Moving frames and compatibility conditions for three-dimensional director fields

Luiz C. B. da Silva · Efi Efrati

Received: date / Accepted: date

Abstract The geometry and topology of the region in which a director field is embedded impose limitations on the kind of supported orientational order. These limitations manifest as compatibility conditions that relate the quantities describing the director field to the geometry of the embedding space. For example, in two dimensions (2D) the splay and bend fields suffice to determine a director uniquely and must comply with one relation linear in the Gaussian curvature of the embedding manifold. In 3D there are additional local fields describing the director, i.e. fields available to a local observer residing within the material, and a number of distinct ways to yield geometric frustration. So far it was unknown how many such local fields are required to uniquely describe a 3D director field, nor what are the compatibility relations they must satisfy. In this work, we address these questions directly. We employ the method of moving frames to show that a director field in 3D is fully determined by five local fields. These fields are shown to be related to each other and to the curvature of the embedding space through six differential relations. As an application of our method, we characterize all uniform distortion director fields, i.e., directors for which all the local characterizing fields are constant in space, in manifolds of constant curvature. The classification of such phases has been recently provided for directors in Euclidean space, where the textures correspond to foliations of space by parallel congruent helices. For non-vanishing curvature, we show that the pure twist phase is the only solution in the sphere while in the hyperbolic space uniform distortion fields correspond to foliations of space by (non-necessarily parallel) congruent helices. Further analysis of

1 Introduction

Liquid crystals are a state of matter characterized by the presence of an orientational order but no, or only partial, positional order. In many cases, the ordering can be described in terms of a unit vector field $n$, called the director [9,27]. Liquid crystals pervade our daily lives, from computer and smart-phone displays to optical switches enabling fast and efficient communication. In recent years, liquid crystals also found applications as controllable and responsive materials [1,11,30,24], and similar phases were identified outside soft matter systems, for example in the nematic order observed in iron based superconductors [8,29].

The liquid crystalline orientational “texture” often manifests the shape and interactions between its constituents. Elongated and straight constituents favor the nematic phase in which the director’s orientation is uniform in space. In contrast, chiral constituents may favor a twisted director field, while elongated and curved constituents may favor a bent director. However, not all such locally preferred tendencies can be globally realized by a director field in a finite domain. For example, the 2D straight nematic texture with vanishing splay and bend cannot be realized on any open region on the sphere [16]. Here, the splay and bend of a director field $n$ are given by $s = \nabla \cdot n$ and $b = \| (n \cdot \nabla) n \|$, respectively, and constitute the basic distortion modes of any 2D director field. Similarly, the phase of constant non-vanishing bend and vanishing splay cannot be realized in the plane [15]. It is thus natural to ask what local tendencies could be realized by a director texture, and conversely how many such local descriptors are required to uniquely determine a texture.

Recently, it was shown that any 2D director field is fully described by its bend and splay fields, and that the values these scalar fields obtain for any realizable texture satisfy $K = -b^2 - s^2 - n \cdot \nabla s + n_\perp \cdot \nabla b$ [16], where $K$ is the Gaussian curvature of the surface $S$ in which the field is embedded and $n_\perp$ is the field in $S$ normal to $n$. The identification of the class of all admissible textures also allowed addressing the notion of optimal compromise for unrealizable frustrated states. These results are, however, presently limited to 2D systems. For 3D liquid crystals there are additional distortion fields, such as the twist and saddle-splay that do not have corresponding fields in 2D systems. Moreover, the 3D geometry is associated with additional compatibility conditions; while for 2D Riemannian geometry there is only one local geometric charge, in 3D there are three independent scalar Riemannian charges. Thus, the 3D case is expected to lead to a larger set of relations involving a greater number of fields. Presently, it is unknown how many fields are required to
uniquely determine a director field in 3D, nor how many relations these fields must satisfy to correspond to a realizable texture.

Many frustrated assemblies, in which the constituents locally favor an arrangement that cannot be globally realized, exhibit a super-extensive ground state energy for isotropic domains; i.e. the energetic cost of the optimal compromise in these systems increases faster than linearly with their mass. Recently, it was shown that the exact order and structure of the compatibility conditions completely determines this super-extensive behavior and can be used to predict the exponent related to the super-extensive growth of the ground state energy [14]. The purpose of the work presented here is to further advance recent efforts aimed at understanding and quantifying frustration in 3D liquid crystals. We provide a definitive answer to the above questions by writing explicitly the six differential relations that form the compatibility conditions relating the five fields that uniquely determine a director field in 3D. These six equations relate the fields and their derivatives to each other and to the curvature tensor of the 3D manifold where the director field lives. As an application of our results, we also characterize all uniform distortion fields in the sphere and hyperbolic space, showing in particular that in hyperbolic space uniform distortion fields also correspond to a foliation of space by (non-necessarily parallel) helices. Thus, together with the results of Ref. [28], we complete the characterization of uniform distortion fields for all the 3D homogeneous and isotropic geometries.

2 Background:
Geometric frustration in three dimensional director fields

The present work joins ongoing efforts to better understand the underlying geometry of 3D director fields. Recent insightful interpretations of the basic distortion modes of unit director fields in 3D identified these distortion modes with distinct components of the director gradient, \( J = \nabla n \) [13,21]. The splay corresponds to the trace of \( J \), while the bend is a vector in the space perpendicular to \( n \) and thus contributes two degrees of freedom. The remaining modes contribute to the components of \( J \) in the two dimensional space normal to \( n \), and are traceless. The twist \( t = n \cdot (\nabla \times n) \) corresponds to the anti-symmetric component, while the biaxial splay is identified with the remaining traceless symmetric structure and thus contributes two degrees of freedom as well. This yields a total count of six independent contributions to \( J \) [13,21]. However, the freedom in assigning a base to the space perpendicular to \( n \) eliminates one of these to yield five total intrinsic fields that describe a director. We identify these as the splay, bend, twist, saddle-splay and the relative orientation between the direction of the bend vector and the principal direction of the biaxial splay.

These local descriptors of the liquid crystalline order may be associated with non trivial reference values induced by the structure and relative inter-

\[^{1}\text{By a helix we mean a curve of constant curvature and constant torsion.}\]
actions of their constituents. Considering phases composed of identical constituents, it is natural to assume that these reference values will be uniform in space and manifest the underlying symmetry of their constituent. However, as was recently shown in [28], the space of phases associated with such constant descriptors, termed “uniform distortions”, is very limited, necessitating more complex textures. For example, chiral constituents favoring the unrealizable uniform double twist produce the Blue phase in which defect lines, separating biaxially twisted columns, are periodically arranged [9]. Similarly, achiral twisted core liquid crystals form chiral meso-phases displaying giant optical activity [2,12] and heliconical ordering [6]. The constituents in this case locally favor a phase of vanishing twist, splay and saddle-splay and a constant non-vanishing bend. Such a phase cannot be realized in Euclidean space and instead the system incorporates a twist in order to accommodate the uniform bend resulting in the observed heliconical phase [15].

Focusing on uniform distortions Virga showed that all such textures correspond to foliations of the three dimensional Euclidean space by parallel helices [28]. His results relied on vector calculus, where the motion of the frame \{n_1, n_2, n_3\} is described in terms of the so-called connectors vector fields and the compatibility conditions for the deformation modes associated with a director then follow from the symmetry of the tensors \( n_i \cdot \nabla^2 n_j \) [28]. In particular, it was shown that the pure bend phase favored by bent core liquid crystals is indeed frustrated, and predicted the heliconical phase with uniform twist as a plausible compromise. For small enough domains, however, one might expect other non-uniform distortions to yield the optimal compromise [14].

Similar arguments show that the attempted pure double twist phase resulting in the blue phase is also frustrated in Euclidean space [28]. This attempted phase, however, can be accommodated in a 3D spherical geometry of an appropriate radius [22]. Other examples of uniform distortion fields have been recently provided for all the eight Thurston geometries [20], where it is shown that each pure mode of director deformation can fill space without frustration for at least one type of geometry.

In this work, we seek to obtain the full compatibility conditions for 3D director fields. Naturally, one may seek to exploit the same reasoning that was exploited to yield the compatibility conditions in 2D [16]. However, the method employed there relies heavily on the existence of a natural orthogonal frame of coordinates such that the parametric curves are tangent to \( n \) and to the perpendicular unit vector \( n_\perp \). This, however, could not be generalized to 3D. A general field of an orthonormal triad in 3D cannot be associated with the tangents of parametric curves. Instead, one needs to study the properties of the orthonormal triad field without resorting to coordinates; the mathematical formalism which achieves this is called the method of moving frames [7], also known as vielbein formalism in the context of relativity [5]. Given a 3D director field \( n_1 = n \) and its two normals \( n_2 \) and \( n_3 = n_1 \times n_2 \) one can build the corresponding dual frame of differential forms which together with the so-called connection forms describe the geometry of 3D space using the differential form structure equations. This formalism also allows for an
variant formulation of vector calculus operators, which means that quantities
and energy functionals used in the description of 3D liquid crystals can be
rewritten as exterior differential systems, i.e., differential equations in terms
of differential forms and operations defined on them. Though more abstract
than the vector calculus method [28], the approach based on differential forms
allows us to obtain manageable equations and to investigate director fields in
both Euclidean and curved Riemannian spaces in an equal foot. This helps
in better understanding how the Euclidean space frustrates the existence of
certain phases.

