Abstract

We propose three constructions of classically verifiable non-interactive proofs (CV-NIP) and non-interactive zero-knowledge proofs and arguments (CV-NIZK) for \textsc{QMA} in various preprocessing models.

1. We construct an information theoretically sound CV-NIP for \textsc{QMA} in the quantum secret parameter model where a trusted party generates a quantum proving key and classical verification key and gives them to the corresponding parties while keeping it secret from the other party. Alternatively, we can think of the protocol as one in a model where the verifier sends an instance-independent quantum message to the prover as preprocessing.

2. We construct a CV-NIZK for \textsc{QMA} in the quantum secret parameter model. It is information theoretically sound and zero-knowledge.

3. Assuming the quantum hardness of the learning with errors problem, we construct a CV-NIZK for \textsc{QMA} in a model where a trusted party generates a CRS and the verifier sends an instance-independent quantum message to the prover as preprocessing. This model is the same as one considered in the recent work by Coladangelo, Vidick, and Zhang (CRYPTO ’20). Our construction has the so-called dual-mode property, which means that there are two computationally indistinguishable modes of generating CRS, and we have information theoretical soundness in one mode and information theoretical zero-knowledge property in the other. This answers an open problem left by Coladangelo et al, which is to achieve either of soundness or zero-knowledge information theoretically. To the best of our knowledge, ours is the first dual-mode NIZK for \textsc{QMA} in any kind of model.

1 Introduction

1.1 Background

Classical verification of quantum computation. Verification of quantum computing is an interactive protocol between a verifier and a prover. The verifier is required to be as classical as possible, and the prover can do any polynomial-time quantum computing. Intuitively, the goal of the verifier is to verify the correctness of quantum computing with the help of the prover. The prover might be malicious, and try to make the verifier accept a wrong statement. More
precisely, we say that an interactive protocol between a verifier and a prover is a verification of quantum computing if the following is satisfied for any BQP problem $L$: for any yes instance $x \in L$, a quantum polynomial-time prover makes the verifier accept with high probability, and for any no instance $x \notin L$, the verifier does not accept except for a small probability whatever the (unbounded/quantum polynomial-time) prover does. If the verifier can do any polynomial-time quantum computing, the verification of quantum computing is trivially possible, but if the verifier’s quantum ability is restricted, verification of quantum computing is highly non-trivial.

The most ideal case would be the classical verifier, the information-theoretical soundness (i.e., proofs), and the non-interactive property. We immediately notice, however, that it will be impossible, because it means $\text{BQP} \subseteq \text{MA}$, which is not believed to happen [Wat00]. Furthermore, even a constant-round protocol will be impossible because it means $\text{BQP} \subseteq \text{AM}$, which is not likely either [RT19]. If we allow a polynomial-round communication between the verifier and the prover, though there is no known negative result, we do not know how to construct a verification of quantum computing, and in fact, whether $\text{BQP} \subseteq \text{IP}_{\text{BQP}}$ or not is a long-standing open problem in quantum complexity theory [Got04, AV12, GKK19], where $\text{IP}_{\text{BQP}}$ is $\text{IP}$ with an honest quantum polynomial-time prover.

The protocols [FK17, ABOEM17] achieve verifications of quantum computing with the information-theoretical soundness and “almost classical” verifiers, but the interaction is polynomial round. Protocols [RUV13, Gri19, CGJV19] have classical verifiers and information-theoretical soundness, but the extra assumption of the non-communicating multiple provers is required. The recent breakthrough by Mahadev [Mah18b] (and a related protocol [GV19]) enables the verification of quantum computing with a completely classical verifier, but the soundness is computational one, i.e., arguments [BC90]. The protocols [HM15, FHM18] are close to the most ideal case, because they are non-interactive, information-theoretically sound, and verifiers are “almost classical” in the sense that they need only single-qubit measurements. However, the verifiers in these protocols [HM15, FHM18] are still quantum, and therefore we have the following open question.

*Can we construct a non-interactive proof for BQP with a quantum polynomial-time honest prover and classical verifier with quantum preprocessing?*

Note that the quantum preprocessing is unavoidable as long as we require the classical verifier and the information-theoretical soundness.

**Non-interactive zero-knowledge.** A desirable feature of a (non-)interactive proof is the zero-knowledge property [GMR89], which ensures that the verifier learns nothing beyond the statement proven by the prover. Recently, there have been many works that constructed non-interactive zero-knowledge (NIZK) [BFM88] proofs or arguments for QMA, which is the “quantum counterpart” of NP, in various kind of models [ACGH20, CVZ20, BG20, Shm20, BCKM20]. We note that we require the honest prover to run in quantum polynomial-time receiving sufficiently many copies of a witness when we consider NIZK proofs or arguments for QMA. All known protocols except for the protocol of Broadbent and Grilo [BG20] only satisfy computational soundness. The protocol of [BG20] satisfies information theoretical soundness and zero-knowledge in the secret parameter (SP) model [Ps05] where a trusted party generates proving and verification keys and gives them to the corresponding party while keeping it secret to the other party as setup. A drawback of their

---

1. Note that the well-known result $\text{BQP} \subseteq \text{PSPACE} = \text{IP}$ does not solve the open problem, because the honest prover is not quantum polynomial-time.
2. The SP model is also often referred to as preprocessing model [DMP90].
protocol is that the prover sends a quantum proof to the verifier, and thus the verifier should be quantum. Then it is natural to ask the following question.

*Can we construct a NIZK proof for QMA with classical verification assuming a trusted party that generates proving and verification keys?*

In addition, the SP model is not a very desirable model since it assumes a strong trust on the setup. In the classical literature, there are constructions of NIZK proofs for NP in the common reference string (CRS) model \[BFM88, FLS99, PS19\] where the only trust on the setup is that a classical string is chosen according to a certain distribution and then published. Compared to the SP model, we need to put much less trust on the setup in the CRS model. Indeed, several works \[BG20, CVZ20, Shm20\] mention it as an open problem to construct a NIZK proofs (or even arguments) for QMA in the CRS model. Though this is still open, there are several constructions of NIZKs for QMA in different models that assume less trust on the setup than in the SP model \[CVZ20, Shm20, BCKM20\]. However, all of them are arguments. Therefore, we ask the following question.

*Can we construct a NIZK proof for QMA with classical verification in a model that assumes less trust on the setup than in the SP model?*

### 1.2 Our Results

We answer the above questions affirmatively.

1. We construct a (not zero-knowledge) classically verifiable non-interactive proof (CV-NIP) for QMA in the quantum secret parameter (QSP) model where a trusted party generates a quantum proving key and classical verification key and gives them to the corresponding parties. We do not rely on any computational assumption for this construction. Furthermore, the proving key is the simplest quantum state, i.e., a tensor product of random computational or Hadamard basis states. Alternatively, we can think of the protocol as one in a model where the verifier sends an instance-independent quantum message to the prover as preprocessing since soundness is not harmed even if the verifier plays the role of the trusted party. In the preprocessing, the verifier only needs to do single-qubit quantum operations (Hadamard or bit-flip gates) and send qubits one-by-one, and the online phase of the verifier is completely classical. Note that the honest prover in our construction runs in quantum polynomial time receiving a witness state. Because BQP is in QMA with a trivial witness state (such as the all-zero state), this answers our first question.

2. We extend the above construction to a classically verifiable NIZK (CV-NIZK) for QMA in the QSP model where a trusted party generates a quantum proving key and classical verification key and gives them to the corresponding parties. We do not rely on any computational assumption for this construction either, and thus both soundness and the zero-knowledge property are satisfied information theoretically. This answers our second question. Compared with \[BG20\], ours has an advantage that verification is classical at the cost of making the proving key quantum. The proving key is again a very simple state, i.e., a tensor product of randomly chosen Pauli X, Y, or Z basis states. We note that we should not let the verifier play the role of the trusted party for this construction since that would break the zero-knowledge property.

3. Assuming the quantum hardness of the learning with errors problem (the LWE assumption) \[Reg09\], we construct a CV-NIZK for QMA in a model where a trusted party generates
a CRS and the verifier sends an instance-independent quantum message to the prover as preprocessing. We note that the CRS is reusable for generating multiple proofs but the quantum message in the preprocessing is not reusable. In this model, we only assume a trusted party that just generates a CRS once, and thus this answers our third question. This model is the same as one considered in [CVZ20] recently, and we call it the CR S + (V → P) model. Compared to their work, our construction has the following advantages.

(a) In their protocol, both soundness and the zero-knowledge property hold only against quantum polynomial-time adversaries, and they left it open to achieve either of them information theoretically. We answer the open problem. Indeed, our construction has the so-called dual-mode property [GOS12, PS19], which means that there are two computationally indistinguishable modes of generating CRS, and we have information theoretical soundness in one mode and information theoretical zero-knowledge property in the other. To the best of our knowledge, ours is the first dual-mode NIZK for QMA in any kind of model.

(b) Our protocol uses underlying cryptographic primitives (which are lossy encryption and oblivious transfer with certain security) only in a black-box manner whereas their protocol heavily relies on non-black-box usage of the underlying primitives. Indeed, their protocol uses fully homomorphic encryption to homomorphically runs the proving algorithm of a NIZK for NP, which would make the protocol extremely inefficient. On the other hand, our construction uses the underlying primitives only in a black-box manner, which results in a much more efficient construction. We note that black-box constructions have been considered desirable for both theoretical and practical reasons in the cryptography community (e.g., see introduction of [IKLP06]).

