of a simple system of three ordinary differential equations called the Glukhovsky-Dolzhansky system, which describes a three-mode model of rotating fluid convection inside the ellipsoid. (1) Our results show that it has no polynomial, rational, or Darboux first integrals for any value of parameters in the physical sense, that is, positive parameters. (2) We also provide some integrable cases of this model when parameters are allowed to be non-positive. (3) We finally give some links between the Glukhovsky-Dolzhansky system and other similar systems in $\mathbb{R}^3$, which admits rotational symmetry and has three nonlinear cross terms.

Keywords: Glukhovsky-Dolzhansky system; Darboux integrability; Darboux polynomials; Exponential factor

1. Introduction

Consider the convection of viscous incompressible fluid motion inside the ellipsoid

$$\left(\frac{x_1}{a_1}\right)^2 + \left(\frac{x_2}{a_2}\right)^2 + \left(\frac{x_3}{a_3}\right)^2 = 1, \quad a_1 > a_2 > a_3 > 0,$$

under the condition of stationary inhomogeneous external heating. Glukhovsky and Dolzhansky $^{[1]}$ assumed that the ellipsoid rotates with the constant velocity $\Omega_0$ along the axis $a_3$, and the axis $a_3$ has a constant angle $\alpha$ with the gravity vector $g$. They also assumed that the temperature difference is generated along the axis $a_1$ and its gradient

$^{[1]}$S. Yang, corresponding author
has a constant value $q_0$. Denote by $\lambda, \mu, \beta$ the coefficients of viscosity, heat conduction, and volume expansion, respectively. Then they proposed the following system of ordinary differential equations

$$
\begin{align*}
\dot{x} &= Ayz + Cz - \sigma x := P(x, y, z), \\
\dot{y} &= -xz + Ra - y := Q(x, y, z), \\
\dot{z} &= -z + xy := R(x, y, z),
\end{align*}
$$

which can be interpreted as one of the models of ocean flows. Here

$$
\begin{align*}
\sigma &= \frac{\lambda}{\mu}, \quad T_\alpha = \frac{\Omega^2}{\lambda^2}, \quad Ra = \frac{g\beta a_3 q_0}{2a_1 a_2 \lambda \mu}, \\
A &= \frac{a_1^2 - a_2^2}{a_1^2 + a_2^2} \cos^2 \alpha T_\alpha^{-1}, \quad C = \frac{a_1^2 - a_2^2}{a_1^2 + a_2^2} \cos^2 \alpha T_\alpha^{-1}, \\
x(t) &= \mu^{-1} \omega_3(t), \quad y(t) = \frac{g\beta a_3}{2a_1 a_2 \lambda \mu} q_1(t), \quad z(t) = \frac{g\beta a_3}{2a_1 a_2 \lambda \mu} q_2(t),
\end{align*}
$$

$\omega_3(t)$ is the projection of the vector of angular velocity on the axis $a_3$, $q_1(t)$ and $q_2(t)$ are the projections of temperature gradients on the axes $a_1$ and $a_2$. The parameters $\sigma, T_\alpha$ and $Ra$ are the Prandtl, Taylor and Rayleigh numbers, respectively. Clearly, the parameters $A, C, \sigma$ and $Ra$ of system (1) are positive.

In spite of its simple form, the Glukhovsky-Dolzhansky system (1) admits rich dynamics and has been intensively investigated, see [2, 3, 4, 5] and the references therein. However, this system has never been studied from the integrability point of view. The main purpose of this work is to cover this gap and to investigate the integrability of system (1). The investigation of integrability for systems of differential equations has been one of significant topics not only in mathematics but also in physics. Generally, a system of differential equations is integrable if it possesses a sufficient number of first integrals (and/or other tensor invariants) such that we can solve this system explicitly. Hence we could obtain its global information and understand its topological structure [8, 9]. Furthermore, non-integrability of the system also seems necessary for better understanding of the complex phenomenon [6, 7]. However, to study the integrability of a given system is not an easy task, since there is no any effective approach to determine the existence or nonexistence of first integrals.

In this paper, we aim to study the integrability of system (1) in the framework of Darboux integrability theory. Darboux integrability theory plays an important role in the integrability of the polynomial differential systems [10, 11, 12, 13, 14], which helps us find first integrals by knowing a sufficient number of algebraic invariant surfaces (the Darboux polynomials) and of the exponential factors, see [15, 16, 17, 18, 19] for instance. Moreover, it can also help us make a more precise analysis of the global dynamics of the considered system topologically [20, 8]. In addition, let us mention that the Darboux integrability of the Rabinovich system, 3D forced-damped system and $D2$ vector field, which are similar but different from the Glukhovsky-Dolzhansky system (1), have been studied in [28, 29, 30, 31]. These systems admit a common structure: the original is
Fig. 1: (a) chaotic attractor for the system with parameter values \((A, C, \sigma, Ra) = (0.04, 1, 4, 250)\); (b) its projections onto the planes \((x, y)\).

