CHARACTERS OF IRREDUCIBLE UNITARY REPRESENTATIONS OF $U(n, n+1)$ VIA DOUBLE LIFTING FROM $U(1)$

ALLAN MERINO

Abstract. In this paper, we obtained character formulas of irreducible unitary representations of $U(n, n+1)$ by using Howe’s correspondence and the Cauchy–Harish-Chandra integral. The representations of $U(n, n+1)$ we are dealing with are obtained from a double lifting of a representation of $U(1)$ via the dual pairs $(U(1), U(1, 1))$ and $(U(1, 1), U(n, n+1))$.

1. Introduction

For a finite dimensional representation $(\Pi, V)$ of a group $G$, one can associate a function $\Theta_{\Pi}$ on $G$ given by

$$\Theta_{\Pi} : G \ni g \rightarrow \text{tr}(\Pi(g)) \in \mathbb{C}.$$ 

The function $\Theta_{\Pi}$ is the character of the representation $(\Pi, V)$, and it determines entirely the representation. Obviously, if we remove the assumption that $V$ is finite dimensional, the map $\Theta_{\Pi}$ does not necessarily makes sense in general. In [S, Section 5], Harish-Chandra extended the concept of character for a particular class of representations of a real reductive Lie group. More precisely, he proved that for a quasi-simple representation $(\Pi, \mathcal{H})$ (see [7, Section 10]) of a real reductive Lie group $G$, the operator $\Pi(\Psi), \Psi \in C^\infty_c(G)$, given by

$$\Pi(\Psi) = \int_G \Psi(g)\Pi(g)dg,$$

is a trace class operator and the corresponding map

$$\Theta_{\Pi} : C^\infty_c(G) \ni \Psi \rightarrow \text{tr}(\Pi(\Psi)) \in \mathbb{C}$$

is a distribution; $\Theta_{\Pi}$ is usually called the distribution character of $\Pi$. Moreover, Harish-Chandra proved (see [9, Theorem 2]) that there exists a locally integrable function $\Theta_{\Pi}$ on $G$, analytic on $G^\text{reg}$ (where $G^\text{reg}$ is the set of regular points of $G$, see [9, Section 3]), such that

$$\Theta_{\Pi}(\Psi) = \int_G \Theta_{\Pi}(g)\Psi(g)dg, \quad (\Psi \in C^\infty_c(G)).$$

The locally integrable function $\Theta_{\Pi}$ is the character of $\Pi$. In few cases, an explicit value of $\Theta_{\Pi}$ is well-known:

1. $G$ compact (H. Weyl),
2. $(\Pi, \mathcal{K})$ a discrete series representation:
   (a) Harish-Chandra (see [5]) established a formula for $\Theta_{\Pi}$ on the compact Cartan subgroup $T$ of $G$,
   (b) Hecht (see [10]) determined the value of $\Theta_{\Pi}$ on every Cartan subgroup of $G$ for holomorphic discrete series representation,
3. $(\Pi, \mathcal{H})$ irreducible unitary highest weight module (Enright, [5] Corollary 2.3, see also [20]).

The goal of this paper is to explain how to use Howe’s correspondence and the Cauchy–Harish-Chandra integral introduced by T. Przebinda to get explicit values of characters for some particular irreducible unitary non-highest weight modules of $U(n, n+1)$ starting from a representation of $U(1)$. Our method is as follows. Let $(G, G') = (U(1), U(p, q)), p, q \geq 1$, be a dual pair in $\text{Sp}(2(p+q), \mathbb{R}), \text{Sp}(2(p+q), \mathbb{R})$ be the corresponding metaplectic group (see Equation (1)), $\omega_{pq}^1$ be the metaplectic representation of $\text{Sp}(2(p+q), \mathbb{R})$ (see Theorem 2.2), $\widetilde{G}$ and $\widetilde{G}'$ be the

$\textbf{2010 Mathematics Subject Classification.}$ Primary: 22E45; Secondary: 22E46, 22E30.

$\textbf{Key words and phrases.}$ Howe correspondence, Characters, Cauchy–Harish-Chandra integral, Orbital Integrals.
preimages of $G$ and $G'$ in $\widetilde{Sp}(2(p+q),\mathbb{R})$ and $\Pi$ be a representation of $U(1)$. We denote by $\theta_{p,q}^1$ the map coming from Howe’s duality theorem (see Equation (3))

$$\theta_{p,q}^1 : \mathcal{A}(U(1), \omega_{p,q}) \to \mathcal{A}(U(p,q), \omega_{p,q}),$$

where $\mathcal{A}(U(1), \omega_{p,q})$ and $\mathcal{A}(U(p,q), \omega_{p,q})$ are defined in Notation [14]. By assumption on $p$ and $q$, $\Pi' := \theta_{p,q}^1(\Pi)$ is a non-zero irreducible unitary highest weight module of $U(p,q)$. In Appendix A we computed the value of the character $\Theta_{\Pi'}$ of every Cartan subgroup of $U(p,q)$. A similar result was obtained in [21] for $p = q = 1$.

We now consider the dual pair $(G', G_n) = (U(p,q), U(n, n+1))$ in $Sp(2(p+q)(2n+1), \mathbb{R})$. As before, we denote by $\widetilde{Sp}(2(p+q)(2n+1), \mathbb{R})$ the metaplectic group of $Sp(2(p+q)(2n+1), \mathbb{R})$, $\omega_{p,q}^*_{n,n+1}$ the metaplectic representation of $\widetilde{Sp}(2(p+q)(2n+1), \mathbb{R})$ and

$$\theta_{p,q}^{'*}_{a,n+1} : \mathcal{A}(U(p,q), \omega_{p,q}^*_{n,n+1}) \to \mathcal{A}(U(n,n+1), \omega_{p,q}^*_{n,n+1})$$

the map obtained from Howe’s correspondence (see Equation (3)). Using a result of Kudla (see [18]), it follows that $\Pi'' := \theta_{p,q}^{'*}_{n,n+1}(\Pi') \neq 0$ for every $n \geq 2$, i.e. $\Pi'' \in \mathcal{A}(U(n,n+1), \omega_{p,q}^*_{n,n+1})$. Note that by using [19], it follows that $\Pi'' = \Pi''$, where $\Pi''$ is usually called the "big theta" and is defined in Section 5.

As explained in [25] (see also Remark 4.5), by using that $\Pi''$ is unitary, we get that if $p + q \leq n$, the distribution character $\Theta_{\Pi''}$ of $\Pi''$ can be obtained by using the Cauchy–Harish-Chandra integral (see Section 4). More precisely, because $\Pi'' = \Pi''$, we get from Equation (4), Theorem 5.5 and Equation (9) that:

$$\Theta_{\Pi''}(\Psi) = \sum_{n=1}^{\min(p,q)+1} \int_{H_n'} \Theta_{\Pi''}(h'_n') |\det(Id - Ad(h'_n')^{-1})|_{g_n'}^{1/2} \text{Chc}_{h'_n'}(\Psi) d\mu'_n', \quad (\Psi \in \mathcal{C}^\infty_c(G_n)), $$

where $H'_1, \ldots, H'_{\min(p,q)+1}$ is a maximal set of non-conjugate Cartan subgroups of $G'$ and $\text{Chc}_{h'_n'}$ is a family of distributions on $G_n$ parametrized by regular elements on the different Cartan subgroups of $G'$ as recalled in Section 4.

In this paper, we compute explicitly the value of $\Theta_{\Pi''}$ on every Cartan subgroup of $G_n$ for $p = q = 1$. We keep the notations of Appendix [13] and parametrize the $n + 1$ Cartan subgroups of $G_n$ by subsets $S_0 = \{0\}, S_1, \ldots, S_n$ of strongly orthogonal imaginary roots of $g_n$ (see also [26, Section 2]) and let $H_{\alpha(S_0)}, \ldots, H_{\alpha(S_n)}$ be the corresponding Cartan subgroups of $G_n$ and $H_{\alpha(S_0)} \subset \ldots \subset H_{\alpha(S_n)}$, by the diagonal subgroups of $GL(2n + 1, \mathbb{C})$ given, for $0 \leq t \leq n$, by $H_{\alpha(S_t)} = c(S_t)^{-1}H_{\alpha(S_t)}c(S_t)$, where $c(S_t)$ is the Cayley transform defined in Equation (32).

In Theorem 6.10 we explain how to go from the distribution character $\Theta_{\Pi''}$ to the locally integrable function $\Theta_{\Pi''}$ by using results of Bernon and Przebinda from [3] and [2] (see also Section 5). In Theorem 6.10 we computed the value of $\Theta_{\Pi''}$ of the different Cartan subgroups of $G_n$ and get for every $t \in \{0, \ldots, n\}$

$$\Theta_{\Pi''}(c(S_t)) \hat{\rho}(h)c(S_t)^{-1}) = \pm C \sum_{j \in K(\alpha(S_t))} h^j h^j + \pi \Omega_{\alpha(S_t)}(h) + \delta_{0,0} B e^{-(m+1)\pi \text{sgn}(X_{2n+1})X_{2n+1}} \Sigma(h) \quad \text{if } m \geq 1$$

$$\Theta_{\Pi''}(c(S_t)) \hat{\rho}(h)c(S_t)^{-1}) = \pm C \sum_{j \in K(\alpha(S_t))} h^j h^j + \pi \Omega_{\alpha(S_t)}(h) + \delta_{0,0} B e^{-(m+1)\pi \text{sgn}(X_{2n+1})X_{2n+1}} \Sigma(h) \quad \text{if } m = 0$$

$$\Theta_{\Pi''}(c(S_t)) \hat{\rho}(h)c(S_t)^{-1}) = \pm C \sum_{j \in K(\alpha(S_t))} h^j h^j + \pi \Omega_{\alpha(S_t)}(h) + \delta_{0,0} B e^{-(m-1)\pi \text{sgn}(X_{2n+1})X_{2n+1}} \Sigma(h) \quad \text{if } m \leq -1$$

where $C$ is a constant, $m$ is the highest weight of $\Pi$ (see Notation [14]), $\hat{H}_{\alpha(S_t)}$ is a double cover of $H_{\alpha(S_t)}$ defined in Equation (5), $\hat{\rho} : \hat{H}_{\alpha(S_t)} \to \hat{H}_{\alpha(S_t)}$ is defined in Section 5 $h$ is the element of $H_{\alpha(S_t)}$, given, as in Equation (17), by

$$h = (h_1, \ldots, h_{2n+1}) = \text{diag}(e^{iX_1}, \ldots, e^{iX_{2n+1}}, e^{iX_{-2}}, e^{iX_{-1}}, e^{iX_{-2}}, \ldots, e^{i(2n+1)}, X_j \in \mathbb{R},$$
where $\Omega_{i,j}$, $1 \leq i \neq j \leq 2n + 1$, and $\Sigma$ are the functions on $H^\text{reg}_{n,S_i}$ are given by

$$\Omega_{i,j}(h) = \frac{2n+1}{\prod_{k=1}^{2n+1} h_k} \prod_{k=1}^{2n+1} (h_i - h_k) \prod_{j=1}^{2n+1} (h_j - h_l), \quad \Sigma(h) = \frac{\text{sgn}(X_{2n+1}) e^{\text{im}X_1} \left(e^{2n-2}X_{2n+1}\right)}{\prod_{k=2}^{2n} \left(1 - h_k h_{k+1}^{-1}\right) \prod_{k=2}^{2n} \left(1 - h_k h_{2n+1}^{-1}\right)} \left(1 - e^{-2X_{2n+1}}\right)^2}.$$  

$K(h)$ and $J(h)$ are the subsets of $[1, \ldots, t]$ defined by

$$J(h) = \{j \in [1, \ldots, t], \text{sgn}(X_{2n+2-j}) = 1\}, \quad K(h) = \{j \in [1, \ldots, t], \text{sgn}(X_{2n+2-j}) = -1\},$$

$A_t$ and $B_t$ are the subsets of $[1, \ldots, 2n + 1]$ given by

$$A_t = \{t + 1, \ldots, n\}, \quad B_t = \{n + 1, \ldots, 2n + 1 - t\},$$

sgn is the sign-function on $\mathbb{R}^*$ given by

$$\text{sgn}(X) = \begin{cases} 1 & \text{if } X > 0, \\ -1 & \text{if } X < 0, \end{cases} \quad (X \in \mathbb{R}^*),$$

and $\bar{A}$ and $B$ are constants defined in Theorems 6.8 and 6.10. As explained in Lemma 6.11 the denominator

$$\prod_{k=2}^{2n} \left(1 - h_k h_{k+1}^{-1}\right) \prod_{k=2}^{2n} \left(1 - h_k h_{2n+1}^{-1}\right)$$

is real and its sign is constant on every Weyl chamber.

Note that the representation $\Pi^n$ is irreducible and unitary but not an highest weight module. In particular, its character $\Theta_{\Pi^n}$ cannot be obtained by using Enright’s formula (see [5, Corollary 2.3]) or [20]. Our formula for the character is Weyl denominator free. The method we used in this paper gives a general procedure to give characters of non-highest weight representations by starting from an highest weight representation of a compact group. In particular, proving Conjecture 4.2 could make our method more general, by removing the assumption of stable range for the second lifting.

The paper is organised as follows. In Section 2 we recalled a construction of the metaplectic representation given by Aubert and Przebinda in [11]. The goal is to define the embedding $T$ of the metaplectic group into the set of tempered distributions on the symplectic space $W$ (see Equation 3) which is crucial in the construction of the Cauchy–Harish-Chandra integral. After recalling Harish-Chandra’s character theory and Howe’s correspondence in Section 3 we define in Section 4 the Cauchy–Harish-Chandra integral and explain a conjecture of Przebinda on the transfer of characters in the theta correspondence (see Conjecture 4.3). In Section 5 we summarized the results of 3 and 4 on how to compute the Cauchy–Harish-Chandra integral on the different Cartan subgroups, and we adapt the results to unitary groups, which are the one we consider in this paper, and make the computations for $\Theta_{\Pi^n}$ in Section 6 (see Theorem 6.5 and Proposition 6.10). The document contains three appendices: in Appendix A we make computations for $\Pi'$ for the dual pair $(G, G') = (U(1), U(p,q))$ on every Cartan subgroup of $G'$, in Appendix B we recall how to parametrize the Cartan subgroups of $U(p,q)$ by using strongly orthogonal roots (see also [26, Section 1]) and in Appendix C we define a character $\epsilon$ appearing in the formulas for the Cauchy–Harish-Chandra integrals and proved a lemma for $\epsilon$ useful in the proof of Lemma 6.4.

Acknowledgements: I would like to thank Tomasz Przebinda for the useful discussions during the preparation of this paper. This research was supported by the MOE-NUS AcRF Tier 1 grants R-146-000-261-114 and R-146-000-302-114.
2. METAPLECTIC REPRESENTATION

Let $\chi$ be the character of $\mathbb{R}$ given by $\chi(t) = e^{2\pi it}$ and let $W$ be a finite dimensional vector over $\mathbb{R}$ endowed with a non-degenerate, skew-symmetric, bilinear form $\langle \cdot, \cdot \rangle$. We denote by $\text{Sp}(W)$ the corresponding group of isometries, i.e.

$$\text{Sp}(W) = \{ g \in \text{GL}(W), \langle g(w_1), g(w_2) \rangle = \langle w_1, w_2 \rangle, (\forall w_1, w_2 \in W) \} ,$$

and by $\text{sp}(W)$ its Lie algebra given by:

$$\text{sp}(W) = \{ X \in \text{End}(W), \langle X(w_1), w_2 \rangle + \langle w_1, X(w_2) \rangle = 0, (\forall w_1, w_2 \in W) \} .$$

We first start by recalling the construction of the metaplectic group $\widetilde{\text{Sp}}(W)$: it is a connected two-fold cover of $\text{Sp}(W)$. We use the formalism of [1]. Let $J$ be a compatible positive complex structure on $W$, i.e. an element of the Lie algebra $\text{sp}(W)$ satisfying $J^2 = -\text{Id}_W$ and such that the symmetric form $\langle J \cdot, \cdot \rangle$ is positive definite. For every element $g \in \text{Sp}(W)$, we denote by $J_g$ the element of $\text{End}(W)$ given by $J_g = J^{-1}(g - 1)$. One can easily check that the restriction of $J_g$ to $\phi_g(W)$ is invertible and let $\text{Sp}(W)$ be the subset of $\text{Sp}(W) \times \mathbb{C}^\times$ defined by

$$\text{Sp}(W) = \left\{ \bar{g} = (g, \xi) \in \text{Sp}(W) \times \mathbb{C}^\times, \xi^2 = \text{dim}_W \det(J_g)^{-1} \right\} ,$$

where $\det(J_g)^{-1}$ denotes the determinant of the endomorphism $J_g$ restricted to $J_g(W)$. On $\widetilde{\text{Sp}}(W)$, we define a multiplication by:

$$(g_1, \xi_1)(g_2, \xi_2) = (g_1 g_2, \xi_1 \xi_2 C(g_1, g_2)) \quad (g_1, g_2 \in \text{Sp}(W), \xi_1, \xi_2 \in \mathbb{C}^\times) ,$$

where $C : \text{Sp}(W) \times \text{Sp}(W) \to \mathbb{C}^\times$ is a cocycle defined in [1] Proposition 4.13. Let $\Theta$ be the map defined by:

$$\Theta : \widetilde{\text{Sp}}(W) \ni \bar{g} = (g, \xi) \to \xi \in \mathbb{C}^\times .$$

One can check easily that $\widetilde{\text{Sp}}(W)$ is a connected two-fold cover of $\text{Sp}(W)$, where the covering map $\pi : \widetilde{\text{Sp}}(W) \to \text{Sp}(W)$ is given by $\pi((g, \xi)) = g$.

