Tractable Structured Natural-Gradient Descent Using Local Parameterizations

Wu Lin 1 Frank Nielsen 2 Mohammad Emtyiyaz Khan 3 Mark Schmidt 1

Abstract
Natural-gradient descent on structured parameter spaces (e.g., low-rank covariances) is computationally challenging due to complicated inverse Fisher-matrix computations. We address this issue for optimization, inference, and search problems by using local-parameter coordinates. Our method generalizes an existing evolutionary-strategy method, recovers Newton and Riemannian-gradient methods as special cases, and also yields new tractable natural-gradient algorithms for learning flexible covariance structures of Gaussian and Wishart-based distributions via matrix groups. We show results on a range of applications on deep learning, variational inference, and evolution strategies. Our work opens a new direction for scalable structured geometric methods via local parameterizations.

1. Introduction
A wide-variety of problems in optimization, inference, and search problems can be expressed as

\[
\min_{q(w) \in Q} \mathbb{E}_{q(w)} \left[ \ell(w) \right] - \gamma \mathcal{H}(q(w)),
\]

where \( w \) is the parameter of interest, \( q(w) \) is a distribution over the parameter in the space of distributions \( Q \), \( \mathcal{H}(q(w)) \) is the entropy, \( \ell(w) \) is a loss function defined using data, and \( \gamma \geq 0 \) is a scalar, often set to 0. For example, \( q(w) \) is called the search distribution in random search (Baba, 1981), stochastic optimization (Spall, 2005), and evolutionary strategies (Beyer, 2001), used to find a global minimum of a black-box function \( \ell(w) \). In reinforcement learning, it can be the policy distribution which minimizes the expected value function \( \ell(w) \) parameterized by a model with parameter \( w \) (Sutton et al., 1998), sometimes with entropy regularization (Williams & Peng, 1991; Mnih et al., 2016).

For Bayesian learning, \( q(w) \) is the posterior distribution or its approximation and the \( \ell(w) \) includes a log-prior regularization term, with \( \gamma = 1 \) (Zellner, 1986). Finally, many robust or global optimization techniques employ a distribution \( q(w) \) to smooth out local minima (Mobahi & Fisher III, 2015; Leordeanu & Hebert, 2008; Hazan et al., 2016), often with \( \gamma = 0 \). Developing fast and scalable algorithms for solving (1) potentially impacts all these fields.

Natural-gradient descent (NGD) is an attractive algorithm to solve (1) and can speed up the optimization by exploiting the information geometry of the parametric family of distributions \( Q \) (Wierstra et al., 2008; Sun et al., 2009; Hoffman et al., 2013; Khan & Lin, 2017; Salimbeni et al., 2018). It also unifies a wide variety of learning algorithms which can be seen as instances of NGD obtained by choosing a specific distribution class \( Q \) (Khan & Rue, 2020). This is shown by Khan & Lin (2017) for approximate-inference algorithms and by Khan et al. (2018) for deep-learning algorithms. Khan & Rue (2020) additionally show connections to gradient-descent and Newton’s method. Such connections make it easy to derive new algorithms by simply changing the class \( Q \) (Lin et al., 2019a; Osawa et al., 2019a). Due to its generality and good properties (e.g., Fisher efficiency in online learning or plateau avoiding in deep learning), NGD is preferable to methods that ignore the distributions’ geometry (Ranganath et al., 2014; Lezcano Casado, 2019).

Unfortunately, natural gradients can be intractable or costly when parameter spaces of \( q(w) \) involve complex structures (e.g., low-rank or structured covariances for Gaussian distributions). Such structures lead to complicated Fisher-matrices, which require complicated derivations on a case-by-case basis, and ad-hoc structural approximations for tractability and cost reductions (Sun et al., 2013; Akimoto & Hansen, 2016; Li & Zhang, 2017; Mishkin et al., 2018; Tran et al., 2020) (see Appendix G.1 about difficulties of using black-box approaches). The approximations themselves involve new delicate choices to get a desired computation-accuracy trade-off. For example, for neural networks layer-wise structured approximations (Zhang et al., 2018; Lin et al., 2019a) might be better than low-rank/diagonal structures (Mishkin et al., 2018; Tran et al., 2020; Ros & Hansen, 2008; Khan et al., 2018), but may also involve much more computations. Our goal in this paper is to present methods that remove these difficulties with structured NGD.

1University of British Columbia, Canada. 2Sony Computer Science Laboratories Inc, Japan 3RIKEN Center for Advanced Intelligence Project, Japan. Correspondence to: Wu Lin <wlin2018@cs.ubc.ca>.

We present local parameterizations for tractable NGD in structured parameter spaces. The approach involves specifying (i) a "local parameter coordinate" that satisfies the structural constraints in the original (global) parameters of \( q(w) \), (ii) a map to convert back to the global parameters (via auxiliary parameters if required), and finally (iii) a tractable natural-gradient computation in the local-parameter space. These three steps can enable a tractable NGD while preserving the structure of the parameter spaces and exploiting their information geometry. Our approach builds upon a method by Glasmachers et al. (2010) for evolution strategies with Gaussian covariances using a local parameterization. Our approach generalizes the local-parameterization method to more general distributions and covariance structures.

The standard NGD (in the “global” parameters) can be seen as a special case of our local-parameterization approach. We can also recover an existing Newton method derived using Riemannian gradients (Lin et al., 2020). Our approach is more widely applicable, and we give an example involving Wishart distribution over positive-definite matrices. We also derive Newton-like updates for flexible covariance structures (including a mix of low-rank, diagonal, and sparse structures). These variants are obtained using several local parameterizations based on the Block-Triangular and Heisenberg matrix groups (Pennec & Arsigny, 2013; Schulz & Seesanea, 2018). These variants are much simpler and more flexible than the existing NGD strategies for structured and low-rank covariance matrices. But these variants notably only have a slightly-higher computation cost than the methods that employ diagonal structures.

We show applications to various problems for search, variational inference, and deep learning. Our method shows much faster convergence than the methods that do not exploit the geometry of the structure, while only slightly increasing the computation complexity. Our work expands the scope of exponential natural evolution strategies (xNES) and opens a new direction to design efficient and structured geometric methods via local parameterizations.

2. Structured NGD and its Challenges

The candidate distributions \( q(w) \in Q \) used in problem (1) are often parameterized, say using parameters \( \tau \in \Omega_\tau \). The problem can then be conveniently expressed as an optimization problem in the space \( \Omega_\tau \):

\[
\tau^* = \arg \min_{\tau \in \Omega_\tau} \mathbb{E}_{q(w|\tau)} [\ell(w)]
\]

where we assume \( \gamma = 0 \) for simplicity (see Lemma 4 in Appendix C for a general case). NGD uses the following update: \( \tau_{t+1} \leftarrow \tau_t - \beta \hat{g}_\tau \), where \( \beta > 0 \) is the step size and natural gradients are defined as

\[
\hat{g}_\tau := F_\tau (\tau) \nabla \mathbb{E}_{q(w|\tau)} [\ell(w)],
\]

by using the Fisher information matrix (FIM) \( F_\tau (\tau) := \mathbb{E}_{q(w|\tau)} [\nabla_\tau \log q(w|\tau)(\nabla_\tau \log q(w|\tau))^T] \) if the regularity condition is satisfied (see Appendix C).

The natural-gradient computation involves inversion of the Fisher matrix, which sometimes can be simplified. For example, when \( q(w|\tau) \) is a minimal exponential-family (EF) distribution, the Fisher matrix is invertible and the natural gradients can be computed by taking derivatives with respect to the expectation parameters of \( q(w|\tau) \), denoted by \( m \) (Khan & Lin, 2017; Khan & Nielsen, 2018). Whenever the map \( \tau \leftrightarrow m \) is easy to compute, NGD can be computed efficiently. When \( Q \) is chosen appropriately, these updates take well-known forms adapted by popular algorithms in the literature (Khan & Rue, 2020). For example, for Gaussian \( q(w|\tau) = \mathcal{N}(w|\mu, S^{-1}) \) where \( S \) denotes the precision matrix, Khan et al. (2018) derive a Newton-like update for variational inference:

\[
\begin{align*}
\mu_{t+1} &\leftarrow \mu_t - \beta S^{-1}_t \mathbb{E}_{q(w|\tau)} [\nabla_w \ell(w)] \\
S_{t+1} &\leftarrow S_t + \beta \mathbb{E}_{q(w|\tau)} [\nabla^2_w \ell(w)]
\end{align*}
\]

and also provide connections to deep-learning optimizers. The standard Newton update for optimization is recovered by approximating the expectation at the mean and using a step-size of 1 with \( \gamma = 1 \) (Khan & Rue, 2020). Several connections and extensions have been derived in the recent years establishing NGD as an important algorithm for optimization, search, and inference (Khan & Lin, 2017; Khan & Nielsen, 2018; Lin et al., 2019a; Osawa et al., 2019b).

The simplifications above break down as soon as (2) involves constrained parameter spaces \( \Omega_\tau \). Even for the Gaussian case, where the covariance matrix lies in the space of positive-definite matrices, the update (4) may violate the constraint (Khan et al., 2018). Extensions have been derived using Riemannian gradient descent (RGD) to fix this issue (Lin et al., 2020). Other solutions based on Cholesky (Sun et al., 2009; Salimbeni et al., 2018) or square-root parameterization (Glasmachers et al., 2010) have also been considered, where the problem is converted to an unconstrained parameter space. For example, Glasmachers et al. (2010) use a square-root-parameterization \( q(w) = \mathcal{N}(w|\mu, AA^T) \), where \( A \) is the square-root of \( S^{-1} \), and use the update:

\[
\begin{align*}
\mu_{t+1} &\leftarrow \mu_t - \beta \mathbb{E}_{q(w|\tau)} [(A(z_t - \mu_t) \ell(w)] \\
A_{t+1} &\leftarrow A_t \exp \left( \frac{\beta}{2} \mathbb{E}_{q(w|\tau)} [(z_t z_t^T - 1) \ell(w)] \right)
\end{align*}
\]

where \( z_t = A_t^{-1}(w - \mu_t) \) and \( \exp(X) = I + \sum_{k=1}^{\infty} \frac{X^k}{k!} \) is the matrix exponential function. These solutions however do not easily generalize. For example, it is not obvious how to apply these updates to cases where the covariance is low-rank (Mishkin et al., 2018; Tran et al., 2020), Kronecker structured (Zhang et al., 2018; Lin et al., 2019a), or to non-
Gaussian distributions such as the Wishart, Wald (Lin et al., 2020), and Gaussian mixtures (Lin et al., 2019a).

In fact, the issue with the structure and its effect on parameterization is a bit more complicated than it might appear at first. Certain choices of the structure/parameterization can make the Fisher matrix singular which can make NGD undefined. For example, for curved exponential-family the issue requires new tricks such as those based on auxiliary parameterization (Lin et al., 2019a), ad-hoc structural approximations (Tran et al., 2020), algorithmic approximations (Mishkin et al., 2018), or damping (Zhang et al., 2018).

The computational cost is also dependent on the parameterization. Some methods exploit structure in the covariances (Glasmachers et al., 2010) while the others work with its inverse such as (4). Customized structures, such as layer-wise and Kronecker-factored covariances in deep neural networks, may work well in one parameterization but not in the other. It is therefore important to have a flexible method that works well for a wide-variety of structures, parameterizations, and distributions. Our goal in this paper is to propose such a method.

3. Local Parameter Coordinates

We will describe a NGD strategy based on local parameter coordinates. We will describe the following three steps required to specify the method, and then give examples and extensions to illustrate its usage.

Step (1) is to specify a local parameterization, denoted by \( \eta \in \Omega_\eta \), such that the Fisher matrix with respect to it at a point \( \eta_0 \) is always non-singular (i.e., \( |F_\eta(\eta_0)| \neq 0 \) where \( |\cdot| \) denotes the matrix determinant).

**Assumption 1:** The Fisher matrix \( F_\eta(\eta_0) \) is non-singular.

Throughout the paper, we will choose \( \eta_0 = 0 \).

To specify the Fisher matrix \( F_\eta(\eta_0) \), Step (2) is to connect \( \eta \) to the original (global) parameters \( \tau \in \Omega_\tau \). We propose to do so via an additional auxiliary parameter \( \lambda \in \Omega_\lambda \) which is chosen so that \( \tau = \psi(\lambda) \) for a given function \( \psi(\cdot) \). The map from \( \eta \) to \( \lambda \) is then defined at a fixed value of \( \lambda_t \) as

\[
\lambda = \phi_{\lambda_t}(\eta) \quad \text{such that} \quad \lambda_t = \phi_{\lambda_t}(\eta_0).
\]

The map is tight at \( \eta_0 \) since it matches the current \( \lambda_t \), and by changing \( \eta \) we can obtain the auxiliary parameter \( \lambda \). In other words, \( \eta_0 \) is a relative origin tied to \( \lambda_t \), where we assume \( \eta_0 = 0 \). The overall map is \( \tau = \psi \circ \phi_{\lambda_t}(\eta) \). This choice might seem arbitrary but as we will see next, such maps let us use natural gradients computed at \( \eta_0 \) to update \( \tau \) under a mild coordinate compatibility assumption.

**Assumption 2:** For all \( \lambda \in \Omega_\lambda \), the map \( \eta \mapsto \psi \circ \phi_{\lambda_t}(\eta) \) is locally \( C^1 \)-diffeomorphic at an open neighborhood of \( \eta_0 \).

Assumptions 1 and 2 together define an implicit constraint over the two spaces \( \Omega_\lambda \) and \( \Omega_\eta \).

Step (3) is to compute natural gradients \( \hat{g}^{(t)}_{\eta}(\eta_0) \) and update \( \tau \). We directly obtain \( \hat{g}^{(t)}_{\eta}(\eta_0) \) by the chain rule using the map at \( \lambda_t \) (see Appendix C for an indirect method)

\[
\hat{g}^{(t)}_{\eta}(\eta_0) = F_\eta(\eta_0)^{-1} \nabla_{\eta} \left[ \psi \circ \phi_{\lambda_t}(\eta_0) \right] \quad \text{g}_\tau,
\]

where \( \text{g}_\tau := \nabla_{\tau} \mathbb{E}_{f(w|\tau)}[\ell(w)] \). This is most useful when the computation of (7) is tractable. When that is the case, the global parameter can be updated using a NGD step in the local parameters: \( \eta_0 = \beta \hat{g}^{(t)}_{\eta_0} \), which gives the following

\[
\tau_{t+1} \leftarrow \psi \circ \phi_{\lambda_t} \left( -\beta \hat{g}^{(t)}_{\eta_0} \right)
\]

since we have assumed \( \eta_0 = 0 \). In summary, given an auxiliary parameter \( \lambda_t \), we can use the natural gradient (7) to update \( \tau \) according to (8). We shown in Appendix F that NGD step using (3) is a special case of our local parameterization method. To illustrate the steps, we give examples where we derive existing methods as special cases.

3.1. Gaussian with square-root covariance structure

For a Gaussian distribution \( \mathcal{N}(w|\mu, \Sigma) \), the covariance matrix \( \Sigma \) is positive definite. Standard NGD steps such as (4), may violate this constraint (Khan et al., 2018). Glasmachers et al. (2010) use \( \Sigma = AA^\top \) where \( A \) is an invertible matrix (not a Cholesky), and derived an update using a specific local parameterization. Since our approach is a generalization of Glasmachers et al. (2010), we use it as a first example.

Following Glasmachers et al. (2010), we choose the following parameterization, where we use \( S^{p\times p}_{++}, S^{p\times p}, \) and \( R^{p\times p}_{++} \) to denote the set of symmetric positive definite matrices, symmetric matrices, and invertible matrices, respectively,

\[
\tau := \{\mu \in \mathbb{R}^p, \Sigma \in S^{p\times p}_{++}\},
\lambda := \{\mu \in \mathbb{R}^p, A \in R^{p\times p}_{++}\},
\eta := \{\delta \in \mathbb{R}^p, M \in S^{p\times p}\},
\]

where \( \delta \) and \( M \) are the local parameters.

The map \( \psi \circ \phi_{\lambda_t}(\eta) \) at \( \lambda_t := \{\mu_t, A_t\} \) is chosen to be

\[
\left\{ \begin{array}{l}
\mu \\
\Sigma \\
\end{array} \right\} = \psi(\lambda) := \left\{ \begin{array}{l}
\mu \\
A A^\top \\
\end{array} \right\},
\left\{ \begin{array}{l}
\mu \\
A \\
\end{array} \right\} = \phi_{\lambda_t}(\eta) := \left\{ \begin{array}{l}
\mu_t + A_t \delta \\
A_t \exp \left( \frac{1}{2} M \right) \\
\end{array} \right\}.
\]

Finally, we can get the natural gradients (7) by using the Fisher matrix \( F_\eta(\eta_0) \) (see Appendix D.2 for a derivation),

\[
\left( \frac{\partial g_{\beta \eta_0}^{(t)}}{\partial B_{\lambda_t}} \right) = \left( \begin{array}{cc}
I_p & 0 \\
0 & \frac{1}{2} I_p^2 \\
\end{array} \right)^{-1} \left( \begin{array}{cc}
A^\top g_{\mu_t} \\
A_t G_{\Sigma;A_t} \\
\end{array} \right)
\]
By plugging into (10), (11) in (7), our update can be written in the space of $\lambda$ as below, where $S_t^{-1} = \Sigma_t$. 

$$
\begin{align*}
\mu_{t+1} &\leftarrow \mu_t - \beta S_t^{-1} g_{\mu_t} \\
A_{t+1} &\leftarrow A_t \text{Exp}(\ -\beta A_t^T g_{\Sigma_t} A_t) \\
\end{align*}
$$

(12)

By the REINFORCE trick (Williams, 1992), the gradients with respect to global parameters are

$$
\begin{align*}
g_{\mu_t} &:= E_q[\ell(w)] \left( A^{-T} z \ell(w) \right) \\
g_{\Sigma_t} &:= \frac{1}{2} E_q[\ell(w)] \left( A^{-T} (zz^T - I) A^{-1} \ell(w) \right)
\end{align*}
$$

(13)

where $z = A^{-1} (w - \mu)$. By plugging into (13) into (12), we recover the update (5) used in Glassmachers et al. (2010). Appendix D.2 shows that Assumption 1-2 are satisfied.

Glassmachers et al. (2010) only demonstrated their method in the Gaussian case, without providing complete derivations1 which makes generalization difficult. In addition, their approach only applied to a square-root structure of the covariance and it is not clear how to generalize it to other structures (e.g., low-rank and sparse structures). We now give more examples, establishing relationships to Newton’s method and an extension to the Wishart distribution.

### 3.2. Connection to Newton’s method

We now show that surprisingly the update (5) derived using local parameterization is in fact closely related to a Newton’s update derived using global parameterization. Specifically, we will convert the update of $A_{t+1}$ in (5) to the update over $S_{t+1}$, as in (4), and recover the Newton’s update derived by Lin et al. (2020). To do so, we need to make two changes. First, we will expand the matrix exponential $\text{Exp}(\beta M) = I + \sum_{k=1}^{\infty} (\frac{\beta M}{k!})^k$. And second, instead of using (13) with Monte-Carlo (MC), we will use Stein’s identity (Opper & Archambeau, 2009; Lin et al., 2019b): $g_{\Sigma_t} = \frac{1}{2} E_q[\nabla^2 \ell(w)]$. Using these changes, the update over $S_{t+1}$ can be rewritten as a modified version of Newton’s update proposed by Lin et al. (2020),

$$
\begin{align*}
S_{t+1} = (A_t A_t^T)^{-1} = A_t^{-T} \text{Exp}(2\beta A_t^T g_{\Sigma_t} A_t) A_t^{-1} \\
&= S_t + \beta E_q[\nabla^2 \ell(w)] + \frac{\beta^2}{2} G_{S_t}^{-1} G + O(\beta^3)
\end{align*}
$$

(15)

where $G = E_q[\nabla^2 \ell(w)]$. Ignoring the red term gives us the Newton update (4). This term is added by Lin et al. (2020) to fix the positive-definite constraint violation. Their derivation is based on using Riemannian gradient descent.

Thus, both the update (4) and the method of Lin et al. (2020) can be seen as a special cases of our approach with a different approximation of the exponential map.

### 3.3. Wishart with square-root precision structure

We will now show an example that goes beyond Gaussians. We consider a Wishart distribution which is a distribution over $p$-by-$p$ positive-definite matrices,

$$
W_p(W|S, n) = \frac{|W|^{(n-p-1)/2} |S|^{n/2}}{\Gamma_p(n/2)^{2np/2}} e^{-\frac{1}{2} \text{Tr}(SW)},
$$

where $\Gamma_p(\cdot)$ is the multivariate gamma function. Here, the global parameters are based on the precision matrix $S$, unlike the example in Section 3.1. We will see that our update will automatically take care of this difference and obtain a similar update to the one obtained using $\Sigma$ in (12).

We start by specifying the parameterization,

$$
\begin{align*}
\tau := \{n \in \mathbb{R} \mid S \in S^p_{++} \mid n > p - 1\}, \\
\lambda := \{b \in \mathbb{R} \mid B \in R^p_{++}\}, \\
\eta := \{\delta \in \mathbb{R} \mid M \in S^p_{++}\},
\end{align*}
$$

and their respective maps defined at $\lambda_t := \{b_t, B_t\}$

$$
\begin{align*}
\{ n \mid S \} &= \psi(\lambda) := \left\{ \begin{array}{ll} 2f(b) + p - 1 \\
(2f(b) + p - 1)BB^T \end{array} \right\}, \\
\{ b \mid B \} &= \phi_\lambda(\eta) := \left\{ b_t + \delta \\
B_t \text{Exp}(M) \right\}.
\end{align*}
$$

where $f(b) = \log(1 + \exp(b))$ is the soft-plus function. The auxiliary parameter $B$ here is defined as the square-root the precision matrix $S$, unlike in the previous examples.

Denoting the gradients by

$$
G_{S_t} := \nabla_{S_t} E_q[\ell(W)], \quad g_n := \nabla_n E_q[\ell(W)],
$$

(16)

we can write the updates as (derivation in Appendix E):

$$
\begin{align*}
B_{t+1} &\leftarrow B_t \text{Exp} \left( \frac{\beta}{n_t} B_t^{-1} G_{S_t}^{-1} B_t^{-T} \right) \\
B_{t+1} &\leftarrow B_t - \beta c_t \left[ g_n - \frac{1}{n_t} \text{Tr} \left( G_{S_t}^{-1} S_t^{-1} \right) \right]
\end{align*}
$$

(17)

(18)

where $c_t = \frac{2(1+\exp(b_t))}{\exp(b_t)} (\frac{2p}{n_t} + D_{\psi,p}(\frac{n_t}{2}))^{-1}$ and $D_{\psi,p}(x)$ is the multivariate trigamma function. Moreover, we can use re-parameterizable gradients (Figurnov et al., 2018; Lin et al., 2019b) for $G_{S_t}$ and $g_n$, due to the Bartlett decomposition (Smith et al., 1972) (see Appendix E.1 for details).