Fig. 2: Projections of the chaotic attractor into the plane \((x, z)\) (a) and into the plane \((y, z)\) (b).
the equilibrium point, symmetry with respect to certain coordinate axis, only three cross nonlinear terms \{yz, xz, xy\}. In the appendix, we provide some linear rescaling of time and coordinate to show the Glukhovsky-Dolzhansky system (1) can be transformed into the Rabinovich system or 3D forced-damped system or \(D^2\) vector field only when the parameters satisfies some conditions: \(C = -2AR_a\) or \(\sigma = 1\) or \(Ra = C = 0\) respectively.

The main result of this paper is as follows.

**Theorem 1.** The following statements hold for the Glukhovsky-Dolzhansky system (1).

(a.) It has no polynomial first integrals.
(b.) It has no Darboux polynomials with non-zero cofactors.
(c.) It has no exponential factors.
(d.) It admits no Darboux first integrals.

**Remark 1.** The Glukhovsky-Dolzhansky system admits complex dynamics for a larger range of its parameters. For example, it has a strange attractor with \((A, C, \sigma, Ra) = (0.04, 1, 4, 250)\), see Fig 1 and 2. Our non-integrability results coincide with this fact. As mentioned above, from a physical point of view, the parameters in the Glukhovsky-Dolzhansky system (1) is positive due to their physical meaning. Whereas, from a mathematical point of view, one may consider non-positive parameters and then some integrable cases of system (1) are founded:

- \(Ra = 0\) and \(\sigma = 1\), system (1) has a Darboux polynomial \(f = y^2 + z^2\) with a constant cofactor \(k = -2\).
- \(C = 0\) and \(\sigma = 1\), system (1) has a Darboux polynomial \(f = x^2 - Az^2\) with a constant cofactor \(k = -2\).
- \(Ra = C = 0\) and \(\sigma = 1\), system (1) has a rational first integral \(\Phi = (y^2 + z^2)/(x^2 - Az^2)\).

But we do not have a clear physical understanding of the above integrable results for the Glukhovsky-Dolzhansky system (1).

**Remark 2.** Another tool to study the non-integrability of non-Hamiltonian systems is the differential Galois theory \[21, 22, 23\]. Observing system (1) has a straight line solution \((x(t), y(t), z(t)) = (0, Ra - e^{-t}, 0)\), we can analyze the differential Galois group of the normal variational equations along this solution, and show that system (1) is not rationally integrable in Bogoyavlenskij sense for almost all parameter values, see \[24, 25, 26, 27\] for more details.

The paper is organized as follows. In Section 2 we introduce some preliminary notions and results related to Darboux theory of integrability that we will use later. The proof of Theorem 1 is given in Section 3.
2. Preliminary results

Let \( \mathbb{R}[x, y, z] \) be the ring of the real polynomials in the variables \( x, y \) and \( z \). We say that \( f(x, y, z) \in \mathbb{R}[x, y, z] \) is a Darboux polynomial of system (1) if it satisfies

\[
\frac{\partial f}{\partial x} P + \frac{\partial f}{\partial y} Q + \frac{\partial f}{\partial z} R = K f,
\]

for some polynomial \( K \), called the cofactor of \( f(x, y, z) \). If \( f(x, y, z) \) is a Darboux polynomial, then the surface \( f(x, y, z) = 0 \) is an invariant manifold of system (1). Particularly, if \( K = 0 \), \( f(x, y, z) \) satisfies the following equation

\[
\frac{\partial f}{\partial x} P + \frac{\partial f}{\partial y} Q + \frac{\partial f}{\partial z} R = 0,
\]

then polynomial \( f(x, y, z) \) is called a polynomial first integral of system (1).

Let \( g, h \in \mathbb{R}[x, y, z] \) be coprime. We say that a nonconstant function \( E = \exp(g/h) \) is an exponential factor of system (1) if \( E \) satisfies

\[
\frac{\partial E}{\partial x} P + \frac{\partial E}{\partial y} Q + \frac{\partial E}{\partial z} R = LE,
\]

for some polynomial \( L \in \mathbb{R}[x, y, z] \) with the degree at most one, called the cofactor of \( E \).

A first integral \( G \) of system (1) is called Darboux type if it is a first integral of the form

\[
G = f_1^{\lambda_1} \cdots f_p^{\lambda_p} E_1^{\mu_1} \cdots E_q^{\mu_q},
\]

where \( f_1, \ldots, f_p \) are Darboux polynomials, \( E_1, \ldots, E_q \) are exponential factors and \( \lambda_i, \mu_j \in \mathbb{R} \), for \( i = 1, \ldots, p \) and \( j = 1, \ldots, q \).

To prove Theorem 1, we need the following results.

**Proposition 1.** Suppose that a polynomial vector field \( X \) defined in \( \mathbb{R}^n \) of degree \( m \) admits \( p \) Darboux polynomials \( f_i \) with cofactor \( K_i \) for \( i = 1, \ldots, p \), and \( q \) exponential factors \( E_j = \exp(g_j/h_j) \) with cofactors \( L_j \) for \( j = 1, \ldots, q \). If there exist \( \lambda_i, \mu_j \in \mathbb{R} \) not all zero such that

\[
\sum_{i=1}^{p} \lambda_i K_i + \sum_{j=1}^{q} \mu_j L_j = 0,
\]

then the following real (multivalued) function of Darboux type

\[
f_1^{\lambda_1} \cdots f_p^{\lambda_p} E_1^{\mu_1} \cdots E_q^{\mu_q},
\]

substituting \( f_i^{\lambda_i} \) by \( |f_i|^{\lambda_i} \) if \( \lambda_i \in \mathbb{R} \), is a first integral of the vector field \( X \).

