AN IMPROVED UPPER BOUND ON SELF-DUAL CODES OVER FINITE FIELDS $GF(11), GF(19),$ AND $GF(23)$

WHAN-HYUK CHOI∗ AND JON-LARK KIM∗∗†

Abstract. This paper gives new methods of constructing symmetric self-dual codes over a finite field $GF(q)$ where $q$ is a power of an odd prime. These methods are motivated by the well-known Pless symmetry codes and quadratic double circulant codes. Using these methods, we construct an amount of symmetric self-dual codes over $GF(11)$, $GF(19)$, and $GF(23)$ of every length less than 42. We also find 153 new self-dual codes up to equivalence: they are $[32, 16, 12]$, $[36, 18, 13]$, and $[40, 20, 14]$ codes over $GF(11)$, $[36, 18, 14]$ and $[40, 20, 15]$ codes over $GF(19)$, and $[32, 16, 12]$, $[36, 18, 14]$, and $[40, 20, 15]$ codes over $GF(23)$. They all have new parameters with respect to self-dual codes. Consequently, we improve bounds on the highest minimum distance of self-dual codes, which have not been significantly updated for almost two decades.

1. Introduction

Coding theory, one of the most interesting areas of applied mathematics, was born almost simultaneously with the invention of modern computers - the beginning of the error-correcting code came from Claude Shannon’s paper “A mathematical theory of communication” in 1948, and Richard W. Hamming’s paper “Error detecting and error correcting codes” in 1950. These days, binary and nonbinary codes such as $q$-ary Hamming codes, the binary and ternary Golay codes, and $q$-ary Reed-Solomon codes are used in internet communication, GPS signals, mobile phones, and computer devices. It is well known that error-correcting codes are closely related to cryptography [6], [23]. Moreover, researchers have recently started investigating the relation between error-correcting codes and deep learning. [3], [18].

On the other hand, self-dual codes have been the subject of much interest and are regarded as one of the most important classes of error-correcting codes. This is because of both theoretical reason and connections to various fields of mathematics such as designs [16], lattices [2], sphere-packings [8], and modular forms [4].

Among various research topics of self-dual codes, it has attained an extensive research effort to find a best code; here, best refers to having the greatest error correction ability as possible. The error correction capability of a code depends on the minimum distance. Thus, it is crucial to find a method to construct codes having the highest minimum distance. To this end, various techniques are studied involving circulant and bordered circulant matrices [5], [14] and quadratic double circulant matrices [12]. Recently, families of codes over rings have been used to construct self-dual codes over finite fields [9], [19].

Despite these efforts, there remain many codes to be found, missed by previous construction methods due to computation complexity. In particular, we hardly know about the optimal minimum distances of self-dual codes over finite fields of order $\geq 5$ and of lengths $\geq 22$. In this case, only the possible bounds of highest minimum distances are known so far. For example, in the case of codes over $GF(11)$, the bounds of highest minimum distances of lengths $\leq 40$ are known, as we can see in Table 4. Moreover, there is no information about the lower bound of the self-dual code of length 28.

In 1972, Vera Pless introduced Pless symmetry codes, as a generalization of ternary extended Golay code [21], [22]. Using this class of codes, Pless obtained many new optimal self-dual codes over $GF(3)$. Three decades later, Gaborit presented a generalization of Pless symmetry codes to different fields, quadratic double circulant codes [12]. He also found many new self-dual codes over $GF(4)$, $GF(5)$, $GF(7)$, and $GF(9)$. We want to remark two things: one is that these two methods used particular symmetric matrices to construct self-dual codes. The other is that these methods have a limitation of lengths; the possible lengths of codes are limited to $n+1$ or $n-1$ where $n$ is a power of an odd prime. Thus, there needs a new method to fill the gap between these lengths. These are the main motivation of this paper.

In [7], we introduced a method of symmetric building-up construction. If a self-dual code has a symmetric generator matrix, it is called a symmetric self-dual code. This method was to construct symmetric self-dual codes over $GF(q)$ for $q \equiv 1 \pmod{4}$. In [7], we showed that this method provides an efficient way to construct all symmetric self-dual codes over $GF(q)$, increasing lengths by two. Stimulated by this result, we have struggled to find a method when $q \equiv 3 \pmod{4}$. However, it is not easy to generalize the method in [7]. In [7], the square root of -1 plays the key role, but unfortunately, it is well-known that the square root of -1 does not exist in $GF(q)$ for $q \equiv 3 \pmod{4}$.

1. Construction A

Let $(I_n \mid A)$ be a generator matrix of a symmetric self-dual code of length $2n$ over $GF(q)$ and assume that $(x_n, y_n)$ is a codeword satisfying $x_n \cdot y_n = 0$ and $x_n \cdot x_n = k$ such that $-1 \pm k$ are squares in $GF(q)$. And let $B = \begin{pmatrix} \alpha x_n + \beta y_n \\ \beta x_n - \alpha y_n \end{pmatrix}$

where $\alpha^2 + \beta^2 = -1$, $E = \frac{1}{s} (s x_n^T x_n + t y_n^T y_n - x_n^T y_n - y_n^T x_n)$ where $s^2 = -1 + k$
and $t^2 = -1 - k$ and let $D = -\frac{1}{k}B(A + E_1)B^TBB^T$. Then
\[
\begin{pmatrix}
I_2 & O & D & B \\
O & I_n & B^T & A + E
\end{pmatrix}
\]
is a generator matrix of symmetric self-dual code of length $2n + 4$.