For every $g \in \text{End}(W)$, we denote by $c(g)$ the Cayley transform of $g$ defined by:

$$c(g) : (g - 1)W \ni (g - 1)w \to (g + 1)w + \text{Ker}(g - 1) \in W/\text{Ker}(g - 1) .$$

We denote by $\text{S}(W)$ the Schwartz space of $W$ and by $\text{S}'(W)$ the corresponding space of tempered distributions. We define the map $t : \widetilde{\text{Sp}}(W) \to \text{S}'(W)$ by $t(g) = X_{c(g)} \mu_{(g - 1)W}$, where $X_{c(g)}$ is the function on $(g - 1)W$ given by

$$X_{c(g)}(w) : (g - 1)W \to \chi \left( \frac{1}{4} c(g)w, w \right) , \quad (w \in (g - 1)W) ,$$

and $\mu_{(g - 1)W}$ is the Lebesgue measure on $(g - 1)W$ such that the volume of the unit cube with respect to the bilinear form $(J, \cdot)$ is $1$. More precisely,

$$t(g) \phi = \int_{(g - 1)W} X_{c(g)}(w) \phi(w) d\mu_{(g - 1)W}(w) , \quad (\phi \in \text{S}(W)) .$$

We define the map $T : \widetilde{\text{Sp}}(W) \to \text{S}'(W)$ given by

$$T(\bar{g}) = \Theta(\bar{g}) t(g) \quad (\bar{g} = (g, \xi) \in \text{Sp}(W), g = \pi(\bar{g})) .$$

**Remark 2.1.** Let $\bar{g}_1, \bar{g}_2 \in \widetilde{\text{Sp}}(W)$. The question of the relation between the distributions $T(\bar{g}_1), T(\bar{g}_2)$ and $T(\bar{g}_1 \bar{g}_2)$ arises naturally. In order to explain this link, we need to recall the notion of twisted convolution.

For two functions $\phi_1, \phi_2 \in \text{S}(W)$, we define $\phi_1 \#_2 \phi_2$ the function on $W$ given by

$$\phi_1 \#_2 \phi_2 (w) = \int_W \phi_1(u) \phi_2(w - u) \chi \left( \frac{1}{2} (u, w) \right) d\mu_W(u) , \quad (w \in W) .$$

One can easily check that $\phi_1 \#_2 \phi_2 \in \text{S}(W)$. We extend $\#_2$ to some tempered distributions on $W$. In fact, for every $g \in \text{Sp}(W)$, the twisted convolution

$$t(g) \phi_1 \#_2 \phi_2 (w) = \int_{(g - 1)W} X_{c(g)}(u) \phi_1(u) \phi_2(w - u) \chi \left( \frac{1}{2} (u, w) \right) d\mu_W(u) , \quad (w \in W, \phi \in \text{S}(W)) ,$$

4
is still a Schwartz function and the map:

\[ \text{S}(W) \ni \phi \rightarrow \Theta(\tilde{g})\phi \in \text{S}(W) \]

is well-defined and continuous (see [11 Proposition 4.11]). Similarly, \( T(\tilde{g})\phi \in \text{S}(W) \) for every \( \tilde{g} \in \text{Sp}(W) \) and \( \phi \in \text{S}(W) \). In particular, it makes sense to consider \( T(\tilde{g}_1)\)\( T(\tilde{g}_2)\phi \) for every \( \tilde{g}_1,\tilde{g}_2 \in \text{Sp}(W) \) and \( \phi \in \text{S}(W) \) and one can prove that \( T(\tilde{g}_1)\)\( T(\tilde{g}_2)\phi = T(\tilde{g}_1\tilde{g}_2)\phi \).

Let \( W = X \oplus Y \) be a complete polarization of the space \( W \) and we denote by \( dx, dy \) the Lebesgue measures on \( X \) and \( Y \) respectively such that \( d\mu_{W} = dx dy \). Using the Weyl transform \( \mathcal{K} \), we have a natural isomorphism between the spaces \( \text{S}(W) \) and \( \text{S}(X \times X) \) given by

\[ \mathcal{K} : \text{S}(W) \ni \phi \rightarrow \mathcal{K}(\phi)(x_1, x_2) = \int_{Y} \phi(x_1 - x_2 + y)h\left( \frac{1}{2}(y, x_1 + x_2) \right) dy \in \text{S}(X \times X), \]

which extends to an isomorphism on the corresponding spaces of distributions. Similarly, every tempered distribution on \( X \times X \) can be identified to an element of \( \text{Hom}(\text{S}(X), \text{S}(X)) \) using the Schwartz Kernel Theorem (see [11 Equation 146]). The corresponding isomorphism will be denoted by \( \text{Op} \) and let \( \omega : \text{Sp}(W) \rightarrow \text{Hom}(\text{S}(X), \text{S}(X)) \) be the map given by

\[ \omega = \text{Op} \circ \mathcal{K} \circ \text{T}. \]

As proved in [11 Section 4], we get that for every \( \tilde{g} \in \text{Sp}(W) \) and \( v \in \text{S}(X) \), \( \omega(\tilde{g})v \in \text{S}(X) \) and that \( \omega(\tilde{g}h) = \omega(\tilde{g}) \circ \omega(h) \) for every \( \tilde{g}, h \in \text{Sp}(W) \). The operator \( \omega(\tilde{g}) \) in \( \text{Hom}(\text{S}(X), \text{S}(X)) \) can be extended to \( L^2(X) \) by

\[ \omega(\tilde{g})v = \lim_{|h| \rightarrow 0} \omega(\tilde{g})v, \quad (\phi \in L^2(X)) . \]

**Theorem 2.2.** For every \( \tilde{g} \in \text{S}(W) \) and \( \phi \in L^2(X) \), the map

\[ \text{Sp}(W) \ni \tilde{g} \rightarrow \omega(\tilde{g})\phi \in L^2(X), \]

is well-defined and continuous. Moreover, \( \omega(\tilde{g}) \in \text{U}(L^2(X)) \), i.e. \( \omega \) is a faithful unitary representation of \( \text{Sp}(W) \), and for every \( \Psi \in \mathcal{C}_c^\infty(\text{Sp}(W)) \), we get:

\[ \int_{\text{Sp}(W)} \Theta(\tilde{g})\Psi(\tilde{g})d\tilde{g} = \text{tr \thinspace } \int_{\text{Sp}(W)} \Psi(\tilde{g})\omega(\tilde{g})d\tilde{g}, \]

where \( d\tilde{g} \) is a Haar measure on \( \text{Sp}(W) \).

**Remark 2.3.**

1. Let \( \text{Sp}'(W) \) be the subset of \( \text{Sp}(W) \) given by \( \text{Sp}'(W) = \{ g \in \text{Sp}(W), \det(g - 1) \neq 0 \} \). This is the domain of the Cayley transform. We will denote by \( \text{Sp}_c(W) \) the preimage of \( \text{Sp}'(W) \) in \( \text{Sp}(W) \).

2. For every \( g \in \text{Sp}'(W) \), \( c(g) \in \text{Sp}(W) \). We denote by \( sp'(W) \) the subspace of \( sp(W) \) defined by \( c(\text{Sp}'(W)) \).

3. Obviously, \( c^2 = \text{id} \) and \( c \). It defines a bijective map \( c : \text{sp}'(W) \rightarrow \text{sp}(W) \).

4. In particular, there exists a unique map \( \tilde{c} : \text{sp}'(W) \rightarrow \text{Sp}^{-1}(W) \) such that \( c = \pi \circ \tilde{c} \) and \( \tilde{c}(0) = -1 \).

Moreover, for every \( \Psi \in \text{Sp}(W) \) whose support is included in \( \text{Sp}_c(W) \), we get:

\[ \int_{\text{Sp}(W)} \Psi(\tilde{g})d\tilde{g} \equiv \int_{\text{sp}(W)} \Psi(\tilde{c}(X))j_{\text{sp}(W)}(X)dX, \]

where \( j_{\text{sp}(W)}(X) = |\det(1 - X)|^r \) when \( r = \frac{2 \dim(\text{sp}(W))}{\dim(W)} \) (see [23 Section 3]).

(2) For every \( \Psi \in \mathcal{C}_c^\infty(\text{Sp}(W)) \), we can consider the following distribution on \( W \)

\[ \int_{\text{Sp}(W)} \Psi(\tilde{g})T(\tilde{g})d\tilde{g}. \]

This distribution is in fact given by a Schwartz function. Indeed, let’s first assume that the support of \( \Psi \) is included in \( \text{Sp}_c(W) \). For every \( \phi \in \text{S}(W) \), we get:

\[ \left( \int_{\text{Sp}(W)} \Psi(\tilde{g})T(\tilde{g})d\tilde{g} \right)(\phi) = \int_{\text{Sp}(W)} \Psi(\tilde{g})T(\tilde{g})\phi d\tilde{g} \]
We denote by $U$ Chapter 2, $D$, $G$ dimensional algebras such that $D(\mathfrak{g})$ is an irreducible quasi-simple representation (see [7, Section 10]). As explained in [6], the map $\Theta : \mathcal{C}_c(G) \to \mathcal{C}_c(G)$, where $dg$ is a Haar measure on $G$, is smooth and compactly supported function on $\mathfrak{sp}(W)$ such that $\text{supp}(\Phi(\mathfrak{g})) \subseteq \mathfrak{sp}(W)$, $\mathcal{F}(\Phi(\mathfrak{g}))$ the Fourier transform of $\Phi(\mathfrak{g})$ for every $\mathfrak{g} \in \mathfrak{sp}(W)$, $\mathcal{F}(\Phi(\mathfrak{g}))$ is the moment map defined by $\tau_{\mathfrak{sp}(W)}(\mathfrak{g})(X) = \langle X(w), w \rangle$, $w \in W$, $X \in \mathfrak{sp}(W)$. In particular, $\mathcal{F}(\Phi(\mathfrak{g}))$ is a Schwarz function on $W$.

We can remove the assumption on the support of $\Psi$ by using the previous result. Indeed, the Zariski topology on $\mathfrak{sp}(W)$ is noetherian. In particular, there exists $g_1, \ldots, g_m \in \mathfrak{sp}(W)'$ such that

$$\mathfrak{Sp}(W) = \bigoplus_{i=1}^m \mathfrak{g}_i \mathfrak{Sp}'(W).$$

We can find functions $\Psi_1, \ldots, \Psi_m \in \mathcal{C}_c(\mathfrak{sp}'(W))$ such that for every $\tilde{g} \in \mathfrak{Sp}(W),$

$$1 = \sum_{i=1}^m \Psi_i(\tilde{g}^{-1} \tilde{g}).$$

Then, for every $\Psi \in \mathcal{C}_c(\mathfrak{Sp}(W))$, we get:

$$\int_{\mathfrak{Sp}(W)} \Psi(\tilde{g})T(\tilde{g})d\tilde{g} = \sum_{i=1}^m \int_{\mathfrak{Sp}(W)} \Psi_i(\tilde{g}^{-1} \tilde{g})\Psi(\tilde{g})T(\tilde{g})d\tilde{g}$$

$$= \sum_{i=1}^m \int_{\mathfrak{Sp}(W)} \Psi_i(\tilde{g})\Psi(\tilde{g})T(\tilde{g})d\tilde{g} = \sum_{i=1}^m T(\tilde{g}_i)\left(\int_{\mathfrak{Sp}(W)} \Psi_i(\tilde{g})\Psi(\tilde{g})T(\tilde{g})d\tilde{g}\right).$$

The result follows from Remark 2.1.

3. Character Theory and Howe’s Correspondence

Let $G$ be a real connected reductive Lie group, $\mathfrak{g} = \text{Lie}(G)$ its Lie algebra and $\mathfrak{g}_c = \mathfrak{g} \otimes \mathbb{C}$ its complexification. We denote by $\mathcal{U}(\mathfrak{g}_c)$ the enveloping algebra of $\mathfrak{g}$ (see [17] Chapter 3.1), $Z(\mathcal{U}(\mathfrak{g}_c))$ its center and $D(G)$ the set of differential operators on $G$ and $D_c(G)$ the set of left-invariant differential operators on $G$. As explained in [11] Chapter 2, $D_c(G)$ is isomorphic to $\mathcal{U}(\mathfrak{g}_c)$. Let $D_{\mathfrak{g}}(G)$ be the set of bi-invariant differential operators on $G$ (which is isomorphic to $Z(\mathcal{U}(\mathfrak{g}_c))$, see [11]), $\mathcal{D}(G)$ be the set of distributions on $G$ and $\mathcal{D}(G)$ the set of $G$-invariant distributions.

Definition 3.1. We say that $T \in \mathcal{D}(G)$ is an eigendistribution if there exists $\chi_T : D_{\mathfrak{g}}(G) \to \mathbb{C}$ an homomorphism of algebras such that $D(T) = \chi_T(D)T$ for every $D \in D_{\mathfrak{g}}(G)$.

We will denote by $\text{Eig}(G)$ the set of eigendistributions on $G$.

Theorem 3.2 (Harish-Chandra, [6]). For every $G$-invariant eigendistribution $T$ on $G$, there exists a locally integrable function $f_T$ on $G$, analytic on $G^\text{reg}$, such that $T = T_{f_T}$, i.e. for every function $\Psi \in \mathcal{C}_c(G)$,

$$T(\Psi) = \int_G f_T(g)\Psi(g)dg,$$

where $dg$ is a Haar measure on $G$.

Let $(\Pi, \mathcal{H})$ be an irreducible quasi-simple representation (see [7] Section 10]. As explained in [6], the map

$$\Theta_{\Pi} : \mathcal{C}_c(G) \ni \Psi \to \text{tr}(\Pi(\Psi)) \in \mathbb{C}$$

is an isomorphism of $\mathcal{C}_c(G)$ to the space of traces of the representations $\Pi$ of $G$.
be the set of equivalence classes of irreducible admissible representations of \( \tilde{G} \) which are infinitesimally equivalent.

**Notation 3.4.** For a subgroup \( H \) of \( \text{Sp}(W) \), we denote by \( H \).

**Theorem 3.5**. More precisely, if \( H \) and \( \text{Sp}(W) \). If we denote by \( (\Pi, \omega, g) \) and \( (\Pi', \omega', g') \) respectively. \( W \) is a finite dimensional vector space, and to avoid any confusion, we will denote by \( W \). As in Section 2, we can be seen as a real vector space, and any orthogonal decomposition \( W = W_1 \oplus W_2 \) where both \( W_1 \) and \( W_2 \) are \( G \cdot G' \)-invariant, and called reductive if the actions of \( G \) and \( G' \) on \( W \) are both reductive. The set of irreducible reductive dual pairs in \( \text{Sp}(W) \) had been classified by Howe in [14].

**Remark 3.3.** In this paper, we will focus our attention on a dual pair consisting of two unitary groups. More precisely, let \( V \) and \( V' \) be two complex vector spaces endowed with an hermitian form \( (\cdot, \cdot) \) and skew-hermitian form \( (\cdot, \cdot)' \) respectively. We denote by \( U(V) \) and \( U(V') \) the corresponding group of isometries and by \( W \) the complex vector space given by \( W = V \otimes_C V' \). The space \( W \) can naturally be seen as a real vector space, and to avoid any confusion, we will denote by \( W \) the corresponding real vector space. The skew-hermitian form \( b = (\cdot, \cdot) \otimes (\cdot, \cdot)' \) on \( W \) defines a skew-symmetric form \( (\cdot, \cdot) \) on \( W \) by \( (\cdot, \cdot) = \text{Im}(b) \). In particular, \( (U(V), U(V')) \) is a dual pair in \( \text{Sp}(W) \). If we denote by \( (p, q) \) and \( (r, s) \) the signatures of \( (\cdot, \cdot) \) and \( (\cdot, \cdot)' \) respectively, we get that \( (U(p, q), U(r, s)) \) form a dual pair in \( \text{Sp}(2(p + q)(r + s), \mathbb{R}) \).

**Notation 3.4.** For a subgroup \( H \) of \( \text{Sp}(W) \), we denote by \( \tilde{H} = \pi^{-1}(H) \) the preimage of \( H \) in \( \tilde{\text{Sp}}(W) \) and let \( \tilde{\mathcal{R}}(\tilde{H}, \omega) \) be the set of equivalence classes of irreducible admissible representations of \( \tilde{G} \) which are infinitesimally equivalent to a quotient of \( \mathcal{H}_1 \) by a closed \( \omega^\infty(\tilde{H}) \)-invariant subspace.

**Theorem 3.5 (R. Howe, [15]).** For every irreducible dual pair \( (G, G') \) of \( \text{Sp}(W) \), we get a bijection between \( \tilde{\mathcal{R}}(\tilde{G}, \omega) \) and \( \tilde{\mathcal{R}}(\tilde{G}', \omega) \), whose graph is \( \tilde{\mathcal{R}}(\tilde{G} \cdot \tilde{G}', \omega) \).

More precisely, if \( \Pi \in \tilde{\mathcal{R}}(\tilde{G}, \omega) \), we denote by \( N(\Pi) \) the intersection of all the closed \( \tilde{G} \)-invariant subspaces \( \mathcal{N} \) such that \( \Pi \approx \mathcal{H}_1 \mathcal{N} \). Then, the space \( \mathcal{H}(\Pi) = \mathcal{H}_1 \mathcal{N}(\Pi) \) is a \( \tilde{G} \)-modular; more precisely, \( \mathcal{H}(\Pi) = \Pi \otimes \Pi' \), where \( \Pi' \) is a \( \tilde{G} \)-modular, not irreducible in general, but Howe’s duality theorem says that there exists a unique irreducible quotient \( \Pi' \) of \( \Pi' \) with \( \Pi' \in \tilde{\mathcal{R}}(\tilde{G}', \omega) \) and \( \Pi \otimes \Pi' \in \tilde{\mathcal{R}}(\tilde{G} \cdot \tilde{G}', \omega) \).

We will denote by
\[
\theta : \tilde{\mathcal{R}}(\tilde{G}, \omega) \to \tilde{\mathcal{R}}(\tilde{G}', \omega)
\]
the corresponding bijection.