The update (17) for $B$ (square-root of the precision matrix) is very similar to the update for $A$ (square-root of covariance) in (12). The change from covariance to precision...
parameterization changes the sign of the update. The step size is modified using the degree-of-freedom \( n_t \). The local parameterization can automatically adjust to such changes in the parameter specification, giving rise to intuitive updates.

Next, we will show another surprising result: the updates on the Wishart distribution is a generalization of RGD over the space of positive-definite matrices.

### 3.4. Connection to Riemannian Gradient Descent

Given an optimization problem

\[
\min_{Z \in S^{p \times p}_{++}} \ell(Z)
\]

over the space of symmetric positive-definite matrices, the RGD update with retraction can be written in terms of the inverse \( U = Z^{-1} \) (see Appendix E.2 for the details),

\[
U_{t+1} \leftarrow U_t + \beta_t \nabla \ell(U_t) \left[ \nabla \ell(U_t) \right] U_t^{-1} \left[ \nabla \ell(U_t) \right]
\]

where \( \nabla \) is taken with respect to \( Z \), and \( \beta_t \) is the step size. We now show that this is a special case of (17) where gradients (16) are approximated at the mean of the Wishart distribution as \( \mathbb{E}_q \left[ \nabla \ell(Z_t) \right] = n S^{-1} \). Denoting the mean by \( Z_t \), the approximation is (see the derivation in Appendix E.3),

\[
G_{S^{-1}} \approx n_t \nabla \ell(Z_t), \quad g_{n_t} \approx \text{Tr} \left[ \nabla \ell(Z_t) S_t^{-1} \right]
\]

Plugging (19) into (18), we find that value of \( b \) does not change during the update,

\[
b_{t+1} \leftarrow b_t - \beta c_t \left[ \text{Tr} \left[ \nabla \ell(Z_t) S_t^{-1} \right] - \text{Tr} \left[ \nabla \ell(Z_t) S_t^{-1} \right] \right]
\]

so that \( b_{t+1} = b_t \) and \( n_t \) becomes a constant since \( n = 2 f(b) + p - 1 \). Resetting the step-size to be \( \beta = \frac{1}{2} \beta_1 n_t^2 \) (17) becomes

\[
B_{t+1} \leftarrow B_t \exp \left( \frac{\beta_1}{2} B_t^{-1} \left[ \nabla \ell(Z_t) \right] B_t^{-T} \right)
\]

Finally, we express the update in terms of \( U_t = Z_t^{-1} = B B^T \) to rewrite (20) as by using the second order terms in the matrix exponential (14),

\[
U_{t+1} \leftarrow B_t \exp(\beta_1 B_t^{-1} \left[ \nabla \ell(Z_t) \right] B_t^{-T}) B_t^T
\]

recovering the RGD update. Thus, the RGD update is a special case of our update for Wishart distribution, where the expectation is approximated at the mean. This is a local approximation that avoids sampling from the distribution. This derivation is another instance of reduction to a local method using NGD over distributions, similar to the ones obtained by Khan & Rue (2020).

### 3.5. Generalizations and Extensions

In previous sections, we used the matrix exponential map to define \( \phi_\lambda(\eta) \), but other maps can be used. This is convenient since the exponential map can be difficult to compute and numerically unstable. We propose to use this map:

\[
h(M) = I + M + \frac{1}{2} M^2.
\]

This simplifies the inverse FIM computation in Gaussian and Wishart cases without changing the form of the updates. For example, consider the Gaussian case in Section 3.1 where covariance \( \Sigma \) is used. An advantage of our approach is that we could easily change the parameterization to the precision \( S = \Sigma^{-1} \) instead, by changing the parameters in (9) to

\[
\tau := \{ \mu \in \mathbb{R}^p, \ S \in S^{p \times p}_{++} \}
\]

\[
\lambda := \{ \mu \in \mathbb{R}^p, \ B \in \mathbb{R}^{p \times p} \}
\]

\[
\eta := \{ \delta \in \mathbb{R}^p, \ M \in S^{p \times p} \}.
\]

We can use map \( h(\cdot) \) in the following transformations:

\[
\begin{align*}
\{ \mu \} & \mapsto \psi(\lambda) := \left\{ \mu, B B^T \right\} \\
\{ \mu \} & \mapsto \phi_\lambda(\eta) := \left\{ \mu + B_i^T \delta \right\}
\end{align*}
\]

An update (see (35) at Appendix D.1) almost identical to (15) is obtained with this very different parameterization and map. The difference only appears in the \( O(\beta^3) \) term. Our approach makes it easy to use different distributions and derivation possible for a variety of parameterizations and maps, unlike the method originally described by Glasmachers et al. (2010). Moreover, we have Stein’s first-order identity (Lin et al., 2019b; 2020) known as the re-parameterization trick for Gaussian, \( g_S = \frac{1}{2} \mathbb{E}_q \left[ \nabla^2 \ell(w) \right] \), to avoid using the Hessian \( \nabla^2 \ell(w) \). We also obtain a NGD update in an unconstrained space for univariate EFs in Appendix G.

In practice, Assumption 1 may be too restrictive. The FIM of both curved exponential-family (Lin et al., 2019a) and MLP (Amari et al., 2018) under a global parameterization are singular. However, Lin et al. (2019a) show that for a minimal conditional mixture, the FIM of the joint distribution of the mixture under a global parameterization is non-singular. Thus, we can extend our approach to the mixture such as Gaussian mixtures (see Appendix H) . Alternatively, Tran et al. (2020); Glasmachers et al. (2010); Lin et al. (2019a) use a block-diagonal approximation of the original FIM. In Appendix I, we adapt our approach to the block-diagonal approximation for matrix Gaussian used in NNs, where each block of the FIM is non-singular (Lin et al., 2019a) unlike noisy-KFAC that has to use damping (Zhang et al., 2018).

### 4. NGD for Structured Matrix Groups

We now show applications to NGD on matrices with special structures. The key idea is to use the fact that the auxiliary-

\[\text{Since } n \text{ remains constant, } \beta = \frac{1}{2} \beta_1 n \text{ is a constant step-size.}\]
parameter space \( \mathcal{R}_{++}^{p \times p} \), used in Sec 3, is a general linear group (Belk, 2013) and structured restrictions give us its subgroups. We can specify local parameterizations for the subgroups to get a tractable NGD. We will use the Gaussian example considered in Sec 3.5 to illustrate this idea. A similar technique could be applied to the Wishart example. We will discuss the triangular group in the precision form first, and then discuss an extension to the Hesisenberg group.

We use \( \mathcal{B}_{up}(k) \) to denote the space of following block upper-triangular \( p \times p \) matrices as an auxiliary parameter space, where \( k \) is the block size with \( 0 < k < p \) and \( d_0 = p - k \), and \( \mathcal{D}_{++}^{d_0 \times d_0} \) is the space of diagonal and invertible matrices.

\[
\mathcal{B}_{up}(k) = \left\{ \begin{bmatrix} B_A & B_B \\ 0 & B_D \end{bmatrix} \mid B_A \in \mathcal{R}_{++}^{k \times k}, B_D \in \mathcal{D}_{++}^{d_0 \times d_0} \right\}
\]

When \( k = 0 \), \( \mathcal{B}_{up}(k) = \mathcal{D}_{++}^{p \times p} \) becomes a diagonal auxiliary space. When \( k = p \), \( \mathcal{B}_{up}(k) = \mathcal{R}_{++}^{p \times p} \) becomes a full auxiliary space. The following lemma shows it is a matrix group.

**Lemma 1** \( \mathcal{B}_{up}(k) \) is a matrix group that is closed under matrix multiplication.

A local parameter space for \( \mathcal{B}_{up}(k) \) is defined by:

\[
\mathcal{M}_{up}(k) = \left\{ \begin{bmatrix} M_A & M_B \\ 0 & M_D \end{bmatrix} \mid M_A \in \mathcal{S}^{k \times k}, M_D \in \mathcal{D}_{++}^{d_0 \times d_0} \right\}
\]

where \( \mathcal{D}_{++}^{d_0 \times d_0} \) denotes the space of diagonal matrices.

**Lemma 2** For any \( M \in \mathcal{M}_{up}(k) \), \( h(M) \in \mathcal{B}_{up}(k) \).

Using these spaces, we specify the parameterization for the Gaussian \( \mathcal{N}(w | \mu, S^{-1}) \), where the precision \( S \) belongs to \( \mathcal{S}_{++}^{p \times p} \), auxiliary parameter \( B \) belongs to \( \mathcal{B}_{up}(k) \), and local parameter \( M \) belongs to \( \mathcal{M}_{up}(k) \),

\[
\tau := \{ \mu \in \mathbb{R}^p, S \in \mathcal{S}_{++}^{p \times p} \}, \quad \lambda := \{ \mu \in \mathbb{R}^p, B \in \mathcal{B}_{up}(k) \}, \quad \eta := \{ \delta \in \mathbb{R}^p, M \in \mathcal{M}_{up}(k) \}.
\]

The map \( \psi \circ \phi_{\lambda_{t}}(\eta) \) at \( \lambda_{t} := \{ \mu_{t}, B_{t} \} \) is chosen to be the same as (21) due to Lemma 1 and Lemma 2. Lemma 3 below shows that this local parameterization is valid.

**Lemma 3** Assumption 1 and 2 are satisfied for this local parameterization.

The natural-gradients (shown in Appendix J.1.4) are

\[
\hat{g}_{\mu_{t}}^{(t)} = B_{T}^{-1}g_{\mu_{t}}; \quad \hat{g}_{\lambda_{t}}^{(t)} = C_{up} \odot \kappa_{up}(-2B_{T}^{-1}g_{\Sigma_{t}}B_{T}^{T})
\]

where \( \odot \) denotes the element-wise product, \( \kappa_{up}(X) \) extracts non-zero entries of \( \mathcal{M}_{up}(k) \) from \( X \) so that \( \kappa_{up}(X) \in \mathcal{M}_{up}(k) \). \( C_{up} \) is a constant matrix defined by

\[
C_{up} = \begin{bmatrix} \frac{1}{2}J_{A} & J_{B} \end{bmatrix} \odot_{i} \mathcal{M}_{up}(k)
\]

where \( J \) denotes a matrix of ones and factor \( \frac{1}{2} \) appears in the symmetric part of \( C_{up} \). This gives us the following NGD update over the auxiliary parameters,

\[
\mu_{t+1} \leftarrow \mu_{t} - \beta S_{t}^{-1}g_{\mu_{t}}
\]

\[
B_{t+1} \leftarrow B_{t}h\left(\beta C_{up} \odot \kappa_{up}(2B_{T}^{-1}g_{\Sigma_{t}}B_{T}^{T})\right)
\]

where the updates preserves the block-triangular structure: \( B_{t+1} \in \mathcal{B}_{up}(k) \) whenever \( B_{t} \in \mathcal{B}_{up}(k) \). The form of the update is very similar to the Newton updates derived previously. Even though the structure is enforced, the updates essentially remains the same.

By exploiting the block-structure of \( B \) (see Appendix J.1.6 for the details), the update enjoys low computational complexity that are linear in \( p \) and quadratic in \( k \). The product \( S^{-1}g_{\mu_{t}} \) can be computed in \( O(k^2p) \). We can compute \( B_{t}h(M) \) in \( O(k^2p) \) when \( B_{t} \) and \( h(M) \) are block upper triangular matrices. The gradient \( g_{\Sigma_{t}} \) can be obtained using Hessian where we only require to compute/approximate diagonal entries and \( k \) Hessian-vector-products to compute non-zero entries of \( \kappa_{up}(2B_{T}^{-1}g_{\Sigma_{t}}B_{T}^{T}) \). We store the non-zero entries of \( B \) with space complexity \( O((k + 1)p) \).

As shown in Appendix J.1.5, the local parameterization induces structure over \( S_{up} = BB^{T} \), which is a block arrowhead matrix (Stor et al., 2015):

\[
S_{up} = \begin{bmatrix} B_{A}B_{A}^{T} + B_{D}B_{D}^{T}, B_{A}B_{D}^{T} \\ B_{D}B_{B}^{T} \end{bmatrix}
\]
Tractable structured natural gradient descent using local parameterizations

and over \( \Sigma_{\text{up}} = S_{\text{up}}^{-1} \), which is a low-rank structured matrix:

\[
\Sigma_{\text{up}} = U_k U_k^T + \begin{bmatrix} 0 & 0 \\ 0 & B_D^{-2} \end{bmatrix}; \quad U_k = \begin{bmatrix} -B_A^{-T} \\ B_D^{-1} B_B B_A^{-T} \end{bmatrix}
\]

where \( U_k \) is a rank-\( k \) matrix since \( B_A^{-T} \) is invertible.

In Appendix J.1.7, we obtain a similar update for a block lower-triangular group \( B_{\text{low}}(k) \). The update in the precision form obtained with \( B \in B_{\text{low}}(k) \) are similar to the BFGS method which exploits a low-rank structure in the Hessian. This is because \( S_{\text{low}} \) has a low-rank structure. Likewise, an update in the precision form with \( B \in B_{\text{up}}(k) \) is similar to the DFP method since \( S_{\text{up}} = S_{\text{up}}^{-1} \) has a low-rank structure.

An alternative is to construct the following group inspired by the Heisenberg group (Schulz & Seesanea, 2018), where \( 1 < k_1 + k_2 < p \) and \( d_0 = p - k_1 - k_2 \).

\[
B_{\text{up}}(k_1, k_2) = \left\{ \begin{bmatrix} B_A & B_B \\ 0 & B_D \end{bmatrix} | B_D = \begin{bmatrix} B_{D_1} & B_{D_2} \\ 0 & B_{D_3} \end{bmatrix} \right\}
\]

where \( B_A \in \mathcal{R}^{k_1 \times k_1}, B_{D_1} \in \mathcal{D}_d^{d_0 \times d_0}, B_{D_3} \in \mathcal{R}^{k_2 \times k_2} \). Similarly, we could define a lower block Heisenberg group \( B_{\text{low}}(k_1, k_2) \). In Appendix J.2, we show that these groups can be used as structured parameter spaces. This new kind of group has a more flexible structure than the block triangular group defined previously, which could be useful for problems of interest in optimization, inference, and search.

Last but not least, if the Hessian has a model-specific structure, we can even design a customized matrix group to capture such structure. For example, the Heisenberg of layer-wise matrix weights in a NN (see Appendix I.2) has a Kronecker form. A low-rank Kronecker structure can further reduce the time complexity from the quadratic complexity to a linear complexity in \( k \) (see Appendix I.1 and Figure 3).

5. Numerical Results

We present results on problems involving search, inference, optimization, and deep learning, where Table 1 in Appendix A summarizes our updates. We use \( h(\cdot) \) defined in Sec 3.5 to replace the matrix exponential map in all experiments.

5.1. Search with Re-parameterizable Gradients

We validate our update in the metric nearness task (Brickell et al., 2008) using a Wishart distribution as a search distribution \( q \) with \( \gamma = 0 \) in (1). The objective function is \( \ell(W) = \frac{1}{N} \sum_{i=1}^{N} \| W Q x_i - x_i \|^2_2 \), where \( x_i \in \mathcal{R}^d \), \( Q \in S_{++}^{d \times d} \) and \( W \in S_{++}^{d \times d} \). The optimal solution is \( Q^{-1} \). We randomly generate \( x_i \) and \( Q \) with \( d = 50 \), \( N_{\text{train}} = 125,000 \) for training and \( N_{\text{test}} = 25,000 \) for testing. All methods are trained using mini-batches, where the size of mini-batch is 100. We use re-parameterizable gradients with 1 MC sample in our update (referred to as “our-rep”), where we update \( B \) and \( b \). We also consider to only update \( B \) with re-parameterizable gradients (referred to as “our-fixed-rep”). To numerically show the similarity between RGD and our update, we consider a case where gradients are evaluated at the mean (referred to as “-mean”). We consider baseline methods: the classic RGD update for positive-definite manifolds and the Riemannian trivialization (Lezcano Casado, 2019), where gradients are evaluated at the mean. For the trivialization method, we consider trivializations for the positive-definite manifold: a Cholesky factor and the matrix logarithmic function. We report the best result of the trivializations denoted by “Adami”, where we use Adam to perform updates in a trivialized (Euclidean) space. From Figure 2(a), we can see our update performs similarly to RGD if gradients are evaluated at the mean while the trivialization method is trapped in a local mode. If we use re-parameterizable gradients, jointly updating both parameters is better than only updating \( B \).

5.2. Variational Inference

We consider the Gaussian mixture approximation problem (Lin et al., 2020), where we use a Gaussian mixture with \( K \) mixtures \( q(w) = \frac{1}{K} \sum_{k=1}^{K} N(w|\mu_k, S_k^{-1}) \) as a variational distribution \( q \) with \( \gamma = 1 \) in (1). The goal of the problem is to approximate a mixture of \( d \)-dimensional Student’s t distributions \( \exp(-\ell(w)) = \frac{1}{\alpha} \sum_{c=1}^{C} T(w|u_c, V_c, \alpha) \) with degrees of freedom \( \alpha = 2 \). We consider six kinds of structures of each Gaussian component: full precision (referred to as “full”), diagonal precision (referred to as “diag”), precision with the block upper triangular structure (referred to as “Tri-up”), precision with the block lower triangular structure (referred to as “Tri-low”), precision with the block upper Heisenberg structure (referred to as “Hs-up”), precision with the block lower Heisenberg structure (referred to as “Hs-low”). Each entry of \( u_c \) is generated uniformly in an interval \((-s, s)\). Each matrix \( V_c \) is generated as suggested by Lin et al. (2020). We consider a case with \( K = 40, C = 10, d = 80, s = 20 \). We update each component during training, where 10 MC samples are used to compute gradients. We compute gradients as suggested by Lin et al. (2020), where second-order information is used. For structured updates, we compute Hessian-vector products and diagonal entries of the Hessian without directly computing the Hessian \( \nabla^2 \ell(w) \). From Figure 1, we can see an upper structure can capture more off-diagonal correlations, which is good for inference problems. Appendix B shows more results on structures such as Heisenberg structures.

5.3. Structured Second-order Optimization

We consider non-separable valley-shaped test functions for optimization: Rosenbrock: \( \ell_{rb}(w) = \frac{1}{d} \sum_{i=1}^{d-1} \left[ 100(w_{i+1} - w_i)^2 + (w_i - 1)^2 \right] \), and Dixon-Price: \( \ell_{dp}(w) = \frac{1}{d} \sum_{i=1}^{d} \left[ (w_i - 1)^2 + \sum_{j=2}^{d} (2w_i^2 - w_{i+1})^2 \right] \). We test our structured Newton’s updates, where we set \( d = 200 \) and \( \gamma = 1 \) in (1). We
Figure 2. The performances of our updates for search and optimization problems. Figure 2(a) shows the performances using a Wishart distribution to search the optimal solution of a metric nearness task where our method evaluated at the mean behaves like RGD and converges faster than the Riemannian trivialization (Lezcano Casado, 2019) with Adam. Our updates with re-parameterizable gradients also can find a solution near the optimal solution. Figure 2(b) and 2(c) show the performances using structured Newton’s updates to optimize non-separable, valley-shaped, 200-dimensional functions, where our updates only require to compute diagonal entries of Hessian and Hessian-vector products. Our updates with a lower Heisenberg structure in the precision form converge faster than BFGS and Adam.

Figure 3. The performances for optimization of a CNN using matrix Gaussian with low-rank in a Kronecker precision form, where our updates \((O(\kappa|\omega|))\) have a linear iteration cost like Adam \((O(|\omega|))\) and are automatically parallelized by Auto-Diff. Our updates achieve higher test accuracy (75.8% on “STL-10” and 85.0% on “CIFAR-10”) than Adam (69.5% on “STL-10” and 82.3% on “CIFAR-10”).

Consider the following structures: precision with the upper triangular structure (denoted by “Tri-up”), precision with the lower triangular structure (denoted by “Tri-low”), precision with the upper Heisenberg structure (denoted by “Hs-up”), precision with the lower Heisenberg structure (denoted by “Hs-low”), where second-order information is used. For our updates, we compute Hessian-vector products and diagonal entries of the Hessian without directly computing the Hessian. We consider baseline methods: the BFGS method from SciPy and the Adam optimizer, where the step-size for each method is tuned by grid search. We use the same initialization and hyper-parameters in all methods. We report results in terms of test accuracy, where we average the results over 5 runs with distinct random seeds. From Figure 3, we can see our structured updates have a linear iteration cost as Adam while achieve higher test accuracy.

5.4. Optimization for Deep Learning

We consider a CNN model with 9 hidden layers, where 6 layers are convolution layers. For a smooth objective, we use average pooling and GELU (Hendrycks & Gimpel, 2016) as activation functions. We use \(L^2\) regularization with weight \(10^{-2}\) and set \(\gamma = 1\) in (1) during training. We train the model with our updates (see Appendix I) with the lower triangular structure for each layer-wise matrix weight\(^4\) (referred to as “Tri-low”) on datasets “CIFAR-10”, “STL-10”. For “CIFAR-10” and “STL-10”, we train the model with mini-batch size 20. Additional results on “CIFAR-100” can be found at Appendix B. We evaluate gradients at the mean and approximate the Hessian by the Gauss-Newton approximation. We compare our updates to Adam, where the step-size for each method is tuned by grid search. We use the same initialization and hyper-parameters in all methods. We report results in terms of test accuracy, where we average the results over 5 runs with distinct random seeds. From Figure 3, we can see our structured updates have a linear iteration cost as Adam while achieve higher test accuracy.

6. Conclusion

We propose a tractable NGD for structure parameter space. The method allows for flexible covariance structures and lower computational complexity than other methods. We show a few experimental results where the method seems promising. An interesting direction is to evaluate its performance on large-scale problems such as deep neural nets.

Table 1. Summary of our updates. See Table 2 for the parameterizations used in our updates.
Figure 4. The performances of our updates for optimization of a CNN model on CIFAR-100 using layer-wise matrix Gaussian with low-rank Kronecker covariance of the precision form, where our updates ($O(k|w|)$) have a linear iteration cost like Adam ($O(|w|)$) in terms of time. For dataset "CIFAR-100", we train the model with mini-batch size 120. Our updates achieve higher test accuracy (55.2% on "CIFAR-100") than Adam (53.3% on "CIFAR-100").

B. More Results

Figure 5. Comparison results of structured Gaussian mixtures to fit a 80-D mixture of Student’s t distributions with 10 components. The first 9 marginal dimensions obtained by our updates is shown in the figure, where we consider the full covariance structure and the diagonal structure.
Figure 6. Comparison results of structured Gaussian mixtures to fit a 80-D mixture of Student’s t distributions with 10 components. The first 9 marginal dimensions obtained by our updates is shown in the figure, where we consider the upper triangular structure and the lower triangular structure in the precision form. The upper triangular structure performs comparably to the full covariance structure with lower computational cost.