2. Construction B

Let $(I_n | A)$ be a generator matrix of a symmetric self-dual code of length $2n$ over $GF(q)$, let $P = \begin{pmatrix} \alpha & \beta \\ \beta & -\alpha \end{pmatrix}$ be a $2 \times 2$ matrix such that $P^2 = -I_2$, and let a matrix $M = \begin{pmatrix} x \\ \beta^{-1}x(A - \alpha I) \end{pmatrix}$ for a vector $x$ in $GF(q)^n$. Assume that $H$ is a $2 \times 2$ symmetric matrix satisfying $(H + P)(H - P) = -MM^T$ and $H - P$ is non-singular. Then
\[
\begin{pmatrix}
I_2 & O & H & M \\
O & I_n & M^T & A + M^T(H - P)^{-1}M
\end{pmatrix}
\]
is a generator matrix of symmetric self-dual code of length $2n + 4$.

Using these methods, we obtain many new self-dual codes. Consequently, we improve the bounds on the minimum distances of self-dual codes. We revised these results in Table 1. In Table 1, new parameters are written in bold. Throughout this paper, $d_{sym}$ denotes the highest minimum distance of a symmetric self-dual code over $GF(p)$ and $d_{sd}$ denotes the previously best-known minimum distance of self-dual codes over $GF(p)$. More precisely, we give new self-dual codes with highest minimum weights: they are $[32, 16, 12]$, $[36, 18, 13]$, and $[40, 20, 14]$ codes over $GF(11)$, $[36, 18, 14]$ and $[40, 20, 15]$ codes over $GF(19)$, and $[32, 16, 12]$, $[36, 18, 14]$, and $[40, 20, 15]$ codes over $GF(23)$. We also provide numbers of new symmetric self-dual codes, up to equivalence, in Table 2.

2. Preliminaries

Let n be a natural number, and GF(q) be the finite field of order q where q is a prime power. A linear code C of length n and dimension k over GF(q) is a k-dimensional subspace of GF(q)^n. An element of C is called a codeword. A generator matrix of C is a matrix whose rows form a basis of C; therefore, a generator matrix of a linear code C of length n and dimension k over GF(q) is a k × n matrix over GF(q). For vectors x = (x_i) and y = (y_i) in GF(q)^n, we define the inner product x · y = \sum_{i=1}^{n} x_i y_i. If vectors are identified with row matrices, the inner product can also be written as a matrix multiplication x · y = xy^T, where y^T denotes the transpose of y. For a linear code C, dual code C^⊥ is defined as a set of orthogonal vectors of C, i.e.,

C^⊥ = \{ x \in GF(q)^n \mid x · c = 0 \text{ for all } c \in C \}.

A linear code C is called self-dual if C = C^⊥ and self-orthogonal if C ⊆ C^⊥.

The weight of a codeword c is the number of non-zero symbols in the codeword and denoted by wt(c). The Hamming distance between two codewords x and y is defined by d(x, y) =
wt(x − y). The minimum distance of C, denoted by d(C), is the smallest Hamming distance between distinct codewords in C. The minimum distance determines the error-capability; thus, the minimum distance is regarded as the most important parameter of a code. If a code has the minimum distance that meets some upper bounds, it is called an optimal code. It is well-known [17, chapter 2.4] that a linear code of length n and dimension k satisfy the Singleton bound,

\[ d(C) \leq n - k + 1. \]

A code that achieves the equality in the Singleton bound is called a maximum distance separable (MDS) code. Obviously, a self-dual code of length 2n over GF(q) is MDS if the minimum distance equals n + 1. Although every MDS code is optimal, the MDS conjecture shows that there exists an MDS self-dual code of length 2n over GF(q) only if 2n ≤ q + 1 [1]. Therefore, if 2n > q + 1, the minimum distance of self-dual code of length 2n over GF(q) is upper bounded by n.

Let \( I_n \) be a identity matrix of order n and let \( A^T \) denote the transpose of a matrix A. It is well-known that a self-dual code \( C \) of length 2n over GF(q) is equivalent to a code with a standard generator matrix

\[
\begin{pmatrix}
I_n & A
\end{pmatrix},
\]

where A is a \( n \times n \) matrix satisfying \( AA^T = -I_n \).

A matrix A is called symmetric if \( A^T = A \). If a self-dual code of length 2n over GF(q) has a standard generator matrix \( G = (I_n \mid A) \) where A is symmetric, it is called a symmetric self-dual code. Since the class of symmetric self-dual codes is a subclass of general self-dual codes, the bound on minimum distances of symmetric self-dual code may be different from that of self-dual codes. However, if a symmetric self-dual code has the same parameter as an optimal (resp. MDS) self-dual code, it is called a optimal (resp. MDS) symmetric self-dual code. If the minimum distance of a symmetric self-dual code meets the best known minimum distance of a self-dual code, it is called a best symmetric self-dual code.