**Remark 3.6.** If \( G \) is compact, the situation turns out to be slightly easier. The action of \( \tilde{G} \) on \( \mathcal{H}_1 \) can be decomposed as
\[
\mathcal{H}_1 = \bigoplus_{\Pi \in \tilde{\mathcal{R}}(\tilde{G}, \omega)} \mathcal{H}(\Pi),
\]
where \( \mathcal{H}(\Pi) \) is the closure of \( \{T(\mathcal{H}_1) : T \in \text{Hom}_{\tilde{G}}(\mathcal{H}_1, \mathcal{H}_1^\infty) \neq \{0\} \} \) and \( \tilde{\mathcal{R}}(\tilde{G}, \omega) \) is the set of representations \( \Pi \) of \( \tilde{G} \) such that \( \text{Hom}_{\tilde{G}}(V_\Pi, \mathcal{H}_1) \neq \{0\} \). Obviously, \( G' \) acts on \( \mathcal{H}(\Pi) \) and we get that \( \mathcal{H}(\Pi) = \Pi \otimes \Pi' \) where \( \Pi' \) is an irreducible unitary representation of \( G' \).
4. Cauchy Harish-Chandra integral and transfer of invariant eigendistributions

We start this section by recalling the construction of the Cauchy–Harish-Chandra integral introduced in Section [24, Section 2]. Let \((G, G')\) be an irreducible reductive dual pair in \(\text{Sp}(W)\) and \(T: \widetilde{\text{Sp}}(W) \to S^*(W)\) the map defined in Equation (2). Let \(H_1, \ldots, H_n\) be a maximal set of non-conjugate Cartan subgroups of \(G\) and let \(H_i = T\chi_i\); the decomposition of \(H_i\) as in [28, Section 2.3.6], where \(T_i\) is maximal compact in \(H_i\). For every \(1 \leq i \leq n\), we denote by \(A_i'\) the subgroup of \(\text{Sp}(W)\) given by \(A_i' = C_{\text{Sp}(W)}(A_i)\) and let \(A_i'' = C_{\text{Sp}(W)}(A_i')\). As recalled in [24, Section 1], there exists an open and dense subset \(W_{A_i''}\), which is \(A_i''\)-invariant and such that \(A_i' \setminus W_{A_i''}\) is a manifold, endowed with a measure \(dw\) such that for every \(\phi \in \mathcal{E}_c^\infty(W)\) such that \(\text{supp}(\phi) \subseteq W_{A_i''}\),

\[
\int_{W_{A_i''}} \phi(w) dw = \int_{A_i'' \setminus W_{A_i''}} \int_{A_i''} \phi(aw) daw dw.
\]

For every \(\Psi \in \mathcal{E}_c^\infty(\widetilde{A_i'})\), we denote by \(\text{Chc}(\Psi)\) the following integral:

\[
\text{Chc}(\Psi) = \int_{\widetilde{A_i''} \setminus W_{A_i''}} T(\Psi)(w) dw.
\]

According to Remark 2.3, the previous integral is well-defined and as proved in [24, Lemma 2.9], the corresponding map \(\text{Chc} : \mathcal{E}_c^\infty(\widetilde{A_i'}) \to \mathbb{C}\) defines a distribution on \(\widetilde{A_i'}\).

**Remark 4.1.** We say few worlds about the dual pair \((A_i', A_i'')\) and the space \(W_{A_i''}\). Let \(V_{0,j}\) be the subspace of \(V\) on which \(A_i\) acts trivially and \(V_{1,j} = V_{0,j}^\perp\). The restriction of \((\cdot, \cdot)\) to \(V_{1,j}\) is non-degenerate and even dimensional. In particular, there exists a complete polarization of \(V_{1,j}\) of the form \(V_{1,j} = X_i \oplus Y_j\), where both spaces \(X_i\) and \(Y_j\) are \(H_i\)-invariant.

By looking at the action of \(A_i\) on \(V_{1,j}\), we get:

\[X_i = X^j_1 \oplus \ldots \oplus X^j_i, \quad Y_j = Y^j_1 \oplus \ldots \oplus Y^j_k,\]

where all the spaces \(X^j_i, 1 \leq i \leq n, 1 \leq j \leq k\), are \(A_i\)-invariant and mutually non-equivalent. In particular,

\[W = \text{Hom}(V, V') = \text{Hom}(V_{0,j}, V') \oplus \text{Hom}(V_{1,j}, V') = \text{Hom}(V_{0,j}, V') \oplus \bigoplus_{j=1}^k \left(\text{Hom}(X^j_i, V') \oplus \text{Hom}(Y^j_i, V')\right).
\]

To simplify the notations, we denote by \(W_j^i\) the subspace of \(W\) given by \(\text{Hom}(X^j_i, V') \oplus \text{Hom}(Y^j_i, V')\) and \(W_{0,j} = \text{Hom}(V_{0,j}, V')\). One can easily check that:

\[A_i' = \text{Sp}(W_{0,j}) \times \text{GL}(\text{Hom}(X^j_i, V')) \times \ldots \times \text{GL}(\text{Hom}(X^j_i, V')),\]

and

\[A_i'' = \text{O}(1) \times \text{GL}(1, \mathbb{R}) \times \ldots \times \text{GL}(1, \mathbb{R}).\]

Moreover,

\[W_{A_i''} = (W_{0,j} \setminus \{0\}) \times \tilde{W}_{1,j} \times \ldots \times \tilde{W}_{n,j},\]

where \(\tilde{W}_{j,i} = \{(x, y) \in \text{Hom}(X^j_i, V') \oplus \text{Hom}(Y^j_i, V'), x \neq 0, y \neq 0\}, 1 \leq j \leq k\).

For every \(\tilde{h}_i \in \tilde{H}_i\), we denote by \(\tau_{\tilde{h}_i}\) the map:

\[\tau_{\tilde{h}_i} : \tilde{G}' \ni \tilde{g}' \mapsto \tilde{h}_i \tilde{g}' \in \widetilde{A_i'}.
\]

As proved in [24], for every \(\tilde{h}_i \in \text{Reg}(\tilde{H}_i)\), the pull-back \(\tau_{\tilde{h}_i}^{-1}(\text{Chc})\) of \(\text{Chc}\) via \(\tau_{\tilde{h}_i}\) (see [13, Theorem 8.2.4]) is a well-defined distribution on \(\tilde{G}'\). For every \(\tilde{h}_i \in \tilde{H}_i^\text{reg}\), we denote by \(\text{Chc}_{\tilde{h}_i} := \tau_{\tilde{h}_i}^\ast(\text{Chc})\) the corresponding distribution on \(\tilde{G}'\).
Notation 4.2. For every reductive group $G$, we denote by $I(G)$ the space of orbital integrals on $G$ as in [4] Section 3], endowed with a natural topology defined in [4] Section 3.3. We denote by $J_G$ the map $J_G : \mathcal{C}^\infty_c(G) \to \mathcal{C}^\infty_c(G^{\text{reg}})$ given as follows: for every $\gamma \in G^{\text{reg}}$, there exists a unique, up to conjugation, Cartan subgroups $H(\gamma)$ of $G$ such that $\gamma \in H(\gamma)$, and for every $\Psi \in \mathcal{C}^\infty_c(G)$, we define $J_G(\Psi)(\gamma)$ by:

$$J_G(\Psi)(\gamma) = |\det(\text{Id} - \text{Ad}(\gamma^{-1}))|_{\mathfrak{h}/\mathfrak{h}(\gamma)} |^2 \int_{G/\mathfrak{h}(\gamma)} \Psi(g) g^{-1} dg.$$ 

As proved in [4] Theorem 3.2.1, the map:

$$J_G : \mathcal{C}^\infty_c(G) \to I(G)$$

is well-defined and surjective. We denote by $I^*(G)$ the space of continuous linear forms on $I(G)$ and let $I_G : I(G)^* \to \mathcal{D}'(G)$ be the transpose of $J_G$. In [4] Theorem 3.2.1, Bouaziz proved that the map

$$I_G : I(G)^* \to \mathcal{D}'(G)^G$$

is bijective.

We now apply these results to construct a map $\text{Chc}^*$, transferring the invariant distributions for a given dual pair $(G, G')$. Let $(G, G')$ be an irreducible dual pair in $\text{Sp}(W)$ such that $\text{rk}(G) \leq \text{rk}(G')$. For every function $\Psi \in \mathcal{C}^\infty_c(G)$, we denote by $\text{Chc}(\Psi)$ the $G$-invariant function on $G^{\text{reg}}$ given by:

$$\text{Chc}(\Psi)(\tilde{h}) = \text{Chc}_h(\Psi), \quad (\tilde{h} \in H^{\text{reg}}).$$

As proved in [3], the corresponding map

$$\text{Chc} : \mathcal{C}^\infty_c(G') \to I(G)$$

is well-defined and continuous and factors through $I(G')$, i.e.

$$\text{Chc} : I(G') \to I(G)$$

and the corresponding map is continuous. In particular, we get a map

$$\text{Chc}^* : \mathcal{D}'(G)^G \ni T \to (\text{Chc}^{'-1} \circ I_G^{'-1})(T) \in \mathcal{D}'(G)^{\tilde{G}}.$$ 

Theorem 4.3. The map $\text{Chc}^*$ sends $\text{Eig}(G)^G$ into $\text{Eig}(G)^{\tilde{G}}$. Moreover, if $\Theta$ is a distribution on $G$ given by a locally integrable function $\Theta$ on $G'$, we get for every $\Psi \in \mathcal{C}^\infty_c(G)$ that:

$$\text{Chc}^*(\Theta)(\Psi) = \sum_{i=1}^m \frac{1}{|\mathcal{W}(H_i)|} \int_{H_i^{\text{reg}}} \Theta(\tilde{h}_i) |\det(1 - \text{Ad}(\tilde{h}_i^{-1}))|_{\mathfrak{h}/\mathfrak{h}_i} |\text{Chc}(\Psi)(\tilde{h}_i)| d\tilde{h}_i, \quad (\tilde{h}_i \in H_i^{\text{reg}}).$$

where $H_1, \ldots, H_n$ is a maximal set of non-conjugate Cartan subgroups of $G$.

In [24], T. Przebinda conjectured that the correspondence of characters in the theta correspondence should be obtained via $\text{Chc}^*$. More precisely,

Conjecture 4.4. Let $G_1$ and $G_1'$ be the Zariski identity components of $G$ and $G'$ respectively. Let $\Pi \in \mathcal{R}(\tilde{G}, \omega)$ satisfying $\Theta_{\Pi|_{H_1^{\text{reg}}}} = 0$ if $G = O(V)$, where $V$ is an even dimensional vector space over $\mathbb{R}$ or $\mathbb{C}$. Then, up to a constant, $\text{Chc}^*(\Theta_{\Pi}) = \Theta_{\Pi|_{\tilde{G}_1}}$ on $\tilde{G}_1$.

Remark 4.5. The conjecture is known to be true in few cases:

1. $G$ compact,
2. $(G, G')$ in the stable range and $\Pi$ a unitary representation of $\tilde{G}$ (see [25]),
3. $(G, G') = (U(p, q), U(r, s))$, with $p + q = r + s$ and $\Pi$ a discrete series representation of $\tilde{G}$ (see [24]).
In this section, we quickly explain how to compute explicitly the Cauchy–Harish-Chandra integral on the different Cartan subgroups. Because our papers will only concerns characters of some unitary groups, we will adapt the results of [3] and [2] in this context, but similar results can be obtained for other dual pairs.

Let \( V = \mathbb{C}^{p+q} \) and \( V' = \mathbb{C}^{r+s} \) be two complex vector spaces endowed with non-degenerate bilinear forms \((\cdot,\cdot)\) and \((\cdot',\cdot')\) respectively, with \((\cdot,\cdot)\) hermitian and \((\cdot',\cdot')\) skew-hermitian, and let \((p,q)\) (resp. \((r,s)\)) be the signature of \((\cdot,\cdot)\) (resp. \((\cdot',\cdot')\)). We assume that \( p + q \leq r + s \).

Let \( \mathcal{H}_V = \{ f_1, \ldots, f_n \} \), \( n = p + q \) (resp. \( \mathcal{B}_V = \{ f'_1, \ldots, f'_n \} \), \( n' = r + s \) be a basis of \( V \) (resp. \( V' \)) such that \( \text{Mat}(\langle \cdot,\cdot \rangle, \mathcal{B}_V) = \text{Id}_{p,q} \) (resp. \( \text{Mat}(\langle \cdot',\cdot' \rangle, \mathcal{B}_V) = \text{Id}_{r,s} \)). Let \( G \) and \( G' \) be the corresponding group of isometries, i.e. \( \mathcal{B} = \text{GL}(n) \), \( \mathcal{B}' = \text{GL}(n') \) respectively, with \( \mathcal{B} \) and \( \mathcal{B}' \) the linear form on \( V \) and \( V' \) given by \( \langle w_1, w_2 \rangle = \text{tr}_{\mathbb{C}/\mathbb{R}}(w_2^*w_1) \), \( (w_1, w_2) \in W \),

where \( \approx \) is a Lie group isomorphism.

Let \( K = U(p) \times U(q) \) and \( K' = U(r) \times U(s) \) be the maximal compact subgroups of \( G \) and \( G' \) respectively and let \( H \) and \( H' \) be the diagonal Cartan subgroups of \( K \) and \( K' \) respectively. By looking at the action of \( H \) on the space \( V \), we get a decomposition of \( V \) of the form:

\[
V = V_1 \oplus \ldots \oplus V_n,
\]

where the spaces \( V_a \) given by \( V_a = \mathcal{H}_a \) are irreducible \( H \)-modules. We denote by \( J \) the element of \( \mathfrak{h} \) such that \( J = i\mathfrak{d}_V \) and let \( J = i\mathfrak{e}_{J} \). Similarly, we write

\[
V' = V'_1 \oplus \ldots \oplus V'_{n'},
\]

with \( V'_a = \mathcal{H}'_a \), \( J' \) the element of \( \mathfrak{h}' \) given by \( J' = i\mathfrak{d}_{V'} \) and \( J'_a = i\mathfrak{e}_{J_a} \). Let \( W = \text{Hom}_\mathbb{C}(V',V) \) endowed with the symplectic form \( \langle \cdot,\cdot \rangle \) given by:

\[
\langle w_1, w_2 \rangle = \text{tr}_{\mathbb{C}/\mathbb{R}}(w_2^*w_1), \quad (w_1, w_2) \in W,
\]

where \( w_2^* \) is the element of \( \text{Hom}(V,V') \) satisfying:

\[
\langle w_2^*(v'), v \rangle = (v', w_2(v))', \quad (v \in V, v' \in V').
\]

The space \( W \) can be seen as a complex vector space by

\[
iw = J \circ w, \quad (w \in W).
\]

We define a double cover \( \widetilde{\text{GL}}_\mathbb{C}(W) \) of the complex group \( \text{GL}_\mathbb{C}(W) \) by:

\[
\widetilde{\text{GL}}_\mathbb{C}(W) = \left\{ \tilde{g} = (g,\xi) \in \text{GL}_\mathbb{C}(W) \times \mathbb{C}^\times, \xi^2 = \det(g) \right\}.
\]

Because \( p + q \leq r + s \), we get a natural embedding of \( \mathfrak{h}_\mathbb{C} \) into \( \mathfrak{h}'_\mathbb{C} \) and we denote by \( Z' = G'^\theta \) the centralizer of \( \mathfrak{h} \) in \( G' \).

**Notation 5.1.** We denote by \( \Delta \) (resp. \( \Delta'(\ell) \)) the root system corresponding to \( (\mathfrak{g}_\mathbb{C}, \mathfrak{h}_\mathbb{C}) \) (resp. \( (\mathfrak{l}_\mathbb{C}, \mathfrak{b}_\mathbb{C}) \)), by \( \Psi \) (resp. \( \Psi'(\ell) \)) a system of positive roots of \( \Delta \) (resp. \( \Delta'(\ell) \)) and let \( \Phi = -\Psi \) (resp. \( \Phi'(\ell) = -\Psi'(\ell) \)) the set of negative roots.

Let \( e_i \) be the linear form on \( \mathfrak{h}_\mathbb{C} = \mathbb{C}^{p+q} \) given by \( e_i(\lambda_1, \ldots, \lambda_{p+q}) = \lambda_i \). As explained in [17, Chapter 2], we know that:

\[
\Delta = \left\{ \pm(e_i - e_j), 1 \leq i < j \leq p + q \right\}, \quad \Psi = \left\{ e_i - e_j, 1 \leq i < j \leq p + q \right\},
\]

and

\[
\Delta(\ell) = \left\{ \pm(e_i - e_j), 1 \leq i < j \leq p \right\} \cup \left\{ \pm(e_i - e_j), p + 1 \leq i < j \leq p + q \right\}, \quad \Psi(\ell) = \Psi \cap \Delta(\ell).
\]

We define \( \Delta', \Delta'(\ell), \Psi', \Psi'(\ell), \Phi', \Phi'(\ell) \) similarly and denote by \( e'_i \), \( 1 \leq i \leq r + s \) the linear form on \( \mathfrak{h}'_\mathbb{C} = \mathbb{C}^{r+s} \) given by \( e'_i(\lambda_1, \ldots, \lambda_{r+s}) = \lambda_i \).

Let \( H'_\mathbb{C} \) be the complexification of \( H' \) in \( \text{GL}_\mathbb{C}(W) \). In particular, \( H'_\mathbb{C} \) is isomorphic to

\[
\mathfrak{h}'_\mathbb{C} / \left\{ \sum_{j=1}^{n'} 2\pi x_j J_j, x_j \in \mathbb{Z} \right\}.
\]
We denote by $\tilde{H}_c$ the connected two-fold cover of $H_c$ isomorphic to
\begin{equation}
(5)
b_c'/\left\{ \sum_{j=1}^n 2\pi i x_j' j, \sum_{j=1}^n x_j / 2\right\}.
\end{equation}

One can easily check that $\rho' = \frac{1}{2} \sum_{\alpha \in \Phi^\ast} \alpha$ is analytic integral on $\tilde{H}_c$. As explained in [24, Section 2], we construct a map $\hat{\rho} : \tilde{H}_c \to \tilde{H}_c$ which is bijective (but not an isomorphism of covering of $H_c$ in general).