Figure 7. Comparison results of structured Gaussian mixtures to fit a 80-D mixture of Student’s t distributions with 10 components. The first 9 marginal dimensions obtained by our updates is shown in the figure, where we consider the upper Heisenberg structure and the lower Heisenberg structure in the precision form. The upper triangular structure performs comparably to the full covariance structure with lower computational cost.
C. Fisher information matrix and Some Useful Lemmas

The Fisher information matrix (FIM) $F_\tau(\tau)$ of a parametric family of probability distributions $\{q_\tau\}$ is expressed by $F_\tau(\tau) = \text{Cov}_{q_\tau}(\nabla_\tau \log q_\tau(w), \nabla_\tau \log q_\tau(w))$. Under mild regularity conditions (i.e., expectation of the score is zero and interchange of integrals with gradient operators), we have $F_\tau(\tau) = \left[E_{q_\tau} \left[ \nabla_\tau \log q_\tau(w) (\nabla_\tau \log q_\tau(w))^T \right] \right] = -\nabla_{q_\tau} \left[ \nabla_\tau^2 \log q_\tau(w) \right]$.

**Lemma 4** In general case, Eq (1) can be expressed as:

$$L(\tau) := \mathbb{E}_{q(w|\tau)}[\ell(w)] - \gamma H(q(w|\tau))$$

We have the following result:

$$g_{\tau_i} := \nabla_\tau L(\tau_i) = \nabla_\tau \mathbb{E}_{q(w|\tau)}[\ell(w) + \gamma \log q(w|\tau_i)] \bigg|_{\tau=\tau_i}$$

Therefore, we could re-define $\ell(w)$ to include $\gamma \log q(w|\tau_i)$ when we compute gradient $\nabla_\tau L(\tau_i)$, where $\tau_i$ is considered as a constant.

**Lemma 5** (Indirect Natural-gradient Computation) If $\tau = \psi \circ \phi_{\lambda_i}(\eta)$ is $C^1$-smooth w.r.t. $\eta$, we have the following (covariant) transformation:

$$F_\eta(\eta_0) = \left[ \nabla_\eta \tau \right] \left[ F_\tau(\tau_i) \right] \left[ \nabla_\eta \tau \right]^T \bigg|_{\eta=\eta_0}$$

where we use a layout so that $\nabla_\eta \tau$ and $\nabla_\eta \tau_i$ present a row vector and a column vector, respectively.

If $\hat{g}_{\tau_i}$ is easy to compute, the natural gradient $\hat{g}_{\eta_0}$ can be computed via the following (contravariant) transformation, where we assume $F_\tau(\tau_i)$ and the Jacobian $\left[ \nabla_\eta \tau \right] \bigg|_{\eta=\eta_0}$ are both non-singular

$$\hat{g}_{\eta_0} = \left[ \nabla_\tau \eta \right]^T \hat{g}_{\tau_i} \bigg|_{\tau=\tau_i} = \left[ \nabla_\eta \tau \right]^T \hat{g}_{\tau_i} \bigg|_{\eta=\eta_0}$$

where $\hat{g}_{\eta_0} = \sum_i \left[ \nabla_\tau \eta_i \right] \hat{g}_{\tau_i}$.

Therefore, $\hat{g}_{\eta_0}$ can be computed via a Jacobian-vector product used in forward-mode differentiation.

We will use the following lemmas to show that $h(\cdot)$ can replace the matrix exponential map in our approach.

**Lemma 6** Let $h(M) = I + M + \frac{1}{2}M^2$. If $h(M)$ is invertible, we have the identity:

$$\nabla_M \log |h(M)| = I + C(M),$$

where $\nabla_M C(M) \bigg|_{M=0} = 0$ and $M_{i,j}$ is the entry of $M$ at position $(i, j)$.

**Lemma 7** Let $\text{Exp}(M) := I + \sum_{k=1}^{\infty} \frac{M^k}{k!}$. We have a similar identity as Lemma 6:

$$\nabla_M \log |\text{Exp}(M)| = I + C(M),$$

where $\nabla_M C(M) \bigg|_{M=0} = 0$ and $M_{i,j}$ is the entry of $M$ at position $(i, j)$.

**Lemma 8** Let $f(M) = h(M)$ or $f(M) = \text{Exp}(M)$. We have the following expressions:

$$[\nabla_{M_{i,j}} f(M)] f(M)^T = \left[ (\nabla_{M_{i,j}} M) + \frac{1}{2}M (\nabla_{M_{i,j}} M) + \frac{1}{2} (\nabla_{M_{i,j}} M) M + (\nabla_{M_{i,j}} M) M^T \right] + O(M^2)(\nabla_{M_{i,j}} M)$$

$$f(M) [\nabla_{M_{i,j}} f(M)^T] = \left[ (\nabla_{M_{i,j}} M)^T + \frac{1}{2}M^T (\nabla_{M_{i,j}} M)^T + \frac{1}{2} (\nabla_{M_{i,j}} M)^T M^T + M (\nabla_{M_{i,j}} M^T) \right] + O(M^2)(\nabla_{M_{i,j}} M)$$

This is the component transformation for a $(0,2)$-tensor in Riemannian geometry.

We assume $\eta$ and $\tau$ are vectors. For a matrix parameter, we could use the vector representation of the matrix via vec($\cdot$).

This is the component transformation for a $(1,0)$-tensor in Riemannian geometry.
C.1. Proof of Lemma 4

Proof Since $\mathcal{H}(q(w|\tau)) = -\mathbb{E}_{q(w|\tau)}[\log q(w|\tau)]$, we can re-express $\nabla_{\tau} \mathcal{L}(\tau_t)$ as

$$\nabla_{\tau} \mathcal{L}(\tau_t) = \nabla_{\tau} \mathbb{E}_{q(w|\tau)}[\ell(w) + \gamma \log q(w|\tau)] \bigg|_{\tau = \tau_t}$$

$$= \nabla_{\tau} \mathbb{E}_{q(w|\tau)}[\ell(w) + \gamma \log q(w|\tau)] + \gamma \mathbb{E}_{q(w|\tau)}[\nabla_{\tau} \log q(w|\tau)] \bigg|_{\tau = \tau_t}$$

(By the chain rule)

Note that

$$\mathbb{E}_{q(w|\tau)}[\nabla_{\tau} \log q(w|\tau)] \bigg|_{\tau = \tau_t} = 0$$

Therefore,

$$\nabla_{\tau} \mathcal{L}(\tau_t) = \nabla_{\tau} \mathbb{E}_{q(w|\tau)}[\ell(w) + \gamma \log q(w|\tau)] \bigg|_{\tau = \tau_t}$$

(24)

C.2. Proof of Lemma 5

Proof Let’s consider an entry of the FIM $F_{\eta}(\eta_0)$ at position $(j, i)$.

$$F_{\eta_{ij}}(\eta_0) = \mathbb{E}_{q(w|\eta)}[[\nabla_{\eta_j} \log q(w|\eta)] [\nabla_{\eta_i} \log q(w|\eta)]] \bigg|_{\eta = \eta_0}$$

$$= \mathbb{E}_{q(w|\eta)}[[\nabla_{\eta_j} \tau \nabla_{\tau} \log q(w|\tau)] [\nabla_{\eta_i} \tau \nabla_{\tau} \log q(w|\tau)] \bigg|_{\eta = \eta_0}$$

$$= \left[ \nabla_{\eta_j} \tau \right] \mathbb{E}_{q(w|\eta)}[[\nabla_{\tau} \log q(w|\tau)] [\nabla_{\tau} \log q(w|\tau)]^T] \left[ \nabla_{\eta_i} \tau \right]^T \bigg|_{\eta = \eta_0}$$

$$= \left[ \nabla_{\eta_j} \tau \right] F_{\tau}(\tau_t) \left[ \nabla_{\eta_i} \tau \right]^T \bigg|_{\eta = \eta_0}$$

Therefore, we have $F_{\eta}(\eta_0) = \left[ \nabla_{\eta} \tau \right] F_{\tau}(\tau_t) \left[ \nabla_{\eta} \tau \right]^T \bigg|_{\eta = \eta_0}$.

The natural gradient $\hat{g}_{\eta_0}$ can be computed as follows.

$$\hat{g}_{\eta_0} = \left( F_{\eta}(\eta_0) \right)^{-1} g_{\eta_0} \bigg|_{\eta = \eta_0}$$

$$= \left[ \nabla_{\eta} \tau \right]^{-T} \left( F_{\tau}(\tau_t) \right)^{-1} \left[ \nabla_{\eta} \tau \right]^{-1} g_{\eta_0} \bigg|_{\eta = \eta_0}$$

$$= \left[ \nabla_{\tau} \eta \right]^T \left( F_{\tau}(\tau_t) \right)^{-1} \left[ \nabla_{\tau} \eta \right] g_{\tau_0} \bigg|_{\eta = \eta_0}$$

$$= \left[ \nabla_{\tau} \eta \right]^T \hat{g}_{\tau_0} \bigg|_{\tau = \tau_t}$$

where $F_{\tau}(\tau_t)$ and $\nabla_{\eta} \tau$ are invertible by the assumption, and $\tau_t = \psi \circ \phi_{\lambda_t}(\eta_0)$. 
C.3. Proof of Lemma 6

Proof We first consider the entry \( M_{ij} \) of \( M \). By matrix calculus, we have the following expression.

\[
\nabla_{M_{ij}} \log |h(M)| = \text{Tr}((h(M))^{-1} \nabla_{M_{ij}} h(M))
\]

\[
= \text{Tr}((h(M))^{-1} [(\nabla_{M_{ij}} M) + \frac{1}{2} M(\nabla_{M_{ij}} M) + \frac{1}{2} (\nabla_{M_{ij}} M) M])
\]

\[
= \text{Tr}((h(M))^{-1} \left[ \frac{1}{2} (I + M)(\nabla_{M_{ij}} M) + \frac{1}{2} (\nabla_{M_{ij}} M)(I + M) \right])
\]

\[
= \text{Tr}((h(M))^{-1} \left[ \frac{1}{2} h(M)(\nabla_{M_{ij}} M) + \frac{1}{2} (\nabla_{M_{ij}} M)h(M) - \frac{1}{4} [M^2(\nabla_{M_{ij}} M) + (\nabla_{M_{ij}} M) M^2] \right])
\]

\[
= \text{Tr}((\nabla_{M_{ij}} M)) - \frac{1}{4} \text{Tr}((h(M))^{-1} [M^2(\nabla_{M_{ij}} M) + (\nabla_{M_{ij}} M) M^2])
\]

Therefore, we can express the gradient in a matrix form.

\[
\nabla_M \log |h(M)| = I - \frac{1}{4}(M^2)^T h(M)^{-T} - \frac{1}{4} h(M)^{-T} (M^2)^T
\]

We now show that

\[
\nabla_{M_{ij}} [M^2 h(M)^{-1}] \big|_{M=0} = 0
\]

By the product rule, we have

\[
\nabla_{M_{ij}} [M^2 h(M)^{-1}] \big|_{M=0} = \left( \nabla_{M_{ij}} M \right) \left( \frac{M}{h(M)^{-1}} \right) \bigg|_{M=0} + \left( \nabla_{M_{ij}} h(M)^{-1} \right) \left( \frac{M}{h(M)^{-1}} \right) \bigg|_{M=0} = 0
\]

Similarly, we can show

\[
\nabla_{M_{ij}} \left[ (M^2)^T h(M)^{-T} \right] \big|_{M=0} = 0; \quad \nabla_{M_{ij}} \left[ h(M)^{-T} (M^2)^T \right] \big|_{M=0} = 0
\]

Finally, we obtain the result as \( \nabla_M \log |h(M)| = I + C(M) \), where \( C(M) = -\frac{1}{4}(M^2)^T h(M)^{-T} - \frac{1}{4} h(M)^{-T} (M^2)^T \)

C.4. Proof of Lemma 7

Proof First of all, \( \text{Exp}(M) \) is always invertible and \( (\text{Exp}(M))^{-1} = \text{Exp}(-M) \). We consider the following expressions.

\[
\text{Exp}(-M) = I - M + O(M^2)
\]

remaining higher-order terms

\[
\text{Exp}(M) = I + M + \frac{1}{2} M^2 + O(M^3)
\]

remaining higher-order terms

\[
\nabla_{M_{ij}} \text{Exp}(M) = (\nabla_{M_{ij}} M) + \frac{1}{2} M(\nabla_{M_{ij}} M) + \frac{1}{2} (\nabla_{M_{ij}} M)M + O(M^2)(\nabla_{M_{ij}} M)
\]

remaining higher-order terms

By matrix calculus, we have the following expression.

\[
\nabla_{M_{ij}} \log |\text{Exp}(M)|
\]

\[
= \text{Tr}(\text{Exp}(-M) \nabla_{M_{ij}} \text{Exp}(M))
\]

\[
= \text{Tr}(\text{Exp}(-M) \left[ (\nabla_{M_{ij}} M) + \frac{1}{2} M(\nabla_{M_{ij}} M) + \frac{1}{2} (\nabla_{M_{ij}} M)M + O(M^2)(\nabla_{M_{ij}} M) \right])
\]

\[
= \text{Tr}(\text{Exp}(-M) \left[ \left( \nabla_{M_{ij}} M \right) + \frac{1}{2} M(\nabla_{M_{ij}} M) + \frac{1}{2} (\nabla_{M_{ij}} M)M + O(M^2)(\nabla_{M_{ij}} M) \right])
\]

\[
= \text{Tr}(\left( I - M + O(M^2) \right) \left[ \left( \nabla_{M_{ij}} M \right) + \frac{1}{2} M(\nabla_{M_{ij}} M) + \frac{1}{2} (\nabla_{M_{ij}} M)M + O(M^2)(\nabla_{M_{ij}} M) \right])
\]

\[
= \text{Tr}(\left( \nabla_{M_{ij}} M \right)) + \text{Tr}(- \frac{1}{2} M(\nabla_{M_{ij}} M) + \frac{1}{2} (\nabla_{M_{ij}} M)M + O(M^2)(\nabla_{M_{ij}} M))
\]
Therefore, we have
\[ \nabla_M \log |\text{Exp}(M)| = \mathbf{I} - \frac{1}{2} M^T + \frac{1}{2} M T + O(M^2) = \mathbf{I} + O(M^2) \]
Now, we show that \( C(M) = O(M^2) \). Note that
\[ \nabla_{M_{ij}} C(M) \bigg|_{M=0} = \nabla_{M_{ij}} O(M^2) \bigg|_{M=0} = \text{Tr}(O(M) \left[ \nabla_{M_{ij}} M \right]) \bigg|_{M=0} = 0 \]
where \( O(M) \) contains at least the first order term of \( M \).

C.5. Proof of Lemma 8

Proof
First note that
\[
\begin{align*}
\mathbf{f}(M)^T &= \mathbf{I} + M^T + O(M^2) \\
\mathbf{f}(M) &= \mathbf{I} + M + \frac{1}{2} M^2 + D(M^3) \\
\nabla_{M_{ij}} \mathbf{f}(M) &= (\nabla_{M_{ij}} M) + \frac{1}{2} M (\nabla_{M_{ij}} M) + \frac{1}{2} (\nabla_{M_{ij}} M) M + D(M^2)(\nabla_{M_{ij}} M)
\end{align*}
\]
where \( D(M^3) = O(M^3) \) and \( D(M^2) = O(M^2) \) when \( \mathbf{f}(M) = \text{Exp}(M) \) while \( D(M^3) = 0 \) and \( D(M^2) = 0 \) when \( \mathbf{f}(M) = \mathbf{h}(M) \).

We will show the first identity.
\[
\begin{align*}
[\nabla_{M_{ij}} \mathbf{f}(M)] \mathbf{f}(M)^T &= \left[ (\nabla_{M_{ij}} M) + \frac{1}{2} M (\nabla_{M_{ij}} M) + \frac{1}{2} (\nabla_{M_{ij}} M) M + D(M^2)(\nabla_{M_{ij}} M) \right] \mathbf{f}(M)^T \\
&= \left[ (\nabla_{M_{ij}} M) + \frac{1}{2} M (\nabla_{M_{ij}} M) + \frac{1}{2} (\nabla_{M_{ij}} M) M + D(M^2)(\nabla_{M_{ij}} M) \right] (\mathbf{I} + M^T + O(M^2)) \\
&= \left[ (\nabla_{M_{ij}} M) + \frac{1}{2} M (\nabla_{M_{ij}} M) + \frac{1}{2} (\nabla_{M_{ij}} M) M + (\nabla_{M_{ij}} M) M^T \right] + D(M^2)(\nabla_{M_{ij}} M),
\end{align*}
\]
where \( M(\nabla_{M_{ij}} M) M^T, (\nabla_{M_{ij}} M) M M^T \in O(M^2)(\nabla_{M_{ij}} M) \).
Similarly, we can show the second expression holds.

D. Gaussian Distribution

D.1. Gaussian with square-root precision structure

Let’s consider a global parameterization \( \tau = \{ \mu, S \} \), where \( S \) is the precision and \( \mu \) is the mean. We use the following parameterizations:
\[
\tau := \{ \mu \in \mathbb{R}^p, \ S \in \mathcal{S}_{++}^{p \times p} \} \\
\lambda := \{ \mu \in \mathbb{R}^p, \ B \in \mathcal{R}_{++}^{p \times p} \} \\
\eta := \{ \delta \in \mathbb{R}^p, \ M \in \mathcal{S}^{p \times p} \}.
\]
and maps:
\[
\begin{align*}
\{ \mu \} \quad &= \psi(\lambda) := \{ \mu \} \\
\{ \mu \} \quad &= \phi_{\lambda_t}(\eta) := \{ \mu_t + B_t^{-T} \delta \}.
\end{align*}
\]
Under this local parametization, we can re-expressed the negative logarithm of the Gaussian P.D.F. as below.
\[
-\log q(w|\eta) = -\log |B_t h(M)| + \frac{1}{2} (\mu_t + B_t^{-T} \delta - w)^T B_t h(M) h(M)^T B_t^T (\mu_t + B_t^{-T} \delta - w) + C
\]
where \( C \) is a constant number and \( \lambda_t = \{ \mu_t, B_t \} \) is the auxiliary parameterization evaluated at iteration \( t \).
Lemma 9 Under this local parametrization $\eta$, $F_\eta$ is block diagonal with two blocks—the $\delta$ block and the $M$ block. The claim holds even when $M$ is not symmetric.

Proof Any cross term of $F_\eta$ between these two blocks is zero as shown below.

$$\begin{align*}
- \mathbb{E}_{q(\eta|w)} \left[ \nabla_{M_{ij}} \nabla_\delta \log q(w|\eta) \right] &= \mathbb{E}_{q(\eta|w)} \left[ \nabla_{M_{ij}} \left( h(M)h(M)^T B_t^T (\mu_t + B_t^{-T} \delta - w) \right) \right] \\
&= \nabla_{M_{ij}} \left( h(M)h(M)^T \right) \left( B_t^T \mathbb{E}_{q(\eta|w)} \left[ (\mu_t + B_t^{-T} \delta - w) \right] \right) \\
&= 0
\end{align*}$$

where $\mathbb{E}_{q(\eta|w)}[w] = \mu_t + B_t^{-T} \delta$ and $M_{ij}$ denotes the element of the matrix $M$ at $(i, j)$.

Lemma 10 The FIM w.r.t. block $\delta$ denoted by $F_\delta$ is $I_\delta$ when we evaluate it at $\eta_0 = \{\delta_0, M_0\} = 0$. The claim holds even when $M$ is not symmetric.

Proof

$$F_\delta(\eta_0) = -\mathbb{E}_{q(\eta|w)} \left[ \nabla_\delta^2 \log q(w|\eta) \right] \bigg|_{\eta=0} = \mathbb{E}_{q(\eta|w)} \left[ \nabla_\delta \left( h(M)h(M)^T B_t^T (\mu_t + B_t^{-T} \delta - w) \right) \right] \bigg|_{\eta=0} = \mathbb{E}_{q(\eta|w)} \left[ \nabla_\delta \left( \delta + B_t^T (\mu_t - w) \right) \right] \bigg|_{\eta=0} = I_\delta$$

where we use the fact that $h(M) = I$ when $M = 0$ to move from step 2 to step 3.

Now, we discuss how to compute the FIM w.r.t. $M$, where the following expressions hold even when $M$ is not symmetric since we deliberately do not make use the symmetric constraint. The only requirement for $M$ is $h(M)$ is invertible due to Lemma 6.

Let $Z = B_t^T (\mu_t + B_t^{-T} \delta - w)(\mu_t + B_t^{-T} \delta - w)^T B_t$. By matrix calculus, we have the following expression.

$$\begin{align*}
\frac{1}{2} \nabla_{M_{ij}} \left[ (\mu_t + B_t^{-T} \delta - w)^T B_t h(M)h(M)^T B_t^T (\mu_t + B_t^{-T} \delta - w) \right] &= \frac{1}{2} \nabla_{M_{ij}} \text{Tr} \left( Z h(M)h(M)^T B_t \left( Z h(M)h(M)^T B_t^T \right) \right) \\
&= \frac{1}{2} \text{Tr} \left( Z \left[ \nabla_{M_{ij}} h(M) \right] h(M)^T + Z h(M) \nabla_{M_{ij}} [h(M)^T] \right)
\end{align*}$$

By Lemma 8, we obtain a simplified expression.

$$\begin{align*}
\frac{1}{2} \nabla_{M} \left[ (\mu_t + B_t^{-T} \delta - w)^T B_t h(M)h(M)^T B_t^T (\mu_t + B_t^{-T} \delta - w) \right] &= \frac{1}{2} \left[ 2Q + QM^T + M^T Q + 2QM \right] + O(M^2)Z \\
&= Z + (ZM^T + M^T Z)/2 + ZM + O(M^2)Z
\end{align*}$$

where $Q = (Z^T + Z)/2 = Z$

By Lemma 6, we can re-express the gradient w.r.t. $M$ as

$$- \nabla_M \log q(w|\eta) = \frac{1}{2} I - C(M) - Z + (ZM^T + M^T Z)/2 + ZM + O(M^2)Z$$

Finally, we have the following lemma to compute the FIM w.r.t. $M$ (denoted by $F_M$) evaluated at $\eta_0 = 0$. 

$$- \nabla_M \log |h(M)|$$
Lemma 11 \(-E_{q(w|\eta)} \left[ \nabla_{M_{ij}} \nabla_{M} \log q(w|\eta) \right]_{\eta=0} = \nabla_{M_{ij}} \left( M + M^T \right)\). The claim holds even when \(M\) is not symmetric as long as \(h(M)\) is invertible.

Proof

\[
\begin{align*}
- E_{q(w|\eta)} \left[ \nabla_{M_{ij}} \nabla_{M} \log q(w|\eta) \right]_{\eta=0} &= E_{q(w|\eta)} \left[ \nabla_{M_{ij}} \left( -I - C(M) + Z + (ZM^T + M^T Z)/2 + ZM + O(M^2)Z \right) \right]_{\eta=0} \quad \text{(by Eq 25)} \\
&= \nabla_{M_{ij}} \left( (M^T + M^T)/2 + M + O(M^2) \right) \bigg|_{\eta=0} - \nabla_{M_{ij}} C(M) \bigg|_{\eta=0} = 0 \\
&= \nabla_{M_{ij}} \left( M + M^T \right) + O(M) \bigg|_{\eta=0} \\
&= \nabla_{M_{ij}} \left( M + M^T \right) \quad \text{(26)}
\end{align*}
\]

where we use the fact that \(E_{q(w|\eta)} [Z] = E_{q(w|\eta)} \left[ B_t^T (\mu_t + B_t^T \delta - w)(\mu_t + B_t^T \delta - w)^T B_t \right] = I\) evaluated at \(\eta = 0\) to move from step 2 to step 3.