When concluding the writing of this manuscript a parallel effort to obtain
the compatibility conditions using moving frames by Pollard and Alexander
came to our attention [18]. We briefly relate to the similarities and differences
between these works in the discussion section.

3 Differential forms and moving frames

Given a coordinate system \((x^1, \ldots, x^m)\) on an open and connected set \(U \subseteq \mathbb{R}^m\),
the corresponding vector fields tangent to the coordinate curves are denoted
by \(\{\frac{\partial}{\partial x^i}\}\), while their dual fields (or covectors) are denoted by \(dx^i\), i.e., when
applied to a vector \(v = v^i \frac{\partial}{\partial x^i}\) (sum on repeated indices), we have \(dx^i(v) = v^i\).

The differential of a scalar function \(f\) is defined as \(df = \frac{\partial f}{\partial x^i} dx^i\) and,
consequently, \(dx^i\) can be alternatively seen as the differential of the \(i\)-th co-
ordinate function. From now on, a field of covectors \(p \in U \mapsto \eta_p \in (T_u U)^*\)
is called a differential 1-form, while a function is a 0-form. Notice that we
can write any 1-form as \(\eta = a_i dx^i\) for some scalar fields \(a_i\) and that there
is an isomorphism between vector fields and 1-forms: \(a_i dx^i \leftrightarrow a_i \frac{\partial}{\partial x^i}\). Given
two differential 1-forms \(\eta\) and \(\omega\), we define the exterior product \(\eta \wedge \omega\) as the
anti-symmetric bilinear map \((\eta \wedge \omega)(u, v) = \eta(u)\omega(v) - \eta(v)\omega(u)\). We shall
refer to \(\eta \wedge \omega\) as a differential 2-form. We can define the exterior derivative
d of a 1-form \(\eta = a_i dx^i\) as the 2-form \(d\eta = da_i \wedge dx^i\). The vector space of 2-forms is generated by \(\{dx^i \wedge dx^j\}_{1 \leq i < j \leq m}\) and, therefore,
it has dimension \(m(m-1)/2\). More generally, a differential \(k\)-form is an anti-
symmetric \(k\)-linear map and the corresponding vector space is generated by the
basis \(\{dx^{i_1} \wedge \cdots \wedge dx^{i_k}\}_{1 \leq i_1 < \cdots < i_k \leq m}\), where \((dx^{i_1} \wedge \cdots \wedge dx^{i_k})(v_1, \ldots, v_m) = \det(dx^{i_1}(v_i))_{rs}\). The exterior derivative of a \(k\)-form \(\eta = a_{i_1 \cdots i_k} dx^{i_1} \wedge \cdots \wedge dx^{i_k}\) is the \((k + 1)\)-form \(d\eta = da_{i_1 \cdots i_k} \wedge dx^{i_1} \cdots \wedge dx^{i_k}\). In addition, \(d\) is linear and
satisfies the product rule \(d(\eta \wedge \omega) = d\eta \wedge \omega + (-1)^k \eta \wedge d\omega\), where \(\eta\) is a \(k\)-form
and \(\omega\) is a \(\ell\)-form. A remarkable property of the exterior derivative \(d\) is that
\(d^2 = 0\), i.e., the differential of the \(k\)-form \(d\eta\) always vanishes. (As an exercise,
the reader can easily verify this property for 0- and 1-forms.)

Instead of using coordinate fields, we may consider in \(U\) any set of orthono-
mal vector fields \(\{n_1, \ldots, n_m\}\) along with its set of dual fields \(\{\eta^1, \ldots, \eta^m\}\), i.e.,
\(\eta^i(n_j) = \delta^i_j\), where \(\delta^i_j\) is the Kronecker delta. Since each \(n_i\) is a smooth map
from $U$ to $\mathbb{R}^m$, if we write it in coordinates $n_i = n_i^j \frac{\partial}{\partial x_j}$, its differential is $dn_i = (dn_i^1, \ldots, dn_i^m) = \frac{\partial n_i}{\partial x^j} dx_j$, where $\frac{\partial n_i}{\partial x^j}$ is the Jacobian matrix acting by matrix multiplication on $dx = (dx^1, \ldots, dx^m)$. Alternatively, the differential $dn_i$ acting on a tangent vector $v \in T_p U$ can be written as a linear combination

$$(dn_i)_p(v) = n_i^j (p, v) n_j(p).$$

In what follows, we shall omit the explicit dependence on $p$ and $v$ and simply write $dn_i = n_i^j n_j$. For a fixed point $p$, the functions $n_i^j$ are linear and, therefore, each $p \mapsto n_i^j(p, \cdot)$ defines a 1-form. From the orthonormality of $\{n_i\}$ it follows that $n_i^j(n_j) = \delta^i_j$.

If $r : U \to \mathbb{R}^m$ denotes the inclusion map, its differential can be written as $dr = n^i n_i$. Geometrically, given a moving frame $\{n_i\}$, the set of 1-forms $\{n_i^j\}$ describes infinitesimal translations of the moving frame while the 1-forms $\{n_i^j\}$ describes infinitesimal rotations. Now, using that $d^2 r = 0$ and $d^2 n_i = 0$, we have the so-called structure equations

$$\begin{cases}
   dn_i = n^k \wedge n_k^i, & i \in \{1, \ldots, m\}
\end{cases}$$

For the Euclidean case, these constitute the integrability conditions for the existence of a moving frame with dual frame $\{n^i\}$ and connection forms $\{n_i^j\}$ [10]. See [26], lemma 2 with $k = 0$, for an elementary proof.

As an example of these ideas, consider in $\mathbb{R}^3$ the moving frame given by the vector fields $n_1 = (\cos \phi \cos \theta, \cos \phi \sin \theta, \sin \phi)$, $n_2 = (-\sin \theta, \cos \theta, 0)$ and $n_3 = (-\sin \phi \cos \theta, -\sin \phi \sin \theta, \cos \phi)$, where $\theta = \theta(x, y, z)$ and $\phi = \phi(x, y, z)$ are smooth functions on $U \subseteq \mathbb{R}^3$. Computing their differential gives

$$\begin{align*}
dn_1 &= d\phi(-\sin \cos \phi \cos \theta, -\sin \cos \phi \sin \theta, \cos \phi) + d\theta(-\cos \phi \sin \theta, \cos \phi \cos \theta, 0) \\
&= \cos \phi d\theta n_2 + d\phi n_3, \\
dn_2 &= d\theta(-\cos \theta, -\sin \theta, 0) = -\cos \phi d\theta n_1 + \sin \phi d\theta n_3, \\
dn_3 &= d\phi(-\cos \phi \cos \theta, -\cos \phi \sin \theta, -\sin \phi) + d\theta(\sin \phi \sin \theta, -\sin \phi \cos \theta, 0) \\
&= -d\phi n_1 - \sin \phi d\theta n_2.
\end{align*}$$

Therefore, the 1-forms $n_i^j$ associated with $\{n_1, n_2, n_3\}$ are $n_i^2 = \cos \phi d\theta$, $n_i^3 = d\phi$, and $n_3^2 = \sin \phi d\theta$. We leave as an exercise checking the validity of the structure equations $dn_i^j = n^k \wedge n_k^j$.

The 1-forms $n_i^k$ are also known as connection forms since they determine the connection coefficients of the covariant derivative. Indeed, given two vector fields $u = u^i n_i$ and $v = v^i n_i$ in $U$, the covariant derivative of $u$ in the direction of $v$, $\nabla_v u$, can be written using moving frames as

$$\nabla_v u = (d(u))(v) = d(u^k n_k)(v) = \left[d(u^k) + u^j n_k^j(v)\right] n_k.$$
Therefore, the connection forms can be alternatively computed from the Levi-Civita connection $\nabla$ by using the relation $\eta_i^j(v) = \langle \nabla_v n_i, n_j \rangle$. In addition, given two tangent vectors $u, v \in T_p U$, the inner product between them is $g(u^n_1, v^n_1) = u^n_1 v^n_1 - \eta^i(u) \eta^j(v)$. The metric $g$ in $U$ is then written as $g = (\eta^{1})^2 + \cdots + (\eta^{m})^2$. It follows that the geometry of $U \subseteq \mathbb{R}^m$ is entirely contained in the sets of 1-forms $\{\eta^i\}$ and $\{\eta^j\}$.