The proof can be seen in [10].

**Proposition 2.** The following statements hold.

(a) If \( e^{g/h} \) is an exponential factor for the polynomial differential system (1) and \( h \) is not a constant polynomial, then \( h \) is a Darboux polynomial.

(b) Eventually \( e^g \) can be an exponential factor, coming from the multiplicity of the infinite invariant plane.
For a proof of this result see [11].

**Proposition 3.** Let \( f \) be a polynomial and \( f = \prod_{j=1}^{s} f_j^{\alpha_j} \) be its decomposition into irreducible factors in \( \mathbb{R}[x, y, z] \). Then \( f \) is a Darboux polynomial of system (1) if and only if all the \( f_j \) are Darboux polynomials of system (1). Moreover, if \( K \) and \( K_j \) are the cofactors of \( f \) and \( f_j \), then \( K = \sum_{j=1}^{s} \alpha_j K_j \).

The proof of Proposition 3 can be found in [12].

3. **Proof of Theorem 1**

We separate the proof of Theorem 1 into the following different propositions.

**Proposition 4.** System (1) has no polynomial first integrals.

**Proof:** Suppose

\[
\sum_{i=0}^{n} f_i(x, y, z) = 0
\]

is a polynomial first integral of system (1), where \( f_i \) are the homogeneous polynomials of degree \( i \) and \( f_n \neq 0 \). Firstly, substituting (1) into (3) and identifying the homogeneous components of degree \( n + 1 \), we get

\[
Ayz \frac{\partial f_n}{\partial x} - xz \frac{\partial f_n}{\partial y} + xy \frac{\partial f_n}{\partial z} = 0. \tag{5}
\]

The characteristic equations associated with (5) are

\[
\frac{dx}{dy} = Ay, \quad \frac{dz}{dy} = x, \quad \frac{dy}{dz} = -xz.
\]

Its general solution are

\[
x^2 + Ay^2 = c_1, \quad y^2 + z^2 = c_2,
\]

where \( c_1 \) and \( c_2 \) are arbitrary constants. We make the change of variables

\[
u = x^2 + Ay^2, \quad w = y, \quad v = y^2 + z^2.
\]

Correspondingly, the inverse transformation is

\[
x = \pm \sqrt{u - Aw^2}, \quad y = w, \quad z = \pm \sqrt{v - w^2}. \tag{6}
\]

Without loss of generality, we set

\[
x = \sqrt{u - Aw^2}, \quad y = w, \quad z = -\sqrt{v - w^2}, \tag{7}
\]
and transform (5) into
\[ \frac{d\bar{f}_n}{dw} = 0, \] (8)
where \( \bar{f}_n(u, v, w) = f_n(x, y, z) \). In the following, unless otherwise specified, we always denote the function \( R(x, y, z) \) by \( \bar{R}(u, v, w) \). Hence we obtain
\[ f_n(x, y, z) = f_{2m}(x, y, z) = \sum_{i=0}^{m} a_i^m (x^2 + A y^2)^{m-i} (y^2 + z^2)^i, \quad a_i^m \in \mathbb{R}, \]
where \( n = 2m \) must be an even number. Secondly, substituting (4) into (3) and identifying the homogeneous components of degree \( n \) yields
\[ Ayz \frac{\partial f_n}{\partial x} - xz \frac{\partial f_n}{\partial y} + xy \frac{\partial f_n}{\partial z} = (\sigma x - Cz) \frac{\partial f_n}{\partial x} + y \frac{\partial f_n}{\partial y} + z \frac{\partial f_n}{\partial z} \]
\[ = \sum_{i=0}^{m} a_i^m 2\sigma (m - i) (x^2 + A y^2)^{m-i-1} (y^2 + z^2)^i x^2 \]
\[ - \sum_{i=0}^{m} a_i^m 2C (m - i) (x^2 + A y^2)^{m-i-1} (y^2 + z^2)^i xz \]
\[ + \sum_{i=0}^{m} a_i^m 2A (m - i) (x^2 + A y^2)^{m-i-1} (y^2 + z^2)^i y^2 \]
\[ + \sum_{i=0}^{m} a_i^m 2i (x^2 + A y^2)^{m-i} (y^2 + z^2)^{i-1} y^2 \]
\[ + \sum_{i=0}^{m} a_i^m 2i (x^2 + A y^2)^{m-i} (y^2 + z^2)^{i-1} z^2. \]