(c) The verifier’s quantum operation in our preprocessing is simpler than that in theirs: in the preprocessing of our protocol, the verifier has only to do single-qubit gate operations (Hadamard, bit-flip or phase gates), while in the preprocessing of their protocol, the verifier has to do five-qubit (entangled) Clifford operations. In their paper [CVZ20], they left the following open problem: how far their preprocessing phase could be weakened? Our construction with the weaker verifier therefore partially answers the open problem.

On the other hand, Coladangelo et al. [CVZ20] proved that their protocol is also an argument of quantum knowledge (AoQK). We leave it open to study if ours is also a proof/argument of knowledge.

**Comparison among NIZKs for QMA.** We give more comparisons among our and known constructions of NIZKs for QMA. Since we already discuss comparisons with ours and [BG20, CVZ20], we discuss comparisons with other works. A summary of the comparisons is given in Table 1.

Alagic et al. [ACGH20] gave a construction of a NIZK for QMA in the SP model. Their protocol has an advantage that both the trusted party and verifier are completely classical. On the other hand, the drawbacks are that their security proof relies on random oracle (RO) heuristic, and only achieves computational soundness and zero-knowledge whereas our constructions achieve (at least) either statistical soundness or zero-knowledge without relying on RO (though in different models).

Shmueli [Shm20] gave a construction of a NIZK for QMA in the malicious designated-verifier (MDV) model, where a trusted party generates a CRS and the verifier sends an instance-independent classical message to the prover as preprocessing. In this model, the preprocessing is reusable, i.e.,
In column “Soundness” (resp. “ZK”), stat., and comp. mean statistical, and computational soundness (resp. zero-knowledge), respectively. In column “Verification”, “quantum+classical” means that the verifier needs to send a quantum message in preprocessing but the online phase of verification is classical.

A single preprocessing can be reused to generate arbitrarily many proofs later. This is a crucial advantage of their construction compared to ours. On the other hand, in their protocol, proofs are quantum and thus the verifier should perform quantum computations in the online phase whereas the online phase of the verifier is classical in our constructions. Also, their protocol only satisfies computational soundness and zero-knowledge whereas we can achieve (at least) either of them statistically. Recently, Bartusek et al. [BCKM20] gave another construction of a NIZK for QMA in the MDV model that has an advantage that the honest prover only uses a single copy of a witness. (Note that all other NIZKs for QMA including ours require the honest prover to take multiple copies of a witness if we require negligible completeness and soundness errors.) However, their construction also requires quantum verifier in the online phase and only achieves computational soundness and zero-knowledge similarly to [Shm20].

1.3 Technical Overview

Classically verifiable non-interactive proof for QMA in the QSP model. Our starting point is the post-hoc verification protocol [FHM18]. Their protocol is based on the fact that any instance $x$ of a QMA language $L$ can be reduced to the local Hamiltonian problem [VW16] with an $N$-qubit Hamiltonian $H_x$ of the form

$$H_x = \sum_{j_1 < j_2} \frac{p_{j_1,j_2}}{2} \left( I + s_{j_1,j_2} X_{j_1} X_{j_2} + I + s_{j_1,j_2} Z_{j_1} Z_{j_2} \right)$$

where $N = \text{poly}(|x|)$, $p_{j_1,j_2} > 0$, $\sum_{j_1 < j_2} p_{j_1,j_2} = 1$, $I$ is the identity operator, $s_{j_1,j_2} \in \{+1, -1\}$, and $X_j$ and $Z_j$ are Pauli $X$ and $Z$ operators acting on $j$-th qubit, respectively. That is, there are $0 < \alpha < \beta < 1$ with $\beta - \alpha = 1/\text{poly}(|x|)$ such that if $x \in L$, then there exists a state $\rho$ (called the history state) such that $\text{Tr}(\rho H_x) \leq \alpha$, and if $x \notin L$, then for any state $\rho$, we have $\text{Tr}(\rho H_x) \geq \beta$. In the post-hoc protocol, the prover prepares the history state and sends it to the verifier. The verifier chooses $(j_1, j_2)$ with probability $p_{j_1,j_2}$, and measures $j_1$-th and $j_2$-th qubits of the state in either of $X$ or $Z$ basis with probability $1/2$. Let $(m_{j_1}, m_{j_2}) \in \{0, 1\}^2$ be the measurement outcomes. The verifier accepts if $(-1)^{m_{j_1} \oplus m_{j_2}} = -s_{j_1,j_2}$ and rejects otherwise. The probability that the verifier accepts is $1 - \text{Tr}(\rho H_x)$ when the prover’s quantum message is $\rho$, and therefore the verifier accepts with probability at least $1 - \alpha$ if $x \in L$ and the prover is honest whereas it accepts with probability at most $1 - \beta$ if $x \notin L$. (See [FHM18] for the proof.) The gap between completeness of soundness can be amplified by simple parallel repetitions.

5
Our first idea is to use the quantum teleportation to replace the quantum communication with classical communication. Suppose that the prover and verifier share sufficiently many Bell pairs at the beginning. Then the prover can send the history state to the verifier with classical communication by the quantum teleportation. Though this removes the necessity of quantum communication, the verifier still needs to be quantum since it has to keep halves of Bell pairs and perform a measurement after receiving a proof.

To solve the problem, we utilize our observation that the verifier’s measurement and the prover’s measurement commute with each other, which is our second idea. In other words, we can let the verifier perform the measurement at the beginning without losing completeness or soundness. In the above quantum-teleportation-based protocol, when the prover sends its measurement outcomes \{ (x_j, z_j) \}_{j \in [N]} to the verifier, the verifier’s state collapses to \( X^x Z^z \rho_{\text{hist}} Z^z X^x \) where \( \rho_{\text{hist}} \) denotes the history state and \( X^x Z^z \) means \( \prod_{j=1}^{N} X^{x_j} Z^{z_j} \). Then the verifier applies the Pauli correction \( X^x Z^z \) and then measures two qubits of it in \( X \) or \( Z \) basis. We observe that the Pauli correction can be applied even after the verifier measures \( X \) or \( Z \) in advance since \( X^{x_j} Z^{z_j} \) before \( X \) (resp. \( Z \) measurement on the \( j \)-th qubit has the same effect as XOR by \( z_j \) (resp. \( x_j \)) after the measurement. Therefore, if a trusted party generates Bell pairs and measures half of them in either of \( X \) or \( Z \) basis with probability \( 1/2 \) and gives the unmeasured halves to the prover as a proving key while the measurement outcomes to the verifier as a verification key, a completely classical verifier can verify the \text{QMA} \) language, which solves our first question affirmatively.

**Classically verifiable NIZK for QMA in the QSP model.** We apply a similar idea to the NIZK of [BG20] to make the verification classical. The NIZK of [BG20] is based on the fact that a \text{QMA} \) language can be reduced to the 5-local Hamiltonian problem with \text{locally simulatable} \) history states [GSY19]. That is, an instance \( x \) corresponds to an \( N \)-qubit Hamiltonian \( \mathcal{H}_x \) of the form

\[
\mathcal{H}_x = \sum_{i=1}^{M} p_i \frac{I + s_i P_i}{2},
\]

where \( N = \text{poly}(|x|), M = \text{poly}(|x|), s_i \in \{+1,-1\}, p_i > 0, \sum_{i=1}^{M} p_i = 1, \) and \( P_i \) is a tensor product of Pauli operators \( (I,X,Y,Z) \) with at most 5 nontrivial Pauli operators \( (X,Y,Z) \). Moreover, the density matrix of the history state over any 5-qubit subsystem is classically simulatable without knowing the witness.

Based on this, they propose a NIZK for \text{QMA} \) in the SP model that roughly works as follows. A trusted party randomly chooses \( (\xi, \tilde{\xi}) \overset{\$}{\leftarrow} \{0,1\}^{N} \times \{0,1\}^{N} \), and randomly picks a random subset \( S_V \subseteq [N] \) such that \( 1 \leq |S_V| \leq 5 \). Then it gives \( (\xi, \tilde{\xi}) \) to the prover as a proving key and gives \( \{(\tilde{x}_j, \tilde{z}_j)\}_{j \in S_V} \) to the verifier as a verification key where \( \tilde{x}_j \) and \( \tilde{z}_j \) denote the \( j \)-th bits of \( \xi \) and \( \tilde{\xi} \), respectively. The prover generates the history state \( \rho_{\text{hist}} \) and sends \( \rho' = X^{\xi} Z^{\tilde{\xi}} \rho_{\text{hist}} Z^{\tilde{\xi}} X^{\xi} \) to the verifier as a proof. The verifier chooses \( i \) with probability \( p_i \), and let \( S_i \subseteq [N] \) be the set of indices on which \( P_i \) nontrivially acts. If \( S_i \neq S_V \), the verifier just accepts. Otherwise, it removes \( X^{\xi} Z^{\tilde{\xi}} \) on qubits corresponding to \( S_i \) by using the verification key, and then measures these qubits in the bases specified by \( P_i \). The rest of the verification is similar to the post-hoc protocol. Since the probability that we have \( S_i = S_V \) is \( \left( \sum_{j=1}^{5} \binom{N}{j} \right)^{-1} = 1/\text{poly}(|x|) \), we can still achieve inverse-polynomial gap between completeness and soundness. (See [BG20] for details.) Moreover, it satisfies the zero-knowledge property since qubits of \( \rho' \) that do not correspond to \( S_V \) are indistinguishable from a maximally mixed state from the view of the verifier by the security of quantum one-time pad, and thus the verifier can only know information of the density matrix of \( \rho' \) corresponding to the
positions of $S_V$, which can be simulated without using the witness. In this NIZK protocol of [BG20], however, the proof is a quantum state, and therefore the verifier has to be quantum.