As explained in Appendix B, every Cartan subgroup of $G$ is parametrized by a subset $S \subseteq \Psi_c$ consisting of non-compact strongly orthogonal roots. We denote by $H(S)$ the corresponding Cartan subgroup and by $\hat{H}_s$ the preimage of the Cartan subgroup $H_s$ in $\tilde{H}_c$ (see Appendix B). For every $\varphi \in \mathcal{C}_c^\infty(\tilde{G})$, we denote by $\mathcal{H}_S \varphi$ the function of $H'_S$ defined by:
\begin{equation}
\mathcal{H}_S \varphi(h') = \psi_{\Psi_{S,s}}(\tilde{h}') \frac{\sum_{\alpha \in \Phi^\ast} (1 - h'^{\alpha})}{\prod_{\alpha \in \Phi^\ast} (1 - h'^{\prime\alpha})} \int_{G/H(S)} \varphi(g' c(S) \tilde{h}' c(S)^{-1} g') dg' \cdot \mathcal{H}(S) \hspace{1cm} (h' \in \hat{H}_s),
\end{equation}
where $\Psi_{S,s}$ is the subset of $\Psi_c$ consisting of real roots for $H'_s$ and $\psi_{\Psi_{S,s}}$ is the function defined on $\tilde{H}_s$ by
\begin{equation}
\psi_{\Psi_{S,s}}(h') = \text{sign} \left( \prod_{\alpha \in \Psi_{S,s}} (1 - h'^{\alpha}) \right).
\end{equation}

We denote by $\Delta_{\Psi}(h')$ the quantity
\begin{equation}
\Delta_{\Psi}(h') = \psi_{\Psi_{S,s}}(\tilde{h}') \prod_{\alpha \in \Phi^\ast} (1 - h'^{\prime\alpha}) \hspace{1cm} (h' \in \hat{H}_s),
\end{equation}
and by $\Delta_{\Phi}$ the function on $\tilde{H}_s$ given by $\Delta_{\Phi}(h') = \frac{1}{\Delta_{\Psi}(h')} \frac{\sum_{\alpha \in \Phi^\ast} (1 - h'^{\alpha})}{\prod_{\alpha \in \Phi^\ast} (1 - h'^{\prime\alpha})}$.

Remark 5.2. For every $h' \in \tilde{H}_s$, $\Delta_{\Phi}(h') \Delta_{\Psi}(h') = \prod_{\alpha \in \Phi^\ast} (1 - h'^{\alpha}) (1 - h'^{\prime\alpha}) = \prod_{\alpha \in \Phi^\ast} (1 - h'^{\alpha}) (1 - h'^{\prime\alpha})$. We denote by $|\Delta_{G}(h')|^2 = \Delta_{\Phi}(h') \Delta_{\Psi}(h')$.

Proposition 5.3 (Weyl’s Integration Formula). For every $\varphi \in \mathcal{C}_c^\infty(\tilde{G})$, we get:
\begin{equation}
\int_{\tilde{G}} \varphi(\tilde{g}') d\tilde{g}' = \sum_{S \subseteq \Psi_c} m_S \int_{\tilde{H}_s} \psi_{\Psi_{S,s}}(h') \Delta_{\Psi}(h') \mathcal{H}_S \varphi(h') dh'.
\end{equation}

where $m_S$ are complex numbers. Here, the subsets $S$ of $\Psi_c$ are defined up to equivalence (see Remark B.2).

Proof. See [24, Section 2, Page 3830].

\square

Remark 5.4. One can easily see that for every $S \subseteq \Psi_c$ and $\varphi \in \mathcal{C}_c^\infty(\tilde{G})$ such that supp$(\varphi) \subseteq \tilde{G} \cdot \hat{H}(S)^{\text{reg}}$, the Equation (6) can be written as follow:
\begin{equation}
\int_{\tilde{G}} \varphi(\tilde{g}') d\tilde{g}' = m_S \int_{\tilde{H}_s} \psi_{\Psi_{S,s}}(h') \Delta_{\Psi}(h') \mathcal{H}_S \varphi(h') dh'.
\end{equation}

For every $S \subseteq \Psi_c$, we denote by $S$ the subset of $[1, \ldots, r + s]$ given by $S = \{ j \in S \text{ such that } \sigma(J) \neq 0 \}$. Let $\sigma \in \mathcal{S}_n$ and $S \subseteq \Psi_c$, we denote by $\Gamma_{\sigma,S}$ the subset of $b'$ defined as
\begin{equation}
\Gamma_{\sigma,S} = \left\{ y \in b', (Y, \cdot)_{\sigma W \Psi(V,V)} \sum_{\alpha \in \Psi(V,V)} > 0 \right\},
\end{equation}
and let $\tilde{\Gamma}_{\sigma,S} = \tilde{\exp}(\Gamma_{\sigma,S})$ the corresponding subset of $\tilde{H}_c$, where $\tilde{\exp}$ is a choice of exponential map $\tilde{\exp} : b \to \tilde{H}_c$ obtained by choosing an element $1$ in $\pi^{-1}_1(1)$. 

11
**Theorem 5.5.** For every \( \tilde{h} \in \tilde{H} = \tilde{H}_0 \) and \( \varphi \in \mathcal{C}(\tilde{G}') \), we get:

\[
\det^{\frac{1}{2}}(h)\varphi(\tilde{h}) \int_{\tilde{G}'} \Theta(p(h)\tilde{g}')\varphi(\tilde{g}')d\tilde{g}' = \sum_{\alpha \in \varnothing} \sum_{t \in \mathcal{O}_\alpha} M_S(\sigma) \lim_{r \to \infty} \int_{\tilde{H}_0} \det^{\frac{1}{2}}(\alpha(\tilde{h}))\varphi(\tilde{h})d\tilde{h},
\]

where \( M_S(\sigma) = \frac{(-1)^{\varphi(\alpha)m_S}}{|W'(Z_{\tilde{G}',H_{\tilde{G}'})|} \alpha \in [0, -1] \) depends only on the choice of the positive roots \( \Psi \) and \( \Psi' \), \( k \in \{0, 1\} \) is defined by

\[
k = \begin{cases} 
-1 & \text{if } n' - n \in 2\mathbb{Z} \\
0 & \text{otherwise}
\end{cases}
\]

and \( W^h \) is the set of elements of \( W \) commuting with \( h \).

Theorem 5.5 tells us how to compute \( Chc_k \) for an element \( \tilde{h} \) in the compact Cartan \( \tilde{H} = \tilde{H}(\emptyset) \). Using \([2]\), it follows that the value of \( Chc \) on the other Cartan subgroups can be computed explicitly by knowing how to do it for the compact Cartan.

**Remark 5.6.** One can easily check that the space \( W^h \) is given by

\[
W^h = \sum_{i=1}^{n} \text{Hom}(V_i', V_{i}).
\]

From now on, we assume that \( p \leq q, r \leq s \) and \( p \leq r \).

**Notation 5.7.** For every \( t \in [1, p] \), we denote by \( S_t \) and \( S_t' \) the subsets of \( \Psi_n^a \) and \( \Psi_n'^{a} \) respectively given by

\[
S_t = \left\{ e_1 - e_{p+1}, \ldots, e_t - e_{p+1} \right\}, \quad S_t' = \left\{ e_1' - e_{r+1}', \ldots, e_t' - e_{r+1}' \right\},
\]

where the linear forms \( e_i, e_i' \) have been introduced in Notation 5.3.

For every \( t \in [0, p] \), we denote by \( H(S_t) \) and \( H'(S_t) \) the Cartan subgroups of \( G \) and \( G' \) respectively and let \( H(S_t) = T(S_t)A(S_t) \) (resp. \( H'(S_t) = T'(S_t)A'(S_t) \)) be the decompositions of \( H(S_t) \) (resp. \( H'(S_t) \)) as in \([28], \text{Section 2.3.6} \).

As in Remark 4.4, we denote by \( V_{0,j} \) the subspace of \( V \) on which \( A(S_t) \) acts trivially, by \( V_{1,j} \), the orthogonal complement of \( V_{0,j} \) in \( V \) and by \( V_{1,j} = X_t \oplus Y_t \), a complete polarization of \( V_{1,j} \). Because \( p \leq r \), we have a natural embedding of \( V_{1,j} \) into \( V' \) such that \( X_t \oplus Y_t \) is a complete polarization with respect to \( (\cdot, \cdot)' \). We denote by \( U_t \) the orthogonal complement of \( V_{1,j} \) in \( V' \); in particular, we get a natural embedding:

\[
\text{GL}(X_t) \times \text{G}(U_t) \subseteq G' = U(r, s).
\]

We denote by \( T_1(S_t) \) the maximal subgroup of \( T(S_t) \) which acts trivially on \( V_{0,j} \) and let \( T_2(S_t) \) the subgroup of \( T(S_t) \) such that \( T_2(S_t) = T_1(S_t) \times T_2(S_t) \) with \( T_2(S_t) \subseteq G(V_{0,j}) \). In particular,

\[
H(S_t) = T_1(S_t) \times A(S_t) \times T_2(S_t).
\]

Similarly, we get a decomposition of \( H'(S_t) \) of the form:

\[
H'(S_t) = T'(S_t') \times A'(S_t') \times T_2(S_t').
\]

**Remark 5.8.** One can easily see that for every \( 0 \leq j < i \leq r \), we get:

\[
H'(S_t') = T'(S_t') \times A'(S_t') \times H'(S_{t-j}'),
\]

where \( S_{t-j} = S_t \setminus S_j' \) and \( H'(S_{t-j}) \) is the Cartan subgroup of \( U(r - j, s - j) \) whose split part has dimension \( i - j \). In particular,

\[
H'_S = T'_S \times A'_S \times H'_{S_{t-j}}.
\]
Let \( \eta(S_t) \) and \( \eta'(S_t') \) be the nilpotent Lie subalgebras of \( u(p, q) \) and \( u(r, s) \) respectively given by

\[
\eta(S_t) = \text{Hom}(X_t, V_{0,t}) \oplus \text{Hom}(X_t, Y_t) \cap u(p, q), \quad \eta'(S_t') = \text{Hom}(U_t, X_t) \oplus \text{Hom}(X_t, Y_t) \cap u(r, s).
\]

We will denote by \( W_{0,t} \), the subspace of \( W \) defined by \( \text{Hom}(U_t, V_{0,t}) \) and by \( P(S_t) \) and \( P'(S_t') \) the parabolic subgroups of \( G \) and \( G' \) respectively whose Levi factors \( L(S_t) \) and \( L'(S_t') \) are given by

\[
L(S_t) = \text{GL}(X_t) \times G(V_{0,t}), \quad L'(S_t') = \text{GL}(X_t) \times G(U_t),
\]

and by \( N(S_t) := \exp(\eta(S_t)) \) and \( N'(S_t') := \exp(\eta'(S_t')) \) the unipotent radicals of \( P(S_t) \) and \( P'(S_t') \) respectively.

**Remark 5.9.** One can easily check that the forms on \( V_{0,t} \) and \( U_t \) have signature \( (p-t, q-t) \) and \( (r-t, s-t) \) respectively.

As proved in [2] Theorem 0.9], for every \( \tilde{h} = \tilde{t}_1 \tilde{t}_2 \in \tilde{H}(S_t)^{\text{reg}} \) (using the decomposition of \( \tilde{H}(S_t) \) given in Equation (7)) and \( \varphi \in \mathcal{E}_{\text{reg}}(\tilde{G}) \), we get:

\[
(8) \quad |\text{det}(\text{Ad}(\tilde{h}) - \text{Id})_{\eta(S_t)}| \text{Chc}_{\tilde{h}}(\varphi) = \frac{C_{\tilde{h}} \det(\tilde{h}(\tilde{t}_1, \tilde{t}_2)) \prod_{(\tilde{t}_1, \tilde{t}_2) \in (\tilde{G}(\tilde{t}_1, \tilde{t}_2) \cap \tilde{G}(\tilde{t}_2, \tilde{t}_1))}}{(r + s - 2t)} \prod_{\theta \in \tilde{G} / \mu(\tilde{S}_t)} 1,
\]

where \( C_{\tilde{h}} \) is the constant defined by

\[
(9) \quad C_{\tilde{h}} = \prod_{r \in \mathbb{R}} \mathcal{E}_{\text{reg}}(\tilde{S}_t),
\]

\( \varepsilon \) is the character defined in [2] Lemma 6.3], \( d_{S_t} : \tilde{L}(S_t) \to \mathbb{R} \) and \( d'_{S_t} : \tilde{L}'(S_t) \to \mathbb{R} \) are given by

\[
d_{S_t}(\tilde{h}) = |\text{det}(\text{Ad}(\tilde{h}(\eta(S_t))))|^{\frac{1}{2}}, \quad d'_{S_t}(\tilde{h}) = |\text{det}(\text{Ad}^{\text{reg}}(\tilde{h}(\eta(S_t))))|^{\frac{1}{2}}
\]

and \( \varphi_{\tilde{G}/\mu(\tilde{S}_t)}^{\text{reg}}(\tilde{h}) \) is the Harish-Chandra transform of \( \varphi \), i.e. the function on \( \tilde{L}'(S_t) \) defined by:

\[
\varphi_{\tilde{G}/\mu(\tilde{S}_t)}^{\text{reg}}(\tilde{h}) = \int_{\tilde{G}/\mu(\tilde{S}_t)} \varphi(k,hk^{-1})dkd\tilde{n}, \quad (\tilde{h} \in \tilde{G}/\mu(\tilde{S}_t))
\]

Let’s explain the method we will use in the next section to get character formulas of representations of \( U(n, n+1) \) by using the Cauchy–Harish-Chandra in the stable range.

Let \( (G, G') = (U(p), U(r, s)) \) be a dual pair in \( \text{Sp}(2p + r + s, \mathbb{R}) \). To avoid any confusions, we will denote by \( \omega_{n,p}^{\text{reg}} \) the metaplectic representation of \( \text{Sp}(2p + r + s, \mathbb{R}) \) and by \( \theta_{n,p}^{\text{reg}} : \tilde{\Theta}(\tilde{U}(p), \omega_{n,p}^{\text{reg}}) \to \tilde{\Theta}(\tilde{U}(r, s), \omega_{n,p}^{\text{reg}}) \) the map defined in Equation (4).

Let \( \Pi \in \tilde{\Theta}(\tilde{U}(p), \omega_{n,p}^{\text{reg}}) \). In this case, as explained in Remark 1.9, we get that \( \Pi' = \Pi_1 \) and the corresponding representation \( \Pi' \) is an irreducible unitary representation of \( U(r, s) \) (and \( \Pi' \in \tilde{\Theta}(\tilde{U}(r, s)), \omega_{n,p}^{\text{reg}} \)). In particular, Theorem 5.5 tell us how to compute \( \Theta_{n,p}^{\text{reg}} \) on every Cartan subgroups of \( U(r, s) \) (see Appendix A for \( p = 1 \)).

For every \( n \geq 0 \), we denote by \( G_n \) the unitary group corresponding to an hermitian form of signature \( (n, n+1) \), i.e. \( G_n = U(n, n+1) \), by \( \omega_{n,n+1}^{\text{reg}} \) the metaplectic representation of \( \text{Sp}(2n+1, \mathbb{R}) \), where \( W_{2} = (\mathbb{C}^{2n+1} \otimes \mathbb{C}^{2n+1})_{\otimes 2} \) and by \( \theta_{n,n+1}^{\text{reg}} : \tilde{\Theta}(\tilde{U}(r, s), \omega_{n,n+1}^{\text{reg}}) \to \tilde{\Theta}(\tilde{U}(n, n+1), \omega_{n,n+1}^{\text{reg}}) \) the map as in (3).

Using Kudla’s persistence principle (see [1]), we know that the representation \( \Pi' \in \tilde{\Theta}(\tilde{U}(r, s), \omega_{n,n+1}^{\text{reg}}) \), \( \theta_{n,n+1}^{\text{reg}}(\Pi') \neq \{0\} \), i.e. \( \Pi' \in \tilde{\Theta}(\tilde{U}(r, s), \omega_{n,n+1}^{\text{reg}}) \). We denote by \( \Pi_1^{\text{reg}} \) the corresponding representation of \( G_n \) as in Section 3 by \( \Pi_0 \in \tilde{\Theta}(\tilde{U}(n, n+1), \omega_{n,n+1}^{\text{reg}}) \) it’s unique irreducible quotient, and by \( \Theta_{n,p}^{\text{reg}} \) and \( \Theta_{n,p}^{\text{reg}} \) the characters of \( \Pi_1^{\text{reg}} \) and \( \Pi_0^{\text{reg}} \) respectively.

Using Theorems 3.2 and 4.3, we know that the \( \tilde{G}^{\text{reg}} \)-invariant eigendistribution \( \Theta_{n,p}^{\text{reg}} : \text{Chc}(\tilde{G}) \) is given by a locally integrable function \( \Theta_{n,p}^{\text{reg}} \) on \( \tilde{G}^{\text{reg}} \). Note that an explicit value of \( \Theta_{n,p}^{\text{reg}} \) on every Cartan subgroups of \( G_n \) can be obtained using Equation (4). Theorem 5.5 and Equation (8).
Lemma 6.2. If $n \geq r + s$, we get that $\Pi'_1 = \Pi'$ because $\Pi'$ is unitary and by Remark 4.5, it follows that $\Theta'_n, \Pi' = \Theta'_r$. It is also well-known that for $n \geq 1$, the representations $\Pi''$ are unitary but are not highest weight modules, and in particular, its character cannot be obtained via Enright’s formula (5 Corollary 2.3).

In the next section, we are going to make $\Theta'_r$ explicit for $p = r = s = 1$.

6. Character formulas for some representations of $\text{U}(n, n + 1)$

We first start with the dual pair $(G, G') = (\text{U}(1), \text{U}(1, 1))$ in $\text{Sp}(4, \mathbb{R})$. Because the set of irreducible genuine representations of $\text{U}(1)$ is isomorphic to $\mathbb{Z}$, the corresponding representation of $\mathbb{R}(\text{U}(1), \omega^1_{1,1})$ will be denoted by $\Pi_m, m \in \mathbb{Z}$ and let $\Pi'_m$ be the corresponding representation of $G'$. Moreover, as explained in Section 5, $\Pi'' = \theta_{n+1}(\Pi'_m)$ the lift of $\Pi'_m$ on $G_n$ is non-zero and its character $\Theta'_r$ is equal to $\text{Ch}^r(\Theta'_r)$. In this section, we are going to give an explicit formula for $\Theta'_r$ on every Cartan subgroups of $G_n$.