Using the transformations (7) again, the above equation becomes
\[ \sqrt{u-Aw^2} \sqrt{v-w^2} \frac{d\bar{f}_{2m}}{dw} = \sum_{i=0}^{m} a_i^m 2\sigma (m - i) u^{m-i-1} v^i (u - Aw^2) \]
\[ + \sum_{i=0}^{m} a_i^m 2C (m - i) u^{m-i-1} v^i \sqrt{u-Aw^2} \sqrt{v-w^2} \]
\[ + \sum_{i=0}^{m} a_i^m 2A (m - i) u^{m-i-1} v^i w^2 \]
\[ + \sum_{i=0}^{m} a_i^m 2i u^{m-i-1} v^i - (v - w^2). \]
We obtain
\[
\bar{f}_{2m-1} = \sum_{i=0}^{m} a_i^m 2\sigma (m-i) u^{m-i-1} v^i \int \sqrt{u-Aw^2} \sqrt{v-w^2} \, dw \\
+ \sum_{i=0}^{m-1} 2[a_i^m A(m-i) + a_{i+1}^m (i+1)] u^{m-i-1} v^i \int \frac{w^2 \, dw}{\sqrt{u-Aw^2} \sqrt{v-w^2}} \\
+ \sum_{i=0}^{m} a_i^m 2i v^{i-1} \int \frac{\sqrt{v-w^2} \, dw}{\sqrt{u-Aw^2}} \\
+ \sum_{i=0}^{m} a_i^m 2C(m-i) u^{m-i-1} v^i w + A_{n-1}(u,v),
\]
where \(A_{n-1}(u,v)\) is an arbitrary smooth function in \(u\) and \(v\). It is easy to check
\[
\int \frac{w^2 \, dw}{\sqrt{u-Aw^2} \sqrt{v-w^2}} = - \int \frac{\sqrt{u-Aw^2} \, dw}{\sqrt{v-w^2}} + u \int \frac{dw}{\sqrt{u-Aw^2} \sqrt{v-w^2}}.
\]
Since
\[
\int \frac{\sqrt{u-Aw^2} \, dw}{\sqrt{v-w^2}} \quad \int \frac{dw}{\sqrt{u-Aw^2} \sqrt{v-w^2}}
\]
are elliptic integrals of the second and first kinds, respectively, in order that \(\bar{f}_{2m-1}(x,y,z) = \bar{f}_{2m-1}(u,v,w)\) is a homogeneous polynomial of degree \(2m-1\), we must have
\[
\begin{cases}
a_i^m 2\sigma (m-i) = 0, & i = 0, 1, \ldots, m \\a_i^m 2C(m-i) = 0, & i = 0, 1, \ldots, m \\a_i^m 2i = 0, & i = 0, 1, \ldots, m \\a_i^m A(m-i) + a_{i+1}^m (i+1) = 0, & i = 0, 1, \ldots, m - 1.
\end{cases}
\]
By (11) and \(A, C, \sigma\) being positive, we obtain \(a_i^m = 0, i = 0, \ldots, m\). This leads to a contradiction. So system (11) has no polynomial first integrals.

**Proposition 5.** System (11) has no Darboux polynomial with nonzero cofactors.

**Proof:** Suppose
\[
f(x,y,z) = \sum_{i=0}^{n} f_i(x,y,z)
\]
is a Darboux polynomial of the system (11) with a non-cofactor \(K(x,y,z)\), where \(f_i\) is a homogeneous polynomial of degree \(i\) for \(i = 0, 1, \ldots, n\). Comparing the degree on both sides of (12) yields \(\deg K \leq 1\). Without loss of generality, we can assume that the cofactor is of the form
\[
K(x,y,z) = k_1 x + k_2 y + k_3 z + k_0, \quad k_i \in \mathbb{R}, \quad i = 0, 1, 2, 3.
\]

Substituting (12) and (27) into (2) and identifying the terms of the same degree, we obtain

$$Ayz \frac{\partial f_n}{\partial x} - xz \frac{\partial f_n}{\partial y} + xy \frac{\partial f_n}{\partial z} = (k_1 x + k_2 y + k_3 z) f_n,$$

(14)

$$Ayz \frac{\partial f_{n-1}}{\partial x} - xz \frac{\partial f_{n-1}}{\partial y} + xy \frac{\partial f_{n-1}}{\partial z} = (k_1 x + k_2 y + k_3 z) f_{n-1} + (\sigma x - C z) \frac{\partial f_n}{\partial x} + y \frac{\partial f_n}{\partial y} + z \frac{\partial f_n}{\partial z} + k_0 f_n,$$

(15)

$$Ayz \frac{\partial f_i}{\partial x} - xz \frac{\partial f_i}{\partial y} + xy \frac{\partial f_i}{\partial z} = (k_1 x + k_2 y + k_3 z) f_i + (\sigma x - C z) \frac{\partial f_{i+1}}{\partial x} + y \frac{\partial f_{i+1}}{\partial y} + z \frac{\partial f_{i+1}}{\partial z} - Ra \frac{\partial f_{i+2}}{\partial y} + k_0 f_{i+1},$$

$$i = n - 2, \ldots, 0.$$

We claim that the cofactor is a constant, i.e., $k_1 = k_2 = k_3 = 0$. Indeed, under the change of (6), we can transform (14) into an ordinary differential equation if we fix $u$ and $v$-

$$-(\pm \sqrt{u - Aw^2})(\pm \sqrt{v - w^2}) \frac{d\bar{f}_n}{dw} = [k_1(\pm \sqrt{u - Aw^2}) + k_2 w + k_3(\pm \sqrt{v - w^2})] \bar{f}_n,$$