Our idea is to use the quantum teleportation to remove the quantum communication and then perform the measurement at the beginning to make the verification key classical similarly to the previous paragraph. A difference is that the above protocol involves $Y$ measurements, but this can be easily dealt with observing that $X_j^z Z_j^{\hat{z}}$ before $Y$ measurement on $j$th qubit has the same effect as $\text{XOR}$ by $x_j \oplus z_j$ after the measurement. Another difference is that the distribution of bases that appear in $P_i$ depends on a statement $x$, and thus we cannot sample the distribution at the setup phase where $x$ is not decided yet. (Note that this problem did not occur in the previous paragraph since we assumed that weights of $XX$ and $ZZ$ terms in the Hamiltonian $H_x$ were equal for any $x$.) To resolve this issue, we use the idea used in [ACGH20]. The trusted party just chooses random bases, and the verifier just accepts if they are inconsistent to $P_i$ chosen by the verifier in the online phase. Since there are only 3 possible choices of the bases and $P_i$ non-trivially acts on at most 5 qubits, the probability that the randomly chosen bases are consistent to $P_i$ is at least $3^{-5}$. Therefore we can still achieve inverse-polynomial gap between completeness and soundness. Finally, we remark that we can amplify the gap by parallel repetition, which preserves the zero-knowledge property (see Lemma 2.10). This results in a classically verifiable NIZK for QMA in the QSP model.

**Classically verifiable NIZK for QMA in the CRS + ($V \rightarrow P$) model.** We want to reduce the trust on the setup, so let us first examine what happens if the verifier runs the setup as preprocessing. Unfortunately, such a construction is not zero-knowledge since the verifier can know whole bits of $(\tilde{x}, \tilde{z})$ and thus it may obtain information of qubits of $\rho_{\text{hist}}$ that are outside of $S_V$, in which case we cannot rely on the local simulatability. Therefore, for ensuring the zero-knowledge property, we have to make sure that the verifier only knows $\{(\tilde{x}_j, \tilde{z}_j)\}_{j \in S_V}$. Then suppose that the prover chooses $(\tilde{x}, \tilde{z})$ whereas other setups are still done by the verifier. Here, the problem is how to let the verifier know $\{(\tilde{x}_j, \tilde{z}_j)\}_{j \in S_V}$. A naive solution is that the verifier sends $S_V$ to the prover and then the prover returns $\{(\tilde{x}_j, \tilde{z}_j)\}_{j \in S_V}$. However, such a construction is not sound since it is essential that the prover “commits” to a single quantum state independently of $S_V$ when reducing soundness to the local Hamiltonian problem. So what we need is a protocol between the prover and verifier where the verifier only gets $\{(\tilde{x}_j, \tilde{z}_j)\}_{j \in S_V}$ and the prover does not learn $S_V$. We observe that this is exactly the functionality of $5$-out-of-$N$ oblivious transfer [BCR87].

Though it may sound easy to solve the problem by just using a known two-round 5-out-of-$N$ oblivious transfer, there is still some subtlety. For example, if we use an oblivious transfer that satisfies only indistinguishability-based notion of receiver’s security (e.g., [NP01, BD18]), which just says that the sender cannot know indices chosen by the receiver, we cannot prove soundness. Intuitively, this is because the indistinguishability-based receiver’s security does not prevent a malicious sender from generating a malicious message such that the message derived on the receiver’s side depends on the chosen indices, which does not force the prover to “commit” to a single state.

If we use a fully-simulatable [Lin08] oblivious transfer, the above problem does not arise and we can prove both soundness and zero-knowledge. However, the problem is that we are not aware of any efficient fully-simulatable 5-out-of-$N$ oblivious transfer based on post-quantum assumptions (in the CRS model). The LWE-based construction of [PVW08] does not suffice for our purpose.

---

4There is a subtle issue that the probability depends on the number of qubits on which $P_i$ non-trivially acts. We adjust this by an additional biased coin flipping.

4The indistinguishability-based receiver’s security is also often referred to as half-simulation security [CNs07].
since a CRS can be reused only a bounded number of times in their construction. Recently, Quach [Qua20] resolved this issue, and proposed an efficient fully-simulatable 1-out-of-2 oblivious transfer based on the LWE assumption.\textsuperscript{5} We can extend his construction to a fully-simulatable 1-out-of-N oblivious transfer efficiently. However, we do not know how to convert this into 5-out-of-N one efficiently without losing the full-simulatability. We note that a conversion from 1-out-of-N to 5-out-of-N oblivious transfer by a simple 5-parallel repetition loses the full-simulatability against malicious senders since a malicious sender can send different inconsistent messages in different sessions, which should be considered as an attack against the full-simulatability. One possible way to prevent such an inconsistent message attack is to let the sender prove that the messages in all sessions are consistent by using (post-quantum) CRS-NIZK for NP [PS19]. However, such a construction is very inefficient since it uses the underlying 1-out-of-N oblivious transfer in a non-black-box manner, which we want to avoid.

We note that the parallel repetition construction preserves indistinguishability-based receiver’s security and fully-simulatable sender’s security for two-round protocols. Therefore, we have an efficient (black-box) construction of 5-out-of-N oblivious transfer if we relax the receiver’s security to the indistinguishability-based one. As already explained, such a security does not suffice for proving soundness. To resolve this issue, we add an additional mechanism to force the prover to “commit” to a single state. Specifically, instead of directly sending $(x, z)$ by a 5-out-of-N oblivious transfer, the prover sends a commitment of $(x, z)$ and then sends $(x, z)$ and the corresponding randomness used in the commitment by a 5-out-of-N oblivious transfer. When the verifier receives \( \{x_j, z_j\}_{j \in S_V} \) and corresponding randomness, it checks if it is consistent to the commitment by recomputing it, and immediately rejects if not. This additional mechanism prevents a malicious prover’s inconsistent behavior, which resolves the problem in the proof of soundness.

Finally, our construction satisfies the dual-mode property if we assume appropriate dual-mode properties for building blocks. A dual-mode oblivious transfer (in the CRS model) has two modes of generating a CRS and it satisfies statistical (indistinguishability-based) receiver’s security in one mode and statistical (full-simulation-based) sender’s security in the other mode. The construction of [Qua20] is an instantiation of a 1-out-of-2 oblivious transfer with such a dual-mode property, and this can be converted into 5-out-of-N one as explained above. We stress again that it is important to relax the receiver’s security to the indistinguishability-based one to make the conversion work. A dual-mode commitment (in the CRS model) has two modes of generating a CRS and it is statistically binding in one mode and statistically hiding in the other mode. We can use lossy encryption [BHY09, Reg09] as an instantiation of such a dual-mode commitment. Both of dual-mode 5-out-of-N oblivious transfer and lossy encryption are based on the LWE assumption (with super-polynomial modulus for the former) and fairly efficient in the sense that they do not rely on non-black-box techniques. Putting everything together, we obtain a fairly efficient (black-box) construction of a dual-mode NIZK for QMA in the CRS + (V → P) model.

1.4 Related Work

Subsequent work. Subsequently to our work, Bartusek and Malavolta [BM21] recently constructed the first CV-NIZK argument for QMA in the CRS model assuming the LWE assumption and ideal obfuscation for classical circuits. An obvious drawback is the usage of ideal obfuscation, which has no provably secure instantiation. They also construct a witness encryption scheme for QMA under the same assumptions. They use the verification protocol of Mahadev [Mah18a] and therefore the LWE assumption is necessary. If our CV-NIP is used, instead, a witness encryption

\textsuperscript{5}Actually, his construction satisfies a stronger UC-security [Can20, PVW08].
for QMA (with quantum ciphertext) would be constructed without the LWE assumption, which is one interesting application of our CV-NIP.

More related works on quantum NIZKs. Kobayashi [Kob03] studied (statistically sound and zero-knowledge) NIZKs in a model where the prover and verifier share Bell pairs, and gave a complete problem in this setting. It is unlikely that the complete problem contains (even a subclass of) NP [MW18] and thus even a NIZK for all NP languages is unlikely to exist in this model. Note that if we consider the prover and verifier sharing Bell pairs in advance like this model, the verifier’s preprocessing message of our protocols (and the protocol of [CVZ20]) becomes classical. Chailloux et al. [CCKV08] showed that there exists a (statistically sound and zero-knowledge) NIZK for all languages in QSZK in the help model where a trusted party generates a pure state depending on the statement to be proven and gives copies of the state to both prover and verifier.