In [21], Pless introduced Pless symmetry codes as a generalization of ternary extended Golay code and their construction method. As a result, Pless obtained optimal self-dual codes of length 24, 36, 48, and 60 over GF(3). Later in [12], Gaborit presented a generalization of Pless symmetry codes to different fields, quadratic double circulant codes and their construction method. Gaborit obtained many new self-dual codes over GF(4), GF(5), GF(7) and GF(9), and improved the bounds on the highest minimum distances. To use as a reference, we additionally obtain quadratic double circulant codes of lengths ≤ 40 over various finite fields, following the same construction method in [12]. We present these codes in Table 3, following the same notations in [12].

We remark that a self-dual code in the class of Pless symmetry codes or quadratic double circulant codes is equivalent to a symmetric self-dual code. In general, a pure double circulant self-dual code is equivalent to a symmetric self-dual code, and a bordered double circulant self-dual code is equivalent to a symmetric self-dual code under a certain condition. We discuss the equivalence between these codes in the next.
Let $S_n$ be a symmetric group of order $n$ and $D^n$ be the set of diagonal matrices over $GF(q)$ of order $n$,

$$D^n = \{ \text{diag}(\gamma_i) \mid \gamma_i \in GF(q), \gamma_i^2 = 1 \}.$$  

The group of all $\gamma$-monomial transformations of length $n$, $\mathcal{M}^n$ is defined by

$$\mathcal{M}^n = \{ p_\sigma \gamma \mid \gamma \in D^n, \sigma \in S_n \}$$  

where $p_\sigma$ is the permutation matrix corresponding $\sigma \in S_n$. We note that a $\gamma$-monomial transformation preserves the self-orthogonality of a code (see [17, Thm 1.7.6]). Let $C_\tau = \{ c \in \mathcal{C} \}$ for an element $\tau \in \mathcal{M}^n$ and a code $C$ of length $n$. If there exists an element $\mu \in \mathcal{M}^n$ such that $C_\mu = C'_\mu$ for two distinct codes $C$ and $C'$, then $C$ and $C'$ are called equivalent and denoted by $C \simeq C'$.

**Proposition 2.1.** Let $G = (I_n \mid A)$ and $G' = (I_n \mid B)$ be generator matrices of self-dual codes $C$ and $C'$ of length $2n$, respectively. If $A = \mu_1 B \mu_2$ for some $\mu_1, \mu_2 \in \mathcal{M}^n$, then $C$ and $C'$ are equivalent.

**Proof.** For $\mu = \begin{pmatrix} \mu_1^{-1} & O \\ O & \mu_2 \end{pmatrix} \in \mathcal{M}^{2n}$,

$$(I_n \mid A) = (I_n \mid \mu_1 B \mu_2) = (\mu_1^{-1} \mid B \mu_2) = (I_n \mid B) \mu.$$  

Thus, $C$ and $C'$ are equivalent.  

**Corollary 2.2.** Let $I_n$ be the identity matrix of order $n$, $A$ is an $n \times n$ circulant matrix, $B$ is an $(n - 1) \times (n - 1)$ circulant matrix. Then,

(i) a pure double circulant code over $GF(q)$ with a generator matrix of the form

$$(I_n \mid A)$$  

is equivalent to a code with symmetric generator matrix, and

(ii) a bordered double circulant code over $GF(q)$ with a generator matrix of the form

$$\begin{pmatrix} \alpha & \beta \cdots \beta \\ I_n & \gamma \beta \\ \gamma \beta & A \end{pmatrix},$$

**Table 3.** New quadratic double circulant codes over $GF(q)$ obtained using methods in [12]
where $\alpha$ and $\beta$ are elements in $GF(q)$ and $\gamma^2 = 1$, is equivalent to a code with symmetric generator matrix.

Proof. It is clear that a column reversed matrix of a circulant matrix $A$ is symmetric. Thus, the corollary follows directly from Proposition 2.1. $\blacksquare$

Let $S_{-1}$ be a set of solutions of the equation $x^2 + y^2 = 1$ over $GF(q)$. Then the cardinality of $S_{-1}$ for an odd prime $q$ is obtained in the next proposition.

**Proposition 2.3** ([20]). Let $GF(q)$ be a finite field of order $q$ such that $q$ is a power of an odd prime. The cardinality of the set

$$S_{-1} = \{(x, y) \in GF(q)^2 \mid x^2 + y^2 + 1 = 0\}$$

is given by

$$|S_{-1}| = q - (-1)^{(q-1)/2} = \begin{cases} q - 1, & \text{if } q \equiv 1 \pmod{4}, \\ q + 1, & \text{if } q \equiv 3 \pmod{4}. \end{cases}$$

Similarly, we define a set $S_{-I_2}$ of $2 \times 2$ symmetric matrices over $GF(q)$ satisfying the matrix equation $X^2 + I_2 = 0$. We also obtain the cardinality of $S_{-I_2}$ in the following corollary.

