THE $*$-EDGE-REINFORCED RANDOM WALK

SERGIO BACALLADO, CHRISTOPHE SABOT, AND PIERRE TARRÈS

ABSTRACT. We define a generalisation of the Edge-Reinforced Random Walk (ERRW) introduced by Coppersmith and Diaconis in 1986 [4], called $*$-Edge-Reinforced Random Walk ($*$-ERRW), which can be seen as an extension of the $r$-dependent ERRW introduced by Bacallado in 2011 [1]. Similarly as for the ERRW, it has a continuous-time counterpart, called $*$-Vertex-Reinforced Jump Process ($*$-VRJP), which itself generalises the Vertex-Reinforced Jump Process proposed by Werner in 2000 and initially studied by Davis and Volkov (see [5, 6]). Under some assumptions on the initial weights, the $*$-ERRW is partially exchangeable in the sense of Diaconis and Freedman [7], and thus it is a random walk in a random environment: we compute the law of that environment.

1. Introduction

1.1. $*$-directed graphs. In this paper, we consider a directed graph $G = (V, E)$ endowed with an involution on the vertices denoted by $*$, and such that

\[(i, j) \in E \iff (j^*, i^*) \in E.\]  

Denote by $V_0$ the set of fixed points of $*$

\[V_0 = \{i \in V \text{ s.t. } i = i^*\},\]

and by $V_1$ a subset of $V$ such that $V$ is a disjoint union

\[V = V_0 \sqcup V_1 \sqcup V_1^*\]

Denote by $\tilde{E}$ the set of edges quotiented by the relation $(i, j) \sim (j^*, i^*)$. In the sequel we let $\tilde{E}$ be the subset of $E$ obtained by choosing a representative among two equivalent edges $(i, j)$ and $(j^*, i^*)$.

We will always suppose that for any vertices $i$ and $j$, there exists a directed path in the graph between $i$ and $j$ or $i$ and $j^*$.

1.2. The $*$-Edge Reinforced Random Walk ($*$-ERRW). Suppose we are given some positive weights $(\alpha_{i,j})_{(i,j) \in E}$ on the edges invariant by the involution, i.e. such that

\[\alpha_{i,j} = \alpha_{j^*,i^*} \text{ for all } (i,j) \in E.\]

Let $(X_n)_{n \in \mathbb{N}}$ be a nearest-neighbor discrete-time process taking values in $V$. For all $(i, j) \in E$, denote by $N_{i,j}(n)$ the number of crossings of the edge $(i, j)$, i.e.

\[N_{i,j}(n) = \sum_{k=0}^{n-1} \mathbb{1}_{(X_k, X_{k+1})=(i,j)},\]

and let

\[\alpha_{i,j}(n) = \alpha_{i,j} + N_{i,j}(n) + N_{j^*,i^*}(n).\]
The process $(X_n)_{n \in \mathbb{N}}$ is called a $\star$-Edge Reinforced Random Walk (\star-ERRW) starting from $i_0$ if $X_0 = i_0$ and, for all $n \in \mathbb{N}$ and $j \sim X_n$,

$$
P(X_{n+1} = j \mid X_0, X_1, \ldots X_n) = \mathbb{1}_{X_n \rightarrow j} \frac{\alpha_{X_n,j}(n)}{\sum_{l \sim X_n} \alpha_{X_n,l}(n)}.
$$

The \star-ERRW can be seen as a generalisation of the Edge-Reinforced Random Walk (ERRW) introduced in the seminal work of Diaconis and Coppersmith [1], corresponding to the case where $\star$ is the identity map.

At fixed time $n$, the transition rates are obviously not reversible. But the $\star$-symmetry on the transition rates can be interpreted as a Yaglom reversibility [19 18 9], where the space involution is given by the $\star$-involution $(i, j) \mapsto (j^\star, i^\star)$ on the oriented edges.

An important example of \star-ERRW is the $k$-dependent Reinforced Random Walk, already considered by Bacallado in [2], which takes values in the de Bruijn graph $G = (V, E)$ of a finite set $S$, defined as follows: $V = S^k$, $E = \{((i_1, \ldots, i_k), (i_2, \ldots, i_{k+1})) \mid i_1, \ldots, i_{k+1} \in S\}$. Let $\star$ be the involution which maps $(i_1, \ldots, i_k) \in V$ to the reversed sequence $(i_{k+1}, \ldots, i_1) \in V$, which obviously satisfies [11]. Note that, in that case, $V_0$ is the set of palindromes. Then the $k$-dependent Reinforced Random Walk is defined as the \star-ERRW on that de Bruijn graph.

The Random Walk in Random Dirichlet Environment (RWDE), considered in [10] [13], can also be seen as a particular case of \star-ERRW. Indeed, given a directed graph $G_1 = (V_1, E_1)$, consider its "reversed" graph $G_1^* = (V_1^*, E_1^*)$, where $V_1^*$ is a copy of $V_1$ and $E_1^*$ is obtained by reversing each edge in $E_1$. Then the full graph $G$ is a disjoint union $(V_1 \cup V_1^*, E_1 \cup E_1^*)$. If $i_0 \in V_1$, then the \star-ERRW is a Random Walk in Dirichlet environment on $G_1$. Therefore the \star-ERRW can be seen as an interpolation between the ERRW and the RWDE. An interesting modification of that construction is obtained by gluing the two graphs $G_1$ and $G_1^*$ at the starting point $i_0$.

1.3. The \star-ERRW as a prior distribution for Bayesian analysis. It will be shown in Section 1.5 that the \star-ERRW has a partial exchangeability property, which implies a de Finetti-style representation as a mixture of Markov chains. The ERRW of Diaconis and Coppersmith is, in particular, a mixture of reversible Markov chains. Diaconis and Rolles [8] first proposed an application of this process as a prior for Bayesian analysis of Markov chains which are known to be reversible. The prior has several appealing features including (i) a formula for the predictive distribution conditional on an observation of the Markov chain, and for other posterior moments, such as cycle probabilities, (ii) full support of the mixing distribution on the space of reversible Markov kernels, and (iii) a characterisation as the only prior with certain sufficient statistics for the predictive distribution, which motivates the choice from a subjectivist perspective [12].

Bacallado [2] extended this idea by introducing the \star-ERRW on the de Bruijn graph as a prior distribution for higher-order Markov chains which are reversible. This work was motivated by an application to the statistical analysis of molecular dynamics simulations with microscopically reversible laws. In the higher-order setting, a stationary Markov chain $(X_n)_{n \in \mathbb{Z}}$ on the de Bruijn graph is said to be reversible if it is identically distributed to the time reversal $(X^*_{-n})_{n \in \mathbb{Z}}$.

Variable-order Markov chains provide a useful, parsimonious alternative to a higher-order Markov model. Consider a random walk $(X_n)_{n \in \mathbb{N}}$ on the de Bruijn graph; we say
it is of variable-order with context set \( \mathcal{C} \subseteq S \cup S^2 \cup \cdots \cup S^k \), if for each \((i_1, \ldots, i_\ell) \in \mathcal{C}\), the transition probabilities out of \( x \) and \( y \) are the same whenever \( x \) and \( y \) both end in \((i_1, \ldots, i_\ell)\). Bacallado \[2\] shows that if \((X_n)_{n \in \mathbb{N}}\) is reversible in the higher-order sense, then \( x \in \mathcal{C} \) implies that \( x^* \in \mathcal{C} \) and any \( y \) which has \( x \) as a prefix is also in \( \mathcal{C} \). This fact is used to define a prior with full support on the space of variable-order, reversible Markov chains with a specific context set. The prior shares many of the computational advantages of the ERRW prior of Diaconis and Rolles.