Interactive zero-knowledge for QMA. There are several works of interactive zero-knowledge proofs/arguments for QMA. The advantage of these constructions compared to non-interactive ones is that they do not require any trusted setup. Broadbent, Ji, Song, and Watrous [BJSW20] gave the first construction of a zero-knowledge proof for QMA. Broadbent and Grilo [BG20] gave an alternative simpler construction. Bitansky and Shmueli [BS20] gave the first constant round zero-knowledge argument for QMA with negligible soundness error. Brakerski and Yuen [BY20] gave a construction of 3-round delayed-input zero-knowledge proof for QMA where the prover needs to know the statement and witness only for generating its last message. By considering the first two rounds as preprocessing, we can view this construction as a NIZK in a certain kind of preprocessing model. However, their protocol has a constant soundness error, and it seems difficult to prove the zero-knowledge property for the parallel repetition version of it.

2 Preliminaries

Notations. We use $\lambda$ to denote the security parameter throughout the paper. For a positive integer $N$, $[N]$ means the set $\{1, 2, \ldots, N\}$. For a probabilistic classical or quantum algorithm $A$, we denote by $y \leftarrow A(x)$ to mean $A$ runs on input $x$ and outputs $y$. For a finite set $S$ of classical strings, $x \overset{\xi}{\leftarrow} S$ means that $x$ is uniformly randomly chosen from $S$. For a classical string $x$, $x_i$ denotes the $i$-th bit of $x$. For classical strings $x$ and $y$, $x\|y$ denotes the concatenation of $x$ and $y$. We write $\text{poly}$ to mean an unspecified polynomial and $\text{negl}$ to mean an unspecified negligible function. We use PPT to stand for (classical) probabilistic polynomial time and QPT to stand for quantum polynomial time. When we say that an algorithm is non-uniform QPT, it is expressed as a family of polynomial size quantum circuits with quantum advice.

2.1 Quantum Computation Preliminaries

Here, we briefly review basic notations and facts on quantum computations.

For any quantum state $\rho$ over registers $A$ and $B$, $\text{Tr}_A(\rho)$ is the partial trace of $\rho$ over $A$. We use $I$ to mean the identity operator. (For simplicity, we use the same $I$ for all identity operators with different dimensions, because the dimension of an identity operator is clear from the context.) We use $X$, $Y$, and $Z$ to mean Pauli operators i.e., $X := \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$, $Z := \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}$, and $Y := iXZ$. We use $H$ to mean Hadamard operator, i.e., $H := \frac{1}{\sqrt{2}} \begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix}$. We also define the $T$ operator
by \( T := \begin{pmatrix} 1 & 0 \\ 0 & e^{i\pi/4} \end{pmatrix} \). The CNOT := |0⟩⟨0| ⊗ I + |1⟩⟨1| ⊗ X is the controlled-NOT operator.

We define \( V(Z) := I, V(X) := H, \) and \( V(Y) := \frac{1}{\sqrt{2}} \begin{pmatrix} 1 & 1 \\ i & -i \end{pmatrix} \) so that for each \( W \in \{X,Y,Z\}, \) \( V(W)|0⟩ \) and \( V(W)|1⟩ \) are the eigenvectors of \( W \) with eigenvalues +1 and −1, respectively. For each \( W \in \{X,Y,Z\}, \) we call \( \{V(W)|0⟩, V(W)|1⟩\} \) the \( W \)-basis.

When we consider an \( N \)-qubit system, for a Pauli operator \( Q \in \{X,Y,Z\}, \) \( Q_j \) denotes the operator that acts on \( j \)-th qubit as \( Q \) and trivially acts on all the other qubits. Similarly, \( V_j(W) \) denotes the operator that acts on \( j \)-th qubit as \( V(W) \) and trivially acts on all the other qubits.

For any \( x \in \{0,1\}^N \) and \( z \in \{0,1\}^N, \) \( X^xZ^z \) means \( \prod_{j=1}^N X_j^{x_j} Z_j^{z_j} \).

We call the state \( \frac{1}{\sqrt{2}} (|0⟩ \otimes |0⟩ + |1⟩ \otimes |1⟩) \) the Bell pair. We call the set \( \{|\phi_{x,z}\rangle\}_{(x,z) \in \{0,1\}^2} \) the Bell basis where \( |\phi_{x,z}\rangle := (X^xZ^z \otimes I)|0⟩ \otimes |0⟩ + |1⟩ \otimes |1⟩ \sqrt{2} \). Let us define \( U(X) := V(X), U(Y) := V(Y)X, \) and \( U(Z) := V(Z) \).

**Lemma 2.1** (State Collapsing). If we project one qubit of a Bell pair onto \( V(W)|m⟩ \) with \( W \in \{X,Y,Z\} \) and \( m \in \{0,1\}, \) the other qubit collapses to \( U(W)|m⟩ \).

**Lemma 2.2** (Effect of \( X^xZ^z \) before measurement). For any \( N \)-qubit state \( \rho, (W_1,...,W_N) \in \{X,Y,Z\}^N, \) and \( (x,z) \in \{0,1\}^N \times \{0,1\}^N, \) the distributions of \( (m'_1,...,m'_n) \) sampled in the following two ways are identical.

1. For \( j \in [N], \) measure \( j \)-th qubit of \( \rho \) in \( W_j \) basis, let \( m_j \in \{0,1\} \) be the outcome, and set

\[
m'_j := \begin{cases} m_j \oplus x_j & (W_j = Z), \\
m_j \oplus z_j & (W_j = X), \\
m_j \oplus x_j \oplus z_j & (W_j = Y). \end{cases}
\]

2. For \( j \in [N], \) measure \( j \)-th qubit of \( X^xZ^z\rho Z^zX^x \) in \( W_j \) basis and let \( m'_j \in \{0,1\} \) be the outcome.

The proofs of the above lemmas are straightforward.

**Lemma 2.3** (Pauli Mixing). Let \( \rho \) be an arbitrary quantum state over registers \( A \) and \( B, \) and let \( N \) be the number of qubits in \( A. \) Then we have

\[
\frac{1}{2^N} \sum_{x \in \{0,1\}^N, z \in \{0,1\}^N} (X^xZ^z \otimes I_B) \rho (Z^xX^z \otimes I_B) = \frac{1}{2^N} I_A \otimes \text{Tr}_A(\rho).
\]

This is well-known, and one can find a proof in e.g., [Mah18a].

**Lemma 2.4** (Quantum Teleportation). Suppose that we have \( N \) Bell pairs between registers \( A \) and \( B, \) i.e., \( \frac{1}{2^N} \sum_s|s⟩_A \otimes |s⟩_B, \) and let \( \rho \) be an arbitrary \( N \)-qubit quantum state in register \( C. \) Suppose that we measure \( j \)-th qubits of \( C \) and \( A \) in the Bell basis and let \( (x_j, z_j) \) be the measurement outcome for all \( j \in [N]. \) Let \( x := x_1||x_2||...||x_N \) and \( z := z_1||z_2||...||z_N. \) Then the \( (x, z) \) is uniformly distributed over \( \{0,1\}^N \times \{0,1\}^N. \) Moreover, conditioned on the measurement outcome \( (x, z), \) the resulting state in \( B \) is \( X^xZ^z\rho Z^zX^x. \)

This is also well-known, and one can find a proof in e.g., [NC00].

The following lemma is implicit in previous works e.g., [MNS18, FHM18].
Lemma 2.5. Let
\[ \mathcal{H} := \frac{I + s(\prod_{j \in S_X} X_j)(\prod_{j \in S_Y} Y_j)(\prod_{j \in S_Z} Z_j)}{2} \]
be an \(N\)-qubit projection operator, where \(s \in \{+1, -1\}\), and \(S_X, S_Y,\) and \(S_Z\) are disjoint subsets of \([N]\). For any \(N\)-qubit quantum state \(\rho\), suppose that for all \(j \in S_W\), where \(W \in \{X, Y, Z\}\), we measure \(j\)-th qubit of \(\rho\) in the \(W\)-basis, and let \(m_j \in \{0, 1\}\) be the outcome. Then we have
\[ \Pr\left[(-1)^{\sum_{j \in S_X \cup S_Y \cup S_Z} m_j} = -s\right] = 1 - \Tr(\rho \mathcal{H}). \]

Proof of Lemma 2.5. Let us define \(V := (\prod_{j \in S_X} V_j(X))(\prod_{j \in S_Y} V_j(Y))(\prod_{j \in S_Z} V_j(Z))\), and \(|m\rangle := \bigotimes_{j=1}^{N} |m_j\rangle\). Then,
\[
\Pr\left[(-1)^{\sum_{j \in S_X \cup S_Y \cup S_Z} m_j} = -s\right] = \sum_{m \in \{0, 1\}^N} \langle m | V^\dagger \rho V | m \rangle \frac{1 - s(-1)^{\sum_{j \in S_X \cup S_Y \cup S_Z} m_j}}{2} = \sum_{m \in \{0, 1\}^N} \langle m | V^\dagger \rho V \frac{1 - s \sum_{j \in S_X \cup S_Y \cup S_Z} Z_j | m} {2} \rangle = \Tr[V^\dagger \rho V \frac{1 - s \sum_{j \in S_X \cup S_Y \cup S_Z} Z_j} {2} V] = \Tr[\rho (I - \mathcal{H})] = 1 - \Tr(\rho \mathcal{H}).
\]

\[\square\]

2.2 QMA Languages and Local Hamiltonian Problem

Definition 2.6 (QMA languages). We say that a language \(L \subseteq \{0, 1\}^\ast\) is in QMA if there is a polynomial \(\ell\) and a QPT algorithm \(V\) such that the following is satisfied:

- For any \(x \in L\), there exists a quantum state \(w\) of \(\ell(|x|)\)-qubit (called a witness) such that we have \(\Pr[V(x, w) = 1] \geq 2/3\).
- For any \(x \notin L\) and any quantum state \(w\) of \(\ell(|x|)\)-qubit, we have \(\Pr[V(x, w) = 1] \leq 1/3\).