Now, we discuss the symmetric constraint in \(M \in S^{p \times p}\). The constraint is essential since the FIM can be singular without a proper constraint.

D.1.1. **Symmetric Constraint** \(S^{p \times p}\) in \(M\)

Instead of directly using the symmetric property of \(M\) to simplify Eq (26), we present a general approach so that we can deal with asymmetric \(M\) discussed in Appendix J. The key idea is to decomposition \(M\) as a sum of special matrices so that the FIM computation is simple. We also numerically verify the following computation of FIM by Auto-Diff.

First of all, we consider a symmetric constraint in \(M\). We will show that this constraint ensures the FIM is non-singular, which implies that we can use Lemma 11 in this case.

**Lemma 12** When \(M\) is symmetric, \(h(M)\) is invertible.

Proof

\[
\begin{align*}
h(M) &= I + M + \frac{1}{2}M^2 \\
&= \frac{1}{2} (I + (I + M)(I + M)) \\
&= \frac{1}{2} (I + (I + M)(I + M)^T) \quad \text{(since \(M\) is symmetric)} \\
&> 0 \quad \text{(positive-definite)}
\end{align*}
\]

Therefore, \(h(M)\) is invertible.

Since \(M\) is symmetric, we can re-express the matrix \(M\) as follows.

\[
M = M_{\text{low}} + M_{\text{low}}^T + M_{\text{diag}},
\]

where \(M_{\text{low}}\) contains the lower-triangular half of \(M\) excluding the diagonal elements, and \(M_{\text{diag}}\) contains the diagonal entries of \(M\).

\[
M_{\text{low}} = \begin{bmatrix}
0 & 0 & \cdots & 0 \\
M_{21} & 0 & \cdots & 0 \\
\cdots & \cdots & \cdots & 0 \\
M_{d1} & M_{d2} & \cdots & 0
\end{bmatrix}, \quad M_{\text{diag}} = \begin{bmatrix}
M_{11} & 0 & \cdots & 0 \\
0 & M_{22} & \cdots & 0 \\
\cdots & \cdots & \cdots & 0 \\
0 & 0 & \cdots & M_{dd}
\end{bmatrix}
\]
By Eq. 25 and the chain rule, we have the following expressions, where \(i > j\).

\[
- \nabla_{M_{\text{low}}} \log q(w | \eta) = - \text{Tr} \left( \left[ \nabla_{M_{\text{low},i,j}} M \right] \left[ \nabla_{M} \log q(w | \eta) \right] \right)_{I_{i,j} + I_{j,i}} \\
- \nabla_{M_{\text{diag}}} \log q(w | \eta) = - \text{Tr} \left( \left[ \nabla_{M_{\text{diag},i,j}} M \right] \left[ \nabla_{M} \log q(w | \eta) \right] \right)_{I_{i}}
\]

Therefore, we have

\[
- \nabla_{M_{\text{low}}} \log q(w | \eta) = - \text{Low} \left( \nabla_{M} \log q(w | \eta) + \nabla_{M}^{T} \log q(w | \eta) \right) \\
- \nabla_{M_{\text{diag}}} \log q(w | \eta) = - \frac{1}{2} \text{Diag} \left( \nabla_{M} \log q(w | \eta) + \nabla_{M}^{T} \log q(w | \eta) \right) = - \text{Diag} \left( \nabla_{M} \log q(w | \eta) \right)
\]

(27)

(28)

where we define the \(\text{Diag}(\cdot)\) function that returns a diagonal matrix with the same structure as \(M_{\text{diag}}\) and the \(\text{Low}(\cdot)\) function that returns a lower-triangular matrix with the same structure as \(M_{\text{low}}\).

By Lemma 9, the FIM \(F_{\eta}\) is block-diagonal with two blocks—the \(\delta\) block and the \(M\) block. We have the following lemma for \(F_{M}\)

**Lemma 13** The \(M\) block of the FIM denoted by \(F_{M}\) is also block-diagonal with two block—the diagonal block denoted by non-zero entries in \(M_{\text{diag}}\), and the lower-triangular block denoted by non-zero entries in \(M_{\text{low}}\).

**Proof** We will prove this lemma by showing any cross term of the FIM between the non-zero entries in \(M_{\text{low}}\) and the non-zero entries in \(M_{\text{diag}}\) is also zero.

Notice that we only consider non-zero entries in \(M_{\text{low}}\), which implies that \(i > j\) in the following expression. Therefore, any cross term can be expressed as below.

\[
- E_{q(w | \eta)} \left[ \nabla_{M_{\text{low},i,j}} \nabla_{M_{\text{diag}}} \log q(w | \eta) \right] \bigg|_{\eta = 0} = - E_{q(w | \eta)} \left[ \nabla_{M_{\text{low},i,j}} \text{Diag} \left( \nabla_{M} \log q(w | \eta) \right) \right] \bigg|_{\eta = 0} \text{ (by Eq. 28)}
\]

\[
= - E_{q(w | \eta)} \left[ \sum_{k,l} \left[ \nabla_{M_{\text{low},i,j}} M_{kl} \right] \nabla_{M_{kl}} \text{Diag} \left( \nabla_{M} \log q(w | \eta) \right) \right] \bigg|_{\eta = 0}
\]

\[
= - E_{q(w | \eta)} \left[ \sum_{i,j} \left[ \nabla_{M_{\text{low},i,j}} M_{ij} \right] \nabla_{M_{ij}} \text{Diag} \left( \nabla_{M} \log q(w | \eta) \right) + \sum_{i,j} \left[ \nabla_{M_{\text{low},i,j}} M_{ji} \right] \nabla_{M_{ji}} \text{Diag} \left( \nabla_{M} \log q(w | \eta) \right) \right] \bigg|_{\eta = 0}
\]

\[
= - E_{q(w | \eta)} \left[ \nabla_{M_{ij}} \text{Diag} \left( \nabla_{M} \log q(w | \eta) \right) + \nabla_{M_{ji}} \text{Diag} \left( \nabla_{M} \log q(w | \eta) \right) \right] \bigg|_{\eta = 0}
\]

\[
= - \text{Diag} \left[ E_{q(w | \eta)} \left[ \nabla_{M_{ij}} \nabla_{M} \log q(w | \eta) + \nabla_{M_{ji}} \nabla_{M} \log q(w | \eta) \right] \right] \bigg|_{\eta = 0}
\]

\[
= \text{Diag} \left[ \nabla_{M_{ij}} (M + M^{T}) + \nabla_{M_{ji}} (M + M^{T}) \right] = 0 \text{ (by Lemma 11)}
\]

where \(M_{\text{low},i,j}\) denotes the entry of \(M_{\text{low}}\) at position \((i, j)\), we use \(M = M_{\text{low}} + M_{\text{low}}^{T} + M_{\text{diag}}\) to move from step 2 to step 3, and obtain the last step since \(i > j\) and \(\text{Diag}(I_{ij}) = 0\).

To compute the FIM w.r.t a symmetric \(M\), we can consider the FIM w.r.t. the non-zero entries in both \(M_{\text{low}}\) and \(M_{\text{diag}}\) separately due to the block-diagonal structure of the FIM. Now, we compute the FIM w.r.t. \(M_{\text{diag}}\) and \(M_{\text{low}}\).
By the chain rule, we have
\[
- \mathbb{E}_{q(w|\eta)} \left[ \nabla_{M_{ij}} \nabla_{M_{kl}} \log q(w|\eta) \right]_{\eta=0} = - \mathbb{E}_{q(w|\eta)} \left[ \nabla_{M_{ij}} \text{Diag} \left( \nabla_{M} \log q(w|\eta) \right) \right]_{\eta=0} 
\]
(by Eq. 28)
\[
= - \mathbb{E}_{q(w|\eta)} \left[ \sum_{j,k} \left[ \nabla_{M_{ijkl}} M_{jk} \right] \nabla_{M_{ij}} \text{Diag} \left( \nabla_{M} \log q(w|\eta) \right) \right]_{\eta=0} 
\]
\[
= - \mathbb{E}_{q(w|\eta)} \left[ \nabla_{M_{ij}} \text{Diag} \left( \nabla_{M} \log q(w|\eta) \right) \right]_{\eta=0} 
\]
\[
= - \text{Diag} \left( \mathbb{E}_{q(w|\eta)} \left[ \nabla_{M_{ij}} \nabla_{M} \log q(w|\eta) \right] \right)_{\eta=0} = \text{Diag} \left( \nabla_{M_{ij}} \left( M + M^{T} \right) \right) = 2 \text{Diag}(I_{ij}) 
\]
(29)

Now, we compute the FIM w.r.t. \( M_{low} \). By the chain rule, we have
\[
- \mathbb{E}_{q(w|\eta)} \left[ \nabla_{M_{low}} \nabla_{M_{low}} \log q(w|\eta) \right]_{\eta=0} = - \mathbb{E}_{q(w|\eta)} \left[ \nabla_{M_{ij}} \text{Low} \left( \nabla_{M} \log q(w|\eta) + \nabla_{M}^{T} \log q(w|\eta) \right) \right]_{\eta=0} 
\]
(by Eq. 27)

We will first consider the following term.
\[
- \mathbb{E}_{q(w|\eta)} \left[ \nabla_{M_{low}} \text{Low} \left( \nabla_{M} \log q(w|\eta) \right) \right]_{\eta=0} 
\]
\[
= - \mathbb{E}_{q(w|\eta)} \left[ \nabla_{M_{low}} \text{Low} \left( \nabla_{M} \log q(w|\eta) \right) \right]_{\eta=0} 
\]
\[
= - \mathbb{E}_{q(w|\eta)} \left[ \nabla_{M_{low}} \text{Low} \left( \nabla_{M} \log q(w|\eta) \right) \right]_{\eta=0} 
\]
\[
= - \text{Low} \left( \mathbb{E}_{q(w|\eta)} \left[ \nabla_{M_{ij}} \nabla_{M} \log q(w|\eta) + \nabla_{M_{ij}} \nabla_{M} \log q(w|\eta) \right] \right)_{\eta=0} 
\]
= \text{Low} \left( \nabla_{M_{ij}} \left[ M + M^{T} \right] + \nabla_{M_{ij}} \left[ M + M^{T} \right] \right) = 2 I_{ij} 
\]
(by Lemma 11)

where we obtain the last step by Eq 26 and the fact that \( M \) is symmetric.

Similarly, we can show
\[
- \mathbb{E}_{q(w|\eta)} \left[ \nabla_{M_{low}} \text{Low} \left( \nabla_{M}^{T} \log q(w|\eta) \right) \right]_{\eta=0} = 2 I_{ij} 
\]
(30)

Therefore, the FIM w.r.t. \( M_{low} \) is
\[
- \mathbb{E}_{q(w|\eta)} \left[ \nabla_{M_{low}} \nabla_{M_{low}} \log q(w|\eta) \right]_{\eta=0} = 4 I_{ij} 
\]
(31)
Tractable structured natural gradient descent using local parameterizations

Now, we discuss how to compute the Euclidean gradients. Recall that

\[ \mu = \mu_t + B_t^{-T} \delta \]
\[ S = B_t h(M) h(M)^T B_t^T \]

Let \( L := \mathbb{E}_q(w) [\ell(w)] - \gamma \mathcal{H}(q(w)) \). By the chain rule, we have

\[
\nabla_\delta L = \left[ \nabla_\delta \mu \right]^T \nabla_\mu L + \operatorname{Tr}\left( \left[ \nabla_\delta S \right] \nabla_S L \right) = \left[ \nabla_\delta \delta \right]^T B_t^{-1} \nabla_\mu L
\]
\[
\nabla_{M_{ij}} L = \left[ \nabla_{M_{ij}} \mu \right]^T \nabla_\mu L + \operatorname{Tr}\left( \left[ \nabla_{M_{ij}} S \right] \nabla_S L \right) = 0
\]
\[
= \operatorname{Tr}\left( \left[ \nabla_{M_{ij}} S \right] \nabla_S L \right) = -\operatorname{Tr}\left( \left[ B_t \left( \nabla_{M_{ij}} h(M) h(M)^T + h(M) \left[ \nabla_{M_{ij}} h(M)^T \right] \right) B_t^T \right] \Sigma \nabla_S L \right) 
\]
\[
\]
where \( \Sigma = S^{-1} \) and we use the gradient identity \( \nabla_S L = -\Sigma \nabla_S L \Sigma \).

Therefore, when we evaluate the gradient at \( \eta_0 = \{ \delta_0, M_0 \} = 0 \), we have

\[
\nabla_\delta L|_{\eta=0} = \left[ \nabla_\delta \delta \right]^T B_t^{-1} \nabla_\mu L \\
\nabla_{M_{ij}} L|_{\eta=0} = -\operatorname{Tr}\left( B_t \left( \nabla_{M_{ij}} h(M)^T \right) B_t^T \right) B_t^{-1} \nabla_S L \Sigma_t \nabla_S L \\
= -\operatorname{Tr}\left( B_t \left( \nabla_{M_{ij}} h(M) + \nabla_{M_{ij}} h(M)^T \right) B_t^T \right) B_t^{-1} \nabla_S L \Sigma_t \nabla_S L \\
= -\operatorname{Tr}\left( \nabla_{M_{ij}} \left( h(M) + h(M)^T \right) B_t^{-1} \nabla_S L \Sigma_t \nabla_S L \right) \\
= -\operatorname{Tr}\left( \nabla_{M_{ij}} \left( M + M^T \right) B_t^{-1} \nabla_S L \Sigma_t \nabla_S L \right) \\
= \left( \nabla_{M_{ij}} h(M) \right)|_{\eta=0} - \left( \nabla_{M_{ij}} h(M)^T \right)|_{\eta=0} = \nabla_{M_{ij}} h(M)
\]

Let’s denote \( G_M = -2B_t^{-1} \nabla_S L \Sigma_t \nabla_S L B_t^{-T} \). Therefore, we can show that

\[
\nabla_{M_{ij}} L|_{\eta=0} = \operatorname{Diag}(G_M); \quad \nabla_{M_{ij}} L|_{\eta=0} = \operatorname{Low}(G_M + G_M^T) = 2\operatorname{Low}(G_M)
\]

The FIM is block-diagonal w.r.t. three blocks, the \( \delta \) block, the \( M_{\text{diag}} \) block, and the \( M_{\text{low}} \) block.

Recall that the FIM w.r.t. \( \delta, M_{\text{diag}} \text{ and } M_{\text{low}} \) are \( I, 2I, 4I \), respectively. The above statement implies that Assumption 1 is satisfied.

The natural gradients w.r.t. \( M_{\text{diag}} \) and \( M_{\text{low}} \) are \( \frac{1}{2} \operatorname{Diag}(G_M) \) and \( \frac{1}{2} \operatorname{Low}(G_M) \).

Therefore, the natural gradients w.r.t. \( \delta \) and w.r.t. \( M \) are

\[
\hat{g}_\delta = B_t^{-1} \nabla_\mu L, \quad \hat{g}_M = \frac{1}{2} G_M = -B_t^{-1} \nabla_S L \Sigma_t \nabla_S L B_t^{-T}
\]

Now, we show that Assumption 2 is also satisfied. Since \( \{ \mu, S \} = \tau = \psi \circ \phi_{\lambda_t}(\{ \delta, M \}) \), where \( \lambda_t = \{ \mu_t, B_t \} \), we have

\[
\begin{bmatrix} \mu \\ S \end{bmatrix} = \psi \circ \phi_{\lambda_t}(\begin{bmatrix} \delta \\ M \end{bmatrix}) = \begin{bmatrix} \mu_t + B_t^{-T} \delta \\ B_t h(M) h(M)^T B_t^T \end{bmatrix}
\]
It is easy to see that $\psi \circ \phi_{\lambda_t} (\eta)$ is $C^1$-smooth w.r.t. $\eta$.

Since we have shown Assumption 1 is satisfied, we have $F_\eta (\eta_0)$ is non-singular. By Lemma 5, we know that both $F_\tau (\tau_t)$ and the Jacobian matrix $\nabla_\eta \tau$ evaluated at $\eta_0$ are non-singular. By the inverse function theorem, we know that there exist a (local) inverse function of $\psi \circ \phi_{\lambda_t} (\eta)$ at an open neighborhood of $\eta_0$, which is also $C^1$-smooth.

Therefore, we know that $\{\mu, S\} = \tau = \psi \circ \phi_{\lambda_t} (\{\delta, M\})$ is locally $C^1$-diffeomorphic at an open neighborhood of $\eta_0$.

### D.1.2. Connection to Newton’s Method

In Eq (1), we consider the following problem.

$$
\min_{q(w) \in \mathcal{Q}} \mathbb{E}_{q(w)} [\ell(w)] - \gamma \mathcal{H}(q(w))
$$

Note that we assume $\gamma = 0$ in Eq (2) for simplicity.

By Eq (33), our update in the auxiliary parameter space with step-size $\beta$ is

$$
\mu_{t+1} \leftarrow \mu_t + B_t^{-T} (-\beta) B_t^{-1} g_\mu = \mu_t - \beta B_t^{-T} B_t^{-1} g_\mu
$$

$$
B_{t+1} \leftarrow B_t h(\beta B_t^{-1} [g_\Sigma] B_t^{-T})
$$

When $\gamma \geq 0$, due to Stein’s identities, we have

$$
g_\mu = \mathbb{E}_{q(w|\mu, \Sigma)} [\nabla_w \ell (w)], \quad g_\Sigma = \frac{1}{2} \left( \mathbb{E}_{q(w|\mu, \Sigma)} [\nabla_w^2 \ell (w)] - \gamma \Sigma^{-1} \right)
$$

Let $G = \mathbb{E}_{q} [\nabla_w^2 \ell (w)] - \gamma \Sigma^{-1} = \mathbb{E}_{q} [\nabla_w^2 \ell (w)] - \gamma S$

Therefore, our update in $S$ is

$$
S_{t+1} = B_{t+1} B_{t+1}^T = B_t h(\beta B_t^{-1} [g_\Sigma] B_t^{-T}) h(\beta B_t^{-1} [g_\Sigma] B_t^{-T})^T B_t^T
$$

$$
= B_t \left[ I + 2(\beta B_t^{-1} [g_\Sigma] B_t^{-T}) + 2(\beta B_t^{-1} [g_\Sigma] B_t^{-T})^2 + O(\beta^3) \right] B_t^T
$$

$$
= B_t \left[ I + \beta B_t^{-1} G B_t^{-T} + \frac{\beta^2}{2} B_t^{-1} G B_t^{-T} B_t^{-1} G B_t^{-T} + O(\beta^3) \right] B_t^T
$$

$$
= S_t + \beta G + \frac{\beta^2}{2} G S_t^{-1} G + O(\beta^3)
$$

where we use the following result when $X$ is symmetric

$$
h(X)h(X)^T = h(X)h(X) = (I + X + \frac{1}{2} X^2)(I + X + \frac{1}{2} X^2) = I + 2X + 2X^2 + O(X^3)
$$

### D.2. Gaussian with square-root covariance structure

Let’s consider a global parameterization $\tau = \{\mu, \Sigma\}$, where $\Sigma$ is the covariance and $\mu$ is the mean. We use the following Parameterizations:

$$
\tau := \{ \mu \in \mathbb{R}^p, \Sigma \in \mathcal{S}_{++}^{p \times p} \}
$$

$$
\lambda := \{ \mu \in \mathbb{R}^p, A \in \mathbb{R}^{p \times p}_{++} \}
$$

$$
\eta := \{ \delta \in \mathbb{R}^p, M \in \mathcal{S}^{p \times p} \}.
$$

and maps:

$$
\left\{ \begin{array}{c}
\mu \\
\Sigma
\end{array} \right\} = \psi(\lambda) := \left\{ \begin{array}{c}
\mu \\
\AA^T
\end{array} \right\}
$$

$$
\left\{ \begin{array}{c}
\mu \\
A
\end{array} \right\} = \phi_{\lambda_t}(\eta) := \left\{ \begin{array}{c}
\mu_t + A_t \delta \\
A_t \text{Exp}(\frac{1}{2} M)
\end{array} \right\}.
$$
Now, we will use the fact that that M is symmetric. Under this local parametrization, we can re-expressed the negative logarithm of the Gaussian P.D.F. as below.

\[- \log q(w|\eta) = \log |A_t \text{Exp}(\frac{1}{2}M)| + \frac{1}{2}(\mu_t + A_t \delta - w)^T A_t^{-T} \text{Exp}(-M) A_t^{-1}(\mu_t + A_t \delta - w) + C\]

where C is a constant number and \(A_t = \{\mu_t, A_t\}\) is the auxiliary parameterization evaluated at iteration \(t\).

Like Sec D.1, we can show the FIM w.r.t. \(\eta\) is block-diagonal w.r.t. two blocks— the \(\delta\) block and the M block.

Now, we show that the FIM w.r.t. block \(\eta\) denoted by \(F_\delta\) is \(I_\delta\) when we evaluate it at \(\eta_0 = \{\delta_0, M_0\} = 0\).

\[
F_\delta(\eta_0) = -\mathbb{E}_{q(w|\eta)} \left[ \nabla^2 \log q(w|\eta) \right]_{\eta=0} = \mathbb{E}_{q(w|\eta)} \left[ \nabla_\delta \left( \text{Exp}(-M) A_t^{-1}(\mu_t + A_t \delta - w) \right) \right]_{\eta=0} = \mathbb{E}_{q(w|\eta)} \left[ \nabla_\delta \left( \delta + A_t^{-1}(\mu_t - w) \right) \right]_{\eta=0} = I_\delta
\]

where we use the fact that \(\text{Exp}(-M) = I\) when \(M = 0\) to move from step 2 to step 3.

Now, we discuss how to compute the FIM w.r.t. \(M\), where we explicitly use the fact that \(M\) is symmetric.

Let \(Z = A_t^{-1}(\mu_t + A_t \delta - w)(\mu_t + A_t \delta - w)^T A_t^{-T}\). By matrix calculus, we have the following expression.

\[
\frac{1}{2} \nabla_{M_{ij}} \left[ (\mu_t + A_t \delta - w)^T A_t^{-T} \text{Exp}(-M) A_t^{-1}(\mu_t + A_t \delta - w) \right] = \frac{1}{2} \nabla_{M_{ij}} \text{Tr}(Z \text{Exp}(-M)) \]

\[
= \frac{1}{2} \text{Tr}(Z \nabla_{M_{ij}} (-M + \frac{1}{2}M^2 + O(M^3)))
\]

Therefore, we have

\[
\frac{1}{2} \nabla_M \left[ (\mu_t + A_t \delta - w)^T A_t^{-T} \text{Exp}(-M) A_t^{-1}(\mu_t + A_t \delta - w) \right] = -\frac{1}{2}Z + \frac{1}{4}(ZM + MZ) + O(M^2)Z
\]

By Lemma 7, we can re-express the gradient w.r.t. \(M\) as

\[
- \nabla_M \log q(w|\eta) = \frac{1}{2}(I + C(M)) \quad -\frac{1}{2}Z + \frac{1}{4}(ZM + MZ) + O(M^2)Z
\]  \hspace{1cm} (36)

Finally, we have the following lemma to compute the FIM w.r.t. \(M\) (denoted by \(F_M\)) evaluated at \(\eta_0 = 0\).