Another example of \( \star \)-ERRW is the reinforced random walk with amnesia of \[3\], which defines a prior for reversible processes with long memory. A random walk with amnesia is a random walk on the graph \( G = (V, E) \) defined by \( V = S \cup S^2 \cup \cdots S^k \) with edges from \((i_1, \ldots, i_m) \in V\) leading to \((i_2, \ldots, i_m)\), if \( m > 1 \), as well as to \((i_1, \ldots, i_m, j)\) for each \( j \in V \), if \( m < k \). The first class of edge “forgets” the most distant element in \( S \) in the history, while the latter appends a new element of \( S \) to the history. A \( \star \)-ERRW on this graph defines a mixture of random walks with amnesia, which can be used in a Bayesian analysis to learn a context-dependent, stochastic length of memory under the assumption of reversibility, avoiding the need to specify a context set a priori. Incidentally, the prior for variable-order, reversible Markov chains in \[2\] emerges from a special case of this reinforced random walk with amnesia. Namely, given a context set \( \mathcal{C} \), we need only choose initial weights \( \alpha \) which disallow transitions of the form \((i_1, \ldots, i_\ell) \rightarrow (i_1, \ldots, i_{\ell+1})\) whenever there is a context \( x \in \mathcal{C} \) of length smaller than \( \ell \) such that \((i_1, \ldots, i_\ell)\) ends in \( x \).

### 1.4. The \( \star \)-Vertex Reinforced Jump Process (\( \star \)-VRJP)

Similarly as for the ERRW, the \( \star \)-ERRW can be represented in terms of a \( \star \)-Vertex-Reinforced Jump Process (\( \star \)-VRJP) with independent gamma conductances.

More precisely, suppose we are given some weights \((W_{i,j})_{(i,j) \in E}\) invariant by the involution, that is, such that

\[ W_{i,j} = W_{j^*,i^*} \quad \text{for all } (i, j) \in E. \]

If \((u_i)_{i \in V} \in \mathbb{R}^V\), then let \( u^* = (u_i^*)_{i \in V} \in \mathbb{R}^V \), and define \( W^u \in \mathbb{R}^E \) by

\[ W^u_{i,j} = W_{i,j} e^{u_i^* + u_j^*}. \]

Remark that \( W^u_{i,j} = W^u_{j^*,i^*} \).

Consider the process \((X_t)_{t \geq 0}\) which, depending on the past at time \( t \), jumps from \( i \) to \( j \) at a rate

\[ W_{i,j} T(t) = W_{i,j} e^{T(t) + T^*(t)}, \]

where \( T(t) \) is the local time of \( X \) at time \( t \)

\[ T_i(t) = \int_0^t \mathbb{1}_{X_u = i} du. \]

We call this process the \( \star \)-VRJP, which can be seen as a generalization of the VRJP (proposed by Werner and first considered by Davis and Volkov in \[5\], \[6\]). We note by \( \mathbb{P}_{i_0}^W \) the law of the \( \star \)-VRJP starting from the point \( i_0 \). We always consider that the \( \star \)-VRJP is defined on the canonical space \( \mathcal{D}([0, \infty), V) \) of càdlàg functions from \([0, \infty)\) to \( V \) and \((X_t)_{t \geq 0}\) will denote the canonical process on \( \mathcal{D}([0, \infty), V) \).

**Lemma 1.** Let \((\alpha_{i,j})_{(i,j) \in E}\) be a set of positive weights on the edges such that \( \alpha_{i,j} = \alpha_{j^*,i^*} \). Let \((W_e)_{e \in E}\) be independent Gamma random variables with parameters \( \alpha_{i,j} \). Let \((X_n)_{n \in \mathbb{N}}\) be the discrete time process describing the successive jumps of \((X_t)_{t \geq 0}\) and let \( \mathbb{P}_{i_0}(\cdot) = \)
\( \mathbb{E} (\mathbb{P}^{i_0}_W (\cdot)) \) be the annealed law obtained after taking expectation with respect to the r.v. \( W \). Then, under the annealed law \( \mathbb{P}^{i_0} \), \((X_n)_{n \geq 0}\) has the law of the \( \star \)-ERRW defined in the first part.

**Proof.** The proof is similar to that of Lemma 4.7 in [17] and Theorem 1 in [16]. □

The \( \star \)-VRJP is not partially exchangeable in the sense of Diaconis and Freedman [7], which makes its study more difficult than the reversible Vertex-Reinforced Jump Process. It is analysed in a separate paper by Sabot and Tarrès [14]: after a suitable randomization of the initial local times, the \( \star \)-VRJP becomes partially exchangeable. After that randomization, the limiting measure can be computed and a random Schrödinger operator approach can be also be taken, as in [16, 15] in the non-directed case. The non-randomized \( \star \)-VRJP can be written as a mixture of conditioned Markov jump processes, after a proper time change.

As shown in the following Section 1.5 extending the corresponding result of Bacallado [2] for the variable-order ERRW, the \( \star \)-ERRW is partially exchangeable under some assumptions on the initial weights \( \alpha \). The main goal of this work is to compute the limiting measure given in Theorem 1. Our technique of proof is based on a discrete Feynman-Kac identity, and it yields in particular a short proof of the so-called magic formula of Diaconis and Coppersmith for ERRW, see [4, 11]: note that in the latter case, the computation of the Gaussian normalization is much simpler.

### 1.5. Partial exchangeability of the \( \star \)-ERRW under assumptions on initial weights \( \alpha \).

We use the notation that, for all \( e = (i,j) \in E \), then \( \underline{e} = i \) and \( \overline{e} = j \).

The divergence operator is defined as the operator \( \text{div} : \mathbb{R}^E \to \mathbb{R}^V \) defined for a function on the edges \((x_e)_{e \in E}\) by

\[
\text{div}(x)(i) = \sum_{e, \underline{e} = i} x_e - \sum_{e, \overline{e} = i} x_e.
\]

For all \( y \in \mathbb{R}^E \) let, for all \( n \in \mathbb{N} \) and \( i \in V \),

\[
y_i = y_i^- = \sum_{j : i \to j} y_{i,j}, \quad y_i^+ = \sum_{j : j \to i} y_{j,i}, \quad y_i^\leftrightarrow = y_i^+ + y_i^-.
\]

**Proposition 1.** Let \( i_0 \in V \) be the starting point of the \( \star \)-ERRW and suppose that the weights \((\alpha_e)_{e \in E}\) have the following property

\[
(1.2) \quad \text{div}(\alpha)(i) = 1_{\{i = i_0^*\}} - 1_{\{i = i_0\}}.
\]

Then the \( \star \)-ERRW \((X_n)\) is partially exchangeable in the sense of [7].

**Proof.** First note that \( \alpha_{i,j}(n) \) counts the sum of the numbers of visits from \( i \) to \( j \) and from \( j^* \) to \( i^* \), so that \( \alpha_{i,j}^\leftrightarrow(n) = \alpha_{j,i}^\leftrightarrow(n) \) counts twice the sum of the numbers of visits to \( i \) and to \( i^* \) (and four times the number of visits to \( i \) if \( i = i^* \)).

It is easy to check that

\[
\alpha_i^{-\uparrow}(n) - \alpha_i^{\uparrow-}(n) + 1_{\{X_n = i\}} - 1_{\{X_n = i^*\}} = \alpha_i^\leftrightarrow(0) - \alpha_i^\leftrightarrow(0) + 1_{\{X_0 = i\}} - 1_{\{X_0 = i^*\}},
\]
so that
\[
\alpha_i^\to(n) = \frac{\alpha_i^+(n)}{2} + \frac{\text{div}(\alpha)(i) + \mathbb{I}_{\{i=i_0\}} - \mathbb{I}_{\{i=i_n^\circ\}} - \mathbb{I}_{\{X_n=i\}} + \mathbb{I}_{\{X_n=i^*\}}}{2}
\]
\[
= \frac{\alpha_i^+(n)}{2} + \mathbb{I}_{\{X_n=i^*\}} - \mathbb{I}_{\{X_n=i\}},
\]
where we use the assumption \(\text{div}(\alpha)(i) = \mathbb{I}_{\{i=i_0^\circ\}} - \mathbb{I}_{\{i=i_0\}}\) in the second equality.