**Corollary 2.4.** Let $S_{-I_2}$ be a set of $2 \times 2$ symmetric matrices over $GF(q)$ where $q$ is a power of odd prime such that

$$S_{-I_2} = \{P \in K \mid P^2 = -I_2\}.$$

Then, the cardinality of $S_{-I_2}$ is given by

$$|S_{-I_2}| = q - (-1)^{(q-1)/2} = \begin{cases} q - 1, & \text{if } q \equiv 1 \pmod{4}, \\ q + 1, & \text{if } q \equiv 3 \pmod{4}. \end{cases}$$

Proof. The condition $P^2 = -I_2$ implies that $P^{-1} = -P$. Since we assumed that $P$ is symmetric, it is easy to show that matrix $P$ is in the form $\begin{pmatrix} \alpha & \beta \\ \beta & -\alpha \end{pmatrix}$, where $(\alpha, \beta)$ is a solution of the equation $x^2 + y^2 = 1$. Thus, the result follows with Proposition 2.3. $\blacksquare$

3. Construction method of symmetric self-dual codes

It is well-known that a self-dual over $GF(q)$ of length $n$ for $q \equiv 1 \pmod{4}$ exists if and only if $n \equiv 0 \pmod{2}$, and a self-dual over $GF(q)$ of length $n$ for $q \equiv 3 \pmod{4}$ exists if and only if $n \equiv 0 \pmod{4}$ [17, Theorem 9.1.3]. In [7], we have introduced a construction method for symmetric self-dual codes over $GF(q)$ for $q \equiv 1 \pmod{4}$. In this section, we introduce two new construction methods for symmetric self-dual codes over $GF(q)$ for $q \equiv 3 \pmod{4}$. These methods generate symmetric self-dual codes of lengths increased by four.
Theorem 3.1 (Construction method 1). Let $G = (I_n \mid A)$ be a generator matrix of symmetric self-dual code $C$ of length $2n$ over $GF(q)$ for an odd prime power $q$. Assume that there exists a codeword $(x_n, y_n)$ in $C$ satisfying $x_n \cdot y_n = 0$, $x_n \cdot x_n = k(\neq 0)$, and $-1 \pm k$ are squares in $GF(q)$. Then, take an element $(\alpha, \beta)$ in $S_{-1}$ and let

$$E = \frac{1}{k}(sx_n^T x_n + ty_n^T y_n - x_n^T y_n - y_n^T x_n)$$

where $s^2 = -1 + k$ and $t^2 = -1 - k$, and let

$$D = -\frac{1}{k}B(A + E_1)B^T B B^T.$$}

Then

$$G_1 = (I_{n+2} \mid A_1) = \begin{pmatrix} I_2 & O \mid D & B \\ O & I_n \mid B^T & A + E \end{pmatrix}$$

is a generator matrix of a symmetric self-dual code of length $2n + 4$.

The proof of Theorem 3.1 is given in Appendix for the brevity. We need following two lemmas to introduce the second construction method.

Lemma 3.2. Let $P = \begin{pmatrix} \alpha & \beta \\ \beta & -\alpha \end{pmatrix}$ be an element in $S_{-I_2}$ and $A$ be a symmetric matrix satisfying $A^2 = -I_n$. For a vector $x$ in $GF(q)^n$, if we let the matrix $M = \begin{pmatrix} x \\ \beta^{-1}x(A - \alpha I) \end{pmatrix}$, then

$$MA = PM.$$}

Proof. Let $y = \beta^{-1}x(A - \alpha I)$. Then $\beta y = xA - \alpha x$ and this implies that $xA = \alpha x + \beta y$. On the other hand,

$$y(A + \alpha I) = \beta^{-1}x(A - \alpha I)(A + \alpha I)$$

$$= \beta^{-1}x(A^2 - \alpha^2 I)$$

$$= \beta^{-1}x(-1 - \alpha^2 I)$$

$$= \beta x,$$

since $\alpha^2 + \beta^2 = -1$ and this implied that $yA = \beta x - \alpha y$. Therefore,

$$MA = \begin{pmatrix} xA \\ yA \end{pmatrix} = \begin{pmatrix} \alpha x + \beta y \\ \beta x - \alpha y \end{pmatrix} = PM.$$}

\[\blacksquare\]

Lemma 3.3. Assume that $n \times n$ matrices $H$ and $P$ are symmetric. If $(H + P)(H - P)$ is also symmetric, then $HP = PH$.

Proof. By the assumption, we have

$$(H - P)(H + P) = ((H - P)(H + P))^T$$

$$= (H + P)^T (H - P)^T$$

$$= (H + P)(H - P),$$

and by equating both sides, the result follows. \[\blacksquare\]
Now, we give the next theorem, which introduces the second construction method.