Remark 6.1. We denote by $g'_1, g'_2$ and $g_n$ the Lie algebras of $G, G'$ and $G_n$ respectively. The Lie algebra $g'_1$ is given by

$$g'_1 = \begin{pmatrix} a & b \\ c & d \end{pmatrix}, \quad a, d \in \mathbb{R}, b, c \in \mathbb{C} = \mathbb{R}(i, 0) \oplus \mathbb{R}(i, 0) \oplus \mathbb{R}(0, 1) \oplus \mathbb{R}(0, i).$$

and the two Cartan subgroups of $G'_1$, up to conjugation, are of the form

$$H' = H'(S_1) = \{ \text{diag}(h, h), h \in \text{U}(1) \}, \quad H'(S'_1) = \exp \left( \begin{pmatrix} i & 0 \\ 0 & i \end{pmatrix} \right) \oplus \mathbb{R}(0, 1) \oplus \mathbb{R}(0, 1) = \left\{ \begin{pmatrix} e^{\text{ch}(X)} & \text{sh}(X) \\ \text{sh}(X) & e^{\text{sh}(X)} \end{pmatrix}, \theta, X \in \mathbb{R} \right\},$$

where $S'_0 = \{ \emptyset \}$ and $S'_1 = \{ e_1 - e_2 \}$ (see Appendix B). We denote by $(V', (\cdot, \cdot))$ the skew-hermitian form corresponding to $G'$ and by $(V_n, (\cdot, \cdot)_n)$ the hermitian form corresponding to $G_n$. Let $\mathcal{B}_V = \{ f'_1, f'_2 \}$ be a basis of $V'$ such that $\text{Mat}_{\mathcal{B}_V} (\cdot, \cdot)' = \tilde{\text{Id}}_{1,1}$. We have the following complete polarization of $V'$

$$V' = X'_1 \oplus Y'_1, \quad X'_1 = \mathcal{C}(f'_1 + f'_2), \quad Y'_1 = \mathcal{C}(f'_1 - f'_2),$$

where both $X'_1$ and $Y'_1$ are $H'_1$-invariant. Let $\mathcal{B}_V = \{ f'_0, \ldots, f'_{2n+1} \}$ be a basis of $V_n$ such that $\text{Mat}_{\mathcal{B}_V} (\cdot, \cdot)_n = \text{Id}_{2n+1}$. We consider the embedding of $V'$ onto $V_n$ sending $f'_1$ onto $f'_0$ and $f'_2$ onto $f'_{2n+1}$. Obviously, $X'_1 \oplus Y'_1$ is a complete polarization of $V' \subseteq V_n$ with respect to $(\cdot, \cdot)_n$. We consider the subspace $U_1$ of $V_n$ given by

$$V_n = V' \oplus U_1, \quad U_1 = V'^{\perp},$$

where $V'^{\perp}$ is the orthogonal complement of $V'$ in $V_n$ with respect to $(\cdot, \cdot)_n$.

Let $G(U_1)$ be the group of isometries corresponding to the hermitian space $(U_1, (\cdot, \cdot)_{h_{b_0}})$. Note that $G(U_1) \approx \text{U}(n-1, n)$.

As explained in Appendix B for every $0 \leq t \leq n$ and $S_t = \{ e_1 - e_{2t+1}, \ldots, e_t - e_{2n+2-t} \}$, we denote by $H_t(S_t)$ the Cartan subgroup of $G_n$ whose split part is of dimension $t$ and by $H_{\text{reg}}$ the subgroup of $H_t(0)_\mathbb{C} = \{ b = \text{diag}(h_1, \ldots, h_{2n+t}), h_i \in \mathbb{C} \}$ given by $H_{\text{reg}} = c(S_t)H_t(0)_\mathbb{C}(S_t)^{-1}$, where $c(S_t)$ is the Cayley transform corresponding to $S_t$ (see Appendix B). We denote by $\mathcal{B}_V(S_t)$ the parabolic subgroup of $G_n$ whose Levi factor $L_n(S_t)$ is given by $L_n(S_t) = \text{GL}(X'_1) \times G(U_1)$.

Lemma 6.2. We get $\text{GL}(X'_1) = H'(S'_1)$.

Proof. The Lie algebra of $\text{GL}(X'_1)$ is the set of matrices $A = \begin{pmatrix} a & b \\ c & d \end{pmatrix}$ of $g'_1$ such that:

$$A \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} = A \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} = \begin{pmatrix} \beta & 0 \\ 0 & \beta \end{pmatrix}, \quad (\alpha, \beta \in \mathbb{C}).$$

We first assume that $A \in \text{End}(V')$ satisfies the conditions of Equation (11). Then, we get:

$$\begin{align*}
\begin{cases}
a + b = \alpha \\
c + d = \alpha \\
a - b = \beta \\
c - d = -\beta
\end{cases}
\end{align*}$$
In particular, $a + b = c + d$ and $a - b = -c + d$. Then, $a = d$ and $b = c$. In particular, if $A \in \mathfrak{g}'$, we get that $a \in i\mathbb{R}$ and $b \in \mathbb{R}$. In particular,

$$\text{GL}(X'_1) = \exp \left( \mathbb{R} \begin{pmatrix} i & 0 \\ 0 & i \end{pmatrix} \right) \oplus \mathbb{R} \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} = \exp(b'(S'_1)) = H'(S'_1).$$

\[ \square \]

In this section, we are going to determine the value of the character $\Theta_{\mathfrak{g}'}$ on the $n + 1$ different Cartan subgroups of $G_n$.

**Notation 6.3.** We denote by $\Delta_n$ the set of roots corresponding to $(\mathfrak{g}_n, \mathfrak{h}_n)$, where $\mathfrak{h}_n = H_n(\emptyset)$ is the compact Cartan of $G_n$, and $\Psi_n$ a set of positive roots of $\Delta_n$, by $\Phi_n = -\Psi_n$, by $\Psi_n^\emptyset(n) = \{e_i - e_{2n+2-i}, 1 \leq b \leq n\}$ the corresponding set of strongly orthogonal roots of $\Psi_n$ and by $\mathcal{Z}_\mathfrak{g}$ the subgroup of $G_n$ defined by $\mathcal{Z}_\mathfrak{g} = G_n^\emptyset$, where $\emptyset' = \text{Lie}(H')$ is the Lie algebra of $H'$ seen as a subspace of $\mathfrak{b}_n$.

We denote by $\eta'(S'_1)$ the subspace of $\mathfrak{g}'$ defined by $\text{Hom}(X'_1, Y'_1) \cap \mathfrak{g}'$ and by $\eta_n(S_1)$ the subspace of $\mathfrak{g}_n = \text{Lie}(G_n)$ given by $\text{Hom}(X'_1, Y'_1) \oplus \text{Hom}(X'_1, Y'_1) \cap \mathfrak{g}_n$.

**Remark 6.4.** As explained in Remark[5.8] we get for every $t \geq 1$ that

$$H_n(S_t) = T_1(S_1) \times \mathcal{X}(S_t) \times H^{t-1}(\tilde{S}_{t-1}),$$

where $\tilde{S}_{t-1} = S_t \setminus \{e_t - e_{2n+1}\}$ and $H^{t-1}(\tilde{S}_{t-1})$ is a Cartan subgroup of $G(U_t)$ whose split part is of dimension $t - 1$.

In particular, every element $\tilde{h} \in \mathcal{H}_{n,S_t}$ can be written as $\tilde{h} = \tilde{t} \tilde{a} \tilde{h}_1$ (where, by convention, $t = a = \text{Id}$ and $\tilde{h} = \tilde{h}_1$ if $t = 0$).

**Theorem 6.5.** For every $t \in [0, n]$ and $\tilde{h} = \tilde{t} \tilde{a} \tilde{h}_1 \in \mathcal{H}_{n,S_t}$ as in Remark[6.4] we get, up to a constant, that:

$$\Theta_{\mathfrak{g}'}(c(S_t)\tilde{h})(c(S_t)^{-1}) = A \sum_{a \in \mathfrak{h}/(1)\mathcal{X}} \theta(s(a)) \frac{\Delta_{\mathfrak{g}_n}(\theta(c(S_t)^{-1}))}{\Delta_{\mathfrak{g}_n}(\theta(c(S_t)))} \lim_{c \in \mathfrak{h} /\mathfrak{h}^0} \int_{\mathfrak{h} /\mathfrak{h}^0} \Theta_{\mathfrak{g}_n}(\theta(c(S_t)) \Delta_{\mathfrak{g}_n}(\theta(c(S_t))) \text{d} \theta(c(S_t)))^2,$$

where $\delta_{t,0} = \begin{cases} 0 & \text{if } t = 0 \\ 1 & \text{otherwise} \end{cases}$, $D$ and $D_1$ are functions on $\mathcal{H}_n(S_t)$, $1 \leq t \leq n$, given by

$$D_1(\tilde{h}) = |\text{det}(\text{Id} - \text{Ad}(\tilde{h}^{-1}))_{\mathfrak{h}_n}(\tilde{h}_t)|^{\frac{1}{2}}, \quad D(\tilde{h}) = |\text{det}(\text{Id} - \text{Ad}(\tilde{h}^{-1}))_{\mathfrak{h}_n}(\tilde{h}_t)|^{\frac{1}{2}}, \quad (\tilde{h} \in \mathcal{H}_n(S_t)),$$

and where $A$ and $B$ are constants given by

$$A = \frac{(-1)^n}{2(2n-1)!}, \quad B = \frac{2^{2n-1}(2n-1)\mathcal{S}_{n-1}}{2(2n+1)^2\mathcal{S}_{n-1}}.$$

Before proving Theorem[6.5] we recall a lemma concerning orbital integrals.

**Lemma 6.6.** For every $t \geq 1$, $\tilde{h} \in \mathcal{H}_n(S_t)^{\mathfrak{g}'}$ and $\Psi' \in \mathfrak{g}'(\mathcal{G}_n)$, we get:

$$\int_{\mathcal{H}_n(S_t)^{\mathfrak{g}'}(\Psi' \mathfrak{g}')} \varphi(\tilde{g}h^{-1}) \text{d} \tilde{g} = C_{n,1} \frac{D_1(\tilde{h})}{D(\tilde{h})} \int_{L(S_1)/H_n(S_t)} \mathfrak{P}_{K_n}^{\mathfrak{g}'} \left( m \mu \mathcal{S}_{n-1} \right) \text{d} m,$$

where $K_n$ is the maximal compact subgroup of $G_n$, $N_n(S_1) = \exp(\eta_n(S_1))$ and $C_{n,1}$ is the constant given by

$$C_{n,1} = \frac{1}{\mu(K_n \cap L_n(S_1)) \sqrt{2} \dim(\eta_n(S_1)) \sqrt{2}^{2n-1}}.$$

**Proof.** We see easily that for $t \geq 1$, $H_n(S_t)$ is a Cartan subgroup of $L_n(S_1)$, and then the result follows from [2 Corollary A.4].

\[ \square \]
Proof of Theorem 6.5. Fix \( t \in [0, n] \) and \( \Psi \in \mathcal{C}_c(\tilde{G}_n) \) such that \( \text{supp}(\Psi) \subseteq \tilde{G}_n \cdot \tilde{H}(S_t) \). Using Remark 5.4, it follows that:

\[
\Theta_{\tilde{H}}(\Psi) = \int_{\tilde{H}} \Theta_{\tilde{H}}(\tilde{g}) \Psi(\tilde{g}) d\tilde{g} = m_S \int_{\tilde{H}_n} \Theta_{\tilde{H}}(c(S_t) \tilde{p}(\tilde{h}) c(S_t)^{-1}) e^{\phi_{S_t}(\tilde{h})} \Psi(\tilde{h}) d\tilde{h}
\]

(12) \[ \quad = m_S \int_{\tilde{H}_n} \Theta_{\tilde{H}}(c(S_t) \tilde{p}(\tilde{h}) c(S_t)^{-1}) |\Delta_{G_n}(\tilde{h})|^2 \int_{G_n/\tilde{H}(S_t)} \Psi(gc(S_t) \tilde{p}(\tilde{h}) c(S_t)^{-1}) g^{-1} \overline{g} d\tilde{g}. \]

According to Remark 4.5, the global character \( \Theta_{\tilde{H}} \) of \( \Pi' \) is given by

\[
\Theta_{\tilde{H}}(\Psi) = \int_{\tilde{H}} \Theta_{\tilde{H}}(\tilde{h}) \det(\text{Id} - \text{Ad}(\tilde{h}^{-1})) d\tilde{h} \]

where \( \tilde{H}, \tilde{H}' \) are the two Cartan subgroups of \( G' \) (up to conjugation) defined in Equation (10). Using that \( \text{supp}(\Psi) \subseteq \tilde{G}_n \cdot \tilde{H}(S_t) \), we get from Theorem 5.5 and 3. Equation 8 that:

\[
\int_{\tilde{H}_n} \Theta_{\tilde{H}}(\tilde{h}) \det(\text{Id} - \text{Ad}(\tilde{h}^{-1})) d\tilde{h} = \int_{\tilde{H}_n} \Theta_{\tilde{H}}(\tilde{h}) \det(\text{Id} - \text{Ad}(\tilde{h}^{-1})) d\tilde{h}
\]

\[
\quad = \int_{\tilde{H}_n} \Theta_{\tilde{H}}(\tilde{h}) \det(\text{Id} - \text{Ad}(\tilde{h}^{-1})) d\tilde{h}
\]

(13) \[ \quad = \sum_{c \in \widehat{P}_n(S_t)} M_c(\sigma) \lim_{r \to 1} \int_{\tilde{H}_n} \Theta_{\tilde{H}}(\tilde{h}) \det(\text{Id} - \text{Ad}(\tilde{h}^{-1})) d\tilde{h} \]

Similarly, by using Equation 9, we get:

\[
\left\{ \begin{array}{ll}
0 & \text{if } S = \emptyset \\
C_1 \int_{\tilde{H}_n} \Theta_{\tilde{H}}(\tilde{h}) \det(\text{Id} - \text{Ad}(\tilde{h}^{-1})) d\tilde{h} & \text{if } S \neq \emptyset \\
\end{array} \right.
\]

where the constant \( C_1 \) defined in Equation (9) is given by

\[ C_1 = \frac{\pi^{2n+1} (2n-1)}{(2n+1)^2} C_n. \]

and \( C_n \) is defined in Lemma 6.6. In particular, the theorem follows for \( t = 0 \), i.e. \( S_0 = \emptyset \). From now on, we assume that \( t \geq 1 \), i.e. without loss of generality that \( e_1 - e_{2n+1} \in S_t \). In this case, using Remark 5.8, we get:

\[ \tilde{H}_n(S_t) = T(S_1) \times G(U_1) \times H_{n-1}(S_{t-1}). \]

The Cartan subgroup \( \tilde{H}_n(S_t) \) is included in the Levi \( L_n(S_t) = GL(X_1) \times G(U_1) \) of \( P_n(S_t) \). In particular, using Lemma 6.6 Equation 13 can be written as:

\[
\sum_{c \in \widehat{P}_n(S_t)} M_c(\sigma) \lim_{r \to 1} \int_{\tilde{H}_n} \Theta_{\tilde{H}}(\tilde{h}) \det(\text{Id} - \text{Ad}(\tilde{h}^{-1})) d\tilde{h}
\]

Similarly, Equation (14) is equal to

\[
C_{n-1} m_{n-1} \int_{\tilde{H}_n} \int_{\tilde{H}_n} \Theta_{\tilde{H}}(c(S_t) \tilde{p}(\tilde{h}) c(S_t)^{-1}) \det(\text{Id} - \text{Ad}(c(S_t) \tilde{p}(\tilde{h}) c(S_t)^{-1})) d\tilde{h} d\tilde{h}
\]

(15) \[ \quad \int_{\tilde{H}_n} \int_{\tilde{H}_n} \Theta_{\tilde{H}}(\tilde{h}) \det(\text{Id} - \text{Ad}(\tilde{h}^{-1})) d\tilde{h} \]

This completes the proof of the theorem.
Proof.  Since \( S_2' \leq S_2 \) and \( h \leq 2+1 \), we get:

\[
\Phi^\sigma_{\{\sigma\}^1} = (c_1 \rho \omega \theta \omega \theta \omega \theta \omega \theta \omega \theta \omega \theta \omega \theta \omega \theta \omega \theta \omega \theta \omega \theta \omega Up to a sign, the quotient $\frac{\Delta_{\Phi(Z_\sigma)}(\sigma^{-1}(h))}{\Delta_{\Phi(0)}(h)}$ is "uniquely" determined by $\sigma(1)$ and $\sigma(2n+1)$. For $\sigma \in \mathcal{S}_{2n+1}$ and $i, j \in \{1, \ldots, 2n+1\}$ such that $\sigma(1) = i, \sigma(2n+1) = j$, we denote by $\Delta(i, j, h)$ the following quantity:

$$
\Delta(i, j, h) = e(\sigma) \frac{\Delta_{\Phi(Z_\sigma)}(\sigma^{-1}(h))}{\Delta_{\Phi(0)}(h)} = \frac{h_i^j h_j^i \prod_{k=1}^{2n+1} h_k h_{j-i}^{h_{j-k}} \prod_{i=1}^{2n+1} (h_j - h_i)}{\prod_{k=1}^{2n+1} (h_i - h_k) \prod_{i=1}^{2n+1} (h_j - h_i)}.
$$

**Lemma 6.8.** Let $k \in \mathbb{Z}$ and $a \in \mathbb{C}^* \setminus S^1$. Then,

$$
\frac{1}{2\pi i} \int_{S^1} \frac{z^k}{z-a} dz = \begin{cases} 
 a^k & \text{if } k \geq 0 \text{ and } |a| < 1 \\
 -a^k & \text{if } k < 0 \text{ and } |a| > 1 \\
 0 & \text{otherwise}
\end{cases}
$$