If we let \(t_n(i)\) be the \(n\)-th visit time to \(\{i, i^*\}\). Remark that
\[
\alpha_i^+(t_1(i)) = \alpha_i^+(0) + \mathbb{I}_{\{i\neq i_0, i_0^\circ\}}(1 + \mathbb{I}_{\{i=i^*\}}),
\]
\[
\alpha_{X_{t_n(i)}}(t_1(i)) - \alpha_{X_{t_1(i)}}(t_1(i)) = 2(n-1)(1 + \mathbb{I}_{\{i=i^*\}}).
\]
Therefore
\[
\alpha_{X_{t_n(i)}}(t_n(i)) = \frac{\alpha_i^+(t_n(i)) - 1 + \mathbb{I}_{\{i=i^*\}}}{2} = (1 + \mathbb{I}_{\{i=i^*\}})(n-1) + \beta_i,
\]
where
\[
\beta_i = \frac{\alpha_i^+(0) + (1 + \mathbb{I}_{\{i=i^*\}})(1 + \mathbb{I}_{\{i\neq i_0, i_0^\circ\}})}{2} - 1.
\]

For all \(\alpha, m \in (0, \infty)\), and \(n \in \mathbb{N} \cup \{0\}\), let
\[
f_m(\alpha, n) = \prod_{k=1}^{n}(\alpha + mk).
\]

Let \(\sigma\) be a fixed path. For all \((i, j) \in E\), let \(N_{ij}(\sigma)\) be the number of crossings to edge \((i, j)\). Then, using the computation above, we deduce that
\[
\mathbb{P}_{n_0}^{\to \text{ERRW}}(X \text{ follows } \sigma) = \frac{\prod_{(i,j) \in E} f_1(\alpha_{i,j}, N_{ij}(\sigma))}{\prod_{i \in V_0} f_2(\beta_i, N_i^+)(\sigma) \prod_{i \in V_1} f_1(\beta_i, N_i^+)(\sigma)},
\]
which enables us to conclude that the walk is partially exchangeable.

Set, for all \(r \in \mathbb{R}\),
\[
\mathcal{H} = \{(x_e) \in \mathbb{R}^E, x_{i,j} = x_{j,i^*}\} \simeq \mathbb{R}^{\tilde{E}}, \quad \mathcal{D} = \{(x_e) \in \mathbb{R}^E, \text{div}(x) = 0\}, \quad \mathcal{L} = \mathcal{H} \cap \mathcal{D},
\]
\[
\mathcal{H}_r = \mathcal{H} \cap \left\{ \sum_E x_e = r \right\}, \quad \mathcal{L}_0 = \mathcal{L} \cap \left\{ \sum_E x_e = 0 \right\}, \quad \mathcal{L}_1 = (0, \infty)^E \cap \mathcal{L} \cap \left\{ \sum_E x_e = 1 \right\}.
\]

We let \(\text{Cst}(x_1, \ldots, x_n)\) be a positive constant dependent only on \(x_1, \ldots, x_n\).

**Corollary 1.** Under assumption (L.2), the limit
\[
\lim_{n \to \infty} \frac{1}{n} N_{i,j}(n) = Y_{i,j}
\]
exists a.s. and \((Y_{i,j})_{(i,j) \in E} \in \mathcal{L}_1\).

**Proof.** Since the process \(X_n\) is partially exchangeable the limit above exists a.s.. Moreover,
\[
\text{div}(N(n)) = \delta_{i_0} - \delta_{i_n^\circ} - (\delta_{X_n} - \delta_{X_n^*})
\]
which implies that \(\text{div}(Y) = 0\). Also \(\sum_{(i,j) \in \tilde{E}} N_{i,j}(n) = n\), since at each time one edge of \(\tilde{E}\) is reinforced.
Let us now prove that $Y_{i,j} = Y_{j^*,i^*} > 0$. Remark that asymptotically $\alpha_{i,j}(n)/\alpha_i(n) \to (Y_{i,j} + Y_{j^*,i^*})/2Y_i$, where $Y_i = \sum_{j} Y_{i,j}$, and note that $Y_i = Y_{i^*}$ since $\text{div}(Y) = 0$.

Now $X_n$ is a mixture of irreducible Markov chains by [7], which implies that $Y_i > 0$ for all $i \in V$ and, conditioned on $Y$, it is a Markov chain with transition probabilities $Y_{i,j}/Y_i$. Therefore $Y_{i,j}/Y_i = (Y_{i,j} + Y_{j^*,i^*})/2Y_i > 0$, which is equivalent to $Y_{i,j} = Y_{j^*,i^*} > 0$. \hfill \Box

1.6. Mixing measure of the $\ast$-ERRW.

Definition 1 (Reference measure on $L_0$ and $L_1$). By a slight abuse of notation, we will call basis of the subset $L_0$ a maximal subset $B \subseteq \mathbb{E}$ such that the family $y_e$, $e \in B$ are independent variables (i.e. linear forms) in $L_0$. Note that $L_1$ is an affine space directed by $L_0$. In the sequel we will use as reference measure on $L_0$ and $L_1$

$$dy_{L_0} = \prod_{e \in B} dy_e, \quad dy_{L_1} = \prod_{e \in B} dy_e$$

the measures obtained from the basis $B$. In Appendix 5.1 we describe the bases of $L_0$ and show that $dy_{L_0}$ is independent of the choice of basis $B$.

Remark 1. By $\prod_{e \in B} dy_e$ we mean the pull-back of the Lebesgue measure on $\mathbb{R}^B$ obtained by the projection $(y_e) \in L_0 \mapsto (y_e)_{e \in B}$. The measure $dy_{L_0}$ differs from the volume measure on $L_0$ induced by the Euclidean metric on $\mathbb{R}^E$ by a universal constant.

Theorem 1. (i) The random variable $Y$ has the following distribution on $L_1$

$$\mu_{i_0}^{\alpha}(dy) = C^{\gamma(i_0, \alpha)}\sqrt{y_{i_0}}\frac{1}{\prod_{i \in V} y_i^{\frac{\alpha_i}{2}}} \sqrt{D(y)} dy_{L_1},$$

where

$$\gamma(i_0, \alpha) = \frac{\prod_{i \in V_0} \Gamma\left(\frac{1}{2}(\alpha_i + 1 - \frac{1}{i = i_0} 2^{\frac{1}{2}(\alpha_i - 1_{i = i_0})}ight)}{\prod_{(i,j) \in E} \Gamma\left(\alpha_{i,j}\right)} \frac{2}{\sqrt{2\pi} |V_0|^{-1/2} |V_0 + V_1|},$$

$$D(y) = \sum_T \prod_{(i,j) \in T} y_{i,j}.$$ 

The last sum runs on spanning trees directed towards a root $j_0 \in V$, and the value does not depend on the choice of the root $j_0$.

(ii) The process $X_n$ is a mixture of Markov chains with transition probabilities $p_{i,j} = \frac{y_{i,j}}{y_i}$, and invariant measure $y_i$ where $(y_{i,j})$ is distributed according to $\mu_{i_0}^{\alpha}$.

Remark 2. Note that, as in the (reversible) case of Edge-Reinforced Random Walk (ERRW), the property that the integral of the measure $\mu_{i_0}^{\alpha}(dy)$ in Theorem 1 is 1 is not easy to prove directly. Even the apparently simple fact that the measure is finite is not immediately obvious.