**Theorem 3.4** (Construction 2). Let \( G = (I_n | A) \) be a generator matrix of a symmetric self-dual code \( C \) of length \( 2n \) over \( GF(p) \) for an odd prime \( p \) and let \( S - I_2 \) be the set defined in proposition 2.4 and let \( P = \left( \begin{array}{cc} \alpha & \beta \\ \beta & -\alpha \end{array} \right) \) be an element in \( S - I_2 \). Let \( M = \left( \beta^{-1} \mathbf{x}(A - \alpha I) \right) \) for a vector \( \mathbf{x} \) in \( GF(q)^n \). Assume that \( H \) is a \( 2 \times 2 \) symmetric matrix satisfying the equation

\[
(H + P)(H - P) = -MM^T,
\]

and \( H - P \) is non-singular. Then

\[
G_2 = (I_{n+2} | A_2) = \left( \begin{array}{c|c} I_2 & O \\ \hline O & I_n \end{array} \right) \begin{pmatrix} H & M \\ M^T & A + M^T (H - P)^{-1} M \end{pmatrix}
\]

is a generator matrix of a symmetric self-dual code of length \( 2n + 4 \).

The proof of Theorem 3.4 is also given in Appendix. We illustrate these new construction methods in the following examples.

**Example 3.5.** Let \( C_{8}^{8} \) be a symmetric optimal self-dual [8,4,3] code over \( GF(3) \) with generator matrix

\[
G = \begin{pmatrix} 1 & 0 & 0 & 0 & 1 & 0 & 0 & 1 \\ 0 & 1 & 0 & 0 & 1 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 & 2 & 1 \\ 0 & 0 & 0 & 1 & 0 & 0 & 1 & 1 \\ 1 & 1 & 0 & 0 & 1 & 1 & 0 & 0 \\ 1 & 0 & 1 & 0 & 0 & 0 & 2 & 1 \\ 0 & 1 & 0 & 0 & 0 & 1 & 0 & 1 \\ 0 & 0 & 1 & 0 & 0 & 1 & 0 & 2 \end{pmatrix}.
\]

To apply construction method in Theorem 3.1, take \( (\alpha, \beta) = (1, 1) \) and the codeword \( (\mathbf{x}, \mathbf{y}) = (2, 1, 1, 1, 0, 1, 0, 2) \) in \( C_{8}^{8} \). Then, we compute that

\[
B = \begin{pmatrix} 2 & 2 & 1 & 0 \\ 2 & 0 & 1 & 2 \end{pmatrix}, \ D = \begin{pmatrix} 2 & 1 \\ 1 & 2 \end{pmatrix}, \ \text{and} \ E = \begin{pmatrix} 0 & 1 & 0 & 2 \\ 1 & 2 & 2 & 2 \\ 0 & 2 & 0 & 1 \\ 2 & 2 & 1 & 0 \end{pmatrix}.
\]

Finally, we find an optimal symmetric self-dual [12,6,6] over \( GF(3) \) code with generator matrix

\[
G_1 = \begin{pmatrix} 1 & 0 & 0 & 0 & 2 & 1 & 2 & 2 & 1 & 0 \\ 0 & 1 & 0 & 0 & 0 & 1 & 2 & 6 & 0 & 12 \\ 0 & 0 & 1 & 0 & 0 & 2 & 2 & 1 & 0 & 2 \\ 0 & 0 & 0 & 0 & 0 & 1 & 0 & 2 & 2 & 2 \end{pmatrix}.
\]

**Example 3.6.** Let \( C_{19}^{8} \) be a symmetric self-dual [8,4,3] code over \( GF(19) \) with generator matrix

\[
G = \begin{pmatrix} 1 & 0 & 0 & 0 & 1 & 8 & 13 & 0 \\ 0 & 1 & 0 & 0 & 1 & 3 & 1 & 0 \\ 0 & 0 & 1 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 & 1 & 6 \\ 0 & 0 & 0 & 0 & 0 & 1 & 8 & 9 \end{pmatrix}.
\]

To apply construction method in Theorem 3.1, take \( (\alpha, \beta) = (18, 6) \) and \( \mathbf{x} = (1, 6, 9, 6) \) in \( GF(19)^4 \). Then,

\[
M = \begin{pmatrix} 1 & 6 & 9 & 6 \\ 13 & 1 & 9 & 6 \end{pmatrix} \ \text{and} \ H = \begin{pmatrix} 9 & 12 \\ 12 & 13 \end{pmatrix},
\]

and finally, we obtain a symmetric [12,6,7] self-dual code over \( GF(19) \) of length 12 with generator matrix

\[
G_2 = \begin{pmatrix} 1 & 0 & 0 & 0 & 0 & 2 & 1 & 2 & 1 & 0 \\ 0 & 1 & 0 & 0 & 0 & 1 & 2 & 6 & 12 & 1 \end{pmatrix}.
\]
4. Computational results

In this section, we discuss computational results of symmetric self-dual codes over $GF(q)$ for $q = 11, 19, 23$. Using construction methods in Theorem 3.1 and 3.4, we obtain many new symmetric self-dual codes of lengths $n \leq 40$ which meet the best known bounds on minimum distances of self-dual codes.