We denote by $C_2$ the constant $\frac{(-1)^p}{p+q-2\pi}.$

**Notation 6.9.** For an element $h \in H_{n,S}^{\text{reg}}$ as in Equation (17), we denote by $J(h)$ and $K(h)$ the subsets of $\{1, \ldots, t\}$ given by

$$
J(h) = \{j \in \{1, \ldots, t\}, \text{sgn}(X_{2n+2-j}) = 1\}, \quad K(h) = \{j \in \{1, \ldots, t\}, \text{sgn}(X_{2n+2-j}) = -1\},
$$

where $\text{sgn}(X)$ is defined for every $X \in \mathbb{R}^*$ by

$$
\text{sgn}(X) = \begin{cases} 
 1 & \text{if } X > 0 \\
 -1 & \text{if } X < 0
\end{cases}.
$$

To simplify the notations, we will denote by $(h_1, \ldots, h_{2n+1})$ the components of $h$. Finally, we denote by $A_t$ and $B_t$ the subsets of $\{1, \ldots, 2n+1\}$ given by

$$
A_t = \{t+1, \ldots, n\}, \quad B_r = \{n+1, \ldots, 2n+1-t\}.
$$

**Theorem 6.10.** For every $0 \leq t \leq n$, the value of $\Theta_{\Pi^*}$ on $\tilde{H}_0(S_t)$ is given by

$$
\Theta_{\Pi^*}(c(S_t)\tilde{p}(h)c(S_t)^{-1}) = \pm C \begin{cases} 
 -\bar{\Lambda} \sum_{j \in J(h) \cap A_t} h_i^j h_j^i \Omega_{i,j}(h) + \delta_{i,0} Be^{-(m+1)\text{sgn}(X_{2n+1})X_{2n+1}} \Sigma(h) & \text{if } m \geq 1 \\
 \bar{\Lambda} \sum_{j \in K(h) \cup B_t} h_i^j h_j^i \Omega_{i,j}(h) + \delta_{i,0} Be^{-(m+1)\text{sgn}(X_{2n+1})X_{2n+1}} \Sigma(h) & \text{if } m = 0 \\
 \bar{\Lambda} \sum_{r \in K(h) \cup B_t} h_i^{m+r} h_j^r \Omega_{i,j}(h) + \delta_{i,0} Be^{(m-1)\text{sgn}(X_{2n+1})X_{2n+1}} \Sigma(h) & \text{if } m \leq -1
\end{cases}
$$

where $\Omega_{i,j}, 1 \leq i \neq j \leq 2n+1$, and $\Sigma$ are the functions on $H_{n,S}^{\text{reg}}$ given by

$$
\Omega_{i,j}(h) = \prod_{k=1}^{2n+1} \frac{h_k}{(h_i - h_k) (h_j - h_i)}, \quad \Sigma(h) = \sum_{j \in J(h) \cap A_t} (2n+1)! \left| e^{2\pi i X_{2n+1}} \right| (1 - e^{-2X_{2n+1}}) \left| 1 - e^{-2X_{2n+1}} \right|^2,
$$

and where $h \in \tilde{H}_0(S_t)$ is as in Equation (17), $\bar{\Lambda} = \frac{A}{(2n-1)!}$ and $C$ is a constant.
Proof. Let $h = \text{tanh} \in \mathbb{H}_{n, S}$. We denote by $(h_1, \ldots, h_{2n+1})$ the components of $h$. In particular,

$$h_c = \begin{cases} 
e(X, -X_{2n+2}) & \text{if } 1 \leq c \leq t \\ e^{X_i} & \text{if } t + 1 \leq c \leq 2n + 1 - t \\ e^{X_{2n+2}+X_i} & \text{if } 2n + 2 - t \leq c \leq 2n + 1 \end{cases}.$$  

We denote by $\Delta_n(l) := \Delta_n(l_n(S_1))$ the set of roots of $l_n(S_1)$ and let $\Psi_n(l) := \Delta_n(l) \cap \Psi_n$. One can easily check that

$$\Psi_n(l) = \{ e_i - e_j, 2 \leq i < j \leq 2n \}.$$  

Similarly, let $\Psi_n(l_l(S_1)) = [e_1 - e_2, 2 \leq k \leq 2n + 1] \cup [e_k - e_{2n+1}, 2 \leq k \leq 2n]$ the roots of $l_l(S_1)$. Then,

$$D(c(S_1)\hat{p}(\hat{h})c(S_1)^{-1}) = \left| \det(\text{Id} - \text{Ad}(c(S_1)\hat{p}(\hat{h})c(S_1)^{-1}))_{l_n(S_1)l_n(S_1)} \right|^2 = d_{s_l}(c(S_1)\hat{p}(\hat{h})c(S_1)^{-1})^2 \prod_{\alpha \in \Psi_n(l_l(S_1))} \left| 1 - \hat{h}^\alpha \right|^2$$  

Moreover,

$$\left| \Delta_{G}(\hat{h}) \right|^2 = \prod_{\alpha \in \Psi_n} \left| 1 - \hat{h}^\alpha \right|^2 = \prod_{\alpha \in \Psi_n} \left| 1 - h_{2n+1}^{-1} \right|^2 \prod_{\alpha \in \Psi_n} \left| 1 - h_{2n+1}^{-1} \right|^2.$$

In particular,

$$\frac{D(c(S_1)\hat{p}(\hat{h})c(S_1)^{-1})}{D_1(c(S_1)\hat{p}(\hat{h})c(S_1)^{-1})} \left| \Delta_{G}(\hat{h}) \right|^2 = d_{s_l}(c(S_1)\hat{p}(\hat{h})c(S_1)^{-1})^{-2} \left| 1 - e^{-2X_{2n+1}} \right|^{-1} \prod_{\alpha \in \Psi_n} \left| 1 - h_{2n+1}^{-1} \right|^2 \prod_{\alpha \in \Psi_n} \left| 1 - h_{2n+1}^{-1} \right|^{-1}.$$

Similarly,

$$\left| \Delta_{\Psi}(\hat{u}) \right|^2 = \left| 1 - h_{2n+1}^{-1} \right|^2 = \left| 1 - e^{-2X_{2n+1}} \right|^2$$

and it follows from Remark AX that

$$\Theta_{1_{\Psi_n}}(c(S_1)\hat{p}(\hat{u})c(S_1)^{-1}) = \begin{cases} \text{sgn}(X_{2n+1}) \frac{e^{ikX_i} - e^{X_i}}{e^{kX_i} - e^{X_i}} & \text{if } m \leq -1 \\ \text{sgn}(X_{2n+1}) \frac{e^{ikX_i}}{e^{kX_i}} & \text{if } m > 0 \end{cases},$$  

i.e.

$$\left| \Delta_{\Psi}(\hat{u}) \right|^2 \Theta_{1_{\Psi_n}}(c(S_1)\hat{p}(\hat{u})c(S_1)^{-1}) = \begin{cases} \text{sgn}(X_{2n+1}) \frac{e^{ikX_i} - e^{X_i}}{e^{kX_i} - e^{X_i}} & \text{if } m \leq -1 \\ \text{sgn}(X_{2n+1}) \frac{e^{ikX_i}}{e^{kX_i}} & \text{if } m > 0 \end{cases}.$$  

Finally, using that

$$\left| \det(\text{Ad}(c(S_1)\hat{p}(\hat{u})c(S_1)^{-1}) - 1)_{l_c(S_1)} \right| = \left| 1 - e^{-2X_{2n+1}} \right|, \quad d_{s_l}(c(S_1)\hat{p}(\hat{u})c(S_1)^{-1}) = \left| e^{-X_{2n+1}} \right|$$

and

$$d_{s_l}(c(S_1)\hat{p}(\hat{h})c(S_1)^{-1}) = \prod_{j=2}^{2n+1} \left( e^{X_{j-1} - X_{j+1}} \right) \prod_{j=2}^{2n} \left( h_j e^{-X_{j-1}} \right) = \left| e^{-2X_{2n+1}} \right|,$$

we get the second members of Equation (13).
We now look at the first member of Equation (13). One can easily check that for every \( \sigma \in \mathcal{S}_{2n+1} \), \( w = w_{1,1}E_{1,1} + w_{2n+2}E_{2n+2} \in W^0 \) and \( y \in b_0 \) such that \( y = (y_1, \ldots, y_{2n+1}) = (x_1, \ldots, x_{2n+1}) \), we get:

\[
\langle y \sigma(w), \sigma(w) \rangle = \begin{cases} 
X_{\sigma(1)}|w_{1,1}|^2 + X_{\sigma(2n+1)}|w_{2n+2}|^2 & \text{if } \sigma(1), \sigma(2n+1) \in \{1, \ldots, n\} \\
-X_{\sigma(1)}|w_{1,1}|^2 - X_{\sigma(2n+1)}|w_{2n+2}|^2 & \text{if } \sigma(1), \sigma(2n+1) \in \{n+1, \ldots, 2n+1\} \\
X_{\sigma(1)}|w_{1,1}|^2 - X_{\sigma(2n+1)}|w_{2n+2}|^2 & \text{if } \sigma(1) \in \{1, \ldots, n\} \text{ and } \sigma(2n+1) \in \{n+1, \ldots, 2n+1\} \\
-X_{\sigma(1)}|w_{1,1}|^2 + X_{\sigma(2n+1)}|w_{2n+2}|^2 & \text{if } \sigma(1) \in \{n+1, \ldots, 2n+1\} \text{ and } \sigma(2n+1) \in \{1, \ldots, n\} 
\end{cases}
\]

(see the proof of Proposition A.3 for an easier computation) and then

\[
\Gamma_{\sigma,S} = \begin{cases} 
b_0 & \text{if } \{\sigma(1), \sigma(2n+1)\} \subseteq S \\
[y = (y_1, \ldots, y_{2n+1}) \in b_0, X_{\sigma(2n+1)} > 0] & \text{if } \{\sigma(1), \sigma(2n+1)\} \subseteq S \\
[y = (y_1, \ldots, y_{2n+1}) \in b_0, X_{\sigma(2n+1)} < 0] & \text{if } \{\sigma(1), \sigma(2n+1)\} \subseteq S \\
[y = (y_1, \ldots, y_{2n+1}) \in b_0, X_{\sigma(2n+1)} > 0, X_{\sigma(2n+1)} < 0] & \text{if } \{\sigma(1), \sigma(2n+1)\} \subseteq S \\
[y = (y_1, \ldots, y_{2n+1}) \in b_0, X_{\sigma(2n+1)} < 0, X_{\sigma(2n+1)} < 0] & \text{if } \{\sigma(1), \sigma(2n+1)\} \subseteq S \\
[y = (y_1, \ldots, y_{2n+1}) \in b_0, X_{\sigma(2n+1)} > 0, X_{\sigma(2n+1)} < 0] & \text{if } \{\sigma(1), \sigma(2n+1)\} \subseteq S \\
[y = (y_1, \ldots, y_{2n+1}) \in b_0, X_{\sigma(2n+1)} < 0, X_{\sigma(2n+1)} < 0] & \text{if } \{\sigma(1), \sigma(2n+1)\} \subseteq S 
\end{cases}
\]

Let \( \hat{h} \in \hat{H}_m(S) \) and \( h = p(h) = (h_1, \ldots, h_{2n+1}) \) as in Notations 6,9. Assume that \( m \geq 1 \). Using Corollary A.2, we get that

\[
\Theta_{\hat{h}'}(p(\hat{h}')) \Delta(p(\hat{h}')) = h_1^{\cdot \cdot \cdot} h_2^{\cdot \cdot \cdot} h_2^{\cdot \cdot \cdot} h_1^{\cdot \cdot \cdot} (h_1' - h_2') = -h_2^{\cdot \cdot \cdot}, \quad (h_0 = \text{diag}(h_1', h_2')).
\]

Then,

\[
\sum_{\sigma \in \mathcal{S}_m} \Theta_{\hat{h}}(p(\hat{h}')) \Delta(p(\hat{h}')) = \lim_{\epsilon \to 0} \int_{\hat{H}_m} \frac{\Theta_{\hat{h}}(p(\hat{h}')) \Delta(p(\hat{h}'))}{\det(1 - p(h_0) - p(h_0))} dh_0
\]

\[
= \lim_{\epsilon \to 0} \int_{\hat{H}_m} \frac{\Theta_{\hat{h}}(p(\hat{h}')) \Delta(p(\hat{h}'))}{\det(1 - p(h_0) - p(h_0))} dh_0
\]

\[
= \lim_{\epsilon \to 0} \int_{\hat{H}_m} \frac{\Theta_{\hat{h}}(p(\hat{h}')) \Delta(p(\hat{h}'))}{\det(1 - p(h_0) - p(h_0))} dh_0
\]

\[
= \frac{1}{(2\pi)^\frac{m}{2}} \sum_{\sigma \in \mathcal{S}_m} \Theta_{\hat{h}}(p(\hat{h}')) \Delta(p(\hat{h}')) = \lim_{\epsilon \to 0} \int_{\hat{H}_m} \frac{\Theta_{\hat{h}}(p(\hat{h}')) \Delta(p(\hat{h}'))}{\det(1 - p(h_0) - p(h_0))} dh_0
\]

\[
= \frac{1}{(2\pi)^\frac{m}{2}} \sum_{\sigma \in \mathcal{S}_m} \Theta_{\hat{h}}(p(\hat{h}')) \Delta(p(\hat{h}')) = \lim_{\epsilon \to 0} \int_{\hat{H}_m} \frac{\Theta_{\hat{h}}(p(\hat{h}')) \Delta(p(\hat{h}'))}{\det(1 - p(h_0) - p(h_0))} dh_0
\]

\[
= \frac{1}{(2\pi)^\frac{m}{2}} \sum_{\sigma \in \mathcal{S}_m} \Theta_{\hat{h}}(p(\hat{h}')) \Delta(p(\hat{h}')) = \lim_{\epsilon \to 0} \int_{\hat{H}_m} \frac{\Theta_{\hat{h}}(p(\hat{h}')) \Delta(p(\hat{h}'))}{\det(1 - p(h_0) - p(h_0))} dh_0
\]

\[
= \frac{1}{(2\pi)^\frac{m}{2}} \sum_{\sigma \in \mathcal{S}_m} \Theta_{\hat{h}}(p(\hat{h}')) \Delta(p(\hat{h}')) = \lim_{\epsilon \to 0} \int_{\hat{H}_m} \frac{\Theta_{\hat{h}}(p(\hat{h}')) \Delta(p(\hat{h}'))}{\det(1 - p(h_0) - p(h_0))} dh_0
\]

\[
= \frac{1}{(2\pi)^\frac{m}{2}} \sum_{\sigma \in \mathcal{S}_m} \Theta_{\hat{h}}(p(\hat{h}')) \Delta(p(\hat{h}')) = \lim_{\epsilon \to 0} \int_{\hat{H}_m} \frac{\Theta_{\hat{h}}(p(\hat{h}')) \Delta(p(\hat{h}'))}{\det(1 - p(h_0) - p(h_0))} dh_0
\]

\[
= \frac{1}{(2\pi)^\frac{m}{2}} \sum_{\sigma \in \mathcal{S}_m} \Theta_{\hat{h}}(p(\hat{h}')) \Delta(p(\hat{h}')) = \lim_{\epsilon \to 0} \int_{\hat{H}_m} \frac{\Theta_{\hat{h}}(p(\hat{h}')) \Delta(p(\hat{h}'))}{\det(1 - p(h_0) - p(h_0))} dh_0
\]
Similarly, if \( m = 0 \), we get:

\[
\sum_{\sigma \in \mathcal{W}(\mathfrak{t})} \varepsilon(\sigma) \frac{\Delta_{\Phi Z_0}(\sigma(\hat{h}))}{\Delta_{\Phi_0}(\hat{h})} \lim_{\text{re} \rightarrow \infty} \int_{\mathfrak{h}'} \Theta_{\Phi_0}(\hat{p}(\hat{h}')) \Delta(\hat{p}(\hat{h}')) d\hat{h}'_i
\]

\[
= \frac{1}{(2\pi)^2} \sum_{1 \leq i, j \leq n+1} h_i h_j \Delta(i, j, \hat{h}) \lim_{\text{re} \rightarrow \infty} \int_{\mathfrak{h}'} \frac{h'^{-1}_i \cdot dh'_i}{h'^{-1}_j \cdot h'^{-1}_j (h'^{-1}_i - h'^{-1}_j)}
\]

\[
= \frac{1}{(2n-1)!} \sum_{i, j \in \mathfrak{h}_i} h_i h_j \Delta(i, j, \hat{h}) h'^{-1}_i h'^{-1}_j = \frac{1}{(2n-1)!} \sum_{i, j \in \mathfrak{h}_i} h'^{2n+1}_i \prod_{k=1}^{2n+1} h_k
\]

Finally, if \( m \leq -1 \), it follows from Corollary \([14, \text{Cor.} 1.4]\) that:

\[
\Theta_{\Phi_0}(\hat{p}(\hat{h}')) \Delta(\hat{p}(\hat{h}')) = h'^{-2}_1 h'^{-2}_2 \frac{h'^{-m}_i}{h'^{-1}_1} h'^{-v}_r (h'^{-1}_i - h'^{-1}_j) = -h'^{-m}_i, \quad (h'_0 = (h'_1, h'_2)).
\]

Then,

\[
\sum_{\sigma \in \mathcal{W}(\mathfrak{t})} \varepsilon(\sigma) \frac{\Delta_{\Phi Z_0}(\sigma(\hat{h}))}{\Delta_{\Phi_0}(\hat{h})} \lim_{\text{re} \rightarrow \infty} \int_{\mathfrak{h}'} \Theta_{\Phi_0}(\hat{p}(\hat{h}')) \Delta(\hat{p}(\hat{h}')) d\hat{h}'_i
\]

\[
= \frac{1}{(2\pi)^2} \sum_{\sigma \in \mathcal{W}(\mathfrak{t})} \varepsilon(\sigma) \frac{\Delta_{\Phi Z_0}(\sigma(\hat{h}))}{\Delta_{\Phi_0}(\hat{h})} \lim_{\text{re} \rightarrow \infty} \int_{\mathfrak{h}'} \frac{h'^{-1}_i \cdot dh'_i}{h'^{-1}_1 (1 - h'^{-1}_i) (h'^{-1}_2)}
\]

\[
= \frac{1}{(2n-1)!} \sum_{i, j \in \mathfrak{h}_i} h_i h_j \Delta(i, j, \hat{h}) h'^{-1}_i h'^{-1}_j
\]

\[
= \frac{1}{(2n-1)!} \sum_{i, j \in \mathfrak{h}_i} \sum_{k=1}^{2n+1} h_i h_j (h_i - h_k) (h_j - h_k)
\]

and the theorem follows. \(\square\)

We finish this section with a Lemma concerning the formulas we got in Theorem \([6.10]\).