Remark 3. The sum on spanning trees $D(y)$ can also be expressed as a determinant:

$$D(y) = \det(M(y))_{V \setminus \{j_0\}}$$
where \( \det(M(y))_{V \setminus \{j_0\}} \) is the diagonal minor obtained after removing line and column \( j_0 \) of the matrix \( M(y) \) defined by

\[
M(y)_{i,j} = \begin{cases} 
  y_{i,j}, & \text{if } i \neq j \\
  -y_i, & \text{if } i = j
\end{cases}
\]

The value of this determinant does not depend on the choice of \( j_0 \) since the sums on any line or column of \( M(y) \) are null.

**Remark 4.** Compared to the "magic formula" for ERRW in Coppersmith, Diaconis, [4, 8, 11], the determinantal term \( \sqrt{D(y)} \) is the same but it is now non symmetric. Also the measure is restricted to the limiting subspace \( L_1 \).

**Remark 5.** One can check that the measure indeed coincides with the magic formula in the case of classic ERRW (cf [4, 8, 11]). When the graph is the disconnected union \( (V_1 \sqcup V_1^*, E_1 \sqcup E_1^*) \) described at the end of Section 1.2 we can easily confirm that it coincides with the measure on the occupation time of the edges of Random Walks in Random Dirichlet Environment computed in lemma 2 [13] (arxiv version).

**Remark 6.** In the expression of \( \gamma, \alpha_i = \alpha_i^* \) if \( i \neq i_0 \) and \( i^* \neq i_0 \), and that \( \alpha_{i_0} = \alpha_{i_0} + 1 \) if \( i_0 \not\in V_0 \), so that, in the definition of \( \gamma(i_0, \alpha) \) we can write, for all \( i \in V_1 \),

\[
\inf(\alpha_i, \alpha_{i^*}) = \frac{1}{2}(\alpha_i + \alpha_{i^*} - 1_{\{i = i_0 \text{ or } i^* = i_0\}}).
\]

2. **Proof of Theorem 1**

Let \( S \) be the set of continuous real function on \( L_1 \), whose support is compact and has empty intersection with \( \cup_{(i,j) \in E} \{y_{(i,j)} = 0\} \). Let, for all \( \varphi \in S \), \( (\alpha_{i,j})_{(i,j) \in \bar{E}} \in (0, \infty)^{\bar{E}} \), and \( k \in V \),

\[
\Psi(k, \alpha)(\varphi) = \int_{L_1} \varphi(y)\mu_k^\alpha(dy)
\]

It is sufficient to prove that, for all such \( \varphi \in S \), \( (\alpha_{i,j})_{(i,j) \in E} \in (0, \infty)^E \), and \( i_0 \in V \),

\[
\mathbb{P}^{(\alpha)}(\varphi(Y)) = \Psi(i_0, \alpha)(\varphi).
\]

to conclude.

Note that, contrary to the Feynman-Kac approach in [16], we do not use Fourier transforms but integration against appropriately chosen test functions, since even integrability of the measures \( \mu_k^\alpha \) (which turn out to be probability measures) is not obvious a priori.

The process \( (X_n, \alpha(n)) \) is a Markov process on \( V \times \mathbb{R}^\bar{E} \) with generator

\[
Lg(i, \alpha) = \sum_{j, i \to j} \alpha_{i,j} \left( f(j, \alpha + 1_{(i,j)} + 1_{(j^*, i^*)}) - f(i, \alpha) \right).
\]
Lemma 2 states that \( \Psi \) is a martingale for the Markov generator \( L \). In the proof and later on, we will use the notation, given \( i_0 \in V \),

\[
\eta_{i}(y) = \frac{\prod_{(i,j) \in E} y_{i,j}^{\alpha_{i,j}}}{\prod_{i \in V} y_i^{\alpha_i}}, \quad \rho(y) = \frac{\sqrt{y_{i_0}}}{\prod_{i \in V_0} \sqrt{y_i} \prod_{(i,j) \in E} y_{i,j}} \sqrt{D(y)}
\]

so that

\[
\zeta_{i_0,\alpha}(y) = C\gamma(i_0, \alpha) \eta_{i}(y) \rho(y)
\]

This immediately implies that

\[
\mu^\alpha_{i_0}(dy) = \zeta_{i_0,\alpha}(y) dy_{E_1}.
\]

**Lemma 2. (Feynman-Kac equation)** We have

\[
L \Psi = 0.
\]

**Proof.** When the process jumps from \( i_0 \) to \( j_0 \), then the normalization term becomes

\[
\gamma(j_0, \alpha + 1 \{ (i_0,j_0) \} + 1 \{ (j_0', i_0') \} ) \rightleftharpoons \frac{\alpha_{i_0}}{\alpha_{i_0,j_0}} \gamma(i_0, \alpha).
\]

Indeed, \( \alpha_{i_0,j_0} \) is incremented by 1; when \( i \in V_0 \) the term \( \frac{1}{2}(\alpha_i + 1 - 1_{i = i_0}) \) is incremented by 1 if \( i = i_0 \), whereas when \( i \in V \) the term \( \inf(\alpha_i, \alpha_{\gamma}) \) is incremented by 1 if \( i = i_0 \) and \( \inf(\alpha_{i_0}, \alpha_{i_0}') = \alpha_{i_0} \); since \( \alpha_{i_0}' = \alpha_{i_0} + 1 \). All the other terms are left unchanged.

On the other hand,

\[
(\gamma(j_0, \alpha + 1 \{ (i_0,j_0) \} + 1 \{ (j_0', i_0') \} ))(y) = \frac{y_{i_0,j_0}}{y_{i_0}} \zeta_{i_0,\alpha}(y).
\]

This immediately implies that

\[
\sum_{i_0 \to j_0} \alpha_{i_0,j_0} \Psi(j_0, \alpha + 1 \{ (i_0,j_0) \} + 1 \{ (j_0', i_0') \})(\varphi) = \alpha_{i_0} \Psi(i_0, \alpha)(\varphi).
\]

This implies that \( \Psi(X_n, \alpha(n))(\varphi) \) is a martingale, and therefore that

\[
\Psi(i_0, \alpha)(\varphi) = \mathbb{E}^{(\alpha)}_{i_0}(\Psi(X_n, \alpha(n))(\varphi))
\]

The next aim is to show that

\[
\lim_{n \to \infty} \Psi(X_n, \alpha(n))(\varphi) = \varphi(Y) \text{ a.s. },
\]

where \( Y = \lim_{n \to \infty} \alpha(n)/n \), which will imply the result by dominated convergence.

To that end we show that \( \Psi(i_0, \alpha(n))(\varphi) \) approximates a Gaussian integral in Proposition 2 proved in Section 3 and then we compute that Gaussian integral in Lemma 3 proved in Section 4.

We use the notation that \( a_n \sim_n b_n \) iff \( a_n/b_n \to_n 1 \).