where $\bar{f}_n(u, v, w) = f_n(x, y, z)$. In the following proof, we only consider the case of $xz < 0$. For the case of $xz > 0$, the proof is similar. Solving the last equation we find that for $xz < 0$,

$$\bar{f}_n = \tilde{A}(u, v) \left[ \frac{2\sqrt{A}\sqrt{(u - Aw^2)(v - w^2)} + 2Aw^2 - (u + Av)}{2\sqrt{A}} \right]^{-\frac{k_2}{2}} \exp \left( -k_1 \arcsin \frac{w}{\sqrt{v}} \right) \exp \left( -\frac{k_3}{\sqrt{A}} \arcsin \frac{w}{\sqrt{u}} \right).$$

In order for $f_n(x, y, z) = f_n(u, v, w)$ to be a homogeneous polynomial of degree $n$ in $x, y, z$, we have $k_1 = k_3 = 0$ and the function $\tilde{A}$ is a homogeneous polynomial in $x^2 + Ay^2$ and $y^2 + z^2$. Then

$$f_n = \tilde{A}(x^2 + Ay^2, y^2 + z^2)(x + \sqrt{Az})^{\frac{k_2}{2}}.$$

Therefor $f$ is a Darboux polynomial of degree $n(= 2m + \frac{k_2}{\sqrt{A}})$ with the cofactor $K = k_2y + k_0$. Set $\tilde{k}_2 = k_2/\sqrt{A}$, we get $f = \sum_{i=0}^{2n+k_2} f_i$ and

$$f_{2m+\tilde{k}_2} = (x + \sqrt{Az})^{\tilde{k}_2} \sum_{i=0}^{m} a_i (x^2 + Ay^2)^{m-i}(y^2 + z^2)^i.$$
Introducing $f_{2m+k_2}$ into \[15\] and performing some calculations, we obtain

$$Ay\frac{\partial f_{2m+k_2-1}}{\partial x} - xz \frac{\partial f_{2m+k_2-1}}{\partial y} + xy \frac{\partial f_{2m+k_2-1}}{\partial z} - k_2 y f_{2m+k_2-1}$$

$$= (x + \sqrt{A}z)^{k_2} \sum_{i=0}^{m} a_i^m [2\sigma(m - i) + k_0 + 2i](x^2 + Ay^2)^{m-i}(y^2 + z^2)^i$$

$$+ (x + \sqrt{A}z)^{k_2-1} \sum_{i=0}^{m} a_i^m k_2 \sigma(x^2 + Ay^2)^{m-i}(y^2 + z^2)^i x$$

$$- (x + \sqrt{A}z)^{k_2} \sum_{i=0}^{m} a_i^m 2C(m - i)(x^2 + Ay^2)^{m-i-1}(y^2 + z^2)^i x z$$

$$+ (x + \sqrt{A}z)^{k_2-1} \sum_{i=0}^{m} a_i^m k_0 (\sqrt{A} - C)(x^2 + Ay^2)^{m-i}(y^2 + z^2)^i z$$

$$+ (x + \sqrt{A}z)^{k_2} \sum_{i=0}^{m} a_i^m 2A(m - i)(1 - \sigma)(x^2 + Ay^2)^{m-i-1}(y^2 + z^2)^i y^2.$$

Using the transformations \[16\], the above equation becomes

$$\sqrt{u - A w^2} \sqrt{v - w^2} \frac{df_{2m+k_2-1}}{dw} - k_2 w f_{2m+k_2-1}$$

$$= (\sqrt{u - A w^2} - \sqrt{A} \sqrt{v - w^2})^{k_2} \sum_{i=0}^{m} a_i^m [2\sigma(m - i) + k_0 + 2i]u^{m-i}v^i$$

$$+ (\sqrt{u - A w^2} - \sqrt{A} \sqrt{v - w^2})^{k_2-1} \sum_{i=0}^{m} a_i^m k_2 \sigma u^{m-i}v^i \sqrt{u - A w^2}$$

$$+ (\sqrt{u - A w^2} - \sqrt{A} \sqrt{v - w^2})^{k_2} \sum_{i=0}^{m} a_i^m 2C(m - i)u^{m-i-1}v^i \sqrt{u - A w^2} \sqrt{v - w^2}$$

$$+ (\sqrt{u - A w^2} - \sqrt{A} \sqrt{v - w^2})^{k_2-1} \sum_{i=0}^{m} a_i^m k_0 (C - \sqrt{A})u^{m-i}v^i \sqrt{v - w^2}$$

$$+ (\sqrt{u - A w^2} - \sqrt{A} \sqrt{v - w^2})^{k_2} \sum_{i=0}^{m} a_i^m 2A(m - i)(1 - \sigma)u^{m-i-1}v^iw^2.$$

which is a non-homogeneous linear ordinary differential equation in $f_{2m+k_2-1}$. The corresponding homogeneous equation