**Lemma 14** \(-\mathbb{E}_{q(w|\eta)} \left[ \nabla_{M_{ij}} \nabla_M \log q(w|\eta) \right]_{\eta=0} = \frac{1}{2} \nabla_{M_{ij}} M. The claim assumes M is symmetric.**

**Proof**

\[
- \mathbb{E}_{q(w|\eta)} \left[ \nabla_{M_{ij}} \nabla_M \log q(w|\eta) \right]_{\eta=0} = \mathbb{E}_{q(w|\eta)} \left[ \nabla_{M_{ij}} \left( \frac{1}{2}(I + C(M)) \right) - \frac{1}{2}Z + \frac{1}{4}(ZM + MZ) + O(M^2)Z \right]_{\eta=0} \quad \text{(by Eq 36)}
\]

\[
= \left[ \nabla_{M_{ij}} \left( \frac{1}{2}M + O(M^2) \right) \right]_{\eta=0} + \frac{1}{2} \nabla_{M_{ij}} C(M)_{\eta=0} = 0
\]

\[
= \frac{1}{2} \nabla_{M_{ij}} \left( M \right) + O(M)_{\eta=0}
\]

\[
= \frac{1}{2} \nabla_{M_{ij}} \left( M \right)
\]  \hspace{1cm} (37)
where we use the fact that \( \mathbb{E}_{q(\omega|\eta)}[Z] = \mathbb{E}_{q(\omega|\eta)}[A^{-1}_t(\mu_t + A_t \delta - w)(\mu_t + A_t \delta - w)^T A_t^{-T}] = I \) evaluated at \( \eta = 0 \) to move from step 2 to step 3.

Therefore, \( F_M(\eta_0) = \frac{1}{2} I_M \).

Now, we discuss how to compute the Euclidean gradients. Recall that
\[
\mu = \mu_t + A_t \delta \\
\Sigma = A_t \text{Exp}(M) A_t^T
\]

Let \( L := \mathbb{E}_{q(w)}[\ell(w)] - \gamma \mathcal{H}(q(w)) \). By the chain rule, we have
\[
\nabla_{\delta_t} L = [\nabla_{\delta_t} \mu]^T \nabla_{\mu} L + \text{Tr} \left( \left[ \nabla_{\delta_t} \Sigma \right] \nabla_{\Sigma} L \right) \\
\nabla_{M_{ij}} L = [\nabla_{M_{ij}} \mu]^T \nabla_{\mu} L + \text{Tr} \left( \left[ \nabla_{M_{ij}} \Sigma \right] \nabla_{\Sigma} L \right)
\]

Therefore, when we evaluate the gradient at \( \eta_0 = \{\delta_0, M_0\} = 0 \), we have
\[
\nabla_{\delta_t} L |_{\eta=0} = [\nabla_{\delta_t} \delta]^T A_t^T \nabla_{\mu} L \\
\nabla_{M_{ij}} L |_{\eta=0} = \text{Tr}(A_t [\nabla_{M_{ij}} \text{Exp}(M)] A_t^T \nabla_{\Sigma} L) |_{\eta=0}
\]

where note that \( \text{Exp}(M) = I + M + O(M^2) \) and its gradient evaluated at \( \eta = 0 \) can be simplified as
\[
\nabla_{M_{ij}} \text{Exp}(M) |_{\eta=0} = \nabla_{M_{ij}} M + O(M) \left[ \nabla_{M_{ij}} M \right] |_{\eta=0} = \nabla_{M_{ij}} M
\]

Therefore,
\[
\nabla_{\delta_t} L |_{\eta=0} = A_t^T \nabla_{\mu} L \\
\nabla_{M_{ij}} L |_{\eta=0} = A_t^T \left[ \nabla_{\Sigma} L \right] A_t
\]

Recall that the FIM w.r.t. \( \delta \) and \( M \) are \( I \) and \( \frac{1}{2} I \), respectively. In other words,
\[
F_\eta(\eta_0) = \begin{bmatrix} I_\delta & 0 \\ 0 & \frac{1}{2} I_M \end{bmatrix},
\]
which implies that Assumption 1 is satisfied.

Therefore, the natural gradient w.r.t. \( \delta \) is \( \hat{g}_\delta = A_t^T \nabla_{\mu} L \). The natural-gradient w.r.t. \( M \) as \( \hat{g}_M = 2 A_t^T \left[ \nabla_{\Sigma} L \right] A_t \).

Therefore, our update in the auxiliary parameter space is
\[
\mu_{t+1} \leftarrow \mu_t - \beta S_t^{-1} g_\mu \\
A_{t+1} \leftarrow A_t \text{Exp}( - \beta A_t^T g_\Sigma A_t )
\]

recall that \( A = A_t \text{Exp}( - \beta \frac{1}{2} \hat{g}_M ) \).
Now, we show that Assumption 2 is also satisfied. Since \( \{ \mu, \Sigma \} = \tau = \psi \circ \phi_{\lambda_i}(\{ \delta, M \}) \), where \( \lambda_i = \{ \mu_i, A_i \} \), we have

\[
\begin{bmatrix} \mu \\ \Sigma \end{bmatrix} = \psi \circ \phi_{\lambda_i}( \begin{bmatrix} \delta \\ M \end{bmatrix} ) = \begin{bmatrix} \mu_i + A_i \delta \\ A_i \text{Exp}(M) A_i^T \end{bmatrix}
\]

It is easy to see that \( \psi \circ \phi_{\lambda_i}(\eta) \) is \( C^1 \)-smooth w.r.t. \( \eta \).

Since we have shown Assumption 1 is satisfied, we have \( F_\eta(\eta_0) \) is non-singular. By Lemma 5, we know that both \( F_{\tau}(\tau_0) \) and the Jacobian matrix \( \nabla_{\eta} \tau \) evaluated at \( \eta_0 \) are non-singular. By the inverse function theorem, we know that there exist a (local) inverse function of \( \psi \circ \phi_{\lambda_i}(\eta) \) at an open neighborhood of \( \eta_0 \), which is also \( C^1 \)-smooth.

Therefore, we know that \( \{ \mu, \Sigma \} = \tau = \psi \circ \phi_{\lambda_i}(\{ \delta, M \}) \) is locally \( C^1 \)-diffeomorphic at an open neighborhood of \( \eta_0 \).

### E. Wishart distribution with square-root precision structure

Let’s consider a global parameterization \( \tau = \{ S, n \} \). The P.D.F. of a Wishart distribution under this parameterization is

\[
q(W | \tau) = \exp\left\{ -\frac{1}{2} \text{Tr}(SW) + \frac{n - p - 1}{2} \log |W| - \frac{np}{2} \log 2 + \frac{n}{2} \log |S| - \log \Gamma_p \left( \frac{n}{2} \right) \right\}
\]

where \( W \) is a \( p \)-by-\( p \) positive-definite matrix. The parameterization constraint for Wishart distribution is \( n > p - 1 \) and \( S \in S^n_{++} \), where \( S^n_{++} \) denotes the set of \( p \)-by-\( p \) positive-definite matrices.

We start by specifying the parameterization,

\[
\begin{align*}
\tau & := \{ n \in \mathbb{R}, \ S \in S^n_{++} \mid n > p - 1 \} , \\
\lambda & := \{ b \in \mathbb{R}, \ B \in R^n_{++} \} , \\
\eta & := \{ \delta \in \mathbb{R}, \ M \in S^n_{++} \},
\end{align*}
\]

and their respective maps defined at \( \lambda_i := \{ b_i, B_i \} \)

\[
\begin{align*}
\begin{bmatrix} n \\ S \end{bmatrix} & = \psi(\lambda) := \begin{cases} 2f(b) + p - 1 \\ (2f(b) + p - 1)B B^T \end{cases} , \\
\begin{bmatrix} b \\ B \end{bmatrix} & = \phi_{\lambda_i}(\eta) := \begin{cases} b_i + \delta \\ B_i \text{Exp}(M) \end{cases} .
\end{align*}
\]

where \( f(b) = \log(1 + \exp(b)) \) is the soft-plus function.

For simplicity, we assume \( M \) is symmetric. We can also exploit structures in the Wishart case.

Under this local parameterization, we have the following result.

\[
-\log q(W | \eta) = (f(b_i + \delta) + c) \text{Tr}(B_i \text{Exp}(M) \text{Exp}(M)^T B_i^T W) - (f(b_i + \delta) + c) \log |W| \\
- (f(b_i + \delta) + c) n \log(n) - (f(b_i + \delta) + c) - 2(f(b_i + \delta) + c) \log |\text{Exp}(M)| + \log |B_i|)
\]

where \( c = \frac{p-1}{2} \).

**Lemma 15** Under this local parametrization \( \eta \), \( F_{\eta}(\eta_0) \) is block diagonal with two blocks—the \( \delta \) block and the \( M \) block.

**Proof** The cross term at \( \eta_0 = 0 \) is

\[
\begin{align*}
- \mathbb{E}_{q(W|\eta)} \left[ \nabla_{\delta} \nabla_{M} \log q(W | \eta) \right] \bigg|_{\eta=0} \\
= \nabla_{\delta} \left[ f(b_i + \delta) + c \right] \mathbb{E}_{q(\eta | \delta)} \left[ B_i^T W B_i - I \right] \bigg|_{\eta=0} \\
= \nabla_{\delta} \left[ f(b_i + \delta) + c \right] \left[ I - I \right] \bigg|_{\eta=0} \\
= 0
\end{align*}
\]
where we have the fact that $E_{q(W|\eta)}[W]|_{\eta=0} = B_t^{-T}B_t^{-1}$.

Let $Z = B_t^TWB_t$. First, we consider the following result.

$$\nabla_{M_j} \text{Tr}(B_t \text{Exp}(M) \text{Exp}(M)^T B_t^T W) = \nabla_{M_j} \text{Tr}(Z \text{Exp}(M) \text{Exp}(M)^T)$$

$$= \text{Tr}(Z \nabla_{M_j} \text{Exp}(M) \text{Exp}(M)^T + Z \text{Exp}(M) \nabla_{M_j} \text{Exp}(M)^T \text{Exp}(M))$$

By Lemma 8, we obtain a simplified expression.

$$\nabla_M [B_t \text{Exp}(M) \text{Exp}(M)^T B_t^T W] = 2Z + (ZM^T + M^T Z) + 2ZM + ZO(M^2)$$

By Lemma 7, we have

$$-\nabla_M \log \text{Exp}(M) = -I - C(M) \quad (39)$$

Now, we can compute the FIM w.r.t. block $M$ as follows. Note that we also numerically verify the following computation of FIM by Auto-Diff.

$$-E_{q(W|\eta)}[\nabla_M^2 \log q(W|\eta)]|_{\eta=0}$$

$$= E_{q(W|\eta)}[(f(b_t + \delta) + c) \nabla_M [2Z + (ZM^T + M^T Z) + 2ZM + ZO(M^2) - 2I - 2C(M)]]|_{\eta=0}$$

$$= (f(b_t + \delta) + c) \nabla_M [2M^T + 2M + O(M^2)]|_{\eta=0}$$

$$= 2(f(b_t) + c) \nabla_M (M^T + M)$$

where we use the fact that $E_{q(W|\eta)}[Z] = E_{q(W|\eta)}[B_t^TWB_t] = I$ evaluated at $\eta = 0$ to move from step 2 to step 3.

When $M$ is symmetric, we have $F_M(\eta_0) = 4(f(b_t) + c)I = 2n_tI$.

Next, we discuss how to compute the FIM w.r.t. $\delta$. Let $z(\delta) := [\text{Tr}(B_t \text{Exp}(M) \text{Exp}(M)^T B_t^T W) - \log |W| - p \log (f(b_t + \delta) + c) - p - 2(\log |\text{Exp}(M)| + \log |B_t|) + \psi_p(f(b_t + \delta) + c)]$, where $\psi_p(x) := \nabla_x \log \Gamma_p(x)$ is the multivariate digamma function.

First, let’s observe that

$$-\nabla_\delta \log q(W|\eta) = \frac{\exp(b_t + \delta)}{1 + \exp(b_t + \delta)}$$

Similarly, we have

$$-\nabla_\delta^2 \log q(W|\eta) = z(\delta) \left[ \nabla_\delta \frac{\exp(b_t + \delta)}{1 + \exp(b_t + \delta)} \right] + \left[ \nabla_\delta z(\delta) \right] \frac{\exp(b_t + \delta)}{1 + \exp(b_t + \delta)}$$

Let’s consider the first term in the above expression.

$$z(\delta) \left[ \nabla_\delta \frac{\exp(b_t + \delta)}{1 + \exp(b_t + \delta)} \right] = - \left[ \nabla_\delta \log q(W|\eta) \right] \frac{1 + \exp(b_t + \delta)}{\exp(b_t + \delta)} \left[ \nabla_\delta \frac{\exp(b_t + \delta)}{1 + \exp(b_t + \delta)} \right]$$

Note that $\eta_0 = \{M_0, \delta_0\} = 0$. We have the following result.

$$E_{q(W|\eta)}[z(\delta) \left[ \nabla_\delta \frac{\exp(b_t + \delta)}{1 + \exp(b_t + \delta)} \right]]|_{\eta=0}$$

$$= -E_{q(W|\eta)}[\nabla_\delta \log q(W|\eta)]|_{\eta=0} \left( \frac{1 + \exp(b_t + \delta)}{\exp(b_t + \delta)} \left[ \nabla_\delta \frac{\exp(b_t + \delta)}{1 + \exp(b_t + \delta)} \right] \right)|_{\eta=0}$$

$$= 0$$
where we will evaluate $n$ at $\delta = 0$ and $M = 0$.

Let $\mathcal{L} := \mathbb{E}_{q(w)} [\ell(w)] - \gamma \mathcal{H}(q(w))$. By the chain rule, we have
\[
\nabla_\delta \mathcal{L} := \text{Tr}(\nabla_V \mathcal{L} \nabla_\delta V) + [\nabla_n \mathcal{L}] \left[ \nabla_\delta n \right] = 0
\]
\[
\nabla_{M_{ij}} \mathcal{L} := \text{Tr}(\nabla_V \mathcal{L} \nabla_{M_{ij}} V) + [\nabla_n \mathcal{L}] \left[ \nabla_{M_{ij}} n \right] = -\text{Tr}(\nabla_V \mathcal{L} \nabla_{M_{ij}} V^{-1} V)
\]

Note that
\[
\nabla_\delta \mathcal{L}_{\eta=0} := \text{Tr}(\nabla_V \mathcal{L} \nabla_\delta V) + [\nabla_n \mathcal{L}] \left[ \nabla_\delta n \right]_{\eta=0} = \frac{1}{2(f(b_t) + \frac{p-1}{2})^2} \frac{\exp(b_t)}{1 + \exp(b_t)} \text{Tr}(\nabla_V \mathcal{L} \mathbf{B}_t^{-T} \mathbf{B}_t^{-1} + \frac{2\exp(b_t)}{1 + \exp(b_t)} [\nabla_n \mathcal{L}]
\]
\[
= \frac{2\exp(b_t)}{1 + \exp(b_t)} \left( \frac{-\frac{1}{n_t}}{n_t} \text{Tr}(\nabla_V \mathcal{L} \mathbf{B}_t^{-T} \mathbf{B}_t^{-1} + [\nabla_n \mathcal{L}]) \right)
\]
\[
= \frac{2\exp(b_t)}{1 + \exp(b_t)} \left( -\frac{\text{Tr}(\nabla_V \mathcal{L} \nabla_{M_{ij}} V^{-1} V)}{n_t} + [\nabla_n \mathcal{L}] \right)
\]

\[
\nabla_{M_{ij}} \mathcal{L}_{\eta=0} := -\text{Tr}(\nabla_V \mathcal{L} \nabla_{M_{ij}} V^{-1} V)_{\eta=0} = -n_t \text{Tr}(\nabla_V \mathcal{L} \nabla_{M_{ij}} \mathbf{V}_i \mathbf{V}_i) (\mathbf{M} + \mathbf{M}^T) \mathbf{B}_t^T \mathbf{V}_t
\]
\[
= -n_t \text{Tr}(\nabla_V \mathcal{L} \nabla_{M_{ij}} \mathbf{B}_t^{-T} \mathbf{B}_t^{-1} \mathbf{B}_t \nabla_{M_{ij}} \mathbf{V}_i \mathbf{V}_i (\mathbf{M} + \mathbf{M}^T) \mathbf{B}_t^T \mathbf{B}_t^T) \nabla_{M_{ij}} \mathbf{V}_i \mathbf{V}_i
\]
\[
= -n_t \text{Tr}(\nabla_V \mathcal{L} \mathbf{B}_t^{-T} \nabla_{M_{ij}} (\mathbf{M} + \mathbf{M}^T) \mathbf{B}_t^T) \nabla_{M_{ij}} \mathbf{V}_i \mathbf{V}_i
\]
when $M$ is symmetric, we have
\[
\nabla_M \mathcal{L}\big|_{\eta=0} := -\frac{2}{n_t} \text{Tr}(B_t^{-1} [\nabla_V \mathcal{L}] B_t^{-T})
\]
\[
\nabla_M \mathcal{L}\big|_{\eta=0} := \frac{2\exp(b_t)}{1 + \exp(b_t)} \left(-\frac{\text{Tr}(\nabla_V \mathcal{L}) V_t}{n_t} + [\nabla_n \mathcal{L}] \right)
\]
where we use the fact that $[\nabla_V \mathcal{L}]$ is symmetric.

In the symmetric case, the FIM w.r.t. $\eta$ at $\eta_0$ is
\[
F_{\eta}(\eta_0) = \begin{bmatrix} 2n_t I_M & 0 \\ 0 & \left(\frac{\exp(b_t)}{1 + \exp(b_t)}\right)^2 \left(-\frac{2p}{n_t} + D_{\psi,\rho}(\frac{n_t}{2})\right) \end{bmatrix},
\]
which implies that Assumption 1 is satisfied.

The natural gradients are
\[
\hat{g}_M := \frac{1}{2n_t} G = -\frac{1}{n_t^2} B_t^{-1} [\nabla_V \mathcal{L}] B_t^{-T}
\]
\[
\hat{g}_\delta := \frac{2(1 + \exp(b_t))}{\exp(b_t)} \left(-\frac{2p}{n_t} + D_{\psi,\rho}(\frac{n_t}{2})\right)^{-1} \left(-\frac{\text{Tr}(\nabla_V \mathcal{L}) V_t}{n_t} + [\nabla_n \mathcal{L}] \right)
\]
where $\nabla_V \mathcal{L}$ and $\nabla_n \mathcal{L}$ can be computed by the implicit reparametrization trick in the following section.

Therefore, our update with step-size $\beta$ is
\[
B_{t+1} \leftarrow B_t \text{Exp}(0 - \beta \hat{g}_M) = B_t \text{Exp}(\frac{\beta}{n_t} B_t^{-1} [\nabla_V \mathcal{L}] B_t^{-T})
\]
\[
b_{t+1} \leftarrow b_t + (0 - \beta \hat{g}_\delta) = b_t - \frac{2\beta(1 + \exp(b_t))}{\exp(b_t)} \left(-\frac{2p}{n_t} + D_{\psi,\rho}(\frac{n_t}{2})\right)^{-1} \left(-\frac{\text{Tr}(\nabla_V \mathcal{L}) V_t}{n_t} + [\nabla_n \mathcal{L}] \right)
\]
(40)

We can similarly show that Assumption 2 is also satisfied by the inverse function theorem as discussed in Gaussian cases (see Appendix D.1) since the soft-plus function $f(b)$ and $\text{Exp}(M)$ are both $C^1$-smooth.

### E.1. Reparametrizable Gradients

Recall that we can generate a Wishart random variable $W$ due to the Bartlett decomposition as shown below. $W = L\Omega\Omega^T L^T$, where $L$ is the lower-triangular Cholesky factor of $S^{-1} = V$ and $\Omega$ is the random lower-triangular matrix defined according to the Bartlett decomposition as follows
\[
\Omega = \begin{bmatrix} c_1 & 0 & 0 & \cdots & 0 \\ n_{21} & c_2 & 0 & \cdots & 0 \\ n_{31} & n_{32} & c_3 & \cdots & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ n_{d1} & n_{d2} & n_{d3} & \cdots & c_d \end{bmatrix}
\]
where the square of diagonal entry $c_i^2$ is independently generated from Gamma distribution with shape $\frac{n-i+1}{2}$ and rate $\frac{1}{2}$, and other non-zero entries $n_{ij}$ are independently drawn from standard normal distribution.

Let $L_1 = E_{q}[\ell(W)]$. According to this sampling scheme, we can clearly see that Wishart distribution is reparametrizable. The gradient w.r.t. $V$ can be computed as
\[
\nabla_V L_1 = E_{q}(\theta) \left[\nabla_W \ell(W) \nabla_V (L\Omega\Omega^T L^T) \right]
\]
Since Gamma distribution is implicitly re-parametrizable, we can also compute the gradient $\nabla_n L_1$ thanks to the implicit reparametrization trick (Figurnov et al., 2018; Lin et al., 2019b) for Gamma distribution.
E.2. Riemannian Gradient Descent at $U$

Instead of optimizing $Z$, we optimize $U = Z^{-1}$. A Riemannian gradient (Hosseini & Sra, 2015; Lin et al., 2020) in the manifold $S_{++}^{p \times p}$ is $\hat{G} = U(\nabla U \ell) U$. The RGD update with retraction and step-size $\beta_1$ is

$$U \leftarrow U - \beta_1 \hat{G} + \frac{\beta_1^2}{2} \hat{G}(U)^{-1} \hat{G}.$$ 

Due to matrix calculus, we have $\nabla Z \ell = -U(\nabla U \ell) U$. We can re-express the RGD update as

$$U \leftarrow U + \beta_1 \nabla Z \ell + \frac{\beta_1^2}{2} \nabla Z \ell [U^{-1} \nabla Z \ell].$$

E.3. Gradients Evaluated at the Mean

Recall that the mean of the Wishart distribution as $Z = E_q[W] = nS^{-1} = nV$. We can approximate the Euclidean gradients as below.

$$\nabla_{V_i} E_q[W] \ell(W) \approx \text{Tr}(\nabla Z \ell(Z) \nabla_{V_i} (nV)) = n\nabla Z \ell(Z)$$

$$\nabla_n E_q[W] \ell(W) \approx \text{Tr}(\nabla Z \ell(Z) \nabla_n (nV)) = \text{Tr}(\nabla Z \ell(Z)V)$$

where $Z = nV$.