For all \( w \in (0, \infty) \cap \mathcal{H} \), we define the following bilinear form on \( \mathcal{H} \) by

\[
Q_w(x, x') = \sum_{(i,j) \in E} \frac{1}{w_{i,j}} x_{i,j} x'_{i,j} - \sum_{i \in V} \frac{1}{w_i} (Bx)_i (Bx')_i + \left( \sum_{(i,j) \in E} x_{i,j} \right) \left( \sum_{(i,j) \in E} x'_{i,j} \right),
\]

where

\[(2.1) \quad Bx_i = \frac{1}{2}(x_i + x_i') = \frac{1}{2} \left( \sum_{j,i \to j} x_{i,j} + \sum_{j \to i} x_{j,i} \right).\]
We will denote \( Q_w \) by \( Q \) when there is no confusion, and let \( Q_w(x) = Q_w(x, x) \) by a slight abuse of notation. Remark that when \( z \in \mathcal{L}_0 \), then \( z_i = z_i^\ast \) and \( B(z)(i) = z_i \) so that

\[
Q_w(z) = 2 \sum_{(i,j) \in E} \frac{1}{w_{i,j}} (z_{i,j})^2 - \sum_{i \in V} \frac{1}{w_i} (z_i)^2 = \sum_{(i,j) \in E} w_{i,j} \left( \frac{z_{i,j}}{w_{i,j}} - \frac{z_i}{w_i} \right)^2.
\]

**Proposition 2.** We have a.s.

\[
\Psi(i_0, \alpha(n))(\varphi) \sim_{n \to \infty} \varphi(Y) \sqrt{D(Y)} \frac{C \sqrt{2\pi}^{V_0 + |V_1| - |E|}}{\prod_{(i,j) \in E} \sqrt{Y_{i,j}}} \int_{\mathcal{L}_0} e^{-\frac{1}{4}Q_{\beta(n)}(z)}(dz)_{\mathcal{L}_0}.
\]

**Lemma 3.** For all \( w \in (0, \infty) \cap \mathcal{H} \), we have

\[
\int_{\mathcal{L}_0} e^{-\frac{1}{4}Q_{\gamma}(z)}(dz)_{\mathcal{L}_0} = \left( \prod_{(i,j) \in E} \sqrt{w_{i,j}} \right) \left( \prod_{i \in V_0 \cup V_1} \sqrt{w_i} \right) \frac{\sqrt{2^{V_0 + |V_1|} \sqrt{2\pi}^{E - |V_0| - 1}}}{2 \sqrt{D(w)}}.
\]

### 3. Proof of Proposition 2

Let, for all \( n \in \mathbb{N} \),

\[
\beta(n) = \frac{\alpha(n)}{n}.
\]

The following Lemma 4 analyses the asymptotic behavior of \( \gamma(X_n, \alpha(n)) \).

**Lemma 4.** We have

\[
\gamma(X_n, \alpha(n)) \sim n^{-|E| - |V_1| - 1} \sqrt{2\pi}^{V_0 + |V_1| - |E|} \frac{\prod_{i,j \in E} \sqrt{Y_{i,j}}}{\sqrt{Y_{X_0} \prod_{i \in V_1} \sqrt{Y_i}}} \left( \frac{1}{\eta_{\beta(n)}(\beta(n))} \right)^n.
\]

**Proof.** Recall the asymptotic behavior of the gamma function

\[
\Gamma(z) \sim_{z \to \infty} \sqrt{2\pi} z^{z - \frac{1}{2}} e^{-z},
\]

which in particular implies \( \Gamma(z \pm \frac{1}{2}) \sim \frac{\sqrt{\pi}}{2} \Gamma(z) \).

Therefore, for \( i \in V_0 \) and large \( \alpha \), we have

\[
\Gamma\left( \frac{1}{2}(\alpha_i + 1 - 1_{i=x}) \right) \sim \sqrt{2\pi} \sqrt{\alpha_i \sqrt{\alpha_i}} \left( \frac{\alpha_i}{2} \right)^{\frac{1}{2} \alpha_i} e^{-\frac{1}{2} \alpha_i}.
\]

Similarly, for \( i \in V_1 \),

\[
\Gamma(\inf(\alpha_i, \alpha_i^*)) = \Gamma\left( \frac{1}{2}(\alpha_i + \alpha_i^* - 1_{i=x or i=x^*}) \right) \sim \sqrt{2\pi} \frac{1}{\sqrt{\alpha_i \alpha_i^*}} \frac{1}{\sqrt{\alpha_i}} \frac{\alpha_i}{\alpha_i^*} e^{-\frac{1}{2} (\alpha_i + \alpha_i^*)}.
\]

This yields that for \( n \) large that

\[
\gamma(x, \alpha(n)) \sim \sqrt{2\pi}^{V_0 + |V_1| - |E|} \frac{1}{\sqrt{\alpha_x(n)}} \left( \prod_{i \in V} \alpha_i(n) \right)^{\frac{1}{2} \alpha_i(n)} \frac{\prod_{i,j \in \mathcal{E}} \alpha_{i,j}(n)^{\frac{1}{2} \alpha_{i,j}(n)}}{\prod_{i \in V_1} \sqrt{\alpha_i(n)}}
\]

where we use that \( \sum \alpha_{i,j}(n) - \frac{1}{2} \sum \alpha_i(n) = 0 \). □
Let us now study the asymptotic behavior of \( \eta_{X_n,\alpha(n)}(y) \) as \( n \to \infty \). We will need the following Lemma 5.

**Lemma 5.** Given \( \beta \in L_1 \), the function \( \log \eta_\beta \) is nonpositive and reaches its maximum on \( L_1 \) at \( y = \beta \), and

\[
\log \left( \frac{\eta_\beta(y)}{\eta_\beta(\beta)} \right) = -\frac{1}{4} Q_\beta(y - \beta) + O(\|y - \beta\|^3_\infty),
\]

where the constant in \( O() \) is a monomial in \( \beta \).

**Proof.** Let

\[
p_{ij} = \frac{y_{ij}}{y_i}, \quad \beta_{ij} = \frac{\beta_{ij}}{\beta_i}.
\]

We have

\[
\log \eta_\beta(y) = \frac{1}{2} \sum_{(i,j) \in E} \beta_{i,j} \log(p_{i,j}) \leq 0,
\]

thus

\[
\log \left( \frac{\eta_\beta(y)}{\eta_\beta(\beta)} \right) = \frac{1}{2} \sum_{(i,j) \in E} \beta_{i,j} \log \left( \frac{p_{i,j}}{\beta_{i,j}} \right) = \frac{1}{2} \sum_{(i,j) \in E} \beta_{i,j} \log \left( 1 + \frac{p_{i,j} - \beta_{i,j}}{p_{i,j}} \right)
\]

\[\leq \frac{1}{2} \sum_{(i,j) \in E} \beta_i (p_{i,j} - \beta_{i,j}) = 0,\]

where we use in the inequality that \( \log(1 + x) \leq x \) for all \( x > -1 \).

Let \( z = y - \beta \): a second order Taylor expansion of (3.4) yields

\[
\log \left( \frac{\eta_\beta(y)}{\eta_\beta(\beta)} \right) = -\frac{1}{4} \sum_{(i,j) \in E} \beta^2_{i,j} (p_{i,j} - \beta_{i,j})^2 + O(\|y - \beta\|^2_\infty)
\]

Now note that

\[
\sum_{(i,j) \in E} \beta^2_{i,j} (p_{i,j} - \beta_{i,j})^2 = \sum_{(i,j) \in E} \beta_{i,j} \left( \frac{z_{i,j}/\beta_{i,j} + 1}{z_i/\beta_i + 1} - 1 \right)^2 = \sum_{(i,j) \in E} \frac{\beta_{i,j}}{(z_i/\beta_i + 1)^2} \left( \frac{z_{i,j}}{\beta_{i,j}} - \frac{z_i}{\beta_i} \right)^2,
\]

which enables us to deduce (3.1) by (2.2). \( \square \)

Given \( \eta \in (0, 1/2) \), let

\[K_n = \{ y \in L_1 : \| y - \beta(n) \|_\infty \leq n^{-1/2+\eta} \}.
\]

**Lemma 6.** For all \( \eta \in (0, 1/2) \), we have

\[\lim_{n \to \infty} \int_{K_\eta^\dagger} \varphi(y) \mu\chi_{\alpha(n)}^n(dy) = 0\]