$$\sqrt{u - A w^2} \sqrt{v - w^2} \frac{df^x}{dw} - k_2 w f^x = 0$$

has a general solution

$$f^x_{2m+k_2-1} = (\sqrt{u - A w^2} - \sqrt{A} \sqrt{v - w^2})^{k_2} A^x_{2m-1}(u,v),$$
where $\tilde{A}_{2m-1}(u,v)$ is an arbitrary smooth function in $u$ and $v$. In order to use the method of variation of constants, we assume that

$$\tilde{f}_{2m+k_2-1} = (\sqrt{u - Aw^2} - \sqrt{A\sqrt{v - w^2}})^k_2 \tilde{A}_{2m-1}(u,v,w)$$

is a solution of (16), then $\tilde{A}_{2m-1}(u,v,w)$ satisfies

$$\frac{d\tilde{A}_{2m-1}}{dw} = \sum_{i=0}^{m} a^m_i [2\sigma (m - i) + b + 2i] u^{m-i}v^i \sqrt{u - Aw^2} \sqrt{v - w^2}$$

$$+ \sum_{i=0}^{m} a^m_i k_2 \sigma u^{m-i}v^i \sqrt{u - Aw^2} - \sqrt{A\sqrt{v - w^2}} \sqrt{u - Aw^2}$$

$$+ \sum_{i=0}^{m} a^m_i 2C(m - i) u^{m-i-1}v^i \sqrt{u - Aw^2} \sqrt{v - w^2}$$

$$+ \sum_{i=0}^{m} a^m_i 2A(m - i)(1 - \sigma) u^{m-i-1}v^i \sqrt{u - Aw^2} \sqrt{v - w^2}.$$

Some easy computations lead to

$$\int \frac{dw}{(\sqrt{u - Aw^2} - \sqrt{A\sqrt{v - w^2}}) \sqrt{u - Aw^2}} = \frac{w}{u - v} + \int \frac{\sqrt{v - w^2}}{\sqrt{u - Aw^2}} dw \quad (17)$$

Since

$$\int \frac{dw}{\sqrt{u - Aw^2} \sqrt{v - w^2}} \quad \int \frac{\sqrt{u - Aw^2}}{\sqrt{v - w^2}} dw$$

are elliptic integrals of the first and second kind, by (16) and (17), in order for $A_{2m-1}(x,y,z) = \tilde{A}_{2m-1}(u,v,w)$ to be a homogeneous polynomial of degree $2m - 1$, we must have

$$\begin{cases} a^m_i [2\sigma (m - i) + k_0 + 2i] = 0, \\ a^m_i k_2 \sigma = 0, \\ a^m_i k_2 (C - \sqrt{A}) = 0, \\ a^m_i 2A(m - i)(1 - \sigma) = 0, \quad i = 0, 1, \ldots, m, \end{cases} \quad (18)$$

which implies $k_2 = 0$, that is to say, $k_2 = 0$. So the cofactor $K = k_0$ is a constant. Then (18) becomes

$$\begin{cases} a^m_i [2\sigma (m - i) + 2i + k_0] = 0, \\ a^m_i 2A(m - i)(1 - \sigma) = 0, \quad i = 0, 1, \ldots, m. \end{cases}$$
Now, we split the proof in two cases.

Case I. \( \sigma = 1, k_0 = -2m \). In this case, we have

\[
f_n = f_{2m} = \sum_{i=0}^{m} a_i^m(x^2 + Ay^2)^{m-i}(y^2 + z^2)^i,
\]

\[
f_{n-1} = f_{2m-1} = \sum_{i=0}^{m} a_i^m 2C(m - i)(x^2 + Ay^2)^{m-i-1}(y^2 + z^2)^i y.
\]

Substituting (19) and (20) into (15) with \( i = n - 2 \), we get

\[
Ayz \frac{\partial f_{n-2}}{\partial x} - xz \frac{\partial f_{n-2}}{\partial y} + xy \frac{\partial f_{n-2}}{\partial z} = - \sum_{i=0}^{m} a_i^m 4C^2(m - i)(m - i - 1)(x^2 + Ay^2)^{m-i-2}(y^2 + z^2)^i xyz
\]

\[- \sum_{i=0}^{m} a_i^m 2Rai(x^2 + Ay^2)^{m-i}(y^2 + z^2)^i-1 z
\]

\[- \sum_{i=0}^{m} a_i^m 4AC(m - i)(x^2 + Ay^2)^{m-i-2}(y^2 + z^2)^i y^3.
\]

By (7), the above equation becomes

\[
\frac{df_{n-2}}{dw} = \sum_{i=0}^{m} a_i^m 4C^2(m - i)(m - i - 1)u^{m-i-2}v^iw
\]

\[+ \sum_{i=0}^{m} a_i^m 2Ra u^{m-i-1} v^{i-1} \frac{1}{\sqrt{u - Aw^2}}
\]

\[- \sum_{i=0}^{m} a_i^m 2C(m - i)u^{m-i-1}v^i \frac{w}{\sqrt{u - Aw^2} \sqrt{v - w^2}}.
\]

that is,

\[
f_{n-2} = \sum_{i=0}^{m} a_i^m 2C^2(m - i)(m - i - 1)u^{m-i-2}v^iw^2
\]

\[+ \sum_{i=0}^{m} a_i^m 2Ra u^{m-i-1} v^{i-1} \frac{1}{\sqrt{A}} \arctan \left( \frac{\sqrt{Aw}}{\sqrt{u - Aw^2}} \right)
\]

\[- \sum_{i=0}^{m} a_i^m 2C(m - i)u^{m-i-1}v^i \ln \left| \frac{\sqrt{u - Aw^2} + \sqrt{A(v - w^2)}}{\sqrt{A}} \right|.
\]

We must have

\[
\begin{cases}
a_i^m 2i Ra = 0, \\
a_i^m 2C(m - i) = 0, \quad i = 0, 1, \ldots, m,
\end{cases}
\]
which yields \( a_i^m = 0 \) for \( i = 0, 1, \cdots, m \). This is a contradiction to \( f_n \neq 0 \).