Therefore,

$$G_{V_t} \approx n_t \nabla \ell(Z_t), \quad g_{n_t} \approx \text{Tr}[\nabla \ell(Z_t)V_t]$$

F. Standard NGD is a Special Case

The standard NGD in a global parameter $\tau$ is a special case of using a local parameter $\eta$. For simplicity, we assume $\tau$ is unconstrained and the FIM is non-singular for $\tau \in \Omega_\tau$. In this case, we choose the auxiliary parameter $\lambda$ to be the same as $\tau$. The map $\psi \circ \phi_{\lambda_t}(\eta)$ is chosen to be

$$\tau = \psi(\lambda) := \lambda; \quad \lambda = \phi_{\lambda_t}(\eta) := \lambda_t + \eta.$$

**Theorem 1** Let $F_\eta$ and $F_\tau$ be the FIM under the local parameter $\eta$ and the global parameter $\tau$, respectively.

$$F_\eta(\eta_0) = F_\eta(0) = F_\tau(\tau_t)$$

It is obvious that Assumption 2 is satisfied since the map is linear. Since $F_\tau(\tau_t)$ is non-singular, we know that Assumption 1 is satisfied due to Theorem 1. Since $\tau = \psi \circ \phi_{\lambda_t}(\eta) = \lambda_t + \eta$, by the chain rule, we have $g_{\eta_0} = [\nabla \eta \tau] g_{\tau_t} = g_{\tau_t}$.

Therefore, the NGD update with step-size $\beta$ in this local parameterization is

$$\eta_{\text{new}} = 0 - \beta F_\eta(0)^{-1} g_{\eta_0} = -\beta F_\tau(\tau_t)^{-1} g_{\tau_t}$$

Finally, we re-express the update in the global parameter as:

$$\tau_{t+1} = \psi \circ \phi_{\lambda_t}(\eta_{\text{new}}) = \tau_t + \eta_{\text{new}} = \tau_t - \beta F_\tau(\tau_t)^{-1} g_{\tau_t}$$

which is exactly the NGD update in $\tau$. 
F.1. Proof of theorem 1

Note that \( \tau = \psi \circ \phi_{\lambda_t}(\eta) = \lambda_t + \eta = \tau_t + \eta \). Now, we will show that the FIM under the local parameter \( \eta \) can be computed as

\[
F_\eta(0) = -E_{q(w|\eta)} \left[ \nabla^2_{\eta} \log q(w|\eta) \right] \big|_{\eta=0} \\
= -E_{q(w|\eta)} \left[ \nabla_{\eta} \left[ \nabla_{\tau} \log q(w|\tau) \right] \right] \big|_{\eta=0} \\
= -E_{q(w|\eta)} \left[ \nabla_{\tau} \log q(w|\tau) \right] \big|_{\eta=0} \\
= -E_{q(w|\eta)} \left[ \nabla_{\tau} \log q(w|\tau) \right] \big|_{\tau=\tau_t} \\
= F_{\tau}(\tau_t)
\]

G. Univariate Minimal Exponential Family Distributions

Using Lemma 5, we can generalize the indirect method of Salimbeni et al. (2018) to compute natural-gradients for univariate minimal EF distributions using a local parameterization. Salimbeni et al. (2018) only consider the method for multivariate Gaussian cases using a global parameterization.

Note that the main issue to perform the standard NGD update in the global parameter space is that the NGD update in \( \tau \) may violate a parameter constraint. However, we can perform a NGD update in an unconstrained space (e.g., the auxiliary space of \( \lambda \)) if the natural gradient computation in the space of unconstrained space of \( \lambda \) is simple. Salimbeni et al. (2018) suggest using the indirect method to compute natural gradients via Auto-Differentiation (Auto-Diff).

For univariate minimal EF distributions, we can also use this indirect method to compute natural gradients. We consider a class of univariate EF distributions. We make the following assumptions for the class of distributions: (A) Each distribution in the class contains separable natural parameter blocks so that each parameter constraint only appears once in a block and each block only contains a scalar parameter. (B) The natural gradient w.r.t. the natural parameterization is easy to compute.

We choose the natural parameterization as a global parameterization \( \tau \) with \( K \) blocks: \( q(w|\tau) = B(w) \exp(\langle T(w), \tau \rangle - A(\tau)) \), where \( B(w) \) is the base measure, \( A(\tau) \) is the log partition function\(^8\), and \( T(w) \) is the sufficient statistics. A common parameter constraint in \( \tau \) is the scalar positivity constraint denoted by \( S^1_{++} \). For simplicity, we assume \( S^1_{++} \) is the only parameter constraint. Common univariate EF distributions such as Bernoulli, exponential, Pareto, Weibull, Laplace, Wald, univariate Gaussian, Beta, and Gamma distribution all satisfy Assumption A. Assumption B is also valid for these univariate EF distributions since we can either compute the natural gradient \( \hat{g}_{\tau_t} \) via the Euclidean gradient w.r.t. the expectation parameter (Khan & Lin, 2017) or use the direct natural gradient computation when \( K \) is small (\( K < 3 \) in common cases).

Given a distribution in the class, we consider the following parameterizations:

\[
\tau := \begin{bmatrix} \tau_1 \in S^1_{++}, \\
\cdots \\
\tau_K \in S^1_{++} \end{bmatrix}, \quad \lambda := \begin{bmatrix} \lambda_1 \\
\cdots \\
\lambda_K \end{bmatrix} \in \mathbb{R}^K, \quad \eta := \begin{bmatrix} \eta_1 \\
\cdots \\
\eta_K \end{bmatrix} \in \mathbb{R}^K
\]

and maps:

\[
\tau = \psi(\lambda) := \begin{bmatrix} f(\lambda_1) \\
\cdots \\
f(\lambda_K) \end{bmatrix}, \quad \lambda = \phi_{\lambda_t}(\eta) := \lambda_t + \eta = \begin{bmatrix} \lambda_{1,t} + \eta_1 \\
\cdots \\
\lambda_{K,t} + \eta_K \end{bmatrix}
\]

where \( f(b) := \log(1 + \exp(b)) \) is the soft-plus function and \( \tau \) is the natural parameterization.

\(^8\) \( A(\tau) \) is \( C^2 \)-smooth w.r.t. \( \tau \) as shown in Johansen (1979).
Tractable structured natural gradient descent using local parameterizations

In this case, we can easily compute the Jacobian, where \( \nabla f(b) := \frac{\exp(b)}{1+\exp(b)} \).

\[
\nabla_{\eta} \tau \bigg|_{\eta = \eta_0 = 0} = \text{Diag} \left( \begin{bmatrix} \nabla f(\lambda_1,t) \\ \vdots \\ \nabla f(\lambda_K,t) \end{bmatrix} \right)
\]

By Lemma 5, we have

\[
\hat{g}_{\eta_0} = \left[ \nabla_{\eta} \tau \right]^{-T} \hat{g}_\tau \bigg|_{\eta = 0}
\]

where natural-gradient \( \hat{g}_\tau \) can be computed via the Euclidean gradient w.r.t. its expectation parameter or via direct inverse FIM computation as below

\[
\hat{g}_\tau = \left( F_\tau(\tau_t) \right)^{-1} g_{\tau_t}
= (\nabla_\tau m)^{-1} g_{\tau_t}
= g_m
\]

where \( m = \mathbb{E}_q [T(w)] = \nabla_\tau A(\tau) \) is the expectation parameter and \( F_\tau(\tau_t) = \nabla^2_\tau A(\tau_t) \) is the FIM which is non-singular due to the minimality of the distribution.

Our update in the auxiliary parameter space is

\[
\lambda_{t+1} \leftarrow \lambda_t - \beta \hat{g}_{\lambda_t}
\]

Since \( \lambda = \phi_{\lambda_t}(\eta) = \lambda_t + \eta \), we can easily show that \( \hat{g}_{\eta_0} = \hat{g}_{\lambda_t} \). In other words, our update recovers the standard NGD update in an unconstrained space of \( \lambda \).

\[
\lambda_{t+1} \leftarrow \lambda_t - \beta \hat{g}_{\lambda_t}
\]

which recovers the method proposed by Salimbeni et al. (2018) in multivariate Gaussian cases.

Therefore, by choosing \( \lambda = \phi_{\lambda_t}(\eta) = \lambda_t + \eta \), Lemma 5 generalizes the indirect method proposed by Salimbeni et al. (2018).

G.1. Discussion about the Indirect Method

Salimbeni et al. (2018) propose an indirect method to compute natural-gradients via Auto-Differentiation (Auto-Diff) for multivariate Gaussian with full covariance structure using a global parameterization. We have shown that this method is a special case of our approach by using a particular local parameterization and have extended it to univariate minimal EF distributions by using Lemma 5.

However, this indirect method has several limitations when it comes to a structured matrix parameter such as the covariance/precision matrix parameter in Gaussian and Wishart cases. The indirect method avoids computing the FIM \( F_{\eta}(\eta_0) \) by computing the Jacobian \( \nabla_{\tau} \eta \) instead. Unfortunately, the Jacobian matrix computation can be very complicated when it comes to a matrix parameter. Salimbeni et al. (2018) suggest using Auto-Diff to track non-zero terms in the Jacobian matrix \( \nabla_{\tau} \eta \) (e.g., \( \eta \) can be a Cholesky factor of \( S \) and \( \tau = S \) is the precision matrix in Gaussian cases with a constant mean) and to perform the Jacobian-vector product used in Lemma 5. However, the Jacobian-vector product requires us to compute a dense natural-gradient \( \hat{g}_{\tau_t} \) (e.g., \( g_{S^{-1}} \) in Gaussian cases with a constant mean) beforehand, which is not efficient for a sparse structured (local) parameter \( \eta \). As shown by Lin et al. (2020), the indirect method can be inefficient and numerically unstable even in multivariate Gaussian cases with full precision \( S \). Moreover, given a structured local parameter \( \eta \), it is difficult to verify the non-singularity of the Jacobian required in the indirect method (see Lemma 5). It is also unclear whether the Jacobian matrix \( \nabla_{\tau} \eta \) computed by Auto-Diff is sparse even when the local parameter \( \eta \) is sparse.

The flexibility of our approach allows us to freely use either the indirect method (see Eq (23)) or the direct method (Eq (7)) to compute natural gradients. By using a proper local parameterization, we can directly compute \( F_{\eta}(\eta_0) \) and \( \hat{g}_{\eta_0} \) without using the indirect method and the Jacobian matrix computation. As shown in the main text, our update recovers the direct...
We define $\lambda$ as discussed in Lin et al. (2019a), the FIM of the joint distribution $B$ where $q$ where we use the entropy of the marginal distribution $\pi$. Therefore, we use the following parameterizations:

This formalization allows us to relax Assumption 1 and use the joint FIM instead. Lin et al. (2019a) further show that the indirect method is also related to the Riemannian trivialization method (Lezcano Casado, 2019), where the unconstrained variational inference is more efficient than block-box variational inference.

In our approach, we push forward the Fisher metric (a pre-defined Riemannian metric) from an original (global) parameter space to a local parameter space so that natural gradients at $\eta_0$ are easy to compute in the local parameter space. Unlike the Riemannian trivialization method, the push-forward of the metric (e.g., Euclidean gradient descent in a unconstrained space) can converge very slowly as shown in our experiments (see Figure 2(a) in the main text). In variational inference, the Riemannian trivialization method is known as the black-box variational inference (Ranganath et al., 2014). Khan & Lin (2017); Lin et al. (2019a) show that natural-gradient variational inference is more efficient than block-box variational inference.

In this appendix, we consider the following Gaussian mixture distribution

\begin{align*}
q(w|z) &= \frac{1}{K} \sum_{k=1}^K N(w|\mu_k, S_k^{-1}) \\
\end{align*}

where $\tau = \{\mu_k, S_k\}_{k=1}^K$ and $S_k$ is the precision matrix of the $k$-th Gaussian component.

As discussed in Lin et al. (2019a), the FIM of $q(w|\eta)$ can be singular. Therefore, Assumption 1 is not satisfied.

We define $\lambda_{z_k} = \log(\frac{\pi_k}{\pi_K}) = 0$, where $\pi_k = \frac{1}{K}$. However, we can consider the Gaussian mixture as the marginal distribution of the following joint distribution such that $\int q(w,z|\tau)dz = q(w|\tau)$.

\begin{align*}
q(w,z|\tau) &= q(z|\lambda)q(w|z, \tau) \\
q(z|\lambda) &= \exp(\sum_{k=1}^{K-1} I(z = k)\lambda_{z_k} - A_z(\lambda_z)) \\
q(w|z, \tau) &= \exp \left( \sum_{k=1}^K I(z = k) \left[ -\frac{1}{2} w^T S_k w + w^T S_k \mu_k - A_w(\tau, z) \right] \right)
\end{align*}

where $B(\mu_k, S_k) = \frac{1}{2} [\mu_k^T S_k \mu_k - \log |S_k|/(2\pi)]$, $A_w(\tau, z) = \sum_{k=1}^K I(z \neq k) B(\mu_k, S_k)$, $A_z(\lambda_z) = \log(1 + \sum_{k=1}^{K-1} \exp(\lambda_{z_k}))$.

As discussed in Lin et al. (2019a), the FIM of the joint distribution $q(w,z|\tau)$ is not singular. To solve a variational inference problem, Lin et al. (2019a) consider the following problem with $\gamma = 1$ in Eq (1).

\[
\min_{q(w,z) \in \mathcal{Q}} E_{q(w,z)}[\ell(w)] - \gamma H(q(w)),
\]

where we use the entropy of the marginal distribution $q(w)$. This approach has been studied by Agakov & Barber (2004).

This formalization allows us to relax Assumption 1 and use the joint FIM instead. Lin et al. (2019a) further show that the joint FIM is block-diagonal for each component.

Therefore, we use the following parameterizations:

\begin{align*}
\tau := \{\mu_k \in \mathbb{R}^p, S_k \in \mathbb{S}_{++}^{p \times p}\}_{k=1}^K \\
\lambda := \{\mu_k \in \mathbb{R}^p, B_k \in \mathbb{R}^{p \times p}_{++}\}_{k=1}^K \\
\eta := \{\delta_k \in \mathbb{R}^p, M_k \in \mathbb{S}^{p \times p}_{++}\}_{k=1}^K.
\end{align*}
and maps are defined as

$$
\psi(\lambda) = \{\psi_k(\lambda_k)\}_{k=1}^K \\
\phi_k(\eta) = \{\phi_k(\eta_k)\}_{k=1}^K \\
\left\{ \begin{array}{l}
\mu_k \\
S_k
\end{array} \right\} = \psi_k(\lambda_k) := \left\{ \begin{array}{l}
\mu_k \\
B_k B_k^T
\end{array} \right\} \\
\left\{ \begin{array}{l}
\mu_k \\
B_k
\end{array} \right\} = \phi_k(\eta_k) := \left\{ \begin{array}{l}
\mu_k + B_k^{-T} \delta_k \\
B_k h(M_k)
\end{array} \right\}
$$

where $B_{k,t}$ denotes the value of $B_k$ at iteration $t$ and $\lambda_t = \{\mu_{k,t}, B_{k,t}\}_{k=1}^K$.

We can show that Assumption 2 is also satisfied as discussed in Gaussian cases (see Appendix D.1).

Natural gradients w.r.t. $\delta_k$ and $M_k$ can be computed as below, which is similar to (33).

$$
\hat{g}_{\delta_k} = \frac{1}{\pi_k} B_{k,t}^{-1} \nabla_{\mu_k} \mathcal{L}, \quad \hat{g}_{M_k} = -\frac{1}{\pi_k} B_{k,t}^{-1} \left[ \nabla_{\Sigma_k} \mathcal{L} \right] B_{k,t}^{-T}
$$

where $\mathcal{L} := \mathbb{E}_{q(w|x)} [\ell(w)] - \gamma \mathcal{H}(q(w))$ and $\pi_k = \frac{1}{K}$.

Therefore, our update for the $k$ Gaussian component is

$$
\mu_{k,t+1} \leftarrow \mu_{k,t} - \frac{\beta}{\pi_k} B_{k,t}^{-T} B_{k,t}^{-1} \nabla_{\mu_k} \mathcal{L} \\
B_{k,t+1} \leftarrow B_{k,t} h\left( \frac{\beta}{\pi_k} B_{k,t}^{-1} \left[ \nabla_{\Sigma_k} \mathcal{L} \right] B_{k,t}^{-T} \right)
$$

where $\pi_k = \frac{1}{K}$.

Euclidean gradients $\nabla_{\mu_k} \mathcal{L}$ and $\nabla_{\Sigma_k} \mathcal{L}$ can be computed as suggested by Lin et al. (2019a), where we use second-order information to compute $\nabla_{\Sigma_k} \mathcal{L}$. Lin et al. (2020) also show that we can compute $\nabla_{\Sigma_k} \mathcal{L}$ by first-order information if second-order information is not available.

$$
\nabla_{\mu_k} \mathcal{L} = \mathbb{E}_{q(w)}[\pi_k \delta_k \nabla_w b(w)] \\
\nabla_{\Sigma_k} \mathcal{L} = \frac{1}{2} \mathbb{E}_{q(w)}[\pi_k \delta_k \nabla^2_w b(w)] \\
= \frac{1}{2} \mathbb{E}_{q(w)}[\pi_k \delta_k S_k (w - \mu_k) \nabla^2_w b(w)]
$$

where $\delta_k := \mathcal{N}(w|\mu_k, S_k)/\sum_{c=1}^K \pi_c \mathcal{N}(w|\mu_c, S_c), b(w) := \ell(w) + \gamma \log q(w|\tau)$.

I. Matrix Gaussian for Matrix Weights in Deep Learning

In this appendix, we consider a matrix Gaussian for layer-wise matrix weights in a neural network, where a precision form will be used.

$$
\mathbb{M} \mathcal{N}(W|E, S^{-1}_E, S^{-1}) := \mathcal{N}(\text{vec}(W)|\text{vec}(E), S^{-1})
$$

where the precision $S = S_V \otimes S_U$ has a Kronecker form, $W \in \mathcal{R}^{d \times p}$ is a matrix, $S_V \in \mathcal{S}_p^{p \times p}$, $S_U \in \mathcal{S}_d^{d \times d}$, and $\otimes$ denotes the Kronecker product.

In this case, Assumption 1 is not satisfied since the FIM of a matrix Gaussian is singular due to the cross terms between $S_U$ and $S_V$ in the FIM. However, a block-diagonal approximation for the FIM is non-singular. This approximation has been used in many works such as Tran et al. (2020); Glasmachers et al. (2010); Lin et al. (2019a). Therefore, we relax Assumption 1 and use the block-diagonal approximation of the FIM instead. The update is known as simultaneous block coordinate (natural-gradient) descent in optimization.

We consider the following optimization problem for NNs with $L_2$ regularization.

$$
\min_{\tau \in \Omega_\tau} \mathbb{E}_{q(W|\tau)} \left[ \ell(W) + \frac{\alpha}{2} \text{Tr}(W^T W) \right] - \gamma \mathcal{H}(q(W|\tau))
$$
where \( q(W) = \prod_l q(W_l) \) and for each layer \( l \), \( q(W_l) \) is a matrix Gaussian distribution with precision matrix \( S_l = S_{l,V} \otimes S_{l,U} \).

For simplicity, we only consider one layer and drop the layer index \( l \).

Let’s consider a global parameterization \( \tau = \{E, S_U, S_V\} \) We use the following parameterizations:

\[
\begin{align*}
\tau & := \left\{ E \in \mathbb{R}^{d \times p} , \; S_V \in S_p^{\times p} , \; S_U \in S_{p \times d} \right\} \\
\lambda & := \left\{ E \in \mathbb{R}^{d \times p} , \; A \in \mathcal{R}_p^{p \times p} , \; B \in \mathcal{R}^{d \times d} \right\} \\
\eta & := \left\{ \Delta \in \mathbb{R}^{d \times p} , \; M \in S_p^{\times p} , \; N \in S_{d \times d} \right\}.
\end{align*}
\]

and maps:

\[
\begin{align*}
\begin{pmatrix} E \\ S_V \\ S_U \end{pmatrix} = \psi(\lambda) & := \begin{pmatrix} E \\ A A^T \\ B B^T \end{pmatrix} \\
\begin{pmatrix} E \\ A \\ B \end{pmatrix} = \phi_{\lambda_t}(\eta) & := \begin{pmatrix} E_t + B_t^{-T} \Delta A_t^{-1} \\ A_t h(M) \\ B_t h(N) \end{pmatrix}.
\end{align*}
\]

Thanks to this parameterization, it is also easy to generate samples from a matrix Gaussian \( \mathcal{M}\mathcal{N}(W|E, S_U^{-1}, S_V^{-1}) \) as

\[
W = E + B^{-T} \text{Mat}(z) A^{-1}
\]

where \( z \sim \mathcal{N}(z|0, I) \).

The block-diagonal approximation of the FIM under the local parameterization \( \eta \) is given below. Note that we also numerically verify the following computation of FIM by Auto-Diff.

\[
F_\eta(\eta_0) = \begin{bmatrix} I_\Delta & 0 & 0 \\ 0 & 2d I_M & 0 \\ 0 & 0 & 2d I_N \end{bmatrix}
\]

where the red terms are set to be zero due to the block-diagonal approximation while the black terms are obtained from the exact FIM.

Thanks to the block-diagonal approximation of the FIM, we can show that Assumption 2 is satisfied for each parameter block by holding the remaining blocks fixed.

Now, we discuss how to compute Euclidean gradients w.r.t. local parameterization \( \eta \). Since each matrix Gaussian \( \mathcal{M}\mathcal{N}(W|E, S_U^{-1}, S_V^{-1}) \) can be re-expressed as a vector Gaussian \( \mathcal{N}(w|\mu, S^{-1}) \), The Euclidean gradients w.r.t. global parameter \( \tau_{\text{vec}} = \{\mu, S\} \) of the vector Gaussian are

\[
\begin{align*}
g_\mu & = \alpha \mu + \mathbb{E}_{\mathcal{N}(w|\tau_{\text{vec}})} [\nabla_w \ell(w)] \\
g_S & = \frac{1}{2} (\alpha I_S + \mathbb{E}_{\mathcal{N}(w|\tau_{\text{vec}})} [\nabla^2_w \ell(w)] - \gamma S) \;
\end{align*}
\]

where \( w = \text{vec}(W), \; \mu = \text{vec}(E), \; \Sigma = S^{-1} = S_V^{-1} \otimes S_U^{-1} \).