We find best symmetric self-dual codes of length $n$ over $GF(q)$ for $q = 11, 19, 23$ and $n \leq 40$ except for the case that $q = 11$ with $n = 16$ or 20, for the case that $q = 19$ with $n = 32$, and for the case that $q = 23$ with $n = 20$ or 24. Moreover, we also find more than 151 self-dual codes with new parameters: 90 inequivalent self-dual codes of length 32, 36 and 40 over $GF(11)$, 5 inequivalent self-dual codes of length 36 and 40 over $GF(19)$ and 56 inequivalent self-dual codes of length 32, 26 and 40 over $GF(23)$. Among them, we introduce five symmetric self-dual codes with their generator matrices in this section.

At the end of this section, we summarize the known bounds on the highest minimum distances of self-dual codes in Table 7.

4.1. Symmetric self-dual codes over $GF(11)$.

**Proposition 4.1.** There exist best symmetric self-dual codes over $GF(11)$ of length $n = 4, 8, 12, 24, 28, 32, 36, 40$. In particular, $[4, 2, 3]_{11}, [8, 4, 5]_{11}$ and $[12, 6, 7]_{11}$ symmetric self-dual codes are MDS. Moreover, $[32, 16, 12]_{11}, [36, 18, 13]_{11}$ and $[40, 20, 14]_{11}$ codes are new.

We give the highest minimum distance $d_{sym}$ of symmetric self-dual codes and the previously best known minimum distance $d_{sd}$ of self-dual codes in Table 4. In this table, new parameters are written in bold. We present three symmetric self-dual codes having new parameters:

- $[32, 16, 12]_{11}$ code with a generator matrix $(I_{16} \mid A_{11}^{32})$ where
  \[
  A_{11}^{32} = \begin{pmatrix}
  6 & 7 & 7 & 1 & 2 & 8 & 5 & 9 & 9 & 8 & 1 & 6 & 4 & 7 & 10 & 6 \\
  7 & 9 & 7 & 8 & 0 & 8 & 4 & 8 & 6 & 10 & 2 & 6 & 9 & 7 & 8 & 10 \\
  7 & 7 & 6 & 0 & 8 & 2 & 4 & 9 & 1 & 6 & 8 & 7 & 6 & 9 & 0 & 4 \\
  1 & 8 & 0 & 7 & 0 & 7 & 10 & 2 & 1 & 9 & 9 & 3 & 2 & 8 & 0 \\
  2 & 0 & 8 & 0 & 10 & 10 & 8 & 10 & 3 & 0 & 10 & 8 & 0 & 8 & 10 \\
  8 & 8 & 2 & 7 & 10 & 10 & 2 & 9 & 7 & 7 & 0 & 6 & 1 & 0 & 3 \\
  5 & 4 & 10 & 8 & 10 & 10 & 8 & 5 & 2 & 5 & 4 & 8 & 3 & 9 \\
  9 & 8 & 2 & 10 & 2 & 7 & 3 & 2 & 8 & 10 & 7 & 8 & 4 & 6 \\
  9 & 6 & 1 & 3 & 9 & 8 & 3 & 0 & 1 & 5 & 10 & 7 & 8 & 10 \\
  8 & 10 & 6 & 9 & 0 & 7 & 5 & 2 & 1 & 9 & 9 & 1 & 19 & 4 & 4 \\
  1 & 2 & 8 & 9 & 10 & 7 & 2 & 8 & 5 & 9 & 3 & 7 & 7 & 2 & 9 & 4 \\
  6 & 6 & 7 & 3 & 8 & 0 & 5 & 10 & 10 & 1 & 7 & 7 & 2 & 6 & 8 & 2 \\
  4 & 9 & 6 & 3 & 0 & 6 & 4 & 7 & 7 & 1 & 7 & 2 & 5 & 7 & 6 \\
  7 & 7 & 9 & 2 & 8 & 1 & 8 & 7 & 9 & 2 & 6 & 4 & 1 & 5 \\
  10 & 8 & 0 & 8 & 10 & 0 & 3 & 4 & 8 & 4 & 9 & 8 & 7 & 1 & 7 & 2 \\
  6 & 10 & 4 & 0 & 0 & 3 & 9 & 6 & 10 & 4 & 4 & 2 & 6 & 5 & 2 & 9
  \end{pmatrix}
There exist best symmetric self-dual codes over $\text{GF}(11)$. Among them, $[36,18,13]_{11}$ code with a generator matrix $A_{11}^{36}$ and $[40,20,14]_{11}$ code with a generator matrix $A_{11}^{40}$ are MDS.

In Table 4, we present two symmetric self-dual codes having new parameters:

<table>

### 5. Conclusions

In this article, we introduced new construction methods of symmetric self-dual codes over finite fields. Then we have constructed many new symmetric self-dual codes, including 153
self-dual codes with new parameters, up to equivalence. This paper contributes in two ways. One is to provide new construction methods of symmetric self-dual codes over $GF(q)$ for the challenging case of $q \equiv 3 \pmod{4}$. The other is to improve bounds on the highest minimum distance of self-dual codes, which have not been significantly updated for almost two decades because of computational complexity. We believe that our methods can produce more results for self-dual codes over larger finite fields and/or of longer lengths.