**Case II**. \( \sigma \neq 1 \), \( a_i^m = 0 \), \( i = 0, 1, \cdots, m-1 \), \( k_0 = -2\sigma m \). In this case, we have

\[
f_n = f_{2m} = a_m^m(y^2 + z^2)^m, \quad f_{n-1} = f_{2m-1} = 0.
\]

Working in a similar way to the previous case, we get

\[
-\sqrt{u - Aw^2}\sqrt{v - w^2} \frac{df_{n-2}}{dw} = -2a_m^m mRa^{m-1} \sqrt{v - w^2},
\]

and

\[
f_{n-2} = 2a_m^m mRa^{m-1} \frac{1}{\sqrt{A}} \arctan \left( \frac{\sqrt{Aw}}{\sqrt{u - Aw^2}} \right).
\]

Therefore, \( a_m^m = 0 \) and \( f_n = 0 \), which is a contradiction.

**Proposition 6.** System (1) has no exponential factors.

**Proof:** Let \( E = \exp(g/h) \) be an exponential factor of system (1) with a cofactor

\[
L = l_0 + l_1 x + l_2 y + l_3 z, \quad l_i \in \mathbb{R}, \quad i = 0, 1, 2, 3,
\]

where \( g, h \in \mathbb{R}[x, y, z] \) with \( f, g \) being prime. From Proposition 2, 4 and 5, \( E = \exp(g) \) with \( g = g(x, y, z) \in \mathbb{R}[x, y, z]/\mathbb{R} \). By definitions, \( g \) satisfies

\[
(Ayz + Cz - \sigma x) \frac{\partial g}{\partial x} + (-xz + Ra - y) \frac{\partial g}{\partial y} + (-z + xy) \frac{\partial g}{\partial z} = l_0 + l_1 x + l_2 y + l_3 z. \quad (21)
\]

If \( g \) is a polynomial of degree \( n \geq 3 \). We write \( g \) as \( g = \sum_{j=0}^{n} g_j(x, y, z) \), where each \( g_j \) is a homogeneous polynomial of degree \( j \) and \( g_n \neq 0 \). Observing the right hand side of (21) has degree at most one, we compute the terms of degree \( n + 1 \) in (21) and get

\[
Ayz \frac{\partial g_n}{\partial x} - xz \frac{\partial g_n}{\partial y} + xy \frac{\partial g_n}{\partial z} = 0,
\]

which is replaced by \( f_n \) by \( g_n \). Then the arguments used in the proof of Proposition 4 imply \( g_n = L_n(y^2 + z^2)^m \) with \( L_n \in \mathbb{R} \). Now computing the terms of degree \( n \) in (21) leads to

\[
Ayz \frac{\partial g_{n-1}}{\partial x} - xz \frac{\partial g_{n-1}}{\partial y} + xy \frac{\partial g_{n-1}}{\partial z} = (\sigma x - Cz) \frac{\partial g_n}{\partial x} + y \frac{\partial g_n}{\partial y} + z \frac{\partial g_n}{\partial z},
\]

which is replaced by \( f_n \) replaced by \( g_n \) and \( f_{n-1} \) replaced by \( g_{n-1} \). Again, the arguments used in the proof of Proposition 4 imply that \( g_n = 0 \), which is a contradiction.

Hence, \( g \) is a polynomial of degree at most two satisfying (21). So we can write \( g \) as

\[
g = b_0 + b_1 x + b_2 y + b_3 z + b_{11}x^2 + b_{22}y^2 + b_{33}z^2 + b_{12}xy + b_{13}xz + b_{23}yz. \quad (22)
\]
Then substituting (22) into (21) yields a system of algebraic equations $g_i = 0$ for $i = 1, \cdots, 15$, where

$$
\begin{align*}
g_1 &= Rab_2 - l_0, \quad g_2 = -\sigma b_1 + Rab_2 - l_1, \\
g_3 &= 2Rab_{22} - b_2 - l_2, \quad g_4 = Cb_1 + Rab_{23} - b_3 - l_3, \\
g_5 &= -\sigma b_{12} - b_{12} + b_1, \quad g_6 = -\sigma b_{13} - b_2 - b_{13}, \\
g_7 &= Ab_1 + Cb_{12} - 2b_{23}, \quad g_8 = -2\sigma b_{11}, \\
g_9 &= -2b_{22}, \quad g_{10} = 2Cb_{11} + Cb_{13} - 2b_{33}, \quad g_{11} = -b_{22} + b_{33}, \\
g_{12} &= b_{13}, \quad g_{13} = b_{12}, \quad g_{14} = b_{23}, \quad g_{15} = 2Ab_{11} + Ab_{13}.
\end{align*}
$$

From the above equations, we obtain that $l_0 = l_1 = l_2 = l_3 = 0$, $b_1 = b_2 = b_3 = 0$, $b_{11} = b_{22} = b_{33} = b_{12} = b_{13} = b_{23} = 0$, which implies $g$ is a constant. This completes the proof.