For any \(x \in L\), we denote by \(R_L(x)\) to mean the (possibly infinite) set of all quantum states \(w\) such that \(\Pr[V(x, w) = 1] \geq 2/3\).

It is known that the 2-local \(\{ZZ, XX\}\)-local Hamiltonian problem is QMA-complete. That is, we have the following lemma.

Lemma 2.7 (QMA-completeness of 2-local \(\{ZZ, XX\}\)-Hamiltonian problem [CM16]). For any QMA language \(L\), there is a classical polynomial-time computable deterministic function that maps \(x \in \{0, 1\}^\ast\) to an \(N\)-qubit Hamiltonian \(\mathcal{H}_x\) of the form
\[ \mathcal{H}_x = \sum_{j_1 < j_2} \frac{p_{j_1, j_2}}{2} \left( I + \frac{s_{j_1, j_2} X_{j_1} X_{j_2}}{2} + \frac{I + s_{j_1, j_2} Z_{j_1} Z_{j_2}}{2} \right) \]
where \(N = \text{poly}(|x|)\), \(p_{j_1, j_2} > 0\), \(\sum_{j_1 < j_2} p_{j_1, j_2} = 1\), and \(s_{j_1, j_2} \in \{+1, -1\}\), and satisfies the following:
There are \(0 < \alpha < \beta < 1\) such that \(\beta - \alpha = 1/\text{poly}(|x|)\) and
• if \( x \in L \), then there exists an \( N \)-qubit state \( \rho \) such that \( \text{Tr}(\rho \mathcal{H}_x) \leq \alpha \), and
• if \( x \notin L \), then for any \( N \)-qubit state \( \rho \), we have \( \text{Tr}(\rho \mathcal{H}_x) \geq \beta \).

Moreover, for any \( x \in L \), we can convert any witness \( \mathbf{w} \in R_L(x) \) into a state \( \rho_{\text{hist}} \), called the history state, such that \( \text{Tr}(\rho_{\text{hist}} \mathcal{H}_x) \leq \alpha \) in quantum polynomial time.

Recently, Broadbent and Grilo [BG20] showed that any QMA problem can be reduced to a 5-local Hamiltonian problem with local simulatability. (See also [GSY19].) Moreover, it is easy to see that we can make the Hamiltonian \( \mathcal{H}_x \) be of the form \( \mathcal{H}_x = \sum_{i=1}^{M} p_i \frac{I + s_i P_i}{2} \) where \( s_i \in \{+1, -1\} \), \( p_i \geq 0 \), \( \sum_{i=1}^{M} p_i = 1 \), and \( P_i \) is a tensor product of Pauli operators \( (I, X, Y, Z) \) with at most 5 nontrivial Pauli operators \( (X, Y, Z) \). See Appendix A for more details. Then we have the following lemma.

**Lemma 2.8 (QMA-completeness of 5-local Hamiltonian problem with local simulatability [BG20]).**

For any QMA language \( L \), there is a classical polynomial-time computable deterministic function that maps \( x \in \{0, 1\}^* \) to an \( N \)-qubit Hamiltonian \( \mathcal{H}_x \) of the form

\[
\mathcal{H}_x = \sum_{i=1}^{M} p_i \frac{I + s_i P_i}{2},
\]

where \( N = \text{poly}(|x|) \), \( M = \text{poly}(|x|) \), \( s_i \in \{+1, -1\} \), \( p_i > 0 \), \( \sum_{i=1}^{M} p_i = 1 \), and \( P_i \) is a tensor product of Pauli operators \( (I, X, Y, Z) \) with at most 5 nontrivial Pauli operators \( (X, Y, Z) \), and satisfies the following: There are \( 0 < \alpha < \beta < 1 \) such that \( \beta - \alpha = 1/\text{poly}(|x|) \) and

• if \( x \in L \), then there exists an \( N \)-qubit state \( \rho \) such that \( \text{Tr}(\rho \mathcal{H}_x) \leq \alpha \), and
• if \( x \notin L \), then for any \( N \)-qubit state \( \rho \), we have \( \text{Tr}(\rho \mathcal{H}_x) \geq \beta \).

Moreover, for any \( x \in L \), we can convert any witness \( \mathbf{w} \in R_L(x) \) into a state \( \rho_{\text{hist}} \), called the history state, such that \( \text{Tr}(\rho_{\text{hist}} \mathcal{H}_x) \leq \alpha \) in quantum polynomial time. Moreover, there exists a classical deterministic polynomial time algorithm \( \text{Sim}_{\text{hist}} \) such that for any \( x \in L \) and any subset \( S \subseteq [N] \) with \( |S| \leq 5 \), \( \text{Sim}_{\text{hist}}(x, S) \) outputs a classical description of an \( |S| \)-qubit density matrix \( \rho_S \) such that \( \| \rho_S - \text{Tr}_{[N]\setminus S} \rho_{\text{hist}} \|_\text{tr} = \text{negl}(\lambda) \) where \( \text{Tr}_{[N]\setminus S} \rho_{\text{hist}} \) is the state of \( \rho_{\text{hist}} \) in registers corresponding to \( S \) tracing out all other registers.

**Remark 1.** It might be possible to prove QMA-completeness of 2-local \( \{ZZ, XX\}\)-Hamiltonian problem with local simulatability by combining the techniques of [BG20, GSY19] and [CM16]. However, this is not clear, and indeed, this is mentioned as an open problem in [BG20]. Therefore we consider the 5-local Hamiltonian problem whenever we need local simulatability.

### 2.3 Classically-Verifiable Non-Interactive Proofs

**Definition 2.9 (Classically-verifiable non-interactive (zero-knowledge) proof).** A classically-verifiable non-interactive proof (CV-NIP) for a QMA language \( L \) in the quantum secret parameter (QSP) model consists of algorithms \( \Pi = (\text{Setup}, \text{Prove}, \text{Verify}) \) with the following syntax:

\begin{itemize}
  \item **Setup(1^\lambda)**: This is a QPT algorithm that takes the security parameter \( 1^\lambda \) as input and outputs a quantum proving key \( k_P \) and a classical verification key \( k_V \).
  \item **Prove(k_P, x, w^\otimes k)**: This is a QPT algorithm that takes the proving key \( k_P \), a statement \( x \), and \( k = \text{poly}(\lambda) \) copies \( w^\otimes k \) of a witness \( w \in R_L(x) \) as input and outputs a classical proof \( \pi \).
\end{itemize}
Verify\((k_V, x, \pi)\): This is a PPT algorithm that takes the verification key \(k_V\), a statement \(x\), and a proof \(\pi\) as input and outputs \(\top\) indicating acceptance or \(\bot\) indicating rejection.

We require \(\Pi\) to satisfy the following properties for some \(0 < s < c < 1\) such that \(c - s > 1/poly(\lambda)\). Especially, when we do not specify \(c\) and \(s\), they are set as \(c = 1 - \text{negl}(\lambda)\) and \(s = \text{negl}(\lambda)\).

**c-Completeness.** For all \(x \in L \cap \{0, 1\}^\lambda\), and \(w \in R_L(x)\), we have

\[
\Pr\left[\text{Verify}(k_V, x, \pi) = \top : (k_P, k_V) \xleftarrow{\$} \text{Setup}(1^\lambda), \pi \xleftarrow{\$} \text{Prove}(k_P, x, w^{\otimes k})\right] \geq c.
\]

**(Adaptive Statistical) s-Soundness.** For all unbounded-time adversary \(A\), we have

\[
\Pr\left[x \notin L \land \text{Verify}(k_V, x, \pi) = \top : (k_P, k_V) \xleftarrow{\$} \text{Setup}(1^\lambda), (x, \pi) \xleftarrow{\$} A(k_P)\right] \leq s.
\]

We say that \(\Pi\) is a classically-verifiable non-interactive zero-knowledge proof (CV-NIZK) if it additionally satisfies the following property.