**Acknowledgment**

The author sincerely thanks Dr. Markus Grassl for his helpful comments which was crucial for the implementation.

**Appendix A. Proof of Theorem 3.1**

*Proof.* It is obvious that the matrix $A_1, A, D,$ and $E$ are symmetric. Thus, we have to show that

*Table 7.* Bounds on the highest minimum distances of self-dual codes over $GF(p)$ for primes $5 \leq p \leq 23$ up to lengths 40. In this table, $^o$ denotes optimal code and $^*$ denotes MDS code.
In other words, we have to show that following three identities are hold:

\[ D^2 + BB^T = -I_2, \quad (3) \]
\[ DB + B(A+E) = O_{2 \times n}, \quad (4) \]
\[ B^T B + (A+E)^2 = -I_n. \quad (5) \]

Firstly, we verify the equality of (3). By the assumptions, we have that \( A^2 = -I_n, \alpha^2 + \beta^2 = -1 \) and \( x_n x_n^T = k \). Since \((x_n, y_n)\) is a codeword of a self-dual code \( \mathcal{C} \), it is also clear that \( x_n x_n^T + y_n y_n^T = 0 \) and \((x_n, y_n^T)\) is a codeword of a self-dual code \( \mathcal{C} \). Thus, \( y_n y_n^T = -k, y_n A = -x_n \) and \( x_n A = y_n \). By direct computations, we obtain that

\[ BAB^T = \begin{pmatrix} \alpha x_n A + \beta y_n A \\ \beta x_n A - \alpha y_n A \end{pmatrix} \begin{pmatrix} \alpha x_n + \beta y_n \\ \beta x_n - \alpha y_n \end{pmatrix}^T 
= \begin{pmatrix} \alpha y_n - \beta x_n \\ \beta y_n + \alpha x_n \end{pmatrix} \begin{pmatrix} \alpha x_n^T + \beta y_n^T \\ \beta x_n^T - \alpha y_n^T \end{pmatrix} 
= \begin{pmatrix} -2k \alpha \beta \\ k^2 - 2k^2 \beta \end{pmatrix}, \]

and

\[ BEB^T = \frac{1}{k} \begin{pmatrix} \alpha x_n + \beta y_n \\ \beta x_n - \alpha y_n \end{pmatrix} \begin{pmatrix} s y_n x_n + t y_n y_n - x_n^T y_n - y_n^T x_n \end{pmatrix} \begin{pmatrix} \alpha x_n + \beta y_n \\ \beta x_n - \alpha y_n \end{pmatrix}^T 
= \frac{1}{k} \begin{pmatrix} k \alpha s x_n - k \alpha y_n - k \beta t y_n + k \beta x_n \end{pmatrix} \begin{pmatrix} \alpha x_n^T + \beta y_n^T \\ \beta x_n^T - \alpha y_n^T \end{pmatrix} 
= \begin{pmatrix} k \alpha^2 s + 2k \alpha \beta + k \beta^2 t \\ k \alpha^2 s + k \beta a^2 - k \alpha \beta t \end{pmatrix} \begin{pmatrix} k \alpha \beta s + k \beta t - k \alpha^2 - k \alpha \beta t \end{pmatrix} 
= \begin{pmatrix} k \alpha^2 s + k \beta^2 t \\ k \alpha^2 s + k \beta a^2 - k \alpha \beta t \end{pmatrix} \begin{pmatrix} k \beta a^2 + k \beta^2 s \end{pmatrix}. \]

Therefore,

\[ B(A+E)B^T = BAB^T + BEB^T = \begin{pmatrix} k \alpha^2 s + k \beta^2 t \\ k \alpha \beta s - k \alpha \beta t \end{pmatrix} \begin{pmatrix} k \alpha \beta s - k \alpha \beta t \\ k \beta a^2 + k \beta^2 s \end{pmatrix}, \]

and

\[ D = -\frac{1}{k^2}(B(A+E)B^T)BB^T 
= -\frac{1}{k} \begin{pmatrix} \alpha^2 s + \beta^2 t \\ \alpha \beta s - \alpha \beta t \end{pmatrix} \begin{pmatrix} \alpha \beta s - \alpha \beta t \\ \alpha^2 t + \beta^2 s \end{pmatrix} BB^T. \]
Since $BB^T = k \begin{pmatrix} \alpha^2 - \beta^2 & 2\alpha\beta \\ 2\alpha\beta & -\alpha^2 + \beta^2 \end{pmatrix}$, we obtain
\[
D = - \begin{pmatrix} \alpha^2 s + \beta^2 t & \alpha\beta s - \alpha\beta t \\ \alpha\beta s - \alpha\beta t & \alpha^2 t + \beta^2 s \end{pmatrix} \begin{pmatrix} \alpha^2 - \beta^2 & 2\alpha\beta \\ 2\alpha\beta & -\alpha^2 + \beta^2 \end{pmatrix} 
\]
\[
= \begin{pmatrix} \alpha^2 s - \beta^2 t & \alpha\beta(s + t) \\ \alpha\beta(s + t) & -\alpha^2 t + \beta^2 s \end{pmatrix}.
\]