To accomplish the goal of doing differential geometry using moving frames, we should be able to compute differential operators using differential forms. For that, we need the Hodge star operator $\star$, which takes $k$-forms to $(m - k)$-forms. Geometrically, we proceed as follows. Given a $k$-form $\omega = \omega^1 \wedge \cdots \wedge \omega^k$, where $\{\omega^i\}$ is linearly independent, consider the $k$-dimensional vector subspace $V$ of $\mathbb{R}^m$ generated by the vectors $\{v_1, \ldots, v_k\}$ associated with $\{\omega^1, \ldots, \omega^k\}$. Then, we pick a basis $\{v_{k+1}, \ldots, v_m\}$ of the vector space $V^\perp$ orthogonal to $V$ and consider $\omega^{k+1}, \ldots, \omega^m$, the 1-forms associated with the vectors of this basis. Then, we define $\star \omega = \pm \lambda \omega^{k+1} \wedge \cdots \wedge \omega^m$, where $\lambda$ is the $k$-volume of the solid generated by $\{v_1\}_{k=1}$ and the sign corresponds to the orientation of $B = \{v_1, \ldots, v_k, v_{k+1}, \ldots, v_m\}$, i.e., plus if $B$ has the same orientation as the canonical basis of $\mathbb{R}^m$ and minus if otherwise. Finally, we compute $\star$ for a generic linear form by demanding linearity. As an example, in $\mathbb{R}^3$ the Hodge star operator acting on 1-forms gives $\star dx^1 = dx^2 \wedge dx^3$, $\star dx^2 = -dx^1 \wedge dx^3$, and $\star dx^3 = dx^1 \wedge dx^2$. Finally, the curl and divergence of $\mathbf{n}$ are associated with differential forms according to

$$\nabla \times \mathbf{n} \leftrightarrow \star (d \eta) \quad \text{and} \quad \nabla \cdot \mathbf{n} = \star [d(\star \eta)],$$

where $\eta$ the 1-form dual to $\mathbf{n}$.

4 Compatibility condition for two-dimensional director fields

Director fields $\mathbf{n}$ in 2D are fully described by their bend $b = \|\mathbf{n} \times \nabla \times \mathbf{n}\|$ and splay $s = \nabla \cdot \mathbf{n}$. However, the splay and bend are not independent functions and they are related to the curvature of the ambient surface by [16]

$$-K = s^2 + b^2 + \mathbf{n} \cdot \nabla s - \mathbf{n}^\perp \cdot \nabla b.$$

In this section we provide an alternative proof for the 2D compatibility equation via moving frames. But, first, we shall illustrate how the moving frame method can be used to describe the geometry of surfaces.

Let $r : U \rightarrow S \subset \mathbb{R}^3$ be a surface and $\mathbf{N}$ its unit normal. If $\{\mathbf{n}_1, \mathbf{n}_2\}$ is a field of orthonormal bases for the tangent planes, we then define a moving frame in 3D as $\{\mathbf{n}_1, \mathbf{n}_2, \mathbf{n}_3 := \mathbf{N}\}$ along with its dual frame $\{\eta^1, \eta^2, \eta^3\}$. Since we are interested on the surface geometry, we shall restrict our attention to $\eta^1, \eta^2, \eta^3$ when applied to tangent vectors. Then, in this restricted setting it follows that

$$\forall v = v^n_1 \mathbf{n}_1 + v^n_2 \mathbf{n}_2 \in T_p S, \eta^3(v) = 0.$$

Therefore, seeing $\eta^3$ as a 2D differential form on $S$ implies $\eta^3 = 0$. Thus, the 1-forms $\eta^1, \eta^2, \eta^3$ can be written as a linear combination of $\eta^1$ and $\eta^2$ only,
i.e., they can also be seen as differential forms on the surface. This process of seeing \( \eta^1 \) and \( \eta^2 \) as 2D differential forms can be rigorously justified by using \( \mathbf{r} \) to pullback the 1-forms \( \eta^1 \) and \( \eta^2 \) to \( U \): the pullback of a k-form \( \eta \) is the k-form \( \omega = \mathbf{r}^*\eta \) defined by \( \omega_p(v_1, \ldots, v_k) = \eta_{\mathbf{r}(p)}(d\mathbf{r}(v_1), \ldots, d\mathbf{r}(v_k)) \). Now, since the pullback operation \( * \) commutes with \( d \) and \( \wedge \), the 1-forms \( \mathbf{r}^*\eta^1 \) and \( \mathbf{r}^*\eta^2 \) satisfy the same structure equations as \( \eta^1 \) and \( \eta^2 \). Thus, with some abuse of notation, we simply write \( \eta^1 = \mathbf{r}^*\eta^1 \) and \( \eta^2 = \mathbf{r}^*\eta^2 \), which finally justifies seeing \( \eta^1 \) and \( \eta^2 \) as 1-forms over \( S = \mathbf{r}(U) \).

From the fact that \( \eta^3 = 0 \) on \( S \), it follows that \( d\eta^3 = 0 \) on \( S \). Then, the structure equations in (2) imply that \( \eta^1 \wedge \eta^2 + \eta^2 \wedge \eta^3 = 0 \). An important result for differential forms is the Cartan lemma \([4, 7]\), which says that if \( \omega^1, \ldots, \omega^k \) are linearly independent 1-forms and if there exist 1-forms \( \theta^1, \ldots, \theta^k \) such that \( \sum_{i=1}^k \omega^i \wedge \theta^i = 0 \), then \( \theta^i = a^i_j \omega^j \) with \( a^i_j = a^j_i \). Therefore, since the set \( \{\eta^1, \eta^2\} \) is linearly independent, from the Cartan lemma we may write

\[
\eta^1 = a^1_1 \eta^1 + a^2_1 \eta^2 \quad \text{and} \quad \eta^2 = a^1_2 \eta^1 + a^2_2 \eta^2, \quad a^1_1 = a^1_2 = a^2_1 = a^2_2.
\]

From \( d\mathbf{n}_1 = \eta^1_2 \mathbf{n}_1 + \eta^2_2 \mathbf{n}_2 = -(\eta^1_3 \mathbf{n}_1 + \eta^2_3 \mathbf{n}_2) \), it follows that the coefficients \( a^1_1 \) precisely describe the shape operator of \( S \). Then, the mean \( (H) \) and Gaussian \( (K) \) curvatures can be written as

\[
H = \frac{1}{2} \text{tr}(a) = \frac{a^1_1 + a^2_2}{2} \quad \text{and} \quad K = \text{det}(a) = a^1_1 a^2_2 - (a^2_1)^2.
\]

It remains to find the interpretation of \( \eta^3_2 \). From \( \eta^3_2(\nu) = \langle \nabla_\nu \mathbf{n}_1, \mathbf{n}_2 \rangle \), we see that we can write \( \eta^3_2 = \eta^3_1(n_1) \eta^1 + \eta^3_2(n_1) \eta^2 = \kappa_g \eta^1 + \kappa_g^\perp \eta^2 \), where \( \kappa_g \) and \( \kappa_g^\perp \) are the geodesic curvatures of the integral curves of \( \mathbf{n}_1 \) and \( \mathbf{n}_2 \), respectively. In addition, taking the exterior derivative provides the important relation \( d\eta^3_2 = \eta^3_1 \wedge \eta^1_2 = -K \eta^1 \wedge \eta^2 \). This relation will be the key to finding the compatibility equation for director fields in 2D.

We have just seen that for a surface in 3D the intrinsic geometry is encoded in \( \eta^1, \eta^2, \) and \( \eta^3_2 \), while the extrinsic geometry comes from \( \eta^1_2 \) and \( \eta^2_2 \). (The second fundamental form \( \mathbf{II} \) can be written as \( \mathbf{II} = \eta^3_2 \mathbf{n}_3 \).) The equation \( d\eta^3_2 = -K \eta^1 \wedge \eta^2 \) in 2D indicates that for moving frames in a Riemannian manifold the second set of structure equations, Eq. (2), must be modified to account for the curvature of the ambient manifold: For a 2D manifold with Gaussian curvature \( K = R_{1212} \), the structure equations associated with the 1-forms \( \{\eta^1, \eta^2\} \) and \( \eta^3_2 \) are \( d\eta^1 = \eta^2 \wedge \eta^1_2, \quad d\eta^2 = \eta^1 \wedge \eta^2_2, \quad \) and \( d\eta^3_2 - \eta^1 \wedge \eta^3_2 - \eta^2 \wedge \eta^3_2 = d\eta^3_2 = -K \eta^1 \wedge \eta^2_2 \).

---

As an alternative to using pullbacks, we could consider a foliation of space by surfaces parallel to \( S \) spanning a region parametrized as \( \mathbf{R}(x^1, x^2, x^3) = \mathbf{r}(x^1, x^2) + x^3 \mathbf{N}(x^1, x^2) \). Since we are only interested on tangent directions, any dependence of \( \eta^i_2 \) on \( \eta^3 \) does not contribute to the final result. In addition, following this idea, \( \eta^3 \) is nothing but the differential of the \( x^3 \)-coordinate, which implies that \( d\eta^3 = 0 \). As shown in the main text, this is the key property allowing us to use the moving frame method to study the differential geometry of surfaces in space.
In general, for a moving frame \( \{ n_i \}_{i=1}^m \) in a Riemannian manifold \( M^m \) with curvature tensor \( R_{ijkl} = R^k_{jkl} \), the structure equations are \([7]\)

\[
d\eta^i = \eta^k \wedge \eta_k^i \quad \text{and} \quad d\eta^i_j - \eta^k_j \wedge \eta_k^i = -\frac{1}{2} R^i_{jkl} \eta^k \wedge \eta^l, \tag{7}\]

where we used that the operation of raising and lowering indices is trivial since the metric coefficients associated with the moving frame are \( \delta_{ij} = \langle n_i, n_j \rangle \).