**Adaptive Statistical Single-Theorem) Zero-Knowledge.** There exists a PPT simulator \(\text{Sim}\) such that for any unbounded-time distinguisher \(D\), we have

\[
\left|\Pr\left[D^{O_P(k_P, \cdots)}(k_V) = 1\right] - \Pr\left[D^{O_S(k_V, \cdots)}(k_V) = 1\right]\right| = \text{negl}(\lambda)
\]

where \((k_P, k_V) \xleftarrow{\$} \text{Setup}(1^\lambda)\), \(D\) can make at most one query, which should be of the form \((x, w^{\otimes k})\) where \(w \in R_L(x)\) and \(w^{\otimes k}\) is unentangled with \(D\)'s internal registers,\(^6\) \(O_P(k_P, x, w^{\otimes k})\) returns \(\text{Prove}(k_P, x, w^{\otimes k})\), and \(O_S(k_V, x, w^{\otimes k})\) returns \(\text{Sim}(k_V, x)\).

**Remark 2.** In a CV-NIP, \(\text{Setup}\) can be think of as an offline quantum preprocessing that is done by the verifier before the instance is determined. This is because there is no security requirement for a malicious verifier, and thus security is not harmed even if \(\text{Setup}\) is run by a verifier. On the other hand, in a CV-NIZK, \(\text{Setup}\) should be run by a trusted third party since a malicious verifier can break the zero-knowledge property if it can run \(\text{Setup}\).

It is easy to see that we can amplify the gap between completeness and soundness thresholds by a simple parallel repetition. Moreover, we can see that this does not lose the zero-knowledge property. Therefore, we have the following lemma.

**Lemma 2.10** (Gap Amplification for CV-NIP and CV-NIZK). If there exists a CV-NIP (resp. CV-NIZK) for \(L\) in the QSP model that satisfies \(c\)-completeness and \(s\)-soundness, for some \(0 < s < c < 1\) such that \(c - s > 1/poly(\lambda)\), then there exists a CV-NIP (resp. CV-NIZK) for \(L\) in the QSP model (with \((1 - \text{negl}(\lambda))\)-completeness and \(\text{negl}(\lambda)\)-soundness).

**Proof.** We prove the lemma for the case of CV-NIZK, from which the case of CV-NIP immediately follows. Let \(\Pi = (\text{Setup}, \text{Prove}, \text{Verify})\) be a CV-NIZK for \(L\) in the SP model that satisfies \(c\)-completeness, \(s\)-soundness, and the zero-knowledge property for some \(0 < s < c < 1\) such that \(c - s > 1/poly(\lambda)\). Let \(k\) be the number of copies of a witness \(\text{Prove}\) takes as input. For any polynomial \(N = \text{poly}(\lambda)\), \(\Pi^N = (\text{Setup}^N, \text{Prove}^N, \text{Verify}^N)\) be the \(N\)-parallel version of \(\Pi\). That is, \(\text{Setup}^N\) and \(\text{Prove}^N\) run \(\text{Setup}\) and \(\text{Prove}\) \(N\) times parallelly and outputs tuples consisting of outputs

\(^6\)Though our protocols are likely to remain secure even if they can be entangled, we assume that they are unentangled for simplicity. To the best of our knowledge, none of existing works on interactive or non-interactive zero-knowledge for QMA [BJSW20, CVZ20, BS20, BG20, Shm20, BCKM20] considered entanglement between a witness and distinguisher’s internal register.
Therefore, it

\[ O \]

by the assumption that \( O \) and works similarly to \( O \) completes the proof of Lemma \( \Pi^N \)

inequality, it is easy to see that we can take \( N = O \left( \frac{\log^2 \lambda}{\beta} \right) \) so that \( \Pi^N \) satisfies \( (1 - \text{negl}(\lambda)) \)-

of each execution, respectively where \( \text{Prove}^N \) takes \( Nk \) copies of the witness as input. \( \text{Verify}^N \) takes \( N \)-tuple of the verification key and proof, runs \( \text{Verify} \) to verify each of them separately, and outputs \( \top \) if the number of executions of \( \text{Verify} \) that outputs \( \top \) is larger than \( \frac{N(\alpha + \beta \cdot k)}{2} \). By Hoeffding’s inequality, it is easy to see that we can take \( N = O \left( \frac{\log^2 \lambda}{\beta} \right) \) so that \( \Pi^N \) satisfies \( (1 - \text{negl}(\lambda)) \)-

What is left is to prove that \( \Pi^N \) satisfies the zero-knowledge property. This can be reduced to the zero-knowledge property of \( \Pi \) by a standard hybrid argument. More precisely, for each \( i \in \{0, \ldots, N\} \), let \( O_i \) be the oracle that works as follows where \( k'_P \) and \( k'_V \) denote the proving and verification keys of \( \Pi^N \), respectively.

\[ O_i(k'_P = (k'_P, \ldots, k'_P^N), k'_V = (k'_V^1, \ldots, k'_V^N), x, w^\otimes Nk) : \text{It works as follows:} \]

- For \( 1 \leq j \leq i \), it computes \( \pi_j \xleftarrow{\$} \text{Sim}(k'_V^j, x) \).
- For \( i < j \leq N \), it computes \( \pi_j \xleftarrow{\$} \text{Prove}(k'_P^j, x, w^\otimes k) \) where it uses the \((k(j - 1) + 1)\)-th to \(kj\)-th copies of \( w \).
- Output \( \pi := (\pi_1, \ldots, \pi_N) \).

Clearly, we have \( O_0(k'_P, k'_V, \cdot, \cdot) = O_P(k'_P, \cdot, \cdot) \) and \( O_N(k'_P, k'_V, \cdot, \cdot) = O_S(k'_V, \cdot, \cdot) \). Therefore, it suffices to prove that no distinguisher can distinguish \( O_i(k'_P, k'_V, \cdot, \cdot) \) and \( O_{i+1}(k'_P, k'_V, \cdot, \cdot) \) for any \( i \in \{0, 1, \ldots, N - 1\} \). For the sake of contradiction, suppose that there exists a distinguisher \( \mathcal{D}' \) that distinguishes \( O_i(k'_P, k'_V, \cdot, \cdot) \) and \( O_{i+1}(k'_P, k'_V, \cdot, \cdot) \) with a non-negligible advantage by making one query of the form \((x, w^\otimes Nk)\). Then we construct a distinguisher \( \mathcal{D} \) that breaks the zero-knowledge property of \( \Pi \) as follows:

\[ \mathcal{D}^O(k'_V) : \mathcal{D} \text{ takes } k'_V \text{ as input and is given a single oracle access to } O, \text{ which is either } O_P(k'_P, \cdot, \cdot) \text{ or } O_S(k'_V, \cdot, \cdot) \text{ where } k'_P \text{ is the proving key corresponding to } k'_V. \]

(Remark that \( \mathcal{D} \) is not given \( k'_P \).) It sets \( k'_{V}^{i+1} := k'_V \) (which implicitly defines \( k'_{V}^{i} := k'_P \)) and generates \((k'_P, k'_V) \xleftarrow{\$} \text{Setup}(1^k)\) for all \( j \in [N] \setminus \{i + 1\} \). It sets \( k'_V := (k'_V^1, \ldots, k'_V^N) \) and runs \( \mathcal{D}'(k'_V^i) \) where when \( \mathcal{D}' \) makes a query \((x, w^\otimes Nk)\) to \( O' \), \( \mathcal{D} \) simulates the oracle \( O' \) for \( \mathcal{D}' \) as follows:

- For \( 1 \leq j \leq i \), \( \mathcal{D} \) computes \( \pi_j \xleftarrow{\$} \text{Sim}(k'_V^j, x) \).
- For \( j = i + 1 \), \( \mathcal{D} \) queries \((x, w^\otimes k)\) to the external oracle \( O \) where it uses the \((ki + 1)\)-th to \(k(i + 1)\)-th copies of \( w \) as part of its query, and lets \( \pi_{i+1} \) be the oracle’s response.
- For \( i + 1 < j \leq N \), it computes \( \pi_j \xleftarrow{\$} \text{Prove}(k'_P^j, x, w^\otimes k) \) where it uses the \((k(j - 1) + 1)\)-th to \(kj\)-th copies of \( w \). We note that this can be simulated by \( \mathcal{D} \) since it knows \( k'_P^j \) for \( j \neq i + 1 \).
- \( \mathcal{D} \) returns \( \pi' := (\pi_1, \ldots, \pi_N) \) to \( \mathcal{D}' \) as a response from the oracle \( O' \).

Finally, when \( \mathcal{D}' \) outputs \( b \), \( \mathcal{D} \) also outputs \( b \).

We can see that the oracle \( O' \) simulated by \( \mathcal{D} \) works similarly to \( O_i(k'_P, k'_V, \cdot, \cdot) \) when \( O \) is \( O_P(k'_P, \cdot, \cdot) \) and works similarly to \( O_{i+1}(k'_P, k'_V, \cdot, \cdot) \) when \( O \) is \( O_S(k'_V, \cdot, \cdot) \). Therefore, by the assumption that \( \mathcal{D}' \) distinguishes \( O_i(k'_P, k'_V, \cdot, \cdot) \) and \( O_{i+1}(k'_P, k'_V, \cdot, \cdot) \) with a non-negligible advantage, \( \mathcal{D} \) distinguishes \( O_P(k'_P, \cdot, \cdot) \) and \( O_S(k'_V, \cdot, \cdot) \) with a non-negligible advantage. However, this contradicts the zero-knowledge property of \( \Pi \). Therefore, such \( \mathcal{D}' \) does not exist, which completes the proof of Lemma 2.10. \[ \square \]

---

\footnote{\( O_P(k'_P, \cdot, \cdot) \) and \( O_S(k'_V, \cdot, \cdot) \) mean the corresponding oracles for \( \Pi^N \).}

\footnote{\( O_P(k'_P, \cdot, \cdot) \) and \( O_S(k'_V, \cdot, \cdot) \) mean the corresponding oracles for \( \Pi \) by abuse of notation.}
Setup($1^\lambda$): The setup algorithm chooses $(h, m_1, ..., m_N) \xleftarrow{\$} \{0, 1\}^{N+1}$, and outputs a proving key $k_P := \bigotimes_{j=1}^{N} (H^h |m_j\rangle)$ and a verification key $k_V := (h, m_1, ..., m_N)$.