To avoid computing the Hessian \( \nabla^2_w \ell(w) \), we use the Per-example Gauss-Newton approximation (Graves, 2011; Osawa et al., 2019) as

\[
g_S \approx \frac{1}{2} (\alpha I_S + \mathbb{E}_{\mathcal{N}(w|\tau_{\text{vec}})} [\nabla_w \ell(w) \nabla^T_w \ell(w)] - \gamma S)
\]

Recall that

\[
\begin{align*}
E & = E_t + B_t^{-T} \Delta A_t^{-1} \\
S_V & = A_t h(M) h(M)^T A_t^T \\
S_U & = B_t h(N) h(N)^T B_t^T
\end{align*}
\]
Let’s denote $\mathbf{g} = \nabla_w \ell(w)$ and $\mathbf{G} = \nabla_W \ell(W)$, where $w = \text{vec}(W)$ and $g = \text{vec}(G)$. By matrix calculus, we have

$$
\mathbf{g}_\Delta \bigg|_{\eta=0} = \mathbf{B}^{-1}_t \text{Mat}(\mu_t) \mathbf{A}_t^{-T} = \mathbf{B}_t^{-1} (\alpha \mathbf{E} + \mathbb{E}_{\eta(W_t)} [\nabla_w \ell(W)] \mathbf{A}_t^{-T} = \mathbf{B}_t^{-1} (\alpha \mathbf{E} + \mathbb{E}_{\eta(W_t)} [\mathbf{G}] \mathbf{A}_t^{-T}
$$

Now, we discuss how to compute a Euclidean gradient w.r.t. $\mathbf{M}$. By the chain rule, we have

$$
\mathbf{g}_{M_{ij}} \bigg|_{\eta=0} = \text{Tr}(\mathbf{M}_i [\nabla_{M_{ij}} \mathbf{G}] \mathbf{A}_t^{-1}) - 2 \text{Tr}(\mathbf{M}_i [\mathbf{A}_t^{-1}] \mathbf{M}_{ij} \mathbf{A}_t^{-1}) \pm \mathbf{B}_t^{-1} \mathbf{B}_t^{-1} \mathbf{g}_\Sigma
$$

where $M_{ij}$ is the entry of $\mathbf{M}$ at position $(i, j)$.

By the Gauss-Newton approximation of the Hessian, we have

$$
\mathbf{g}_{M_{ij}} \bigg|_{\eta=0} \approx -\text{Tr}(\mathbf{M}_i [\nabla_{M_{ij}} \mathbf{G}] \mathbf{A}_t^{-1}) \pm \mathbf{B}_t^{-1} \mathbf{B}_t^{-1} \mathbf{g}_\Sigma
$$

Let’s consider the last term in the approximated $\mathbf{g}_\Sigma$.

$$
-\text{Tr}(\mathbf{M}_i [\nabla_{M_{ij}} \mathbf{G}] \mathbf{A}_t^{-1}) \pm \mathbf{B}_t^{-1} \mathbf{B}_t^{-1} \mathbf{g}_\Sigma = -\alpha \text{Tr}(\mathbf{B}_t^{-1} \mathbf{B}_t^{-1} \mathbf{g}_\Sigma) \text{Tr}(\mathbf{A}^{-1} \mathbf{A}^{-T} [\nabla_{M_{ij}} \mathbf{M}])
$$

Now, we consider the second term in the approximated $\mathbf{g}_\Sigma$.

$$
-\text{Tr}(\mathbf{M}_i [\nabla_{M_{ij}} \mathbf{G}] \mathbf{A}_t^{-1}) \pm \mathbf{B}_t^{-1} \mathbf{B}_t^{-1} \mathbf{g}_\Sigma = -\mathbb{E}_{\eta(W_t)} \text{Tr}(\text{vec}(\mathbf{G})^T [\mathbf{M}_i [\nabla_{M_{ij}} \mathbf{G}] \mathbf{A}_t^{-1}] \pm \mathbf{B}_t^{-1} \mathbf{B}_t^{-1} \mathbf{g}_\Sigma) \text{vec}(\mathbf{G})
$$

Using the identity $(\mathbf{B}^T \otimes \mathbf{A}) \text{vec}(\mathbf{X}) = \text{vec}(\mathbf{AXB})$, we can simplify the above expression as

$$
-\text{Tr}(\mathbf{M}_i [\nabla_{M_{ij}} \mathbf{G}] \mathbf{A}_t^{-1}) \pm \mathbf{B}_t^{-1} \mathbf{B}_t^{-1} \mathbf{g}_\Sigma = -\mathbb{E}_{\eta(W_t)} \text{Tr}(\text{vec}(\mathbf{G})^T [\mathbf{M}_i [\nabla_{M_{ij}} \mathbf{G}] \mathbf{A}_t^{-1}] \pm \mathbf{B}_t^{-1} \mathbf{B}_t^{-1} \mathbf{g}_\Sigma) \text{vec}(\mathbf{G})
$$

Finally, we consider the last term in the approximated $\mathbf{g}_\Sigma$.

$$
-\text{Tr}(\mathbf{M}_i [\nabla_{M_{ij}} \mathbf{G}] \mathbf{A}_t^{-1}) \pm \mathbf{B}_t^{-1} \mathbf{B}_t^{-1} \mathbf{g}_\Sigma = \gamma \text{Tr}(\mathbf{M}_i [\nabla_{M_{ij}} \mathbf{G}] \mathbf{A}_t^{-1}) \pm \mathbf{B}_t^{-1} \mathbf{B}_t^{-1} \mathbf{g}_\Sigma)
$$

Therefore, we have

$$
\mathbf{g}_{M_{ij}} \bigg|_{\eta=0} \approx -\alpha \text{Tr}(\mathbf{B}_t^{-1} \mathbf{B}_t^{-1} \mathbf{g}_\Sigma) \text{Tr}(\mathbf{A}^{-1} \mathbf{A}^{-T} [\nabla_{M_{ij}} \mathbf{M}]) - \mathbb{E}_{\eta(W_t)} \text{Tr}(\mathbf{A}^{-1} \mathbf{G}^T \mathbf{B}_t^{-1} \mathbf{B}_t^{-1} \mathbf{G} \mathbf{A}_t^{-1} \mathbf{A}_t^{-T} [\nabla_{M_{ij}} \mathbf{M}]) + \gamma \text{Tr}(\mathbf{M}_i [\nabla_{M_{ij}} \mathbf{G}] \mathbf{A}_t^{-1}) \pm \mathbf{B}_t^{-1} \mathbf{B}_t^{-1} \mathbf{g}_\Sigma)
$$
Tractable structured natural gradient descent using local parameterizations

We consider the following loss function parameterized by a MLP/CNN evaluated at one data point. We will show that a

\[ g_M \left|_{\eta = 0} \right. \approx -\alpha \text{Tr}(B_t^{-T}B_t^{-1})A_t^{-1}A_t^{-T} - E_{q(w|z)} \left[ A_t^{-1}G^{-T}B_t^{-T}B_t^{-1}GA_t^{-T} \right] + \gamma dI_M \]

Similarly, we can show

\[ g_N \left|_{\eta = 0} \right. \approx -\alpha \text{Tr}(A_t^{-T}A_t^{-1})B_t^{-1}B_t^{-T} - E_{q(w|z)} \left[ B_t^{-1}GA_t^{-T}A_t^{-1}G^{-T}B_t^{-T} \right] + \gamma pI_N \]

Our update in terms of the auxiliary parameterization is

\[
E_{t+1} \leftarrow E_t - \beta \frac{S^{-1}}{\beta} \left[ \alpha E_t + E_{q(w|z)}(G) \right] A_t^{-1}A_t^{-T}^{-1}
\]

\[
A_{t+1} \leftarrow A_t \left[ \frac{\beta}{2d} \left\{ -d\gamma I_A + \alpha \text{Tr}((B_tB_t^{-1})^{-1})A_t^{-1}A_t^{-T} + E_{q(w|z)} \left[ A_t^{-1}G^{-T}(B_tB_t^{-1})^{-1}G^{-T} \right] \right\} \right]
\]

\[
B_{t+1} \leftarrow B_t \left[ \frac{\beta}{2p} \left\{ -p\gamma I_B + \alpha \text{Tr}((A_tA_t^{-1})^{-1})B_t^{-1}B_t^{-T} + E_{q(w|z)} \left[ B_t^{-1}G(A_tA_t^{-1})^{-1}G^{-T}B_t^{-T} \right] \right\} \right]
\]

By adding a natural momentum term \( Z \) (Khan et al., 2018) and an exponential weighted step-size \( \beta_t = \frac{1-c_1}{1-c_2} \), we can obtain the following update for DNN.

\[
Z_t \leftarrow (1 - c_1) \left[ \alpha E_t + E_{q(w|z)}(G) \right] + c_1 Z_{t-1}
\]

\[
E_{t+1} \leftarrow E_t - \beta E_t^{-T}B_t^{-1}Z_t A_t^{-T}^{-1}
\]

\[
A_{t+1} \leftarrow A_t \left[ \frac{\beta}{2d} \left\{ -d\gamma I_A + \alpha \text{Tr}((B_tB_t^{-1})^{-1})A_t^{-1}A_t^{-T} + E_{q(w|z)} \left[ A_t^{-1}G^{-T}(B_tB_t^{-1})^{-1}G^{-T} \right] \right\} \right]
\]

\[
B_{t+1} \leftarrow B_t \left[ \frac{\beta}{2p} \left\{ -p\gamma I_B + \alpha \text{Tr}((A_tA_t^{-1})^{-1})B_t^{-1}B_t^{-T} + E_{q(w|z)} \left[ B_t^{-1}G(A_tA_t^{-1})^{-1}G^{-T}B_t^{-T} \right] \right\} \right]
\]

where \( G = \nabla_W \ell(W) \), \( c_1 \) and \( c_2 \) are fixed to 0.9 and 0.999, respectively, as the same used in the Adam optimizer.

I.1. Complexity Reduction

The time complexity for our above update is \( O(d^3 + p^3) \), which is the same as the noisy-KFAC (Zhang et al., 2018).

A nice property of our update is that we can easily incorporate structures to reduce the time and space complexity. As shown in Appendix J, we can further exploit group-structures both in \( A \) and \( B \).

Recall that the time complexity of Adam for a matrix weight \( W \in \mathbb{R}^{d \times p} \) is linear \( O(dp) \). If a block triangular group structure (see Appendix J.1) is exploited in both \( A \) and \( B \), the time complexity of our update reduces to \( O(kdp) \) from \( O(d^3 + p^3) \), where \( 0 < k < \min(d, p) \) is a sparsity parameter for the group defined in Appendix J. In this case, our update has a linear time complexity like Adam, which is much faster than noisy-KFAC. Although we present the update based on the Gauss-Newton approximation of the Hessian, our update with the triangular group structure can be easily applied to the case where the Hessian information is used. Notice that our update can be automatically parallelized by Auto-Diff since our update only use linear algebra operations, which is more efficient from the Newton-CG type update, where a sequential conjugate-gradient step is used.

I.2. A Layer-wise Hessian and its Approximation

We consider the following loss function parameterized by a MLP/CNN evaluated at one data point. We will show that a layer-wise Hessian of matrix weights has a Kronecker form. This result has been exploited in Dangel et al. (2020); Chen et al. (2019). For simplicity, we only consider the matrix weight \( W \) at the input layer of a MLP. It is easy to extend this computation to other layers and CNN.

\[ \ell(W) = c(f(Wx)) \]
where $x$ is a single data point with shape $p \times 1$, $c(\cdot)$ is a function that returns a scalar output, and $W$ is the matrix weight at the input layer with shape $d \times p$.

We assume $f(z)$ is an element-wise $C^2$-smooth activation function (e.g., the tanh function). Let $u := Wx$ and $v := f(u) = f(Wx)$.

By the chain rule, it is easy to check that

$$
\nabla W \ell(W) = \begin{bmatrix} \nabla_v \ell \nabla_W v \end{bmatrix} = \left[ \begin{array}{c} \left( \sum_{i=1}^{d} \nabla_v \ell \otimes f'(u_i) \right) \end{array} \right] \begin{bmatrix} x \end{bmatrix}^T
$$

where $\otimes$ denotes the element-wise product.

Let $W_{i,:}$ denote the $i$-th row of the matrix $W$. We know that the shape of $W_{i,:}$ is $1 \times p$.

Now, we can show that the Hessian is a Kronecker product.

$$
\nabla_{W_{i,:}} \nabla_{W_{k,:}} \ell(W) = \mathcal{I}(i == k) \left[ \nabla_{v_i} \ell \right] f''(u_i) xx^T + \left[ \nabla_{v_i} \nabla_{v_k} \ell \right] f'(u_k) f'(u_i) xx^T
$$

Now, we discuss the Gauss-Newton approximation of the Hessian. Note that

$$
\nabla_{W_{i,:}} \ell(W) = \left[ \nabla_{v_i} \ell \right] f'(u_i) \begin{bmatrix} x \end{bmatrix}^T
$$

where $\otimes$ denotes the element-wise product.

$$
\nabla_{W_{k,:}} \ell(W) \nabla_{W_{i,:}} \ell(W) = \left[ \nabla_{v_i} \ell \right] f'(u_i) \left[ \nabla_{v_k} \ell \right] f'(u_k) xx^T
$$

Therefore, the Gauss-Newton approximation in term of $w$ can be re-expressed as

$$
B \otimes (xx^T)
$$

where $B$ is a symmetric matrix with entry $B_{ik} = \left[ \nabla_{v_i} \ell \nabla_{v_k} \ell \right] f'(u_k) f'(u_i)$.

From the above expression, we can clearly see that the Gauss-Newton approximation ignores diagonal terms involving $f''(u_i)$ and approximates $\left[ \nabla_{v_i} \nabla_{v_k} \ell \right]$ by $\left[ \nabla_{v_i} \ell \nabla_{v_k} \ell \right]$.

### J. Group Structures

In this section, we use the Gaussian example with square-root precision form to illustrate group structures.

#### J.1. Block Triangular Group

**J.1.1. Proof of Lemma 1**

**Proof** Now, we show that $B_{ap}(k)$ is a matrix group.

$$
B_{ap}(k) = \left\{ \begin{bmatrix} B_A & B_B \\ 0 & B_D \end{bmatrix} \middle| B_A \in \mathcal{R}^{k \times k}, B_B \in \mathcal{D}_{++}^{d_k \times d_k} \right\}
$$
As shown in Appendix J.1.4, the FIM is non-singular. Therefore, Assumption 1 is satisfied.

(1) It is obvious that \( I = \begin{bmatrix} I_A & 0 \\ 0 & I_D \end{bmatrix} \in B_{up}(k) \) since \( I_A \in R_{++}^{k \times k} \) and \( I_D \in D_{++}^{d_A \times d_B} \).

(2) For any \( B \in B_{up}(k) \), we have

\[
B^{-1} = \begin{bmatrix} B_A^{-1} & -B_A^{-1}B_DB_D^{-1} \\ 0 & B_D^{-1} \end{bmatrix} \in B_{up}(k)
\]

since \( B_A^{-1} \in R_{++}^{k \times k} \) and \( B_D^{-1} \in D_{++}^{d_A \times d_B} \).

(3) For any \( B, C \in B_{up}(k) \), the matrix product is

\[
BC = \begin{bmatrix} B_A & B_B \\ 0 & B_D \end{bmatrix} \begin{bmatrix} C_A & C_B \\ 0 & C_D \end{bmatrix} = \begin{bmatrix} B_A C_A & B_A C_B + B_B C_D \\ 0 & B_D C_D \end{bmatrix} \in B_{up}(k)
\]

since \( B_A C_A \in R_{++}^{k \times k} \) and \( B_D C_D \in D_{++}^{d_A \times d_B} \).

J.1.2. Proof of Lemma 2

Proof For any \( M \in M_{up}(k) \), we have

\[
M = \begin{bmatrix} M_A & M_B \\ 0 & M_D \end{bmatrix}
\]

where \( M_A \) is symmetric and \( M_D \) is diagonal. Therefore,

\[
h(M) = I + M + \frac{1}{2} M^2 = \begin{bmatrix} I_A + M_A & M_B \\ 0 & I_D + M_D \end{bmatrix} + \frac{1}{2} \begin{bmatrix} M_A & M_B \\ 0 & M_D \end{bmatrix} \begin{bmatrix} M_A & M_B \\ 0 & M_D \end{bmatrix}
\]

\[
= \begin{bmatrix} I_A + M_A + \frac{1}{2} M_A^2 & M_B + \frac{1}{2} (M_A M_B + M_B M_D) \\ 0 & I_D + M_D + \frac{1}{2} M_D^2 \end{bmatrix} \in B_{up}(k)
\]

Since \( M_A \) is symmetric, we have \( I_A + M_A + \frac{1}{2} M_A^2 = \frac{1}{2} (I_A + (I_A + M_A)(I_A + M_A)^T) > 0 \) is invertible and symmetric. Similarly, \( I_D + M_D + \frac{1}{2} M_D^2 \) is diagonal and invertible.

Thus, \( h(M) \in B_{up}(k) \).

J.1.3. Proof of Lemma 3

Proof we consider the following parametrization for the Gaussian \( \mathcal{N}(w | \mu, S^{-1}) \), where the precision \( S \) belongs to \( S_{++}^{p \times p} \), auxiliary parameter \( B \) belongs to \( B_{up}(k) \), and local parameter \( M \) belongs to \( M_{up}(k) \),

\[
\tau := \{ \mu \in \mathbb{R}^p, \ S \in S_{++}^{p \times p} \},
\]

\[
\lambda := \{ \mu \in \mathbb{R}^p, \ B \in B_{up}(k) \},
\]

\[
\eta := \{ \delta \in \mathbb{R}^p, \ M \in M_{up}(k) \}.
\]

The map \( \psi \circ \phi_{B_t}(\eta) \) at \( \lambda_t := \{ \mu_t, B_t \} \) is chosen as below, which is the same as (21)

\[
\begin{bmatrix} \mu \\ S \end{bmatrix} = \psi \circ \phi_{B_t}(\delta) = \begin{bmatrix} \mu_t + B_t^{-T} \delta \\ B_t h(M) h(M)^T B_t \end{bmatrix}
\]

As shown in Appendix J.1.4, the FIM is non-singular. Therefore, Assumption 1 is satisfied.
In Appendix J.1.4, we show that \( M \) can be decomposed as
\[
M = M_{\text{diag}} + M_{\text{up}} + M_{\text{up}}^T + M_{\text{asym}}
\]

Let \( \mathcal{I}_{\text{up}}, \mathcal{I}_{\text{diag}}, \mathcal{I}_{\text{asym}} \) be the index set of the non-zero entries of \( M_{\text{up}}, M_{\text{diag}}, \) and \( M_{\text{asym}} \) respectively.

Now, we can similarly show that Assumption 2 is also satisfied by the inverse function theorem as discussed in Appendix D.1, since \( \psi \circ \phi(\eta) \) is \( C^1 \)-smooth w.r.t. \( \eta \).

### J.1.4. Natural Gradient Computation for Structured \( M \)

we use a similar technique discussed in Appendix D.1.1 to deal with the FIM computation w.r.t. an asymmetric \( M \). The main idea is to decomposition \( M \) as a sum of special matrices so that the FIM computation is simple. We also numerically verify the following computation of FIM by Auto-Diff.

Since \( M = \begin{bmatrix} M_A & M_B \\ 0 & M_D \end{bmatrix} \in M_{\text{up}}(k) \), by Lemma 2, \( h(M) \) is invertible for any \( M \in M_{\text{up}}(k) \).

Since \( M_A \) is symmetric, we can re-express the matrix \( M_A \) as follows. We use a similar decomposition in Appendix D.1.1.
\[
M_A = M_{A_{\text{up}}} + M_{A_{\text{up}}}^T + M_{A_{\text{diag}}},
\]

where \( M_{A_{\text{up}}} \) contains the upper-triangular half of \( M_A \) excluding the diagonal elements, and \( M_{A_{\text{diag}}} \) contains the diagonal entries of \( M_A \).

We will decompose the \( M \) as follows
\[
M = M_{\text{diag}} + M_{\text{up}} + M_{\text{up}}^T + M_{\text{asym}}
\]

where \( M_{\text{diag}} \) is a diagonal matrix, \( M_{\text{asym}} \) is an asymmetric matrix, and \( M_{\text{low}} \) is a upper-triangular matrix with zero diagonal entries.

\[
M_{\text{diag}} = \begin{bmatrix} M_{A_{\text{diag}}} & 0 \\ 0 & M_D \end{bmatrix},
M_{\text{asym}} = \begin{bmatrix} 0 & M_B \\ 0 & 0 \end{bmatrix},
M_{\text{up}} = \begin{bmatrix} M_{A_{\text{up}}} & 0 \\ 0 & 0 \end{bmatrix}
\]

Note that \( M_{\text{diag}}, M_{\text{asym}}, \) and \( M_{\text{low}} \) respectively contain the diagonal entries of \( M \), the asymmetric entries of \( M \), the upper-triangular half of the symmetric part of \( M \) excluding the diagonal entries.

Recall that the FIM \( F_\eta(\eta_0) \) is block-diagonal with two blocks—the \( \delta \) block and the \( M \) block. We will can show that the \( M \) block of the FIM is also block-diagonal with three blocks, where each block represents the non-zero entries in \( M_{\text{up}}, M_{\text{diag}}, \) and \( M_{\text{asym}} \), respectively.

Now, we will show that any cross term of the FIM between any two of these blocks is zero. We have three cases. Let \( \mathcal{I}_{\text{up}}, \mathcal{I}_{\text{diag}}, \mathcal{I}_{\text{asym}} \) be the index set of the non-zero entries of \( M_{\text{up}}, M_{\text{diag}}, \) and \( M_{\text{asym}} \) respectively.

Case 1: For a cross term of the FIM between \( M_{\text{up}} \) and \( M_{\text{diag}} \), it is zero since this is the case shown in the symmetric case (see Lemma 13 in Appendix D.1.1 for details).

Case 2: For a cross term of the FIM between \( M_{\text{asym}} \) and \( M_{\text{diag}} \), we can compute it as follows.

By Eq. 25 and the chain rule, we have the following expressions, where \( j > i \).
\[
- \nabla_{M_{\text{asym}}ij} \log q(w|\eta) = -\text{Tr}(\left[ \nabla_{M_{\text{asym}}ij} M \right] \left[ \nabla_M \log q(w|\eta) \right])
\]
\[
- \nabla_{M_{\text{diag}}ii} \log q(w|\eta) = -\text{Tr}(\left[ \nabla_{M_{\text{diag}}ii} M \right] \left[ \nabla_M \log q(w|\eta) \right])
\]
Asym(\mathbf{M}) > i \Rightarrow \text{where we obtain the last step since } M \text{ is zero. Let’s denote a } \text{Up}(\cdot) \text{ function that returns a upper-triangular part of an input matrix with the same (non-zero) structure as } M. \text{ Similarly, we can define a Asym}(\cdot) \text{ function.}

It is obvious see that the intersection between any two of these index sets are empty.

For any } i < j, \text{ where } (i, j) \in \mathcal{I}_{up}, \text{ we have } (i, j) \notin \mathcal{I}_{asym} \text{ and } \text{Asym}(I_{ij}) = \text{Asym}(I_{ji}) = 0.