Now, let \( \hat{n} \) be a director field on a 2D Riemannian manifold \( (M^2, \langle \cdot, \cdot \rangle) \). We may introduce a moving frame \( \{ n_1 := \hat{n}, n_2 := \hat{n}^\perp \} \) along with its coframe \( \{ \eta^1, \eta^2 \} \). As we have seen, we can write \( \eta^2 = \kappa_g \eta^1 + \kappa_g^1 \eta^2 \).

On the one hand, the splay \( s = \nabla \cdot \hat{n} \) is computed as

\[
s = \star d \star \eta^1 = \star d \eta^2 = \star (\eta^1 \wedge \eta^2_1) = \kappa_g^1. \tag{8}\]

On the other hand, the bend \( b = ||\hat{n} \times \nabla \times \hat{n}|| \) is

\[
b = ||\star(\eta^1 \wedge \star d\eta^1)|| = ||\star [\eta^1 \wedge \star (\eta^2 \wedge \eta^2_2)]||
= ||\star [\eta^1 \wedge \star (\kappa_g \eta^1 \wedge \eta^2)]|| = ||\kappa_g \eta^2|| = \kappa_g. \tag{9}\]

This last equation also shows that, in 2D, we may write \( b = -\nabla \cdot n_2 = \star d \star \eta^2 \).

In short, we have the following relation

\[
\eta^2_1 = b \eta^1 + s \eta^2. \tag{10}\]

Now we shall apply the findings above in order to write the compatibility equation for 2D director fields as found in \([16]\), but using moving frames.

Theorem 1 (Compatibility condition in 2D) Let \( \hat{n} \) be a director field with splay \( s \) and bend \( b \) on a 2D manifold \( M^2 \) with Gaussian curvature \( K \). Then,

\[
-K = s^2 + b^2 + (\hat{n} \cdot \nabla) s - (\hat{n}^\perp \cdot \nabla) b, \tag{11}\]

where \( (v \cdot \nabla) \) is the directional derivative in the direction of \( v \) and \( \langle \hat{n}, \hat{n}^\perp \rangle = 0 \).

Proof The exterior derivative of \( \eta^2_1 \) is

\[
d\eta^2_1 = d(b \eta^1 + s \eta^2) = db \wedge \eta^1 + b \eta^1 + ds \wedge \eta^2 + s d\eta^2
= [(\hat{n}^\perp \cdot \nabla) b] \eta^2 + b \eta^2 + s d\eta^2
= [(\hat{n} \cdot \nabla) s - (\hat{n}^\perp \cdot \nabla) b + b^2 + s^2] \eta^1 \wedge \eta^2.
\]

Now, using that \( d\eta^2_1 = -K \eta^1 \wedge \eta^2 \) we deduce the desired equality. \( \square \)
5 Three-dimensional director fields

Inspired by the study of 2D director fields, the strategy in 3D will consist of writing the 1-forms \( \eta_i \) in terms of the deformation modes of a director field \( \mathbf{n} \) and then from the structure equations associated with \( d\eta_i \) we will obtain the compatibility equations.

In 2D, there are two deformation modes (bend and splay), while in 3D there are 6 modes, which can be further reduced to 5. Indeed, as discussed in Sect. 2, taking into account rotations that preserve the director \( \mathbf{n} \), the gradient \( \nabla \mathbf{n} \) decomposes as \[ \nabla \mathbf{n} = -n_\alpha n_\beta + s \left( \delta_{\alpha\beta} - n_\alpha n_\beta \right) + \frac{t}{2} \tau_{\alpha\beta\gamma} n_\gamma + \Delta_{\alpha\beta}, \]

where the Greek indices indicate Cartesian coordinates and \( \mathbf{n} \) is the bend vector, where the Greek indices indicate Cartesian coordinates and \( \mathbf{n} = -\mathbf{n} \cdot \nabla \mathbf{n} \) is the bend vector, whose norm \( b \) (the bend) gives the curvature of the integral lines of \( \mathbf{n} \), \( s = \nabla \cdot \mathbf{n} \) is the splay, \( t = \mathbf{n} \cdot \nabla \times \mathbf{n} \) is the twist, and \( \Delta_{ij} \) are the coefficients of the biaxial-splay \[ \Delta_{ij} \]

In 2D, the coefficients of the 1-form \( \eta_j^2 \) are related to the geometry of the integral curves of the director and its orthogonal field. Given an integral curve of \( \mathbf{n} \), in 3D, we can consider \( \{ \mathbf{n}_i, \mathbf{n}_{i+1}, \mathbf{n}_{i+2} \} \) as a positive orthonormal moving trihedron along it, e.g., for \( \mathbf{n}_2 \) we have \( \{ \mathbf{n}_2, \mathbf{n}_3, \mathbf{n}_1 \} \). The equations of motion of such a moving trihedron along the \( \mathbf{n}_i \)-integral curves are

\[
\nabla_{\mathbf{n}_i} \left( \begin{array}{c}
\mathbf{n}_i \\
\mathbf{n}_{i+1} \\
\mathbf{n}_{i+2}
\end{array} \right) = \left( \begin{array}{ccc}
kappa^1_i & \kappa^2_i & 0 \\
-\kappa^1_i & 0 & \omega_i \\
-\kappa^2_i & -\omega_i & 0
\end{array} \right) \left( \begin{array}{c}
\mathbf{n}_i \\
\mathbf{n}_{i+1} \\
\mathbf{n}_{i+2}
\end{array} \right),
\]

where \( \kappa^1_i \) and \( \kappa^2_i \) relate to the (geodesic) curvature function \( \kappa_i \) as \( \kappa_i(s) = \sqrt{[\kappa^1_i(s)]^2 + [\kappa^2_i(s)]^2} \) and \( \omega_i \) relates to the torsion \( \tau_i \) as \( \omega_i(s) = \tau_i(s) - \theta'(s) \), where \( \theta \) is the angle between the (Frenet) principal normal and \( \mathbf{n}_{i+1} \). Thus, using the property \( \eta_i^j(v) = (\nabla_v \mathbf{n}_i, \mathbf{n}_j) \), the 1-forms \( \eta_i^j \) when written in the basis \( \{ \eta^1, \eta^2, \eta^3 \} \) are

\[
\begin{align*}
\eta^1_i &= \kappa^1_i \eta^1 - \kappa^2_i \eta^2 + \omega_i \eta^3 \\
\eta^2_i &= \kappa^2_i \eta^1 - \omega_i \eta^1 - \kappa^3_i \eta^3 \\
\eta^3_i &= \omega_i \eta^1 + \kappa^3_i \eta^2 - \kappa^2_i \eta^3.
\end{align*}
\]

The 1-forms \( \eta^1_i \) and \( \eta^3_i \) provide information about the gradient of the director \( \mathbf{n}_1 \), \( d\mathbf{n}_1 = \eta^1_1 \mathbf{n}_2 + \eta^3_1 \mathbf{n}_3 \). The components dual to the director \( \hat{\mathbf{n}} \) then contains information about the bend vector \( \mathbf{b} = -\nabla_\hat{\mathbf{n}} \mathbf{n} = \mathbf{b} \times \nabla \times \mathbf{n} \), \( \mathbf{b} = \sqrt{(\kappa^1_i)^2 + (\kappa^2_i)^2} \). The remaining components of \( d\mathbf{n}_1 \) can be decomposed into an antisymmetric and a symmetric part, where the symmetric part can be further decomposed into a trace and traceless operator. This decomposition provides the twist \( t \), splay \( s \), and biaxial splay coefficients \( \Delta_{ij} \), respectively. Thus, from

\[
\begin{pmatrix}
-\kappa^2_i & \omega_i \\
-\omega_i & -\kappa^3_i
\end{pmatrix} = \frac{t}{2} \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix} + \frac{s}{2} \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} + \begin{pmatrix} \Delta_1 \\ \Delta_2 \\ -\Delta_1 \\ -\Delta_2 \end{pmatrix},
\]

where \( \kappa_i, \omega_i \) are the (geodesic) curvature and torsion functions, respectively.
we can write
\[ t = -(\omega_2 + \omega_3), \quad s = - (\kappa_2^2 + \kappa_3^2), \quad \Delta_1 = \frac{\kappa_1^3 - \kappa_2^3}{2} \]  
and \[ \Delta_2 = \frac{\omega_3 - \omega_2}{2}. \]  
(16)

By inverting these relations, we can finally rewrite \( \eta_1^2 \) and \( \eta_3^3 \) in Eq. (13) as
\[ \eta_1^2 = - b_\perp \eta^1 + \left( \frac{s}{2} + \Delta_1 \right) \eta^2 + \left( - \frac{t}{2} + \Delta_2 \right) \eta^3 \]  
(17)

and
\[ \eta_3^3 = - b_x \eta^1 + \left( \frac{t}{2} + \Delta_2 \right) \eta^2 + \left( \frac{s}{2} - \Delta_1 \right) \eta^3, \]  
(18)

where we write the bend vector as \( \mathbf{b} = b_\perp \mathbf{n}_2 + b_x \mathbf{n}_3 \).