Prove($k_P, x, w$): The proving algorithm generates the history state $\rho_{\text{hist}}$ for $\mathcal{H}_x$ from $w$ and measures $j$-th qubits of $\rho_{\text{hist}}$ and $k_P$ in the Bell basis for $j \in [N]$. Let $x := x_1 || x_2 || ... || x_N$, and $z := z_1 || z_2 || ... || z_N$ where $(x_j, z_j) \in \{0, 1\}^2$ denotes the outcome of $j$-th measurement. It outputs a proof $\pi := (x, z)$.

Verify($k_V, x, \pi$): The verification algorithm parses $(h, m_1, ..., m_N) \leftarrow k_V$ and $(x, z) \leftarrow \pi$, chooses $(j_1, j_2) \in [N]^2$ according to the probability distribution defined by $\{p_{j_1, j_2}\}_{j_1 < j_2}$ (i.e., chooses $(j_1, j_2)$ with probability $p_{j_1, j_2}$), defines $m_{j_b}' := m_{j_b} \oplus (h z_{j_b} \oplus (1 - h) x_{j_b})$ for $b \in \{1, 2\}$, and outputs $\top$ if $(-1)^{m_{j_1}' \oplus m_{j_2}'} = -s_{j_1, j_2}$ and $\bot$ otherwise.

Figure 1: Our CV-NIP $\Pi_{\text{NIP}}$

Setup$_{\text{vir}}(1^\lambda)$: The setup algorithm generates $N$ Bell-pairs between registers $P$ and $V$ and lets $k_P$ and $k_V$ be quantum states in registers $P$ and $V$, respectively. Then it outputs $(k_P, k_V)$.

Prove$_{\text{vir}}(k_P, x, w)$: This is the same as Prove($k_P, x, w$) in Figure 1.

Verify$_{\text{vir}}(k_V, x, \pi)$: The verification algorithm chooses $h \xleftarrow{\$} \{0, 1\}$, and measures each qubit of $k_V$ in basis $\{H^h |0\rangle, H^h |1\rangle\}$, and lets $(m_1, ..., m_N) \in \{0, 1\}^N$ be the measurement outcomes. The rest of this algorithm is the same as Verify($k_V, x, \pi$) given in Figure 1.

Figure 2: The virtual protocol 1 for $\Pi_{\text{NIP}}$

3 CV-NIP in the QSP model

In this section, we give a construction of an information-theoretically sound CV-NIP for a QMA language $L$ in the QSP model. Specifically, we prove the following theorem.

**Theorem 3.1.** There exists a CV-NIP for all QMA languages in the QSP model (without any computational assumption).

We note that this theorem is subsumed by Theorem 4.1 proven in Section 4. Nonetheless, we give a proof of the theorem because the CV-NIP given here is simpler than the CV-NIZK given in Section 4 and thus we believe that this would enable readers to understand our main idea more easily.

Our construction of a CV-NIP for a QMA language $L$ is given in Figure 1 where $\mathcal{H}_x$, $N$, $p_{j_1, j_2}$, $s_{j_1, j_2}$, $\alpha$, $\beta$, and $\rho_{\text{hist}}$ are as in Lemma 2.7 for the language $L$. We remark that the proving algorithm uses only one witness, and thus we have $k = 1$ in Definition 2.9 for this protocol. Multiple copies of the witness are needed only when we do the gap amplification (Lemma 2.10). A similar remark applies to all protocol proposed in this paper.

We prove the following lemma

---

... (continued)
Setup\textsubscript{vir-2}(1^\lambda): This is the same as Setup\textsubscript{vir-1}(1^\lambda) in Figure 2.

Prove\textsubscript{vir-2}(k_P, x, w): This is the same as Prove(k_P, x, w) in Figure 1.

Verify\textsubscript{vir-2}(k_V, x, π): The verification algorithm parses (x, z) ← π, computes \( k'_V := X^xZ^z k_V Z^z X^x \), chooses \( h \sim \{0, 1\} \), measures each qubit of \( k'_V \) in basis \( \{H^h|0\rangle, H^h|1\rangle\} \), and lets \( (m'_1, \ldots, m'_N) \) be the measurement outcomes. It chooses \( (j_1, j_2) \in [N]^2 \) according to the probability distribution defined by \( \{p_{j_1,j_2}\}_{j_1 < j_2} \) (i.e., chooses \( (j_1, j_2) \) with probability \( p_{j_1,j_2} \)) and outputs \( \top \) if \( (-1)^{m'_{j_1} \oplus m'_{j_2}} = -s_{j_1,j_2} \) and \( \bot \) otherwise.

Figure 3: The virtual protocol 2 for \( Π_{NIP} \)

Lemma 3.2 (Completeness and Soundness). \( Π_{NIP} \) satisfies \((1 - α)\)-completeness and \((1 - β)\)-soundness.

Since \((1 - α) - (1 - β) = β - α \geq 1/\text{poly}(\lambda)\), by combining Lemma 2.10 and Lemma 3.2, Theorem 3.1 follows.

In the following, we give a proof of Lemma 3.2.

Proof of Lemma 3.2. We prove this lemma by considering virtual protocols that do not change completeness and soundness. An alternative direct proof can be found in Appendix B.1. First, we consider the virtual protocol 1 described in Figure 2. The difference from the original protocol is that the setup algorithm generates \( N \) Bell pairs and gives each halves to the prover and verifier, and the verifier obtains \( (m_1, \ldots, m_n) \) by measuring his halves in either standard or Hadamard basis.

Because verifier’s measurement and the prover’s measurement commute with each other, in the virtual protocol 1, verifier’s acceptance probability does not change even if the verifier chooses \( h \) and measures \( k_V \) (i.e., the \( V \) register of the \( N \) Bell-pairs) in the corresponding basis to obtain outcomes \( (m_1, \ldots, m_N) \) before \( k_P \) (i.e., the \( P \) register of the \( N \) Bell-pairs) is given to the prover. Moreover, conditioned on the above measurement outcomes, the state in \( P \) collapses to \( \otimes_{j=1}^N (H^h |m_j\rangle) \). (See Lemma 2.1.) Therefore, the virtual protocol 1 is exactly the same as the original protocol from the prover’s view, and verifier’s acceptance probability of the virtual protocol 1 is the same as that of the original protocol \( Π_{NIP} \) for any possibly malicious prover.

Next, we further modify the protocol to define the virtual protocol 2 described in Figure 3. The difference from the virtual protocol 1 is that instead of setting \( m'_j := m_j \oplus (hz_j + (1 - h)x_j) \), the verification algorithm applies a corresponding Pauli operator to \( (x, z) \) on \( k_V \), and then measures it to obtain \( m'_j \). Since \( X \) and \( Z \) before the measurement has the effect of flipping the measurement outcome for \( Z \) and \( X \) basis measurements, respectively, this does not change the distribution of \( (m'_1, \ldots, m'_N) \). (See Lemma 2.2.) Therefore, verifier’s acceptance probability of the virtual protocol 2 is the same as that of the virtual protocol 1 for any possibly malicious prover.

Therefore, it suffices to prove \((1 - α)\)-completeness and \((1 - β)\)-soundness for the virtual protocol 2. When \( x \in L \) and \( π \) is honestly generated, then \( k'_V \) is the history state \( ρ_{\text{hist}} \), which satisfies \( \text{Tr}(ρ_{\text{hist}} H_x) \leq α \), by the correctness of quantum teleportation (Lemma 2.4). Therefore, by Lemma 2.5 and Lemma 2.7, verifier’s acceptance probability is \( 1 - \text{Tr}(ρ_{\text{hist}} H_x) \geq 1 - α \).