**Proof.** Note that, if \( \xi \) is the differentiable map defined on \( L_1 \) by \( \xi(y) = p \), where \( p \) given as in (3.2), then \( \xi \) is invertible and \( \xi^{-1} \) is differentiable on \( \xi(L_1) \). Indeed, given \( p \in \xi(L_1) \), there exists a unique \( y = (y_{ij})_{(i,j) \in E} \in L_1 \) such that \( \xi(y) = p \), defined as the invariant measure on \( E \) of the Markov Chain with jump probability \( p_{ij} \) from \( i \) to \( j \), and which is given by the Kirchhoff formula.
The sequence \( \beta(n) \) has an a.s. limit \( Y \in \mathcal{L}_1 \). By differentiability of \( \xi^{-1} \) on a neighbourhood of \( \xi(Y) \), if \( \|\beta - Y\|_\infty \leq \text{Cst}(Y) \) then \( \|p - p^0\|_\infty / \|y - \beta\|_\infty \geq \text{Cst}(Y) \). We deduce that a.s., for sufficiently large \( n \in \mathbb{N} \), using (3.3),

\[
\sup_{y \in K_n^c} \log \left( \frac{\eta(\beta(y))}{\eta(\beta(n))} \right) \leq \sup_{\|p-p^0\|_\infty > \text{Cst}(Y)n^{-1/2+\eta}} \log \left( \frac{\eta(\beta) \circ \xi^{-1}(p)}{\eta(\beta) \circ \xi^{-1}(p^0(n))} \right)
\]

\[
= \sup_{\|p-p^0\|_\infty > \text{Cst}(Y)n^{-1/2+\eta}} \frac{1}{2} \sum_{(i,j) \in E} \beta_{i,j}(n) \log \left( \frac{p_{i,j}}{p_{i,j}(n)} \right)
\]

\[
= \sup_{\|p-p^0\|_\infty = \text{Cst}(Y)n^{-1/2+\eta}} \frac{1}{2} \sum_{(i,j) \in E} \beta_{i,j}(n) \log \left( \frac{p_{i,j}}{p_{i,j}(n)} \right) \leq -\text{Cst}(Y)n^{2\eta - 1}.
\]

In the second equality, we use the concavity of the function \( p \) we are maximising.

On the other hand, by Lemma 4

\[
\eta(\beta(n)) \gamma(X_n, \alpha(n)) = (\eta(\beta(n)))^n \gamma(X_n, \alpha(n)) \leq \text{Cst}(Y)n^{-\frac{|E|}{2} - |V_1| - 1}. \]

This implies that

\[
\left| \int_{K_n^c} \varphi(y) \mu_{X_n}(dy) \right| \leq \text{Cst}(Y)n^{-\frac{|E|}{2} - |V_1| - 1} \exp(-\text{Cst}(Y)n^{2\eta}) \int_{K_n^c} (\varphi\rho)(y)dy_{\mathcal{L}_1}.
\]

Now, for all \( y \in K_n \), by Lemmas 4 and 5

\[
\zeta_{X_n, \alpha(n)}(y) = C \gamma(X_n, \alpha(n))(\eta(\beta(n)))^n \eta(\beta(n)) \prod_{i \in V_0} \frac{\sqrt{y_{X_i}}}{\eta(\beta(n))} \prod_{(i,j) \in E} y_{i,j} \prod_{i \in V_0 \cup V_1} \sqrt{y_{Y_i}} \sqrt{\frac{1}{2\pi} \sqrt{2^{|E| - |V_1| - 1} \sqrt{|V_0| + |V_1| - |E|}}}
\]

\[
\sim C \exp \left( -\frac{1}{4} Q_{\beta(n)}(\sqrt{n(y - \beta(n)))} \right) \prod_{(i,j) \in E} \frac{\sqrt{y_{X_i}}}{\eta(\beta(n))} \prod_{i \in V_0 \cup V_1} \sqrt{y_{Y_i}} \prod_{i \in V_0 \cup V_1} \sqrt{y_{Y_i}}
\]

where the notation \( a_n(y) \sim b_n(y) \) means here that \( a_n(y)/b_n(y) \) is close to 1 when \( n \) is large and \( y \in K_n \). We conclude the proof of Proposition 2 by the change of variables \( z = \sqrt{n(y - \beta(n))} \), which yields a Jacobian factor \( \sqrt{n^{-|E| + |V_1| + 1}} \) (since \( \mathcal{L}_1 \) has dimension \( |E| - |V_1| - 1 \)), which cancels the corresponding term above.

Let \( D_{\tilde{E}} \) (resp. \( D_V \)) denote the diagonal \( \tilde{E} \times \tilde{E} \) (resp. \( V \times V \)) matrix with diagonal coefficients \( Y_{i,j} \) (resp. \( Y_{i} \)). We have

\[
Q(x, x') = 2 \sum_{(i,j) \in E} \frac{1}{Y_{i,j}} x_{i,j} x_{i,j}' - \sum_{i \in V} \frac{1}{Y_{i}} B x_i B x_i' + \left( \sum_{i \in V} B x_i \right) \left( \sum_{i \in V} B x_i' \right)
\]

\[
(4.1) \quad = 2t x(D^{-1}_{\tilde{E}}(\text{Id}_{\tilde{E}} - \frac{1}{2} D_{\tilde{E}} B D^{-1}_{\tilde{E}} B + \frac{1}{2} D_{\tilde{E}} B 1^t B)) x'
\]
where in the last formula $1$ is the column vector of size $V$ and containing only 1's, and $B$ stands for the $V \times \tilde{E}$ matrix with coefficients

$$B_{i,e} = \begin{cases} \frac{1}{2}, & \text{if } e = i \text{ or } e = i^* \text{ or } \overline{e} = i \text{ or } \overline{e} = i^* \\ 0, & \text{otherwise} \end{cases}$$

which is the matrix of the operator $B$ defined in (2.1) when $\mathcal{H}$ is identified with $\mathbb{R}^{\tilde{E}}$. (N.B.: in the last formula we understand the subset $\tilde{E}$ as a subset of $E$ obtained by taking a representative among two equivalent edges $(i, j)$ and $(j^*, i^*)$.)

We denote by $G^Y$ the infinitesimal generator of the Markov Jump Process with rate $Y$

$$G^Y f(i) = \sum_{j, i \rightarrow j} Y_{i,j}(f(j) - f(i)), \ \forall f \in \mathbb{R}^V.$$  

Since $Y$ is in $\mathcal{L}_1$, 1 is an invariant measure of $G^Y$ (i.e., $1G^Y = 0$), hence $G^Y$ leaves invariant $\mathcal{K}_0 = \{ x \in \mathbb{R}^V : \sum_{i \in V} x_i = 0 \}$ so that $\text{Im}(G^Y) = \mathcal{K}_0$ by Perron-Frobenius theorem (existence of spectral gap), and $(G^Y)^{-1}$ is well-defined on $\mathcal{K}_0$.