The compatibility conditions then come from the structure equations
\[ \Omega_1^2 = d\eta_1^2 - \eta_1^1 \wedge \eta_1^2, \quad \Omega_2^3 = d\eta_1^3 - \eta_1^2 \wedge \eta_3^3, \quad \]  
and \[ \Omega_3^3 = d\eta_2^3 - \eta_2^1 \wedge \eta_3^3, \]
where \( \Omega_i^k \) are the curvature forms whose coordinates in the basis \( \{ \eta^i \wedge \eta^j \} \) provide the coefficients of the curvature tensor as defined in Eq. (7). Together, the three structure equations provide the 34 = 81 coefficients of the curvature tensor \( R_{ijkl} \). From \( \Omega_i^j = - \Omega_j^i \) and the fact that \( \Omega_i^j \) is a differential form, it follows that \( R_{ijkl} = - R_{jikl} = - R_{ijlk} \) reducing these to only 9 independent entries. However, the first Bianchi identity (which is required to further reduce these to only 6 independent components) cannot be proved directly from the above definition. Proving this identity requires differentiating \( d\Omega_i^j = \eta^k \wedge \eta_i^j \) to obtain \( \eta^k \wedge \Omega_i^j = 0 \), from which follows that \( R_{ijkl} = R_{klij} \) (see [4] or [7], p. 376). While these relations hold for connection forms that are obtained from a moving frame, there could be 1-forms \( \eta_i^j \) that would fail to satisfy these relations. Such forms could not be the connection forms of a moving frame in any Riemannian geometry. Thus, while for any compatible set of moving frames the Riemann curvature tensor contains only six independent entries, requiring the satisfaction of the first Bianchi identity yields three additional non-trivial compatibility conditions resulting in the following nine equations:

\[
\begin{align*}
R_{1212} &= - (\frac{s}{2} + \Delta_1) b_\perp - b_\perp \omega_2 - b_\perp^2 - \frac{s^2}{4} + \frac{t^2}{4} - 2 s \Delta_1 - \Delta_1^2 - (\Delta)^2 + 2 \omega_1 \Delta_2 + \kappa_3^3 b_x, \\
R_{1213} &= - (-\frac{s}{2} + \Delta_2) b_\perp - b_\perp b_x - b_\perp \omega_2 - s(-\frac{s}{2} + \Delta_2) - 2 \omega_1 \Delta_1 - \kappa_3^3 b_x, \\
R_{1223} &= - (-\frac{s}{2} + \Delta_2) b_\perp + b_\perp \omega_2 + b_\perp b_x + 2 \omega_1 \Delta_1 - 2 \kappa_3^3 b_\perp, \\
R_{1312} &= - (\frac{s}{2} + \Delta_2) b_\perp - b_\perp \omega_2 - b_\perp b_x - s(\frac{s}{2} + \Delta_2) - 2 \omega_1 \Delta_1 - \kappa_3^3 b_\perp, \\
R_{1313} &= - (\frac{s}{2} - \Delta_1) b_\perp - b_\perp b_x - b_\perp \omega_2 - s b_\perp^2 + \frac{s^2}{4} + \frac{t^2}{4} + s \Delta_1 - \Delta_1^2 - 2 \omega_1 \Delta_2 + 2 \kappa_3^3 b_\perp, \\
R_{1323} &= - (\frac{s}{2} - \Delta_1) b_\perp + (\frac{s}{2} + \Delta_2) b_\perp b_x - 2 \kappa_3^3 \Delta_2 - 2 \kappa_3^3 \Delta_1, \\
R_{2312} &= - \kappa_3^3 b_\perp + \omega_2 b_x - (b_x + \kappa_3^3) b_\perp - b_\perp b_\perp - \omega_1 b_\perp + \frac{b_\perp \omega_1}{\kappa_3^3 b_\perp} + \frac{b_\perp \omega_1}{\kappa_3^3 b_\perp}, \\
R_{2313} &= \kappa_3^3 b_\perp + \omega_2 b_\perp + (b_\perp + \kappa_3^3) b_\perp - (b_x + \kappa_3^3) b_\perp - \frac{b_\perp \omega_1}{\kappa_3^3 b_\perp} + \frac{b_\perp \omega_1}{\kappa_3^3 b_\perp}, \\
R_{2323} &= \kappa_3^3 b_\perp + \omega_2 b_\perp + (b_\perp + \kappa_3^3) b_\perp - (b_x + \kappa_3^3) b_\perp - \frac{b_\perp \omega_1}{\kappa_3^3 b_\perp} + \frac{b_\perp \omega_1}{\kappa_3^3 b_\perp},
\end{align*}
\]  
(19)
where \( f_i = n_i \cdot \nabla f \) denotes the derivative of \( f \) in the direction of \( n_i \) and we denote \( \Delta = \sqrt{\Delta_1^2 + \Delta_2^2} \).

The gradient of the director field can be written in terms of the deformations modes \( b_{1, 2, s, t, \Delta_1, \Delta_2} \). However, notice that by choosing \( n_2 \) to be either the normalized bend vector or an eigenvector of the biaxial splay implies we have a Gauge freedom allowing us to set either \( b_s = 0 \) or \( \Delta_2 = 0 \). Therefore, this reduces the number of degrees of freedom from 6 to 5. In addition, the equations for the curvature tensor were written in terms of 9 functions, six of which can be written in terms of the deformation modes. Thus, the equations for the curvature tensor were written in terms of 9 functions, which allows us to write \( \omega_b \) we have a Gauge freedom allowing us to set either \( \Delta(b) \) or an eigenvector of the biaxial splay implies we have a Gauge freedom allowing us to set either \( b_s = 0 \) or \( \Delta_2 = 0 \). Therefore, this reduces the number of degrees of freedom to 5. In addition, the last assertion in the next two subsections, where we divide the study into deformations modes, six of which can be written in terms of the deformation modes. Thus, the remaining three, \( \kappa_2, \kappa_3^2, \) and \( \omega_1 \) must be superfluous. We will prove this last assertion in the next two subsections, where we divide the study into director fields with either \( \Delta^2 = (\Delta_1)^2 + (\Delta_2)^2 > 0 \) or \( \Delta^2 = (\Delta_1)^2 + (\Delta_2)^2 = 0 \) on all points. In short, we will have six 6 compatibility equations in 5 functions.

5.1 Director fields with non-vanishing biaxial splay

Let us assume non-vanishing biaxial splay \( (\Delta) = (\Delta_1)^2 + (\Delta_2)^2 > 0 \). Then, using the equations for \( R_{ijk} \) we can compute the sum \( \Delta_1 R_{123} + \Delta_2 R_{132} \), which allows us to write \( \kappa_2 \) as

\[
\kappa_2 = \frac{\Delta_1 R_{123} + \Delta_2 R_{132}}{2\Delta^2} + \frac{\Delta_1 t_2 - \Delta_2 b_2 + \Delta_1 s_2 + \Delta_2 t_3}{2\Delta^2} - \frac{\Delta_1 \Delta_2}{2\Delta^2} - \frac{\Delta_2 \Delta_1}{2\Delta^2} + \frac{(\Delta^2)_3}{2\Delta^2} + \frac{(\Delta^2)_2}{4\Delta^2} + t \frac{b_1 \Delta_1 + b_s \Delta_2}{2\Delta^2}.
\]

Using the equations for \( R_{ijk} \) we can find \( \Delta_2 R_{123} - \Delta_1 R_{132} \), which allows us to write \( \kappa_3^2 \) as

\[
\kappa_3^2 = \frac{\Delta_1 R_{132} - \Delta_2 R_{123}}{2\Delta^2} + \frac{\Delta_2 t_2 + \Delta_1 s_2 - \Delta_1 t_3 + \Delta_2 s_3}{2\Delta^2} + \frac{\Delta_1 \Delta_3}{2\Delta^2} + \frac{\Delta_2 \Delta_1}{2\Delta^2} + \frac{(\Delta^2)_2}{2\Delta^2} - t \frac{b_1 \Delta_2 + b_s \Delta_3}{2\Delta^2}.
\]