**Proof of Theorem 1**: By Proposition 1 and 4-6, it is obvious.

### 4. Appendix

In this section, we provide a relationship between the Glukhovsky-Dolzhansky system (1) and other similar quadric systems including the Rabinovich system, the 3D forced-damped system and the $D^2$ vector field.

The Rabinovich system [28, 29] is a three-wave interaction model and is given by

$$
\begin{align*}
\dot{X} &= hY - v_1 X + Y Z \\
\dot{Y} &= hX - v_2 Y - XZ \\
\dot{Z} &= -v_3 Z + XY.
\end{align*}
$$

(23)

Clearly, system (24) corresponds to the Rabinovich system (23) with parameters $(h, v_1, v_2, v_3) = (\alpha \sqrt{-A}Ra, \alpha \sigma, \alpha, \alpha)$. Hence, if $C = -2ARa$, the Glukhovsky-Dolzhansky system (1) is equivalent to the Rabinovich system (23) in the particular case of the parameter region $\{(h, v_1, v_2, v_3) | v_2 = v_3\}$, that is, two systems are homothetic copies. In addition, the linear scaling $S_\alpha$ forces parameter $A$ is less than zero, which cannot hold in the physical region of parameter $A$. 

$$
\begin{align*}
\frac{dX}{dt} &= \alpha \sqrt{-ARa}Y - \alpha \sigma X + Y Z \\
\frac{dY}{dt} &= \alpha \sqrt{-ARa}X - \alpha Y - XZ \\
\frac{dZ}{dt} &= -\alpha Z + XY.
\end{align*}
$$

(24)
The 3D forced-damped system [30] arises in mechanical, electrical and fluid dynamical contexts and is given by

\[
\begin{align*}
\dot{X} &= -aX + Y + YZ \\
\dot{Y} &= X - aY + bXZ \\
\dot{Z} &= cZ - bXY
\end{align*}
\]  

(25)

where \(a, b, c\) are parameters. Compared with the Glukhovsky-Dolzhansky system [11], the 3D forced-damped system (25) has less parameters. When \(\sigma = 1\), the linear scaling

\[
x = \frac{(ARa + C)^{3/2}}{A\sqrt{Ra}} X, \ y = Ra + \frac{(ARa + C)Z}{A}, \ z = \frac{(ARa + C)Y}{A}, \ t = \frac{T}{\sqrt{(ARa + C)Ra}}
\]

transforms the Glukhovsky-Dolzhansky system (1) into

\[
\begin{align*}
\frac{dX}{dT} &= -\frac{1}{\sqrt{(ARa + C)Ra}} X + Y + YZ \\
\frac{dY}{dT} &= X - \frac{1}{\sqrt{(ARa + C)Ra}} Y + \frac{ARa + C}{ARa} XZ \\
\frac{dZ}{dT} &= -\frac{1}{\sqrt{(ARa + C)Ra}} Z - \frac{ARa + C}{ARa} XY
\end{align*}
\]

(26)

which corresponds to the 3D forced-damped system (25) with parameters \((a, b, c) = \left(\frac{\sigma}{\sqrt{(ARa + C)Ra}}, \frac{ARa + C}{ARa}, -\frac{1}{\sqrt{(ARa + C)Ra}}\right)\).

Therefore, when \(\sigma = 1\), the Glukhovsky-Dolzhansky system (1) is equivalent to the 3D forced-damped system (25) in the particular case of the parameter region \(\{(a, b, c) | a + c = 0\}\).

Consider the vector field equivariant under the \(D2\) symmetry group, called the \(D2\) vector field [31]

\[
\begin{align*}
\dot{X} &= aX + YZ \\
\dot{Y} &= bY + XZ \\
\dot{Z} &= Z - XY.
\end{align*}
\]

(27)

where \(a, b\) are parameters. Similar to above, when \(Ra = C = 0\), we make a linear scaling

\[
x = X, \ y = \frac{Z}{\sqrt{A}}, \ z = -\frac{Y}{\sqrt{A}}, \ t = -T
\]

and transform (1) into

\[
\begin{align*}
\frac{dX}{dT} &= \sigma X + YZ \\
\frac{dY}{dT} &= Y + XZ \\
\frac{dZ}{dT} &= Z - XY.
\end{align*}
\]

(28)

which corresponds to the \(D2\) vector field (27) with parameters \((a, b) = (\sigma, 1)\). Then, when \(Ra = C = 0\), the Glukhovsky-Dolzhansky system (1) is equivalent to the \(D2\) vector field (27) in the particular case of the parameter region \(\{(a, b) | b = 1\}\).