Let

$$\mathcal{S} = \{(h_i)_{i \in V}, \ h_i = h_{i^*}\} \simeq \mathbb{R}^V, \ \mathcal{A} = \{(h_i)_{i \in V}, \ h_i = -h_{i^*}\} \simeq \mathbb{R}^{\mathcal{V}_1}.$$  

and let us consider the corresponding orthogonal projections on $\mathcal{S}$ and $\mathcal{A}$ given by

$$\mathcal{P}_\mathcal{S} h_i = \frac{1}{2}(h_i + h_{i^*}), \ \mathcal{P}_\mathcal{A} h_i = \frac{1}{2}(h_i - h_{i^*})$$

**Lemma 7.** (Orthogonal decomposition) For all $x \in \mathcal{H}$, we have

$$x = \lambda Y + \omega + z,$$

where $\lambda Y$, $\omega$ and $z$ are one by one orthogonal for the $Q$-scalar product, $\text{div}(z) = 0$, and $\lambda, \omega \in \mathcal{H}_0$ are defined by

$$\lambda = \sum_{(i,j) \in E} x_{i,j} \omega_{i,j} = Y_{i,j}(v_i + v_j) \text{ where } v = (G^Y)^{-1}(h) \in \mathcal{A} \text{ with } h = \frac{1}{2}\text{div}(x) \in \mathcal{A}.$$  

Note that

$$Q(\omega, \omega) = -2 < h, (G^Y)^{-1}h >.$$

On the other hand we prove in Section 5.2 that the Jacobian of the change of variables

$$(x_e) \in \mathcal{H} \rightarrow (\lambda, (z_e), (h_i)) \in \mathbb{R} \times \mathcal{L}_0 \times \mathcal{A}$$

is $\pm 1$, so that

$$\int_\mathcal{H} e^{-\frac{1}{2}Q(x)} dx = 2\sqrt{\pi} \int_{\mathcal{L}_0} e^{-\frac{1}{2}Q(z)}(dz) \int_{\mathcal{A}} e^{\frac{1}{2}h, (G^Y)^{-1}h} \prod_{i \in \mathcal{V}_1} dh_i.$$  

**Proof.** Note that $x' := x - \lambda Y \in \mathcal{H}_0$ since $Y \in \mathcal{L}_1$. Moreover, $Q(Y, Y) = 1$ and, for any $x \in \mathcal{H}$, we have

$$Q(x, Y) = \sum_{i \rightarrow j} x_{i,j} - \sum_{i \in V} x_i + \left( \sum_{i \rightarrow j} Y_{i,j} \right) \left( \sum_{i \rightarrow j} x_{i,j} \right) = \sum_{i \rightarrow j} x_{i,j},$$

which implies $Q(z, Y) = Q(\omega, Y) = 0$ since $z, \omega \in \mathcal{H}_0$. 

Let us now find \( \omega \in \mathcal{H}_0 \) such that \( Q\omega = \nabla v \) for some \( v \), and \( \text{div}(\omega) = \text{div}(x') \): note that this will directly imply that \( \omega \) is orthogonal, with respect to the scalar product \( Q(\cdot, \cdot) \), to all \( z \in \mathcal{H}_0 \) such that \( \text{div}(z) = 0 \) (and in particular to \( z = x' - \omega \)), since \( (\text{Im} \nabla)^\perp = \ker \text{div} \). Now it follows from (4.1) that \( Q \) is a diagonal matrix with coefficients \( D_E^{-1} \) on the subspace \( \mathcal{H} \cap \{ x \in \mathbb{R}^E \text{ s.t. } x_i = -x_j \} \), on which we have \( (Q\omega)_{ij} = Y_{ij}^{-1} \omega_{ij} \). Our first condition yields \( \omega_{ij} = Y_{ij}(v_j - v_i) \), and the second is satisfied in particular if \( \omega_i = (G^Y v)_i = \text{div}(x)_i/2 = h_i \) for all \( i \in V \), which is equivalent to \( v = \left( G^Y \right)^{-1} h \).

**Lemma 8.** We have

\[
\int_{\mathcal{H}} e^{-\frac{1}{4}Q(x)} dx = \sqrt{2^{\lvert E \rvert + \lvert V_0 \rvert + \lvert \mathcal{V}_1 \rvert}} \left( \prod_{(i,j) \in \tilde{E}} \sqrt{Y_{i,j}} \right) \left( \prod_{i \in V_0 \cup \mathcal{V}_1} \sqrt{Y_i} \right) \det((-G^Y + 2D_V 1^t D_V)|_{S \times S})
\]

Proof. It follows from (4.1) that

\[
\int_{\mathcal{H}} e^{-\frac{1}{4}Q(x)} dx = \sqrt{2^{|E|}} \left( \prod_{(i,j) \in \tilde{E}} Y_{i,j} \right) \sqrt{\det(\text{Id}_E - \frac{1}{2}D_E^t B D_V^{-1} B + \frac{1}{2}D_E^t B 1^t 1B)}
\]

Using the classical formula \( \det(\text{Id}_n + AB) = \det(\text{Id}_m + BA) \) for \( A \) (resp. \( B \)) a \( n \times n \) (resp. \( m \times m \)) matrix, we deduce

\[
\det \left( \text{Id}_E - \frac{1}{2}D_E^t B D_V^{-1} B + \frac{1}{2}D_E^t B 1^t 1B \right) = \det \left( \text{Id}_E - \frac{1}{2}D_E^t B D_V^{-1} + \frac{1}{2}D_E^t B 1^t 1B \right)
\]

\[
= \det \left( \text{Id}_E - \frac{1}{2}BD_E^t BD_V^{-1} + \frac{1}{2}BD_E^t B 1^t 1 \right)
\]

Direct computation yields, for \( h \in \mathbb{R}^V \), \( (i, j) \in \tilde{E} \)

\[
(D_E^t B h)_{i,j} = \frac{1}{2} Y_{i,j} (h_i + h_j + h_{i^*} + h_{j^*}),
\]

hence,

\[
BD_E^t Bh_i = \frac{1}{4} \left( \sum_{j \to j^*} Y_{i,j}(h_i + h_j + h_{i^*} + h_{j^*}) + \sum_{j^* \to j} Y_{i^*,j^*}(h_j + h_i + h_{j^*} + h_{i^*}) \right)
\]

\[
= \frac{1}{4}(G^Y h_i + G^Y h_i^* + G^Y h_{i^*} + G^Y h_{i^*}) + (Y_i h_i + Y_i h_i^*)
\]

\[
= \mathcal{P}_S G^Y \mathcal{P}_S h_i + 2D_V \mathcal{P}_S h_i.
\]

where in the second line \( h^* \) is the vector \( h_i^* = h_{i^*} \). Since \( Y_i = Y_i^* \) we have

\[
D_V \mathcal{P}_S = \mathcal{P}_S D_V = \mathcal{P}_S D_V \mathcal{P}_S,
\]

hence

\[
BD_E^t B = \mathcal{P}_S G^Y \mathcal{P}_S + 2\mathcal{P}_S D_V \mathcal{P}_S.
\]

Similarly

\[
BD_E^t B 1^t 1h_i = 2Y_i \left( \sum_{j \in V} h_j \right)
\]

thus \( BD_E^t B 1^t 1 = 2D_V 1^t 1 = 2\mathcal{P}_S D_V 1^t 1 \mathcal{P}_S \).
In summary, we have
\[
\det \left( \text{Id}_V - \frac{1}{2} BD_{E} \cdot B D_{E}^{-1} + \frac{1}{2} BD_{E} \cdot B 1 \cdot 1 \right)
\]
\[
= \det \left( \text{Id}_V - \frac{1}{2} \mathcal{P}_S (G^Y (D_V)^{-1} + 2 \text{Id}) \mathcal{P}_S + \mathcal{P}_S D_V 1 \cdot 1 \mathcal{P}_S \right)
\]
\[
= \det \left( \left( \prod_{i \in V_0 \cup V_1} Y_i \right)^{-1} \det \left( \left( -\frac{1}{2} G^Y + D_V 1 \cdot 1 \right) \right) \mathcal{P}_S \right)
\]
\[
= 2^{-|V_0| - |V_1|} \left( \prod_{i \in V_0 \cup V_1} Y_i \right)^{-1} \det \left( \left( -G^Y + 2 D_V 1 \cdot 1 \right) \right)
\]
where by \( \det(M|_S) \) we understand the determinant of the matrix \( \mathcal{P}_S M \mathcal{P}_S \) viewed as a linear operator from \( S \) to \( S \).