Analogously, computing \( -\Delta_2 R_{121} + \Delta_2 R_{131} + \Delta_1 R_{123} + \Delta_1 R_{132} \) allows us to write \( \omega_1 \) as

\[
\omega_1 = \frac{\Delta_2 R_{121} - \Delta_2 R_{131} + \Delta_1 R_{123} - \Delta_1 R_{132}}{2\Delta^2} + \frac{\Delta_2 \Delta_1 - \Delta_1 \Delta_2}{2\Delta^2} - \frac{\Delta_1 b_{x, 2} + \Delta_1 b_{x, 3} - \Delta_2 b_{x, 2} + \Delta_2 b_{x, 3} + (b_{1, 2} - b_{1, 3}) \Delta_2 - 2b_{1, s} \Delta_1}{4\Delta^2} - \frac{\Delta_1 b_1 \Delta_1 + b_s \Delta_2}{4\Delta^2} + \frac{b_1 \Delta_2 - b_s \Delta_1}{4\Delta^2}.
\]

(22)
Now, substituting the expressions for \( \kappa_2^1 \) and \( \kappa_2^3 \) in the equation above, we finally have

\[
\omega_1 = \frac{\Delta_2 R_{1212} - \Delta_1 R_{1313} - \Delta_1 R_{1213} - \Delta_1 R_{1312}}{4 \Delta^2} + \frac{b_x R_{1323} + b_x R_{1323}}{8 \Delta^2} + \\
+ \frac{\Delta_2 \Delta_1,1 - \Delta_1 \Delta_2,1}{2 \Delta^2} - \frac{\Delta_1 b_{x,2} + \Delta_1 b_{x,3} - \Delta_2 b_{x,2} + \Delta_2 b_{x,3}}{4 \Delta^2} - \frac{t b^2}{8 \Delta^2} - \\
- \frac{b_x \Delta_1,2 - b_x \Delta_1,2 + b_x \Delta_1,3 + b_x \Delta_2,3}{8 \Delta^2} + \frac{(b^2 - b_x^2) \Delta_2 - 2 b_x b \Delta_1}{4 \Delta^2},
\]

(23)

There are three other linearly independent combinations we can construct with the equations for \( R_{12ij} \) and \( R_{13ij} \). Indeed, using the equations for \( R_{ijkl} \) we can compute \( R_{1212} + R_{1313}, R_{1312} - R_{1213} = 0, \) and \( \Delta_1 R_{1212} + \Delta_2 R_{1213} + \Delta_2 R_{1312} - \Delta_1 R_{1313}, \) which give

\[
R_{1212} + R_{1313} = -s_1 - b_{x,2} - b_{x,3} - b^2 - \frac{s^2}{2} + \frac{t^2}{2} - 2 \Delta^2 + \kappa_2^1 b_x + \kappa_2^3 b\perp, \quad (24)
\]

\[
0 = R_{1312} - R_{1213} = -t,1 - b_{x,2} + b_{x,3} - st - \kappa_2^1 b_{x,3} + \kappa_2^3 b_x, \quad (25)
\]

and

\[
s = \frac{\Delta_1 [R_{1313} - R_{1212}] - \Delta_2 [R_{1213} + R_{1312}]}{2 \Delta^2} - \frac{\Delta_1 [b_{x,2} - b_{x,3}]}{2 \Delta^2} + \frac{\Delta_2 [b_{x,2} + b_{x,3}]}{2 \Delta^2} - \frac{\kappa_2^1 b_{x,3} - \kappa_2^3 b_{x,2}}{2 \Delta^2}, \quad (26)
\]

Note we can set \( 0 = R_{1312} - R_{1213} \) since this is required by the symmetries of the curvature tensor \( R_{ijkl}. \)

Now, substituting \( \kappa_2^1, \kappa_2^3, \) and \( \omega_1 \) from Eqs. (20), (21), and (23) in the three equations we just obtained, we obtain three differential equations of first order involving the deformations modes. In addition, if we also substitute \( \kappa_2^1, \kappa_2^3, \) and \( \omega_1 \) in the equations for \( R_{23ij} \), we will obtain another set of three differential equations involving the deformations modes and their first and second derivatives.

5.2 Director fields with vanishing biaxial splay

Now, let us assume a vanishing biaxial splay \( \Delta^2 = (\Delta_1)^2 + (\Delta_2)^2 = 0. \) If we assume that \( b \neq 0 \), then from the equations of \( R_{ijkl} \) we can compute \( b_x R_{1212} - b_{x,2} R_{1312}, \) which allows us to write \( \kappa_2^1 \) as

\[
\kappa_2^1 = \frac{b_x R_{1212} - b_{x,2} R_{1312}}{b^2} + \frac{b_x s_1 - b_{x,3} t_1}{2 b^2} + \frac{b_{x,2} b_{x,3} - b_{x,2} b_{x,3}}{b^2} - \frac{(t_2 - s_2) b_x + 2 st b_{x,2}}{4 b^2}.
\]

(27)
In addition, from the equations of $R_{ijk\ell}$ we can compute $b_{\perp}R_{1313} - b_xR_{1213}$, which allows us to write $\kappa_3^2$ as

$$\kappa_3^2 = \frac{b_{\perp}R_{1313} - b_xR_{1213}}{b^2} + \frac{b_x t_1 + b_{\perp} s_{\perp} + b_{\perp} b_{x,3} - b_x b_{\perp,3}}{2b^2} + \frac{(s^2 - t^2)b_{\perp} + 2stb_x}{4b^2}.$$ (28)

Note that when $\Delta = 0$, we can write $\omega_1$ as a function of the deformation modes $\{s, t, b, \Delta_1, \Delta_2\}$ by substituting for $\kappa_1^2$ and $\kappa_3^2$ in the equation for $R_{2323}$. Alternatively, we can get rid of $\omega_1$ by choosing $n_2$ and $n_3$ such that $\omega_1 = 0$.

On the other hand, if $b = 0$, then there are some restrictions on the geometry of the ambient manifold. Indeed, we straightforwardly conclude that $R_{1212} = R_{1313}$ and $R_{1213} = -R_{1312}$, which by using the symmetry $R_{1213} = R_{1312}$ allows us to deduce that $R_{1213} = R_{1312} = 0$.

6 Uniform distortion director fields on manifolds of constant curvature

In this section, we provide a characterization of uniform distortion fields, i.e., director fields $\mathbf{n}$ for which the deformation modes $\{s, t, b, \Delta_1, \Delta_2\}$ are all constant, in manifolds of constant sectional curvature. As a consequence, it will follow that no combination of values other than the pure twist phase exist in positive curvature. For negative curvature, the examples of uniform distortion fields with $s^2 + 4b_{\perp}^2 = 4$ and $t = 0$ provided in [20] are in fact the most general case under the assumption that the biaxial splay vanishes. However, our results will also imply that it is possible to have uniform distortion fields in negative curvature with non-vanishing biaxial splay and, as in the Euclidean space, these phases correspond to foliations of space by helices.

From now on, let us assume that we have a director field in a curved space $M^3$ of constant curvature $R_0$. This means that the curvature tensor is given by $R_{ijk\ell} = R_0(\delta_{ik}\delta_{\ell j} - \delta_{ij}\delta_{k\ell})$ [23]: $R_0 < 0$ if $M^3$ is locally isometric to a hyperbolic space, $R_0 = 0$ if $M^3$ is locally isometric to the Euclidean space, and $R_0 > 0$ if $M^3$ is locally isometric to a 3-sphere. Let us also introduce the shorthand notation $\langle D b, b \rangle = (b_{\perp,1}^2 - b_x^2)\Delta_1 + 2b_{\perp} b_x \Delta_2 = b^2\Delta \cos(2\phi)$ and $\langle J D b, b \rangle = (b_{\perp,1}^2 - b_x^2)\Delta_2 + 2b_{\perp} b_x \Delta_1 = b^2\Delta \sin(2\phi)$, where $\phi$ is the angle formed by the bend vector and the principal direction of the biaxial splay. (In other words, $D$ and $J$ denote the biaxial splay and the counterclockwise $\frac{\pi}{2}$-rotation acting as linear operators on the plane normal to the director field, respectively.)

The results of this section can be summarized as follows

**Theorem 2** Let $M^3$ be a manifold of constant sectional curvature $R_0$ and let $\mathbf{n}$ be a director field in it with constant deformation modes $\{s, t, b, b_{\perp}, b_x, \Delta_1, \Delta_2\}$.

(a) If $R_0 > 0$, then $s = b = \Delta = 0$ and $t = \pm 2\sqrt{R_0}$ is the only solution.
(b) If \( R_0 = 0 \), then \( b = s = t = 0 \) when \( \Delta = 0 \). On the other hand, when \( \Delta \neq 0 \), then \( s = 0 \), \( t = \pm 2\Delta \), and \( \phi = \frac{(2k+1)\pi}{4} \), \( k \in \{0,1,2,3\} \), i.e., the bend vector \( b \) bisects the principal directions of the biaxial splay, where \( k = 0 \) or \( k = 2 \) if \( t = 2\Delta \) and \( k = 1, 3 \) if \( t = -2\Delta \).