Hence,
\[
D^2 + BB^T = \begin{pmatrix} \alpha^2 s - \beta^2 t & -\alpha\beta(s + t) \\ -\alpha\beta(s + t) & \alpha^2 t - \beta^2 s \end{pmatrix}^2 + k \begin{pmatrix} \alpha^2 - \beta^2 & 2\alpha\beta \\ 2\alpha\beta & -\alpha^2 + \beta^2 \end{pmatrix} 
\]
\[
= \begin{pmatrix} -\alpha^2 s^2 - \beta^2 t^2 & -\alpha\beta(s^2 - t^2) \\ -\alpha\beta(s^2 - t^2) & \alpha^2 s^2 - \beta^2 t^2 \end{pmatrix} + k \begin{pmatrix} \alpha^2 - \beta^2 & 2\alpha\beta \\ 2\alpha\beta & -\alpha^2 + \beta^2 \end{pmatrix} 
\]
\[
= \begin{pmatrix} \alpha^2(k - s^2) - \beta^2(k + t^2) & \alpha\beta(2k - s^2 + t^2) \\ \alpha\beta(2k - s^2 + t^2) & -\alpha^2(k + t^2) + \beta^2(k - s^2) \end{pmatrix}.
\]

Since $s^2 = -1 + k$ and $t^2 = -1 - k$, we have that $k - s^2 = 1$, $k + t^2 = -1$ and $-s^2 + t^2 = 2k$. Therefore,
\[
D^2 + BB^T = \begin{pmatrix} \alpha^2 + \beta^2 & \alpha\beta(2k - 2k) \\ \alpha\beta(2k - 2k) & \alpha^2 + \beta^2 \end{pmatrix} 
\]
\[
= -I_2,
\]
which is desired. The identities (4) and (5) are verified by similar computations.

\section*{Appendix B. Proof of Theorem 3.4}

\textit{Proof.} It is easy to check that $A_2$ is symmetric. Therefore, we have only to show that $A_2$ is anti-orthogonal, i.e.,
\[
\begin{pmatrix} H \\ M^T A + M^T (H - P)^{-1} M \end{pmatrix} \begin{pmatrix} H \\ M^T A + M^T (H - P)^{-1} M \end{pmatrix} = -I_{n+2}.
\]
In other words, we have to show that following three identities are hold:
\begin{align*}
(6) & \quad H^2 + MM^T = -I_2, \\
(7) & \quad HM + M(A + M^T (H - P)^{-1} M) = O_{2 \times n}, \\
(8) & \quad MM^T + (A + M^T (H - P)^{-1} M)^2 = -I_n.
\end{align*}
We note that, with the assumption, $MA = PM$ and $HP = PH$ by Propositions 3.2 and 3.3.

First, it is easy to show that the identity (6) is true from the equation (2). For the identity (7), we calculate that
\[
HM + M(A + M^T (H - P)^{-1} M) = HM + MA + MM^T (H - P)^{-1} M
\]
\[(H + P)M + MM^T (H - P)^{-1} M\]
\[= (H + P)(H - P) + MM^T (H - P)^{-1} M\]
\[= O_2 (H - P)^{-1} M\]
\[= O_2 \times n\]

and the result follows.

Finally, for the identity (8), we expand the left hand side of (8):
\[M^T M + (A + M^T (H - P)^{-1} M)^2\]
\[= M^T M + A^2 + AM^T (H - P)^{-1} M + M^T (H - P)^{-1} MA\]
\[+ M^T (H - P)^{-1} MM^T (H - P)^{-1} M.\]

Note that \(A^2\), the second term of (9) equals \(-I_n\). We compute the sum of (9) except the last term:
\[M^T M + A^2 + AM^T (H - P)^{-1} M + M^T (H - P)^{-1} MA\]
\[= M^T M - I_n + M^T P(H - P)^{-1} M + M^T (H - P)^{-1} PM\]
\[= -I_n + M^T (I_n + P(H - P)^{-1} + (H - P)^{-1} P) M\]
\[= -I_n + M^T (H - P)^{-1} ((H - P)^2 + (H - P)P + P(H - P))(H - P)^{-1} M\]
\[= -I_n + M^T (H - P)^{-1} (H^2 - P^2)(H - P)^{-1} M.\]

And we put \(MM^T = -(H + P)(H - P)\) in the last term of (9) to calculate
\[M^T (H - P)^{-1} MM^T (H - P)^{-1} M\]
\[= -M^T (H - P)^{-1} (H + P)(H - P)(H - P)^{-1} M\]
\[= -M^T (H - P)^{-1} (H^2 - P^2)(H - P)^{-1} M.\]

Therefore, we obtain that
\[MM^T + (A + M^T (H - P)^{-1} M)^2 = -I_n,\]
and this is desired.  

\[\square\]