**Lemma 6.11.** For every \( h \in \mathcal{H}_{n, S} \), \( \prod_{k=2}^{2n} (1 - h_k h^{-1}_k) \prod_{k=2}^{2n} (1 - h_k h^{-1}_{2n+1}) \in \mathbb{R} \) and its sign is constant on every Weyl chamber.

**Proof.** This result was obtained in \([21, \text{Lemma} 6.9]\) for \( t = 1 \). We prove this lemma for \( t = 2 \) (the proof of the general statement is similar). Assume that \( t = 2 \). We get:

\[
\prod_{k=2}^{2n} (1 - h_k h^{-1}_k) \prod_{k=2}^{2n} (1 - h_k h^{-1}_{2n+1}) = (1 - h_1 h^{-1}_2)(1 - h_2 h^{-1}_2)(1 - h_2 h^{-1}_{2n+1})(1 - h_2 h^{-1}_{2n+1}) \prod_{k=2}^{2n-1} (1 - h_k h^{-1}_k) (1 - h_k h^{-1}_{2n+1})
\]

Firstly,
\[
\prod_{j=3}^{2n-1} (1 - h_j h_{j+1}^{-1})(1 - h_j h_{j+1}^{-1}) = \prod_{j=3}^{2n-1} \left( 1 - e^{iX_j} e^{-iX_{j+1}} \right)^2 \left( 1 - e^{iX_j} e^{-iX_{j+1}} \right) = \prod_{j=3}^{2n-1} \left( 1 - e^{iX_j} e^{-iX_{j+1}} \right)^2 .
\]

Moreover,
\[
(1 - h_1 h_{2n}^{-1})(1 - h_2 h_{2n+1}^{-1}) = (1 - e^{iX_2} e^{-iX_{2n+1}})(1 - e^{iX_1} e^{-iX_{2n+1}}) = 1 - 2 \cos(X_1 - X_2) e^{X_2 - X_{2n+1} + e^{2X_2 - X_{2n+1}}}
\]
and
\[
(1 - h_2 h_{2n+1}^{-1})(1 - h_1 h_{2n}^{-1}) = (1 - e^{iX_1} e^{-iX_{2n+1}})(1 - e^{iX_2} e^{-iX_{2n+1}}) = 1 - 2 \cos(X_2 - X_1) e^{X_{2n+1} - X_{2n+1} + e^{2X_2 - X_{2n+1}}}
\]
so the lemma follows.

\[\square\]

**Appendix A. The dual pair \((G = U(1), G' = U(p, q))\)**

In [21, Proposition 6.4], the first author gave explicit formulas for the value of the character \(\Theta_0\) on the compact Cartan \(H' = H'(0) \cap G'\). Moreover, for \(p = q = 1\), he computed the character \(\Theta_0\) on \(H'(S_1)\), where \(H'(S_1)\) is the non-compact Cartan subgroup of \(U(1, 1)\) as in Equation (10). In this section, we recover the results proved in [21] using the results of Section 5 and get formulas for \(\Theta_0\) on every Cartan subgroup of \(G'\).

By keeping the notations of Section 5 we get \(V = \mathbb{C}\) with the hermitian form \((\cdot, \cdot)\) given by
\[(u, v) = i \overline{uv}, \quad (u, v \in V),
\]
\(V' = M_{n', 1}(\mathbb{C})\), where \(n' = p + q\), with the skew-hermitian form \((\cdot, \cdot)'\) given by:
\[(u, v) = \overline{u} \text{Id}_{p,q} v,
\]
and \(W = V \otimes_{\mathbb{C}} V'\) the symplectic space defined by
\[(w, w') = \text{Re}(\text{tr}(w^*w)) = \text{Im}(w^* \text{Id}_{p,q} w).
\]

Similarly,
\[H = G = U(1) = \{ h \in \mathbb{C}, |h| = 1 \}, \quad J_1 = i, \quad \mathfrak{h} = \mathbb{R} J_1,
\]
and the group \(\text{GL}_\mathbb{C}(W)\) is given by:
\[\text{GL}_\mathbb{C}(W) = \{ g \in \text{GL}(W), J_1 g = g J_1 \} = G', \quad \text{GL}_\mathbb{C}(W) = \{ \tilde{g} = (g, \xi), g \in \text{GL}_\mathbb{C}(W), \det(g) = \xi \} \}

Using that \(V' = V_1 \oplus \ldots \oplus V_{n'}\), with \(V_j = \mathbb{C}E_{j,1}\), and the embedding
\[\mathbb{H}_\mathbb{C} \ni \lambda \rightarrow (\lambda, 0, \ldots, 0) \in \mathbb{H}_\mathbb{C},
\]
we get that
\[W^h = \{ w = (w_{1,1}, 0, 0, \ldots, 0), w_{1,1} \in \mathbb{C} \}, \quad Z' = G^h = \{ g' \in G', g' = \left( \begin{array}{cc} 1 & 0 \\ 0 & X \end{array} \right), \lambda \in \text{U}(1), X \in \text{GL}(n' - 1, \mathbb{C}) \}.
\]

In particular, \(\Phi'(Z') = \{ (e_i - e_j), 2 \leq i < j \leq n' \}\), where \(e_j\) is the form defined in Notation 5.1. For every \(h' \in \mathbb{H}'_\mathbb{C}\), with \(h' = (h_1', \ldots, h_{n'}')\), we get:
\[\Delta_{\Phi'}(h') = \prod_{i=1}^{n'} (h'_i h'_i) \prod_{1 \leq i < j \leq n'} (h'_i + h'_j)^{j-i} = \prod_{i=1}^{n'} h'^{z_i}_{j-i}
\]
and for every \(\sigma \in \mathscr{S}_{n'}\),
\[\Delta_{\Phi'}(\sigma(h')) = \prod_{i=2}^{n'} h'^{z_i}_{j-i} \prod_{1 \leq i < j \leq n'} (h'_i - h'_j) = \varepsilon(\sigma) \prod_{i=1}^{n'} h'^{z_i}_{j-i} \prod_{1 \leq i < j \leq n'} (h'_i - h'_j).
\]
In particular,

$$\Delta_{\Phi(Z';c(\bar{h}))} \left( \frac{\Delta_{\Phi}(\bar{h}')}{} \right) = \varepsilon(\sigma) \left( \frac{\prod'_{i=1} h'_i - \prod'_{i=1} h_i}{\prod'_{i=1} h'_i - \prod'_{i=1} h_i} \right) = \varepsilon(\sigma) \left( \frac{\prod'_{i=1} h'_i - \prod'_{i=1} h_i}{\prod'_{i=1} h'_i - \prod'_{i=1} h_i} \right) (\bar{h}' \in \check{H}'_{\Sigma}) \, .$$

**Notation A.1.** As in Section 5, because the set of genuine representations of \( \check{U}(1) \) is isomorphic to \( \mathbb{Z} \), we will denote by \( \Pi_{m}, m \in \mathbb{Z} \), the representations of \( \check{U}(1), \) \( \omega \). Using (15), we get that \( \Pi_{m}(\bar{h}) = \pm h^{\pm m} \). We will denote by \( \Pi_{m}' \) the corresponding representation of \( \check{U}(p, q) \) and by \( \Theta_{\Pi_{m}} \) its character.

**Proposition A.2.** For every \( S \subseteq \mathbb{P}^{n}_{\mathbb{R}} \) (see Appendix B), the value of the character \( \Theta_{\Pi_{m}} \) on \( \check{H}'(S)^{\text{reg}} \) is given by the following formula:

$$\Delta_{\Phi(Z';c(\bar{h}'))} \left( \varepsilon(\sigma) \left( \frac{\prod'_{i=1} h'_i - \prod'_{i=1} h_i}{\prod'_{i=1} h'_i - \prod'_{i=1} h_i} \right) \right) \left( \frac{\Delta_{\Phi}(\bar{h}')}{} \right) = \varepsilon(\sigma) \left( \frac{\prod'_{i=1} h'_i - \prod'_{i=1} h_i}{\prod'_{i=1} h'_i - \prod'_{i=1} h_i} \right) \left( \frac{\prod'_{i=1} h'_i - \prod'_{i=1} h_i}{\prod'_{i=1} h'_i - \prod'_{i=1} h_i} \right) (\bar{h}' \in \check{H}'_{\Sigma}) \, .$$

**Proof.** Let \( \Psi \in \mathcal{C}_{\mathbb{R}}^{G_{\bar{h}}}(\check{G}) \) such that \( \text{supp}(\Psi) \subseteq \check{G} \cdot \check{H}'(S) \), we get:

(19)

$$\Theta_{\Pi_{m}}(\Psi) = \text{tr}(\mathcal{P}_{\Pi_{m}} \circ \omega(\Psi)) = \int_{G} \left( \int_{U(1)} \Theta_{\Pi_{m}}(\bar{h}) \Theta(\bar{h}') d\bar{h}' \right) \Psi(\bar{g}') d\bar{g}' \, ,$$

where \( \mathcal{P}_{\Pi_{m}} : \mathcal{H} \to \mathcal{H}(\Pi_{m}) \) is the projection onto the \( \Pi_{m} \)-isotypic component given by \( \mathcal{P}_{\Pi_{m}} = \omega(\Theta_{\Pi_{m}}) \) (see [28] Section 1.4.6), i.e. as a generalized function on \( G' \),

$$\Theta_{\Pi_{m}}(\Psi) = \int_{G} \Theta_{\Pi_{m}}(\bar{h}') \Psi(\bar{h}') d\bar{h}' \, , \quad (\bar{g}' \in \check{G}) \, .$$

Using Remark [5.4] we get:

$$\Theta_{\Pi_{m}}(\Psi) = \int_{G} \Theta_{\Pi_{m}}(\bar{h}') \Psi(\bar{h}') d\bar{h}' = m_{S} \int_{\check{H}'_{S}} \varepsilon(\sigma) \left( \frac{\prod'_{i=1} h'_i - \prod'_{i=1} h_i}{\prod'_{i=1} h'_i - \prod'_{i=1} h_i} \right) \Delta_{\Phi}(\bar{h}') \cdot \check{H}'(S)^{\text{reg}}(\Psi(\bar{h}') d\bar{h}' \, ,$$

(20)

$$\Theta_{\Pi_{m}}(\Psi) = m_{S} \int_{\check{H}'_{S}} \varepsilon(\sigma) \left( \frac{\prod'_{i=1} h'_i - \prod'_{i=1} h_i}{\prod'_{i=1} h'_i - \prod'_{i=1} h_i} \right) \Delta_{\Phi}(\bar{h}') \cdot \check{H}'(S)^{\text{reg}}(\Psi(\bar{h}') d\bar{h}' \, .$$

Using Theorem [5.5] and Equation (19) can be written as:

$$\Theta_{\Pi_{m}}(\Psi) = \int_{G} \Theta_{\Pi_{m}}(\bar{h}') \Psi(\bar{h}') d\bar{h}' = \int_{G} \Theta_{\Pi_{m}}(\bar{h}') \lim_{\text{w} \to \bar{h}'} \left( \frac{\Delta_{\Phi}(\bar{h}')}{\Delta_{\Phi}(\bar{h}') + \epsilon(\sigma) d\bar{h}'} \right) \Psi(\bar{h}') d\bar{h}' \, .$$

Using Theorem [5.5] and Equation (19) can be written as:

$$\Theta_{\Pi_{m}}(\Psi) = \int_{G} \Theta_{\Pi_{m}}(\bar{h}') \Psi(\bar{h}') d\bar{h}' = \int_{G} \Theta_{\Pi_{m}}(\bar{h}') \lim_{\text{w} \to \bar{h}'} \left( \frac{\Delta_{\Phi}(\bar{h}')}{\Delta_{\Phi}(\bar{h}') + \epsilon(\sigma) d\bar{h}'} \right) \Psi(\bar{h}') d\bar{h}' \, .$$

The result follows by comparing Equations [20] and [21] □

Without loss of generality, we assume that \( p \leq q \) and keep the notations of Appendix B (see Equation [23]). In particular, for every \( \bar{h}' \in \check{H}'_{S_{\Sigma}}, 0 \leq t \leq p, \bar{h}' \) is of the form

$$h' = (h'_1, \ldots, h'_t) = \text{diag}(e^{X'_1+X_{p+1}}, \ldots, e^{X'_1+X_{t+1}}, e^{X'_t+X_{p+1}}, \ldots, e^{X'_t+X_{t+1}}, e^{X'_p+X_{r+1}}, \ldots, e^{X'_p+X_{r+1}}), \quad X_j \in \mathbb{R},$$

$$X_j \in \mathbb{R},$$
where $S_t = \{e_1 - e_{p+1}, \ldots, e_t - e_{p+t}\}$.

**Proposition A.3.** The value of the character $\Theta_{\mathcal{H}_t}$ is given, for every $\mathbf{h}' \in \mathcal{H}_t$, $0 \leq t \leq p$, by the formula:

$$
\Theta_{\mathcal{H}_t}(c(S_t)) \hat{p}(\mathbf{h}')c(S_t)^{-1} = \pm C^2 \begin{cases}
- \frac{1}{\sum_{j=1}^{p} (h_j' - h_j)} \sum_{j=1}^{p} \prod_{i=1}^{t} \left( \frac{n^t}{i} \right) h_i' - h_i \quad & \text{if } m \leq -1 - \frac{e_{p+t}}{e_{p+t-1}} \\
- \frac{1}{\sum_{j=1}^{p} (h_j' - h_j)} \sum_{j=1}^{p} \prod_{i=1}^{t} \left( \frac{n^t}{i} \right) h_i' - h_i + \sum_{j=1}^{p} \prod_{i=1}^{t} \left( \frac{n^t}{i} \right) h_i' - h_i \quad & \text{otherwise}
\end{cases}
$$

where $C = \frac{(-1)^{t}}{\prod_{j=t+1}}$, $h' = (h_1', \ldots, h_p')$ and $K(h')$, $J(h')$ are given by:

$$
J(h') = \{ j \in \{1, \ldots, t\}, \text{sgn}(X_{p+j}) = 1 \}, \quad K(h') = \{ j \in \{1, \ldots, t\}, \text{sgn}(X_{p+j}) = -1 \},
$$

To make the equation shorter, we will denote by $C$ the constant $C = \frac{(-1)^{t}}{\prod_{j=t+1}}$.

**Proof.** We start by determining the space $E_{\sigma, \mathcal{H}_t}$ for $\sigma \in \mathcal{J}_t$. For every $w = w_{1,1}E_{1,1}$ and $y' = (y'_1, \ldots, y'_n) \in b'$ with $y'_j = iX_{j}', X_{j}' \in \mathbb{R}$, we get:

$$
\langle y', \sigma(w), \sigma(w) \rangle = \langle y'_1((w_{1,1}E_{1,1}(1,1)), w_{1,1}E_{1,1}(1,1)) \rangle = \langle y'((w_{1,1}E_{1,1}(1,1)), w_{1,1}E_{1,1}(1,1)) \rangle = \text{Im}(w_{1,1}E_{1,1}(1,1), Id_{p,q}w_{1,1}E_{1,1}(1,1)) \quad \text{if } 1 \leq \sigma(1) \leq p
$$

and then

$$
E_{\sigma, \mathcal{H}_t} = \text{exp}(\mathcal{J}_{\sigma, \mathcal{H}_t}) = \begin{cases}
\{ h' \in \mathcal{H}_t', h' = (e^{-X_1'}, \ldots, e^{-X_t'}), X_{\sigma(1)} > 0 \} & \text{if } 1 \leq \sigma(1) \leq p \\
\{ h' \in \mathcal{H}_t', h' = (e^{-X_1'}, \ldots, e^{-X_t'}), X_{\sigma(1)} < 0 \} & \text{if } p + 1 < \sigma(1) \leq n'
\end{cases}
$$

More generally, for every $\sigma \in \mathcal{J}_n$, we get:

$$
\Gamma_{\sigma, \mathcal{H}_t} = \begin{cases}
\{ y' \in \mathcal{H}_t', \text{sgn}(X_{\sigma(1)}) > 0 \} & \text{if } \sigma(1) \in S_t \\
\{ y' \in \mathcal{H}_t', \text{sgn}(X_{\sigma(1)}) < 0 \} & \text{if } \sigma(1) \in \{t + 1, \ldots, p\}
\end{cases}
$$