Equation (4.2) now enables us to conclude. Indeed,
\[
\int_{\mathcal{A}} e^{\frac{1}{2} h (G^Y)^{-1} h} \prod_{i \in V_1} dh_i = \det \left( (G^Y)^{-1} \right)_{\mathcal{A}} = \det \left( (G^Y + 2 D_V 1 \cdot 1 D_V)^{-1} \right)_{\mathcal{A}},
\]
where we use in the last equality that \( \mathcal{P}_A (G^Y)^{-1} \mathcal{P}_A = \mathcal{P}_A (G^Y + 2 D_V 1 \cdot 1 D_V)^{-1} \mathcal{P}_A \) on \( \mathcal{A} \).

On the other hand,
\[
\int_{\mathcal{L}_0} e^{-\frac{1}{2} \mathcal{L}(y)} (d\mathcal{L}_0)_{\mathcal{T}_0} = \frac{1}{2 \sqrt{\pi}} \int_{\mathcal{A}} e^{\frac{1}{2} h (G^Y)^{-1} h} \prod_{i \in V_1} dh_i
\]
\[
= \sqrt{2^{E} + |V_0| + |V_1| - 2} \sqrt{\pi}^{\mid E \mid - |V_1| - 1} \left( \prod_{(i,j) \in E} \sqrt{Y_{i,j}} \right) \left( \prod_{i \in V_0 \cup V_1} \sqrt{Y_i} \right) \sqrt{\det \left( \left( G^Y + 2 D_V 1 \cdot 1 D_V \right)^{-1} \right)_{\mathcal{T}_0}}
\]
\[
= \left( \prod_{(i,j) \in E} \sqrt{Y_{i,j}} \right) \left( \prod_{i \in V_0 \cup V_1} \sqrt{Y_i} \right) \sqrt{2^{2|V_0| + |V_1|}} \sqrt{\det \left( G^Y + 2 D_V 1 \cdot 1 D_V \right)}
\]

since \( S \) and \( A \) are orthogonal. In the last equality, we used that for a matrix \( M \) with block decomposition on a linear decomposition of the space \( E = E_1 + E_2 \)

\[
M = \begin{pmatrix} A & B \\ C & D \end{pmatrix}
\]

then \( \det M = \frac{\det(A)}{\det((M^{-1})_{|E_2})} \). Finally, since, the sum of lines (resp. columns) of \( G^Y \) are zero and since \( \sum Y_i = 1 \), we have, summing all lines in the line \( j_0 \) and all columns in the column \( j_0 \) that

\[
\det (G^Y + 2 D_V 1 \cdot 1 D_V) = 2 \det ((G^Y)_{|V \setminus \{j_0\}}),
\]
for any choice of vertex \( j_0 \).
5. Appendix

5.1. Bases of $\mathcal{L}_0$. Let us first describe the bases of $\mathcal{L} = \{x \in \mathcal{H}, \ \text{div}(x) = 0\}$. Consider the graph $\overline{G} = (\overline{V}_1 \cup \overline{V}_1^* \cup \{\delta\}, E)$ where the edges are obtained from the edges of $G$ by identification of the vertices of $V_0$ to the single point $\delta$.

**Lemma 9.** A subset $B \subseteq \tilde{E}$ is a basis of $\mathcal{L}$ if and only if $E \setminus (B \cup B^*)$ is a spanning tree of $\overline{G}$ (where we understand that $B^* = \{(j^*, i^*), (i, j) \in B\}$).

**Proof.** Indeed, we have $\mathcal{L}^\perp \cap \mathcal{H} = \{\nabla h, \ h \in A\}$. Indeed classically, $\mathcal{L}^\perp = (\ker \text{div} \cap \mathcal{H})^\perp = \text{Im} \nabla + \mathcal{H}^\perp$, hence $\mathcal{L}^\perp \cap \mathcal{H} = \text{Im} \nabla \cap \mathcal{H}$ and $\nabla h \in \mathcal{H}$ if and only if there exists a constant $c$ such that $h - c \in A$.

This implies that if $T \subseteq \tilde{E}$ is a basis of $\mathcal{L}^\perp \cap \mathcal{H}$ then $T \cup T^*$ is a spanning tree of $\overline{G}$. Indeed, $\nabla h(e^*) = \nabla h(e)$ if $h \in A$ and thus $T \cup T^*$ cannot contain any cycle in $\overline{G}$ (otherwise the corresponding $\nabla h(e)$ would be linearly dependent) and must connect the vertices of $\overline{G}$.

Then the bases of $\mathcal{L}_0$ are obtained from the bases of $\mathcal{L}$ by $B \setminus \{e_0\}$ where $e_0 \in \tilde{E} \setminus B$. The fact that the Jacobian between two different bases is $\pm 1$ is a consequence of the computation of the change section.

5.2. The Jacobian of the change of variable in Lemma [7]. The subset $E \setminus (B \cup B^*)$ is a spanning tree of $\overline{G}$; moreover it can always be decomposed in the following way : there exists $\overline{T} \subseteq E$ such that

- $\overline{T}$ is a connected tree in $\overline{G}$ containing the point $\delta$.
- $\overline{T} \cap \overline{T}^* = \emptyset$ and $\overline{T} \cup \overline{T}^* = E \setminus (B \cup B^*)$.

Let $\overline{V}_1$ be the set of vertices connected to $\delta$ by $\overline{T}$. Then $\overline{V}_1^*$ is the set of vertices connected to $\delta$ by $\overline{T}^*$ and $\overline{V}_1 \cap \overline{V}_1^* = \emptyset$, $\overline{V}_1 \cap \overline{V}_1 = \hat{V}$ (i.e. $\overline{V}_1$ is a representation of the points of $\hat{V}$ quotiented by the identification of $i$ with $i^*$, possibly different from $V_1$). Up to a sign, the change of variable in Lemma [7] is the same as the change of variable

$$(x_e)_{e \in E} \in \mathcal{H} \rightarrow (\lambda_e, (z_e)_{e \in E^*}, (h_i)_{i \in \overline{V}_1}) \in \mathbb{R} \times \mathcal{L}_0 \times A$$

We decompose this change of variables in three steps. The first step

$$(x_e)_{e \in \tilde{E}} \rightarrow (\lambda, y = x - \lambda Y) \in \mathbb{R} \times \mathcal{H}_0$$

has clearly Jacobian 1 for any choice of basis $(y_e)_{e \in \tilde{E} \setminus \{e_0\}}$, for some $e_0 \in \tilde{E}$. Since, $\text{div}(Y) = 0$ we have $h = \frac{1}{2} \text{div}(x) = \frac{1}{2} \text{div}(y)$ and we then make the change of variables

$$(y_e)_{e \in B \setminus \{e_0\}}, (y_e)_{e \in T} \rightarrow ((y_e)_{e \in B \setminus \{e_0\}}, (h_i)_{i \in \overline{V}_1})$$

which is linear with matrix

$$
\begin{pmatrix}
\text{Id} & 0 \\
* & J_T
\end{pmatrix}
$$
where $J_T$ is the incident matrix of the tree $T$ given by

$$(J_T)_{e,i} = \begin{cases} 
1, & \text{if } e = i \\
-1, & \text{if } \tau = i \\
0, & \text{otherwise}
\end{cases}$$

for $e \in T$ and $i \in \overline{V}_1$. Since $T$ is a spanning tree on $\overline{V}_1$, then $\det(J_T) = \pm 1$. In the last step we make the change of variables

$$((y_e)_{e \in B \setminus \{e_0\}}, (h_i)_{i \in \overline{V}_1}) \rightarrow ((z_e)_{e \in B \setminus \{e_0\}}, (h_i)_{i \in \overline{V}_1}),$$

which has matrix

$$\begin{pmatrix}
\text{Id} & * \\
0 & \text{Id}
\end{pmatrix}$$

and has Jacobian 1.

Hence, the change of variable of Lemma [7] is $\pm 1$. The fact the the Jacobian does not depend on the choice of the basis $B \setminus \{e_0\}$ implies that the Jacobian between two of these bases is always $\pm 1$.