(c) If \( R_0 < 0 \), then \( t = 0 \) and \( s^2 + 4b^2 = -4R_0 \) when \( \Delta = 0 \). On the other hand, when \( \Delta \neq 0 \), then \( t = \pm 2\Delta \), \( s = -\frac{1}{2\Delta^2}(Db, b) \), and the deformation modes are subjected to the restriction \( 1 + \frac{b^2}{\Delta^2} \geq \sqrt{-\frac{4b}{\Delta^2}} \).

In (b) and (c), the bend and biaxial splay are the free parameters describing the families of solutions.

In the next subsections we are going to provide a proof for this theorem by analyzing the restrictions imposed by the compatibility equations on the values of the deformation modes. But, before that, let us discuss the implications on the geometry of the integral curves of the director field.

For \( R_0 > 0 \), it is known that the vector field tangent to the fibers of the Hopf fibration provides an example of a uniform distortion field [20,22]. It turns out that this is the only possibility. Indeed, given any uniform distortion field \( n \) on a manifold of constant positive curvature, the integral curves of \( n \) are geodesics. In addition, from the fact that \( s, \Delta_1 \), and \( \Delta_2 \) all vanish, we deduce that any two integral curves are parallel to each other, from which follows that the fibration provided by the integral curves of \( n \) is locally a Hopf fibration [17].

For \( R_0 \leq 0 \), the integral curves of a uniform distortion field do not have to be geodesics. In general, they are helices, i.e., curves with constant curvature and torsion. Indeed, the equations of motion of the \( \{n_1, n_2, n_3\} \) are

\[
\nabla n_i \begin{pmatrix} n_1 \\ n_2 \\ n_3 \end{pmatrix} = \begin{pmatrix} 0 & \kappa_1 & \kappa_2 \\ -\kappa_1 & 0 & \omega_1 \\ -\kappa_2 & -\omega_1 & 0 \end{pmatrix} \begin{pmatrix} n_1 \\ n_2 \\ n_3 \end{pmatrix} = \begin{pmatrix} 0 & -b_\perp & -b_\times \\ b_\perp & 0 & \omega_1 \\ b_\times & -\omega_1 & 0 \end{pmatrix} \begin{pmatrix} n_1 \\ n_2 \\ n_3 \end{pmatrix},
\]

where \( \omega_1 \) is constant and given by Eq. (28). We can obtain the Frenet frame \( \{T = n, N, B\} \) from \( \{n_1, n_2, n_3\} \) by a rotation of an angle \( \theta \) on the normal plane. Then, we can write \( \kappa_1 = \kappa \cos \theta, \kappa_2 = \kappa \sin \theta, \) and \( \theta' = \tau - \omega_1 \) [25]. Since \( \kappa_1 \) and \( \omega_1 \) are all constant, we deduce that \( \kappa \) and \( \tau \) are also constant. As a consequence, the integral curves of \( n \) make a constant angle with the Darboux vector field \( w = \omega_1 n_1 - \kappa_1 n_2 + \kappa_2 n_3 \) or \( w = \tau T + \kappa B \) if we use the Frenet frame; if \( s \) denotes the arc-length of the integral curves of \( n \), then \( \frac{d}{ds} \langle w, n \rangle = \langle \nabla n w, n \rangle + \langle w, \nabla n n \rangle = \langle \tau' n + \kappa B + \tau B - \tau B, n \rangle + \langle w, B N \rangle = 0 \).

Virga’s strategy to characterize the helicoidal phases in Euclidean space [28] consisted in investigating the behavior of the frame along a generic curve in space (not necessarily an integral curve). This gives rise to an operator whose eigenvector can be shown to be constant and, in addition, the integral lines of the director field precess around this fixed direction. We can provide an alternative proof by showing that all integral curves of a uniform distortion field \( n \) in a flat manifold have the same axis, i.e., we may show that \( v \cdot \nabla w = 0 \) for every direction \( v \).
Using Eqs. (13) and (15) to write some of the $\kappa_i^1$’s and $\omega_i$’s as functions of the deformation modes, we conclude that

$$w_{1} = (b_x b_{\perp} - b_{\perp} b_x) n_1 + (b_{\perp} \omega_1 - \omega_1 b_{\perp}) n_2 + (b_x \omega_1 - \omega_1 b_x) n_3 = 0,$$

$$w_{2} = [b_{\perp}(\frac{t}{2} + \Delta_2) - b_x \Delta_1] n_1 + (\omega_1 \Delta_1 + b_{\perp} \kappa_1^2) n_2 + [\omega_1(\frac{t}{2} + \Delta_2) + b_x \kappa_2^2] n_3,$$

and

$$w_{3} = [b_x(\frac{t}{2} - \Delta_2) + b_{\perp}(\frac{s}{2} - \Delta_1)] n_1 - [\omega_1(\frac{t}{2} - \Delta_2) + b_{\perp} \kappa_3^2] n_2 + [\omega_1(\frac{s}{2} - \Delta_1) - b_x \kappa_3^2] n_3.$$

On the one hand, for $R_0 = 0$, substitution of the values of the deformation modes of a uniform distortion field allows us to deduce that $\mathbf{n}_i \cdot \nabla w = 0$, $i = 1, 2, 3$. Therefore, $\mathbf{n}$ provides a foliation of hyperbolic space by parallel helices. On the other hand, for $R_0 < 0$, we still have that $w_{1} = 0$ and, therefore, $w$ is parallel transported along the integral curves of $\mathbf{n}$. On the other hand, in general $w_{2}$ and $w_{3}$ do not vanish, implying that $\mathbf{n}$ provides a foliation of hyperbolic space by helices which are not necessarily parallel. In a hyperbolic space, we need to distinguish between three types of helices. First notice that a curve with zero torsion is necessarily contained in a totally geodesic surface, i.e., locally the surface is a copy of a hyperbolic plane of curvature $R_0$. There are three types of planes curves with constant curvature $b > 0$: circles if $b \in (\sqrt{-R_0}, \infty)$, horocycles if $b = \sqrt{-R_0}$, and hypercycles if $b \in (0, \sqrt{-R_0})$. Therefore, depending on the values of the bend $b$, we have three families of helices in hyperbolic geometry.

6.1 Uniform distortion fields with vanishing biaxial splay

$$(\Delta)^2 = (\Delta_1)^2 + (\Delta_2)^2 = 0$$

First, assume we have $b_{\perp} = b_x = 0$. Then, from the equations for $R_{1212}$ and $R_{1213}$, it follows that $R_0 = \frac{1}{4}(t^2 - s^2)$ and $st = 0$. Consequently, $s = 0$ or $t = 0$ and we finally conclude

$$\Delta = 0, b = 0 \Rightarrow \begin{cases} s = 0 \text{ and } t = \pm 2\sqrt{-R_0} & \text{if } R_0 > 0 \\ t = 0 \text{ and } s = \pm 2\sqrt{-R_0} & \text{if } R_0 \leq 0. \end{cases}$$

In particular, in Euclidean space, $\Delta = 0$ and $b = 0$ imply that the director field is constant: $\mathbf{d} n \equiv 0$.

Now, assume that $\Delta = 0$ but $b \neq 0$. From $R_{1223} = 0$ and $R_{1323} = 0$, we necessarily have $t = 0$. From Eqs. (27) and (28) it follows

$$\kappa_2^1 = \frac{b_x}{b^2} \left( R_0 + \frac{s^2}{4} \right) \text{ and } \kappa_3^2 = \frac{b_{\perp}}{b^2} \left( R_0 + \frac{s^2}{4} \right).$$

Substituting the expressions for $\kappa_2^1$, $\kappa_3^2$ in the equation for $R_{2323}$ gives

$$R_0 = -\frac{s^2}{4} - (R_0 + \frac{s^2}{4})^2 \frac{b_{\perp}^2 + b_x^2}{b^4} \Rightarrow \frac{1}{b^2} \left( R_0 + \frac{s^2}{4} \right) \left( b_x^2 + R_0 + \frac{s^2}{4} \right) = 0.$$
Therefore, \( s^2 = -4R_0 \) or \( s^2 = -4b^2 - 4R_0 \).

On the one hand, we see that if \( R_0 \geq 0 \), then there exists no solution with \( b \neq 0 \). On the other hand, if \( R_0 < 0 \), we could equally have either \( s^2 = -4R_0 \) or \( s^2 = -4b^2 - 4R_0 \) (there is is no sign obstruction for \( R_0 < 0 \)). However, only \( s^2 = -4b^2 - 4R_0 \) is allowed. Indeed, if it were \( s^2 = -R_0 \), then substituting the expressions for \( \kappa_1 \) and \( \kappa_2 \) above in the equations for \( R_{1212}, R_{1313} \) and summing them would give

\[
2R_0 = -b^2 - \frac{s^2}{2} + R_0 \Rightarrow R_0 = -b^2 - \frac{s^2}{4} = -\frac{(-4R_0)}{4} \Rightarrow b^2 = 0. \tag{32}
\]

This contradicts the assumption that \( b \neq 0 \). Finally, we conclude that

\[
\Delta = 0, b \neq 0 \Rightarrow \begin{cases} \text{solution} & \text{if } R_0 > 0 \\ t = 0 \text{ and } s^2 + 4b^2 = -4R_0 & \text{if } R_0 \leq 0 \end{cases}. \tag{33}
\]

Notice that in the case \( R_0 < 0 \), such as in hyperbolic space, the configuration with \( \Delta = 0 \) and \( t = 0 \) becomes the trivial director field in Euclidean space in the limit \( R_0 \to 0^- \).