In particular,

$$
\Theta_{\mathcal{H}_t}(c(S_t)) \hat{p}(\mathbf{h}')c(S_t)^{-1} = \frac{\sum_{\sigma \in \mathcal{J}_n} e(\sigma) \Delta_{\mathcal{H}_t}(\sigma^{-1}(\hat{h})))}{\Delta_{\mathcal{H}_t}(\hat{h}')} \lim_{t \to \infty} \int_{[0,1]} \Theta_{\mathcal{H}_t}(\hat{p}(\mathbf{h}')) \frac{\Theta_{\mathcal{H}_t}(\hat{p}(\mathbf{h}'))}{1 - h(\mathbf{h}')}d\mathbf{h}'
$$

where $S_t = \{e_1 - e_{p+1}, \ldots, e_t - e_{p+t}\}$.
\[
\begin{align*}
\Theta_{\Pi_i}(\hat{p}(h)) &= C^2 \sum_{j=1}^{t} \frac{h_{j+1}^{(m+1)}}{\prod_{i=1}^{m+1} h_i^{(j)}} \int_{(1)} \Theta_{\Pi_i}(\hat{p}(\tilde{h})) \, d\tilde{h} + C^2 \sum_{j=1}^{t} \frac{h_{j+1}^{(m+1)}}{\prod_{i=1}^{m+1} h_i^{(j)}} \int_{(1)} \Theta_{\Pi_i}(\hat{p}(\tilde{h})) \, d\tilde{h} \sum_{j=1}^{t} \frac{h_{j+1}^{(m+1)}}{\prod_{i=1}^{m+1} h_i^{(j)}} \int_{(1)} \Theta_{\Pi_i}(\hat{p}(\tilde{h})) \, d\tilde{h} \\
&= -C^2 \sum_{j=1}^{p} \frac{h_{j+1}^{(m+1)}}{\prod_{i=1}^{m+1} h_i^{(j)}} \lim_{r \to 1^+} \int_{(1)} \Theta_{\Pi_i}(\hat{p}(\tilde{h})) \, d\tilde{h} - C^2 \sum_{j=1}^{t} \frac{h_{j+1}^{(m+1)}}{\prod_{i=1}^{m+1} h_i^{(j)}} \lim_{r \to 1^+} \int_{(1)} \Theta_{\Pi_i}(\hat{p}(\tilde{h})) \, d\tilde{h} \\
&= -C^2 \sum_{j=1}^{p} \frac{h_{j+1}^{(m+1)}}{\prod_{i=1}^{m+1} h_i^{(j)}} \lim_{r \to 1^+} \int_{(1)} \Theta_{\Pi_i}(\hat{p}(\tilde{h})) \, d\tilde{h} - C^2 \sum_{j=1}^{t} \frac{h_{j+1}^{(m+1)}}{\prod_{i=1}^{m+1} h_i^{(j)}} \lim_{r \to 1^+} \int_{(1)} \Theta_{\Pi_i}(\hat{p}(\tilde{h})) \, d\tilde{h} \\
&= -\frac{2\pi}{1 - \frac{q-p}{m+1}} \sum_{j=1}^{p} \frac{h_{j+1}^{(m+1)}}{\prod_{i=1}^{m+1} h_i^{(j)}} \lim_{r \to 1^+} \int_{(1)} \Theta_{\Pi_i}(\hat{p}(\tilde{h})) \, d\tilde{h} - C^2 \sum_{j=1}^{t} \frac{h_{j+1}^{(m+1)}}{\prod_{i=1}^{m+1} h_i^{(j)}} \lim_{r \to 1^+} \int_{(1)} \Theta_{\Pi_i}(\hat{p}(\tilde{h})) \, d\tilde{h} \\
\end{align*}
\]

If \(-m - 1 - \frac{q-p}{m+1} \geq 0\), i.e. \(m \leq -1 - \frac{q-p}{m+1}\). Then, according to Lemma 6.3, we get:

\[
\Theta_{\Pi_i}(c(S)\rho(h) c(S)^{-1})
\]

\[
= -\frac{2\pi}{1 - \frac{q-p}{m+1}} \sum_{j=1}^{p} \frac{h_{j+1}^{(m+1)}}{\prod_{i=1}^{m+1} h_i^{(j)}} \lim_{r \to 1^+} \int_{(1)} \Theta_{\Pi_i}(\hat{p}(\tilde{h})) \, d\tilde{h} - C^2 \sum_{j=1}^{t} \frac{h_{j+1}^{(m+1)}}{\prod_{i=1}^{m+1} h_i^{(j)}} \lim_{r \to 1^+} \int_{(1)} \Theta_{\Pi_i}(\hat{p}(\tilde{h})) \, d\tilde{h} \\
\]
Similarly, if \( m > -1 - \frac{q-p}{2} \), we get:

\[
\Theta_{\Gamma \beta}(c(S \beta) \rho(h') c(S \beta)^{-1})
\]

\[
= -\frac{C^2}{2i\pi} \sum_{j=p+1}^t \frac{h_j'\gamma}{\prod_{i \in J} (h_j' - h_i')} \frac{1}{\int_{\mathbb{U}(1)}} \frac{h^{-m-1-\frac{q-p}{2}}_j}{e^{-h^{-m-1-\frac{q-p}{2}}_j} - e^{-h^{-m-1-\frac{q-p}{2}}_j}} dh
\]

\[
- \frac{C^2}{2i\pi} \sum_{j=p+1}^t \frac{h_j'\gamma}{\prod_{i \in J} (h_j' - h_i')} \lim_{n \to \infty} \frac{1}{\int_{\mathbb{U}(1)}} \frac{h^{-m-1-\frac{q-p}{2}}_j}{h^{-m-1-\frac{q-p}{2}}_j - rh_j'} dh
\]

\[
= C^2 \sum_{j=p+1}^t \frac{h_j'^{-m+p-1}}{\prod_{i \in J} (h_j' - h_i')} + C^2 \sum_{j=p+1}^t \frac{h_j'^{-m+p-1}}{\prod_{i \in J} (h_j' - h_i')} + C^2 \sum_{j=p+1}^t \frac{h_j'^{-m+p-1}}{\prod_{i \in J} (h_j' - h_i')}
\]

The computations are similar if \( n' \) is odd.

\[\square\]

**Corollary A.4.** The value of \( \Theta_{\Gamma \beta} \) on \( \tilde{\rho}(h') \) is given, up to a constant, by:

\[
\Theta_{\Gamma \beta}(\tilde{\rho}(h')) = \pm C^2 \begin{cases} 
\frac{\prod_{i \in J} h_i'^\pm \sum_{j \in J} h_j'^{-m+p-1}}{\prod_{i \neq j} (h_j' - h_i')} & \text{if } m \leq -1 - \frac{q-p}{2} \\
- \frac{\prod_{i \in J} h_i'^\pm \sum_{j \in J} h_j'^{-m+p-1}}{\prod_{i \neq j} (h_j' - h_i')} & \text{otherwise}
\end{cases}
\]

where \( C \in \mathbb{R} \).

This result was obtained in [21] Section 6).

**Remark A.5.** Assume that \( p = 1, q = 1 \). Then,

\[
\Theta_{\Gamma \beta}(h') = \pm \begin{cases} 
\left( e^{\theta h - X - m} \right)^2 & \text{if } m \leq -1 \text{ and } X > 0 \\
- e^{\theta h - X - m} & \text{if } m \leq -1 \text{ and } X < 0 \\
e^{\theta h - X - m} & \text{if } m \geq 0 \text{ and } X > 0 \\
e^{\theta h - X - m} & \text{if } m \geq 0 \text{ and } X < 0
\end{cases}
\]

where \( h' = \begin{pmatrix} e^{\theta h - X} & sh(X) \\
sh(X) & e^{\theta h - X} \end{pmatrix} \). We recover the results of [21] Section 7).

**Appendix B. Cartan subgroups for unitary groups**

It is well-known that the number of non-conjugated Cartan subgroups of \( G = U(p, q) \), up to equivalence, is \( \min(p, q) + 1 \) (see [23]). We recall in this appendix how Cartan subgroups can be parametrised using strongly orthogonal roots (see [26] Section 2).

Let \( K = U(p) \times U(q) \) be the maximal compact subgroup of \( G \) and \( H \) be the (diagonal) compact Cartan subgroup of \( K \). We denote by \( h, l \) and \( g \) the Lie algebras of \( H, K \) and \( G \) respectively and \( h_c, l_c \) and \( g_c \) their complexifications.
We denote by \( \Delta = \Delta(\mathfrak{g}_C, \mathfrak{h}_C) \) be the set of roots, by \( \Delta_c := \Delta(\mathfrak{c}_C, \mathfrak{h}_C) \) the set of compact roots and by \( \Delta_u = \Delta \setminus \Delta_c \) the set of non-compact roots. Similarly, we denote by \( \Psi \) a set of positive roots of \( \Delta \) and let \( \Psi_c \) and \( \Psi_u \) the subsets of \( \Psi \) given by \( \Psi_c = \Delta_c \cap \Psi \) and \( \Psi_u = \Delta_u \cap \Psi \). In particular,

\[
\mathfrak{g}_C = \bigoplus_{\alpha \in \Delta} \mathfrak{g}_{C,\alpha} ,
\]

where \( \mathfrak{g}_{C,\alpha} = \{ X \in \mathfrak{g}_C, [H, X] = \alpha(H)X, H \in \mathfrak{h}_C \} \).

**Notation B.1.**

1. For every \( \alpha \in \Delta \), we fix \( X_\alpha \in \mathfrak{g}_{C,\alpha} \), \( Y_\alpha \in \mathfrak{g}_{C,-\alpha} \) and \( H_\alpha \in \mathfrak{h} \) such that:

\[
[H_\alpha, X_\alpha] = 2X_\alpha, \quad [H_\alpha, Y_\alpha] = -2Y_\alpha, \quad [X_\alpha, Y_\alpha] = H_\alpha, \quad \overline{H_\alpha} = -H_\alpha = H_{-\alpha} ,
\]

and such that \( \overline{X_\alpha} = -Y_\alpha \) if \( \alpha \in \Delta_c \) and \( \overline{Y_\alpha} = Y_\alpha \) if \( \alpha \in \Delta_u \).

2. We say that \( \alpha, \beta \in \Delta \) are strongly orthogonal if \( \alpha \neq \pm \beta \) and \( \alpha \pm \beta \notin \Delta \). We denote by \( \Psi_{st}^a \) a maximal family of strongly orthogonal roots of \( \Psi_u \) (i.e. a subset of \( \Psi_u \) such that every pairs \( \alpha, \beta \in \Psi_{st}^a \) are strongly orthogonal).

For every \( \alpha \in \Psi_{st}^a \), we denote by \( c(\alpha) \) the element of \( \text{GL}(p + q, \mathbb{C}) \) given by:

\[
c(\alpha) = \exp\left( \frac{\alpha}{4} (Y_\alpha - X_\alpha) \right) .
\]

For every subset \( S \) of \( \Psi_{st}^a \), we denote by \( c(S) \) the element of \( \text{GL}(p + q, \mathbb{C}) \) defined by

\[
c(S) = \prod_{\alpha \in S} c(\alpha) ,
\]

and let

\[
\mathfrak{h}(S) = \mathfrak{g} \cap \text{Ad}(c(S))(\mathfrak{h}_C) .
\]

We denote by \( H(S) \) the analytic subgroup of \( G \) whose Lie algebra is \( \mathfrak{h}(S) \). Then, \( H(S) \) is a Cartan subgroup of \( G \) and one can prove that all the Cartan subgroups are of this form (up to conjugation).

For every \( S \subseteq \Psi_{st}^a \), we will denote by \( H_S \) the subgroup of \( H \) given by:

\[
H_S = c(S)^{-1} H(S) c(S) ,
\]

where \( H_C = \{ \text{diag}(\lambda_1, \ldots, \lambda_{p+q}), \lambda_i \in \mathbb{C} \} \).

Without loss of generality, we assume that \( p \leq q \). The set of roots \( \Delta \) is given by \( \Delta = \{ \pm(e_i - e_j), 1 \leq i < j \leq p + q \} \), where \( e_i \) is the linear form on \( \mathfrak{h}_C = \mathbb{C}^{p+q} \) given by \( e_i(\lambda_1, \ldots, \lambda_{p+q}) = \lambda_i \). In this case,

\[
\Delta_c = \{ \pm(e_i - e_j), 1 \leq i < j \leq p \} \cup \{ \pm(e_i - e_j), p + 1 \leq i < j \leq p + q \} , \quad \Delta_u = \{ \pm(e_i - e_j), 1 \leq i \leq p, p + 1 \leq j \leq p + q \} ,
\]

and the set \( \Psi_{st}^a \) can be chosen as \( \{ e_i - e_{p+t}, 1 \leq t \leq p \} \). In particular, \( H(\emptyset) = H \) and if \( S_t = \{ e_1 - e_{p+1}, \ldots, e_t - e_{p+t} \} \), \( 1 \leq t \leq p \), we get:

\[
H(S_t) = \exp\left( \bigoplus_{j=1}^{p} \mathbb{R} E_{j,j} \oplus \bigoplus_{j=p+1}^{p+q} \mathbb{R} E_{j,j} \oplus \bigoplus_{j=1}^{t} \mathbb{R} (E_{j,j} + E_{p+j,p+j}) \oplus \bigoplus_{j=1}^{t} \mathbb{R} (E_{j,j} + E_{p+j,p+j}) \right) ,
\]

and

\[
H_S = \left\{ h = \text{diag}(e^{X_1}, \ldots, e^{X_p}, e^{X_{p+1}}, \ldots, e^{X_q}, e^{X_{p+1}} + \mathbb{R} X_{p+1}, \ldots, e^{X_{p+q}}, X_j \in \mathbb{R}) \right\} .
\]

**Remark B.2.** As explained in [26, Proposition 2.16], two Cartan subalgebras \( \mathfrak{h}(S_1) \) and \( \mathfrak{h}(S_2) \), with \( S_1, S_2 \subseteq \Psi_{st}^a \), are conjugate if and only if there exists an element of \( \sigma \in \mathscr{W} \) sending \( S_1 \cup (-S_1) \) onto \( S_2 \cup (-S_2) \).
Let \((W, (\cdot, \cdot))\) be a real symplectic space, \(\text{Sp}(W)\) the corresponding group of isometries and \(\widetilde{\text{Sp}}(W)\) its metaplectic cover as in Equation \((1)\).

Let \(W = X \oplus Y\) be a complete polarization of \(W\). We denote by \(Z\) the subgroup of \(\text{Sp}(W)\) preserving both \(X\) and \(Y\). In particular, we get that

\[
Z = \left\{ \begin{pmatrix} g & 0 \\ 0 & (g^{-1})^T \end{pmatrix}, g \in \text{GL}(X) \right\} \approx \text{GL}(X).
\]

We define a double cover \(\widetilde{\text{GL}}(X)\) of \(\text{GL}(X)\) by

\[
\widetilde{\text{GL}}(X) = \left\{ (g, \eta) \in \text{GL}(X) \times \mathbb{C}^\times, \eta^2 = \det(g) \right\}, \quad \widetilde{\text{GL}}(X) \ni (g, \eta) \rightarrow g \in \text{GL}(X).
\]

As recalled in [2, Section 6], the restriction map

\[
\Theta : \left\{ g \mid g_{14} \in \text{GL}(X) \right\} \rightarrow \left\{ \eta \mid \eta(g) \in \text{GL}(X) \right\},
\]

lifts to a group isomorphism

\[
\tilde{\Theta} : \tilde{Z} \ni \tilde{g} \rightarrow (g_{14}, \eta) \in \tilde{\text{GL}}(X),
\]

where \(\eta = \eta(\tilde{g})\) is defined on \(\tilde{Z}^c = \left\{ \tilde{g} \in \tilde{Z}, \det(g - 1)_W \neq 0 \right\}\) by the following formula:

\[
\eta(\tilde{g}) = \frac{\Theta(\tilde{g})}{|\Theta(\tilde{g})|} \left( \det(g_{14}) \right)^{\frac{1}{2}}.
\]

We denote by \(\varepsilon\) the function on \(\tilde{Z}\) given by:

\[
\varepsilon : \tilde{Z} \ni \tilde{g} \rightarrow \varepsilon(\tilde{g}) = \frac{\eta(\tilde{g})}{|\eta(\tilde{g})|} \in \mathbb{C}.
\]

One can easily prove that \(\varepsilon\) is a character of \(\tilde{Z}\) with values in the set \(\{\pm 1, \pm i\}\) such that

\[
\varepsilon(\tilde{g}) = \frac{\Theta(\tilde{g})}{|\Theta(\tilde{g})|} \left( \tilde{g} \in \tilde{Z} \right).
\]

**Lemma C.1.** For every \(\tilde{g} \in \tilde{Z}^c\), we get:

\[
\Theta(\tilde{g})^2 = \det(g_{14})^{-1} \det\left(\frac{1}{2}(c(g_{14}) + 1)\right)^2.
\]

**Proof.** Then, for every \(\tilde{g} \in \tilde{Z}^c\), we get:

\[
\Theta(\tilde{g})^2 = \det(\tilde{g}(g - 1))^{-1} = (-1)^{\text{dim}(W)} \det(g_{14} - 1)^{-1} \det(g_{14} - 1)^{-1}
\]

\[
= \det(g_{14} - 1)^{-1} \det(1 - g_{14})^{-1} = \det(g_{14} - 1)^{-1} \det(1 - g_{14}^{-1})^{-1}
\]

\[
= \det(g_{14} - 1)^{-1} \det(1 - g_{14}^{-1})^{-1} = \det(g_{14}) \det(g_{14} - 1)^{-2}
\]

We have:

\[
\frac{1}{2}(c(g_{14}) + 1) = \frac{1}{2}((g_{14} + 1)(g_{14} - 1)^{-1} + 1) = \frac{1}{2}((g_{14} + 1)(g_{14} - 1)^{-1} + (g_{14} - 1)(g_{14} - 1)^{-1}) = g_{14}(g_{14} - 1)^{-1}.
\]

Then,

\[
\Theta(\tilde{g})^2 = \det(g_{14}) \det(g_{14} - 1)^{-2} = \left(\det(g_{14}) \det(g_{14} - 1)^{-1}\right)^2 \det(g_{14})^{-1} \det(g_{14})^{-1} \det\left(\frac{1}{2}(c(g_{14}) + 1)\right)^2.
\]

\(\square\)
We define by $\det_X^{-2}(\tilde{g})$ the following quantity:

$$\det_X^{-2}(\tilde{g}) = \Theta(\tilde{g}) \left| \det \left( \frac{1}{2} (c(g_u) + 1) \right) \right|^{-1}. $$

In particular, for every $\tilde{g} \in \widetilde{Z}$, we get:

$$e(\tilde{g}) = \frac{\Theta(\tilde{g})}{|\Theta(\tilde{g})|} \frac{\det_X^{-2}(\tilde{g})}{|\det_X^{-2}(\tilde{g})|} \left( \tilde{g} \in \widetilde{Z} \right).$$