In this case, let } (i, j) \in \mathcal{I}_{up}. \text{ The cross term can be computed as follows.}

\[
- \mathbb{E}_{q(w|\eta)} \left[ \nabla_{M_{up}} \nabla_{M_{asym}} \log q(w|\eta) \right]_{\eta=0} = - \mathbb{E}_{q(w|\eta)} \left[ \nabla_{M_{up}} \text{Asym}(\nabla_{M} \log q(w|\eta)) \right]_{\eta=0}
\]

\[
= - \mathbb{E}_{q(w|\eta)} \left[ \sum_{k,l} [\nabla_{M_{asym,ij}} M_{kl}] \nabla_{M_{k}} \text{Asym}(\nabla_{M} \log q(w|\eta)) \right]_{\eta=0}
\]

\[
= - \mathbb{E}_{q(w|\eta)} \left[ \text{Asym}(\nabla_{M} \log q(w|\eta)) \right]_{\eta=0}
\]

\[
= \text{Asym}(\nabla_{M}(M + M^{T})) = 0
\]

\[
\mathbf{I}_{ij} + \mathbf{I}_{ji}
\]

where we use } M = M_{\text{diag}} + M_{up} + M_{up}^{T} + M_{\text{asym}} \text{ to move from step 2 to step 3, and obtain the last step since } \text{Asym}(I_{ij}) = \text{Asym}(I_{ji}) = 0.
Now, we compute the FIM w.r.t. $M_{\text{diag}}$, $M_{\text{asym}}$ and $M_{\text{up}}$ separately.

Like Eq (31) in Appendix D.1.1, the FIM w.r.t. the upper-triangular block is

$$-\mathbb{E}_{q(w|\eta)} \left[ \nabla_{M_{\text{up},ij}} \nabla_{M_{\text{up}}} \log q(w|\eta) \right]_{\eta=0} = 4I_{ij}$$

Like Eq (30) in Appendix D.1.1, the FIM w.r.t. the diagonal block is

$$-\mathbb{E}_{q(w|\eta)} \left[ \nabla_{M_{\text{diag},ij}} \nabla_{M_{\text{diag}}} \log q(w|\eta) \right]_{\eta=0} = 2I_{ij}$$

By the chain rule, the FIM w.r.t. $M_{\text{asym}}$ can be computed as follows, where $(i, j) \in \mathcal{I}_{\text{asym}}$.

$$-\mathbb{E}_{q(w|\eta)} \left[ \nabla_{M_{\text{asym},ij}} \nabla_{M_{\text{asym}}} \log q(w|\eta) \right]_{\eta=0}$$

$$= -\mathbb{E}_{q(w|\eta)} \left[ \nabla_{M_{\text{asym},ij}} \text{Asym} \left( \nabla_{M} \log q(w|\eta) \right) \right]_{\eta=0}$$

$$= -\mathbb{E}_{q(w|\eta)} \left[ \sum_{k, l} \left[ \nabla_{M_{\text{asym},ij}} M_{kl} \right] \nabla_{M_{ij}} \text{Asym} \left( \nabla_{M} \log q(w|\eta) \right) \right]_{\eta=0}$$

$$= -\text{Asym} \left( \mathbb{E}_{q(w|\eta)} \left[ \nabla_{M_{ij}} \nabla_{M} \log q(w|\eta) \right] \right)_{\eta=0}$$

$$= \text{Asym} \left( \nabla_{M_{ij}} \left[ \mathbf{M} + \mathbf{M}^T \right] \right)$$

(By Lemma 11)

$$= I_{ij} + I_{ji}$$

where we obtain the last step since that $\text{Asym}(I_{ji}) = 0$ when $i < j$ since $(i, j) \in \mathcal{I}_{\text{asym}}$ and $(j, i) \notin \mathcal{I}_{\text{asym}}$. Therefore, the FIM w.r.t. the asymmetric block is

$$-\mathbb{E}_{q(w|\eta)} \left[ \nabla_{M_{\text{asym},ij}} \nabla_{M_{\text{asym}}} \log q(w|\eta) \right]_{\eta=0} = I_{ij}$$

Like the symmetric case (see Eq (32) Appendix D.1.1) when we evaluate gradients at $\eta_0 = \{\delta_0, \mathbf{M}_0\} = 0$, we have

$$\nabla_{\delta_0} \mathcal{L} \big|_{\eta=0} = \left[ \nabla_{\delta_0, \delta} \right]^T \mathbf{B}_t^{-1} \nabla_{\mu} \mathcal{L}$$

$$\nabla_{M_{ij}} \mathcal{L} \big|_{\eta=0} = -\text{Tr} \left( \left[ \nabla_{M_{ij}} \left( \mathbf{M} + \mathbf{M}^T \right) \right] \mathbf{B}_t^{-1} \left[ \nabla_{\Sigma} \mathcal{L} \right] \mathbf{B}_t^{-T} \right)$$

Let’s denote $G_{M_{\text{up}}} = -2\mathbf{B}_t^{-1} \left[ \nabla_{\Sigma} \mathcal{L} \right] \mathbf{B}_t^{-T}$. Therefore, we can show that Euclidean gradients are

$$G_{\text{Mdiag}} = \text{Diag}(G_{M_{\text{diag}}}) ; \quad G_{M_{\text{up}}} = \text{Up}(G_{M_{\text{up}}} + G_{M_{\text{up}}}^T) = 2\text{Up}(G_{M_{\text{diag}}}) ; \quad G_{M_{\text{asym}}} = \text{Asym}(G_{M_{\text{asym}}}) ; \quad g_{\delta} = \mathbf{B}_t^{-1} \nabla_{\mu} \mathcal{L}$$

The natural gradients w.r.t. $M_{\text{diag}}$, $M_{\text{up}}$, and $M_{\text{asym}}$ are $\frac{1}{2}\text{Diag}(G)$, $\frac{1}{2}\text{Up}(G)$, and $\text{Asym}(G)$ respectively. The natural gradient w.r.t. $\delta$ is $\mathbf{B}_t^{-1} \nabla_{\mu} \mathcal{L}$.

Natural gradients can be expressed as in the following compact form:

$$\tilde{g}_{\delta_0}^{(t)} = \mathbf{B}_t^{-1} \nabla_{\mu} \mathcal{L}$$

$$\tilde{g}_{M_0}^{(t)} = C_{\text{up}} \odot \kappa_{\text{up}} \left( -2\mathbf{B}_t^{-1} \left[ \nabla_{\Sigma} \mathcal{L} \right] \mathbf{B}_t^{-T} \right)$$
where

\[ C_{\text{up}} = \begin{bmatrix} \frac{1}{2}J_A & J_B \\ 0 & \frac{1}{2}I_D \end{bmatrix} \in \mathcal{M}_{\text{up}}(k) \]

Therefore, our update is

\[
\mu_{t+1} \leftarrow \mu_t - \beta B_t^{-T}B_t^{-1}g, \\
B_{t+1} \leftarrow B_t h(\beta C_{\text{up}} \odot \kappa_{\text{up}}(2B_t^{-1}g_{\Sigma_t}B_t^{-T}))
\]

(45)

J.1.5. INDUCED STRUCTURES

When \( B \in \mathcal{M}_{\text{up}}(k) \), we can show that the covariance matrix \( \Sigma = (BB^T)^{-1} \) has a low rank structure. The update is like the DFP update in the quasi-Newton family. This structure is useful for posterior approximation.

Notice that the precision matrix \( S = BB^T \) is a block arrowhead matrix as shown below.

\[
S = BB^T \\
= \begin{bmatrix} B_AB_A^T + B_BB_B^T & B_BB_D \\ B_DB_B^T & B_D^2 \end{bmatrix}
\]

Now, we can show that the covariance matrix \( \Sigma = P^{-1} \) admits a rank-\( k \) structure.

\[
\Sigma = \begin{bmatrix} B_A^T B_A^{-1} & -B_A^{-T}B_A^{-1} B_B B_D^{-1} \\ -B_D^{-1}B_DB_A^{-T} & B_D^{-1}B_DB_A^{-1} B_B B_D^{-1} + B_D^{-2} \end{bmatrix} \\
= U_k U_k^T + \begin{bmatrix} 0 \\ B_D^{-2} \end{bmatrix}
\]

where \( U_k \) is a \( p \)-by-\( k \) matrix as shown below and \( U_k \) is a rank-\( k \) matrix since \( B_A^{-T} \) is full \( k \) rank (invertible).

\[
U_k = \begin{bmatrix} -B_A^{-T} \\ B_D^{-1}B_DB_A^{-T} \end{bmatrix}
\]

J.1.6. COMPLEXITY ANALYSIS AND EFFICIENT COMPUTATION

When \( B \in B_{\text{up}}(k) \) is a \( p \)-by-\( p \) invertible matrix, it can be written as

\[
B = \begin{bmatrix} B_A & B_B \\ 0 & B_D \end{bmatrix}
\]

where \( B_A \) is a \( k \)-by-\( k \) invertible matrix and \( B_D \) is a diagonal and invertible matrix.

To generate samples, we first compute the following matrix.

\[
B^{-T} = \begin{bmatrix} B_A^{-T} & 0 \\ -B_D^{-1}B_DB_A^{-T} & B_D^{-2} \end{bmatrix}
\]

Given \( B^{-T} \) is known, for variational inference, we can easily generate a sample in \( O(k^2 p) \) as \( w = \mu + B^{-T} \epsilon \), where \( \epsilon \sim \mathcal{N}(0, I) \). Similarly, \( S^{-1}g = B^{-T}B^{-1}g \) can be computed in \( O(k^2 p) \).

Since \( M \in \mathcal{M}_{\text{up}}(k) \), it can be written as

\[
M = \begin{bmatrix} M_A & M_B \\ 0 & M_D \end{bmatrix}
\]
where $M_A$ is a $k$-by-$k$ symmetric matrix and $M_D$ is a diagonal matrix.

We can compute $h(M)$ in $O(k^2p)$ when $M \in \mathcal{M}_{up}(k)$

$$h(M) := I + M + \frac{1}{2}M^2 = \begin{bmatrix} I_A + M_A + \frac{1}{2}M_A^2 & M_B + \frac{1}{2}(M_AM_B + M_BM_D) \\ 0 & I_D + M_D + \frac{1}{2}M_D^2 \end{bmatrix}$$

Similarly, we can compute the matrix product $Bh(M)$ in $O(k^2p)$.

Now, we discuss how to compute $\kappa_{up}(2B_t^{-1}g_{\Omega}B_t^{-T})$

We assume $g_{\Omega}$ can be expressed as the following form.

$$g_{\Omega} = \frac{1}{2} \begin{bmatrix} H_{11} & H_{12} \\ H_{21} & H_{22} \end{bmatrix}$$

where $H_{21} = H_{12}^T$

$$2B_t^{-1}g_{\Omega}B_t^{-T} = \begin{bmatrix} E - F^T B_B A_T - B_A^{-1} B_B F + B_A^{-1} B_B B_D^{-1} H_2 B_D^{-T} B_B^{-T} F^T - B_A^{-1} B_B B_D^{-1} H_2 B_D^{-T} \\ F - B_B^T H_2 B_D^{-1} B_B^{-T} B_B^T - B_D^{-1} H_2 B_D^{-T} \end{bmatrix}$$

where $E = B_A^{-1} H_1 B_A^T$ and $F = B_D^{-1} H_2 B_A^T$

Therefore, we have

$$\kappa_{up}(2B_t^{-1}g_{\Omega}B_t^{-T}) = \begin{bmatrix} E - F^T B_B A_T - B_A^{-1} B_B F + B_A^{-1} B_B B_D^{-1} H_2 B_D^{-T} B_B^{-T} F^T - B_A^{-1} B_B B_D^{-1} H_2 B_D^{-T} \\ 0 \end{bmatrix}$$

Notice that by Stein's identities, we have

$$g_{\Omega} = \frac{1}{2}E_{\theta(w)} [\nabla^2 w f(w)]$$

where $w = \mu + B^{-T} \epsilon$ and $\epsilon \sim \mathcal{N}(0, I)$.

For a $k$-rank approximation, if we can compute $k$ Hessian-vector products, let's consider the following product.

$$\begin{bmatrix} \nu_1 \\ \nu_2 \end{bmatrix} = \begin{bmatrix} H_{11} B_A^{-T} - H_{12} B_D^{-T} B_B^{-T} B_A^{-T} \\ H_{21} B_A^{-T} - H_{22} B_D^{-T} B_B^{-T} B_A^{-T} \end{bmatrix}$$

$$= E_{\theta(w)} \begin{bmatrix} \nabla^2 w_1 f(w_1, w_2) \\ \nabla w_1 \nabla w_2 f(w_1, w_2) \\ \nabla^2 w_2 f(w_1, w_2) \end{bmatrix} \begin{bmatrix} B_A^{-T} \\ -B_D^{-1} B_B^{-1} B_D^{-T} \end{bmatrix}$$

Therefore, we have

$$\kappa_{up}(2B_t^{-1}g_{\Omega}B_t^{-T}) = \begin{bmatrix} (B_A^{-1} \nu_1 - B_A^{-1} B_B B_D^{-1} \nu_2) \\ 0 \end{bmatrix}$$

We can compute this in $O(k^2p)$ since $B_D$ is diagonal, where we assume we can efficiently compute $k$ Hessian-vector products and compute/approximate diagonal entries of the Hessian $\text{Diag}(H_{22})$.

### J.1.7. Block Lower-Triangular Group

Similarly, we can define a block lower-triangular group $B_{low}(k)$ and a local parameter space $\mathcal{M}_{low}(k)$.

$$B_{low}(k) = \left\{ \begin{bmatrix} B_A & 0 \\ B_C & B_D \end{bmatrix} \middle| B_A \in \mathcal{R}^{k \times k}, B_D \in \mathcal{D}^{d_0 \times d_0} \right\}$$

$$\mathcal{M}_{low}(k) = \left\{ \begin{bmatrix} M_A & 0 \\ M_C & M_D \end{bmatrix} \middle| M_A \in \mathcal{S}^{k \times k}, M_D \in \mathcal{D}^{d_0 \times d_0} \right\}$$
we consider the following parametrization for the Gaussian $\mathcal{N}(\mathbf{w}|\mu, S^{-1})$, where the precision $S$ belongs to $S_{++}^{p\times p}$, auxiliary parameter $B$ belongs to $B_{\text{low}}(k)$, and local parameter $M$ belongs to $\mathcal{M}_{\text{low}}(k)$,

\[
\begin{align*}
\tau & := \{\mu \in \mathbb{R}^p, \ S \in S_{++}^{p\times p}\}, \\
\lambda & := \{\mu \in \mathbb{R}^p, \ B \in B_{\text{low}}(k)\}, \\
\eta & := \{\delta \in \mathbb{R}^p, \ M \in \mathcal{M}_{\text{low}}(k)\}.
\end{align*}
\]

The map $\psi \circ \phi_{\lambda_t}(\eta)$ at $\lambda_t := \{\mu_t, B_t\}$ is chosen as below, which is the same as (21)

\[
\begin{align*}
\left\{ \begin{array}{c}
\mu \\
S
\end{array} \right\} = \psi(\lambda) & := \left\{ \begin{array}{c}
\mu \\
BB^T
\end{array} \right\} \\
\left\{ \begin{array}{c}
\mu \\
B
\end{array} \right\} = \phi_{\lambda_t}(\eta) & := \left\{ \begin{array}{c}
\mu_t + B_{t}^{-T}\delta \\
B_t h(M)
\end{array} \right\}.
\end{align*}
\]

We can show Assumption 1 and 2 are satisfied similar to Appendix J.1.3. Our update over the auxiliary parameters is

\[
\begin{align*}
\mu_{t+1} & \leftarrow \mu_t - \beta B_t^{-T} B_t^{-1} \kappa_{\text{low}}(2B_t^{-1} g_{\Sigma_t} B_t^T)
\end{align*}
\]

where

\[
\begin{align*}
C_{\text{low}} &= \begin{bmatrix}
J_A & 0 \\
\frac{1}{2}I_D
\end{bmatrix} \in \mathcal{M}_{\text{low}}(k)
\end{align*}
\]

where $J$ denotes a matrix of ones and factor $\frac{1}{2}$ appears in the symmetric part of $C_{\text{low}}$, $\circ$ denotes the element-wise product, $\kappa_{\text{low}}(X)$ extracts non-zero entries of $\mathcal{M}_{\text{low}}(k)$ from $X$ so that $\kappa_{\text{low}}(X) \in \mathcal{M}_{\text{low}}(k)$. We can compute this update in $O(k^2 p)$.

When $B \in B_{\text{low}}(k)$, we show that the precision matrix $S = BB^T$ has a low rank structure. This update is like the BFGS update in the quasi-Newton family. This structure is useful for optimization.

The precision matrix $S$ admits a rank-$k$ structure as shown below.

\[
S = BB^T = \begin{bmatrix}
A & T \\
B & A
\end{bmatrix} = V_k V_k^T + [0, B_D] \\
V_k = \begin{bmatrix}
A \\
C
\end{bmatrix}
\]

where $V_k$ is a $d$-by-$k$ matrix and $V_k$ is a rank-$k$ matrix since $A_{A}$ is full $k$ rank.

Similarly, we can show that the covariance matrix $\Sigma = S^{-1}$ is a block arrowhead matrix.

\[
\Sigma = \begin{bmatrix}
B_A^{-T} & -B_A^{-T}B_C^{-1}B_D^{-1} \\
0 & B_D^{-1}
\end{bmatrix} \begin{bmatrix}
B_A^{-1} & 0 \\
-B_D^{-1}B_CB_A^{-1} & B_D^{-1}
\end{bmatrix} = \begin{bmatrix}
B_A^{-T}B_A^{-1} + B_A^{-T}B_C^{-1}B_D^{-1}B_CB_A^{-1} - B_A^{-T}B_C^{-1}B_D^{-2} & -B_D^{-2}B_CB_D^{-1} \\
-B_D^{-2}B_CB_D^{-1} & B_D^{-2}
\end{bmatrix}
\]

\section{J.2. Alternative Structures Inspired by the Heisenberg Group}

First of all, the Heisenberg group is defined as follows.

\[
B = \begin{bmatrix}
1 & a^T & c \\
0 & I & b \\
0 & 0 & 1
\end{bmatrix}
\]

where $a$ and $b$ are column vectors while $c$ is a scalar.
We construct the following set inspired by the Heisenberg group, where $1 < k_1 + k_2 < p$ and $d_0 = p - k_1 - k_2$.

$$\mathcal{B}_{up}(k_1, k_2) = \{ \begin{bmatrix} B_A & B_{B_1} & B_{B_2} \\ 0 & B_{D_1} & B_{D_2} \\ 0 & 0 & \begin{bmatrix} k_2 \times k_2 \end{bmatrix} \end{bmatrix} : B_A \in \mathcal{R}_{++}^{k_1 \times k_1}, B_{D_1} \in \mathcal{D}_{++}^{d_0 \times d_0}, B_{D_4} \in \mathcal{R}_{++}^{k_2 \times k_2} \}$$

We can re-express it as follows

$$\mathcal{B}_{up}(k_1, k_2) = \{ \begin{bmatrix} B_A \\ 0 \\ 0 \end{bmatrix} B_D = \begin{bmatrix} B_{D_1} & B_{D_2} \\ 0 & B_{D_4} \end{bmatrix} \}$$

where $B_A \in \mathcal{R}_{++}^{k_1 \times k_1}, B_{D_1} \in \mathcal{D}_{++}^{d_0 \times d_0}, B_{D_4} \in \mathcal{R}_{++}^{k_2 \times k_2}$.

We can show that $\mathcal{B}_{up}(k_1, k_2)$ is a matrix group, which is more flexible than the block triangular group.

Similarly, we define a local parameter space $\mathcal{M}_{up}(k_1, k_2)$ as

$$\mathcal{M}_{up}(k_1, k_2) = \{ \begin{bmatrix} M_A & M_{B_1} & M_{B_2} \\ 0 & M_{D_1} & M_{D_2} \\ 0 & 0 & \begin{bmatrix} k_2 \times k_2 \end{bmatrix} \end{bmatrix} : M_A \in \mathcal{S}^{k_1 \times k_1}, M_{D_1} \in \mathcal{D}_{++}^{d_0 \times d_0}, M_{D_4} \in \mathcal{S}^{k_2 \times k_2} \}$$

Likewise, we consider the following parametrization for the Gaussian $\mathcal{N}(w|\mu, S^{-1})$, where the precision $S$ belongs to $\mathcal{S}_{++}^{p \times p}$, auxiliary parameter $B$ belongs to $\mathcal{B}_{up}(k_1, k_2)$, and local parameter $M$ belongs to $\mathcal{M}_{up}(k_1, k_2)$,

$$\tau := \{ \mu \in \mathbb{R}^p, \ S \in \mathcal{S}_{++}^{p \times p} \}$$

$$\lambda := \{ \mu \in \mathbb{R}^p, \ B \in \mathcal{B}_{up}(k_1, k_2) \}$$

$$\eta := \{ \delta \in \mathbb{R}^p, \ M \in \mathcal{M}_{up}(k_1, k_2) \}$$

The map $\psi \circ \phi_{\lambda_i}(\eta)$ at $\lambda_i := \{ \mu_i, B_i \}$ is chosen as below, which is the same as (21)

$$\begin{bmatrix} \mu \\ S \end{bmatrix} = \psi(\lambda) := \begin{bmatrix} \mu \\ BB^T \end{bmatrix}$$

$$\begin{bmatrix} \mu \\ B \end{bmatrix} = \phi_{\lambda_i}(\eta) := \begin{bmatrix} \mu_i + B_i^{-T} \delta \\ B_i h(M) \end{bmatrix}.$$}

We can show Assumption 1 and 2 are satisfied similar to Appendix J.1.3. Our update over the auxiliary parameters is

$$\mu_{t+1} \leftarrow \mu_t - \beta B_t^{-T} B_t^{-1} g_{\mu_t}$$

$$B_{t+1} \leftarrow B_t h \left( \beta C_{up} \circ \kappa_{up}(2B_t^{-1} g_{\Sigma_t} B_t^{-T}) \right)$$

where $\circ$ denotes the element-wise product, $\kappa_{up}(X)$ extracts non-zero entries of $\mathcal{M}_{up}(k_1, k_2)$ from $X$ so that $\kappa_{up}(X) \in \mathcal{M}_{up}(k_1, k_2)$, $C_{up}$ is a constant matrix defined below, $J$ denotes a matrix of ones and factor $\frac{1}{2}$ appears in the symmetric part of $C_{up}$.

$$C_{up} = \begin{bmatrix} \frac{1}{2} J_A & \frac{1}{2} J_{B_1} \\ 0 & \frac{1}{2} J_{D_1} \\ \frac{1}{2} J_{B_2} & \frac{1}{2} J_{D_2} \\ 0 & 0 \\ \frac{1}{2} J_{D_4} \end{bmatrix} \in \mathcal{M}_{up}(k_1, k_2)$$

We can also efficiently compute this update.

Moreover, we can define a lower version of this group denoted by $\mathcal{B}_{low}(k_1, k_2)$ and derive our update for this structure.

$$\mathcal{B}_{low}(k_1, k_2) = \{ \begin{bmatrix} B_A \\ B_C \\ B_D \end{bmatrix} B_D = \begin{bmatrix} B_{D_1} & 0 \\ 0 & B_{D_4} \end{bmatrix} \}$$

where $B_A \in \mathcal{R}_{++}^{k_1 \times k_1}, B_{D_1} \in \mathcal{D}_{++}^{d_0 \times d_0}, B_{D_4} \in \mathcal{R}_{++}^{k_2 \times k_2}$.