### 6.2 Uniform distortion fields with non-vanishing biaxial splay

\((\Delta)^2 = (\Delta_1)^2 + (\Delta_2)^2 > 0\)

If all deformation modes are constant, it follows from Eqs. (20), (21), and (23) that \( \kappa_2, \kappa_3, \) and \( \omega_1 \) are also constant and equal to

\[
\kappa_2^1 = \frac{b_x \Delta_1 + b_x \Delta_2}{2\Delta^2}, \quad \kappa_3^3 = -\frac{b_x \Delta_2 - b_x \Delta_1}{2\Delta^2}, \quad \text{and} \quad \omega_1 = -\frac{tb^2}{8\Delta^2} - \frac{(JDb \cdot b)}{4\Delta^2}. \tag{34}
\]

Now, substituting \( \kappa_2^1 \) and \( \kappa_3^3 \) in Eq. (20), implies that the splay is given by

\[
s = -\frac{(Db \cdot b)}{2\Delta^2}. \tag{35}
\]

In addition, substituting \( \kappa_2, \kappa_3, \) and \( \omega_1 \) in Eqs. (21), (25), and \( R_{2323} \) from Eq. (19), gives

\[
2R_0 = -b^2 - \frac{s^2}{2} + \frac{t^2}{2} - 2\Delta^2 + t\frac{(b_x^2 - b_y^2)\Delta_2 + 2b_x b_y \Delta_1}{2\Delta^2}, \tag{36}
\]

\[
0 = -st - t\frac{(b_x^2 - b_y^2)\Delta_1 + 2b_x b_y \Delta_2}{2\Delta^2}, \tag{37}
\]

and

\[
R_0 = -\frac{s^2}{4} - \frac{t^2}{4} + \Delta^2 - \frac{t^2b^2}{8\Delta^2} + t\frac{(b_x^2 - b_y^2)\Delta_2 + 2b_x b_y \Delta_1}{4\Delta^2}. \tag{38}
\]

Notice that from the expression we got for the splay in Eq. (35), it follows that Eq. (37) is redundant. Subtracting Eq. (30) from twice the last equation above allows us to conclude that

\[
0 = \left(1 + \frac{b^2}{4\Delta^2}\right)(t^2 - 4\Delta^2) \Rightarrow t = \pm 2\Delta. \tag{39}
\]
Remark 1 The equations for $R_{2312}$ and $R_{2313}$ in (19) provide no further constraints. In fact, substituting $\kappa_1$, $\kappa_2$, and $\omega_1$ in $R_{2312}$ and in $R_{2313}$ respectively gives

$$[1 + \frac{b^2}{4\Delta^2}][1 - \frac{t^2}{4\Delta^2}][b_{\times} \Delta_1 - b_{\perp} \Delta_2] = 0 \quad \text{and} \quad [1 + \frac{b^2}{4\Delta^2}][1 - \frac{t^2}{4\Delta^2}][b_{\perp} \Delta_1 + b_{\times} \Delta_2] = 0.$$  
(40)

Now, taking into account that $t = \pm 2\Delta$, which is obtained from $R_{2323}$, the two equations above vanish identically.

Let us write $t = 2\delta \Delta$, $\delta = \pm 1$, and substitute for $t$ and $s$ in Eq. (36). Thus,

$$2R_0 = -b^2 - \frac{(Db, b)^2}{8\Delta^4} + \delta \frac{(JDb, b)}{\Delta},$$  
(41)

from which we find that

$$2R_0 \Delta + \frac{(Db, b)^2}{8\Delta^3} + b^2 \Delta + \delta (JDb, b) = 0.$$  
(42)

Now, from the Cauchy-Schwarz inequality, it follows that

$$|(JDb, b)| \leq \|JDb\| \|b\| \leq b^2 \Delta \Rightarrow 0 \leq b^2 \Delta + \delta (JDb, b).$$

We immediately have the following conclusions:

(a) If $R_0 > 0$, then Eq. (42) is a sum of non-negative numbers. However, $R_0 \Delta > 0$ and, consequently, there must be no uniform director field with $\Delta > 0$ on a space of constant positive curvature, such as the 3-sphere.

(b) If $R_0 = 0$, then we must have $(Db, b) = 0$ and also $b^2 \Delta + \delta (JDb, b) = 0$. It follows that in a space of vanishing curvature, such as the Euclidean space, the splay $s$ must vanish and the bend vector $b$ bisects the principal directions of the biaxial splay, i.e., $\phi = \frac{(2k + 1)\pi}{4}$, $k \in \{0, 1, 2, 3\}$, where $k = 0$ or $k = 2$ if $t = 2\Delta$ and $k = 1, 3$ if $t = -2\Delta$.

It remains to further analyze uniform distortion director fields in hyperbolic geometry, i.e., $R_0 < 0$. Seeing Eq. (36) as a quadratic polynomial in $t$, its discriminant is

$$\text{disc.} = 4\Delta^2 \left(1 + \frac{b^2}{4\Delta^2}\right)^2 + 4R_0.$$  
(43)

Thus, the requirement that $t \in \mathbb{R}$ demands $\text{disc.} \geq 0$, which implies

$$1 + \frac{b^2}{4\Delta^2} \geq \sqrt{-\frac{R_0}{\Delta^2}}.$$  
(44)

Note that if we choose $\Delta \geq \sqrt{-R_0}$, then the above inequality imposes no restriction on the values of the bend $b$. 

7 Discussion

In the intrinsic approach materials are described only through quantities available to an observer residing within the material [14]. These quantities may be associated with some non-trivial locally preferred reference values that manifest the constituents’ shape and mutual interactions. We show that a collection of five such scalar (and pseudoscalar) fields suffice to characterize the director texture. These fields can be chosen to be the bend, splay, twist, saddle-splay and the relative orientation between the principal biaxial splay direction and the bend direction.

In two dimensions only two such fields suffice to uniquely prescribe a director field. The compatibility conditions in the two dimensional case amount to a single first order differential relation [16]. In three dimensions we obtained six differential relations. Three of first order, and three of second order. Thus the system is of at most second order; it is presently unknown if the system can be further reduced to yield a purely first order system or not. Understanding the degree and structure of the compatibility conditions is important not for taxonomical reasons, but rather as these determine the super-extensive rate at which energy accumulates when a frustrated phase grows in size [14].

Though more abstract than an approach uniquely based on vector calculus, the method of moving frames allows us to obtain manageable equations and to investigate director fields in both Euclidean and curved Riemannian spaces in an equal foot. In particular it allows us to find all uniform distortion fields for all isotropic homogeneous Riemannian manifolds.

Considering the five characterizing fields as given quantities and solving for the corresponding director field may also be carried out as long as the compatibility conditions are satisfied. The compatibility conditions, in turn, can be interpreted both in terms of a Lagrangian frame, where the fields are given in terms of the material coordinates, and an Eulerian frame in which the field are given explicitly in terms of the embedding space coordinates. It is important to note that the information contained in the two viewpoints is not equivalent. The Lagrangian description, which is more natural from a material perspective, may be used to integrate the director field from knowledge about its local behavior. Such an approach is particularly useful for solving inverse design problems [11], and for constructing new optimal textures. The Eulerian approach is somewhat less natural as it assumes that the fields are given in terms of the stationary embedding space coordinates, yet the director is unknown. For the two dimensional case the Eulerian approach allowed obtaining the director field directly from the gradients of the bend and splay functions, provided that the magnitude of these gradients was large enough [16]. The full analysis of the Eulerian three dimensional case remains outside the scope of the present work.

When finishing this manuscript, it came to our attention that a similar approach to the one presented here was recently pursued by Pollard and Alexander [18]. There, the authors also develop the idea of using the moving frame method to obtain the compatibility conditions for the deformation modes of a
director field expressed in terms of the curvature tensor of the ambient manifold. In addition, they consider methods to reconstruct a 3D director field according to the data which is prescribed. Finally, they discuss the examples constructed by Sadoc et al. in the language of moving frames by exploiting the fact that there exists an underlying Lie algebra structure associated with uniform distortion fields.

While the choice of applications differs between our work and that of Pollard and Alexander, the main guiding principles and calculations of the components of the Riemann curvature tensor are similar, save two differences. First, Pollard and Alexander retain nine variables in their equations, whereas we choose to reduce these to only five. Second, they assume the satisfaction of the first Binachi identity and thus obtain only six equations from the structure equations, instead of the system of nine equations obtained here in Eq. (19). Thus, while in both cases the compatibility conditions consist of six differential relations, the obtained equations are somewhat different.