Let \( A \) be an adaptive adversary against soundness of virtual protocol 2. That is, \( A \) is given \( k_P \) and outputs \( (x, π) \). We say that \( A \) wins if \( x \notin L \) and Verify\textsubscript{vir}(k_V, x, π) = \( \top \). For any \( x \), let \( E_x \) be the event that the statement output by \( A \) is \( x \), and \( k'_{V,x} \) be the state in \( V \) right before the measurement
by Verify conditioned on $E_x$. Similarly to the analysis for the completeness, by Lemma 2.5 and Lemma 2.7, we have

$$\Pr[A \text{ wins}] = \sum_{x \not\in L} \Pr[E_x] \left(1 - \text{Tr}(k'_V, x^H_x)\right) \leq \sum_{x \not\in L} \Pr[E_x] (1 - \beta) \leq 1 - \beta.$$ 

\[ \square \]

**Impossibility of classical setup.** In our protocol, the setup algorithm sends a quantum proving key to the prover. Can it be classical? It is easy to see that such a protocol can exist only for languages in $\text{AM}$. In fact, assume that we have a CV-NIP for $L$ in the SP model where the proving key is classical. Then, we can construct a 2-round interactive proof for $L$ where the verifier runs the setup by itself and sends the proving key to the prover, and then the prover replies as in the original protocol. (Recall that soundness is not harmed even if the verifier runs the setup as noted in Remark 2.) Since $\text{IP}(2) = \text{AM}$, the above implies $L \in \text{AM}$. Since it is believed that $\text{BQP}$ is not contained in $\text{AM}$ [RT19], it is highly unlikely that there is a CV-NIZK even for $\text{BQP}$ in the SP model with classical setup.

### 4 CV-NIZK in the QSP model

In this section, we extend the CV-NIP in Section 3 to construct a CV-NIZK. Specifically, we prove the following theorem.

**Theorem 4.1.** There exists a CV-NIZK for all $\text{QMA}$ languages in the QSP model (without any computational assumption).

Our construction of a CV-NIZK for a $\text{QMA}$ language $L$ is given in Figure 4 where $H_x$, $N$, $M$, $p_i$, $s_i$, $P_i$, $\alpha$, $\beta$, and $\rho_{\text{hist}}$ are as in Lemma 2.7 for the language $L$ and $V_j(W_j)$ is as defined in Section 2.1.

We note that there is a slightly simpler construction of CV-NIZK as shown in Figure 8 in Appendix C. However, we consider the construction given in Figure 4 as our main construction since this is more convenient to extend to the computationally secure construction given in Section 5.

We prove the following lemmas.

**Lemma 4.2 (Completeness and Soundness).** $\Pi_{\text{NIZK}}$ satisfies $(1 - \frac{\alpha}{N'})$-completeness and $(1 - \frac{\beta}{N'})$-soundness where $N' := 3^5 \sum_{i=1}^5 \binom{N}{i}$.

**Lemma 4.3 (Zero-Knowledge).** $\Pi_{\text{NIZK}}$ satisfies the zero-knowledge property.

Since $$(1 - \frac{\alpha}{N'}) - (1 - \frac{\beta}{N'}) = \frac{\beta - \alpha}{N'} \geq 1/\text{poly}(\lambda),$$ by combining Lemmas 2.10, 4.2 and 4.3, Theorem 4.1 follows.

In the following, we give proofs of Lemmas 4.2 and 4.3.

**Proof of Lemma 4.2.** The proof of this lemma is similar to that of Lemma 3.2. We prove this lemma by considering virtual protocols that do not change completeness and soundness. For more details, see Appendix B.2. First, we consider the virtual protocol 1 described in Figure 5. There are two differences from the original protocol. The first is that $k_V$ includes the whole $(\hat{x}, \hat{z})$ instead of $\{\hat{x}_j, \hat{z}_j\}_{j \in S_V}$. This difference does not change the (possibly malicious) prover’s view since $k_V$...
Verify: We note that we have $1 \leq |\lambda| \leq 5$ by the 5-locality of $\mathcal{H}_x$. We say that $P_i$ is consistent to $(S_V, \{W_j\}_{j \in S_V})$ if and only if $S_i = S_V$ and the $i$th Pauli operator of $P_i$ is $W_j$ for all $j \in S_i$. If $P_i$ is not consistent to $(S_V, \{W_j\}_{j \in S_V})$, it outputs $\top$. If $P_i$ is consistent to $(S_V, \{W_j\}_{j \in S_V})$, it flips a biased coin that heads with probability $1 - 3|S_i|^5$. If heads, it outputs $\top$. If tails, it defines

$$m_j' := \begin{cases} 
  m_j \oplus x_j \oplus \hat{x}_j & (W_j = Z), \\
  m_j \oplus z_j \oplus \hat{z}_j & (W_j = X), \\
  m_j \oplus x_j \oplus \hat{x}_j \oplus z_j \oplus \hat{z}_j & (W_j = Y)
\end{cases}$$

for $j \in S_i$, and outputs $\top$ if $(-1)^{m_j'} = -s_i$ and $\bot$ otherwise.

Figure 4: Our CV-NIZK NIZK

\[\]
Setups\textsubscript{vir-1}(1\textsuperscript{λ}): The setup algorithm generates \( N \) Bell-pairs between registers \( P \) and \( V \) and lets \( \rho_P \) and \( \rho_V \) be quantum states in registers \( P \) and \( V \), respectively. It chooses \((\tilde{x}, \tilde{z}) \leftarrow \{0,1\}^N \times \{0,1\}^N\). It chooses a uniformly random subset \( S_V \subseteq [N] \) such that \( 1 \leq |S_V| \leq 5 \), and outputs a proving key \( k_P := (\rho_P, \tilde{x}, \tilde{z}) \) and a verification key \( k_V := (\rho_V, S_V, \tilde{x}, \tilde{z}) \).

Prove\textsubscript{vir-1}(\(k_P, x, w\)): This is the same as \textnormal{Prove}(\(k_P, x, w\)) in Figure 4.

Verify\textsubscript{vir-1}(\(k_V, x, \pi\)): The verification algorithm chooses \((W_1, ..., W_N) \leftarrow \{X, Y, Z\}^N\), and measures \( j \)-th qubit of \( \rho_V \) in the \( W_j \) basis for all \( j \in [N] \), and lets \((m_1, ..., m_N)\) be the measurement outcomes. The rest of this algorithm is the same as \textnormal{Verify}(\(k_V, x, \pi\)) given in Figure 4.

\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{figure5.png}
\caption{The virtual protocol 1 for \(\Pi_{\text{NIZK}}\)}
\end{figure}

Setups\textsubscript{vir-2}(1\textsuperscript{λ}): This is the same as Setups\textsubscript{vir-1}(1\textsuperscript{λ}) in Figure 5.

Prove\textsubscript{vir-2}(\(k_P, x, w\)): This is the same as \textnormal{Prove}(\(k_P, x, w\)) in Figure 4.

Verify\textsubscript{vir-2}(\(k_V, x, \pi\)): The verification algorithm parses \((\rho_V, S_V, \tilde{x}, \tilde{z}) \leftarrow k_V \) and \((x, z) \leftarrow \pi\), computes \( \rho'_V := X^{s_1} Z^{s_2} Z^{s_3} X^{s_4} Z^{s_5} \), chooses \((W_1, ..., W_N) \leftarrow \{X, Y, Z\}^N\), measures \( j \)-th qubit of \( \rho'_V \) in the \( W_j \) basis for all \( j \in [N] \), and lets \((m'_1, ..., m'_N)\) be the measurement outcomes.

It chooses \( i \in [M] \) and defines \( S_i \subseteq [N] \) similarly to Verify\textsubscript{vir-1}(\(k_V, x, \pi\)) in Figure 4. If \( P_i \) is not consistent to \((S_V, \{W_j\}_{j \in S_V})\), it outputs \( \top \). If \( P_i \) is consistent to \((S_V, \{W_j\}_{j \in S_V})\), it flips a biased coin that heads with probability \( 1 - 3^{|S_i| - 5} \). If heads, it outputs \( \top \). If tails, it outputs \( \top \) if \((-1)^{\bigoplus_{j \in S_i} m'_j} = -s_i \) and \( \bot \) otherwise.

\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{figure6.png}
\caption{The virtual protocol 2 for \(\Pi_{\text{NIZK}}\)}
\end{figure}

is not given to the prover. The second is that the setup algorithm generates \( N \) Bell-pairs and gives each halves to the prover and verifier, and the verifier obtains \((m_1, ..., m_N)\) by measuring his halves in \( P \)-basis with \( P \in \{X, Y, Z\} \). Because verifier’s measurement and prover’s measurement commute with each other, in the virtual protocol 1, verifier’s acceptance probability does not change even if the verifier chooses \((W_1, ..., W_N)\) and measures \( \rho_V \) in the corresponding basis to obtain outcomes \((m_1, ..., m_N)\) before \( \rho_P \) is given to the prover. Moreover, conditioned on the above measurement outcomes, the state in \( P \) collapses to \( \bigotimes_{i=1}^N (U(W_j)|m_j)\) (See Lemma 2.1). Therefore, the virtual protocol 1 is exactly the same as the original protocol from the prover’s view, and verifier’s acceptance probability of the virtual protocol 1 is the same as that of the original protocol \(\Pi_{\text{NIZK}}\) for any possibly malicious prover.

Next, we further modify the protocol to define the virtual protocol 2 described in Figure 6. The difference from the virtual protocol 1 is that instead of setting \( m'_j \), the verification algorithm applies a corresponding Pauli \( X^{s_1} Z^{s_2} Z^{s_3} X^{s_4} Z^{s_5} \) on \( \rho_V \), and then measures it to obtain \( m'_j \). By Lemma 2.2, this does not change the distribution of \((m'_1, ..., m'_N)\). Therefore, verifier’s acceptance probability of the virtual protocol 2 is the same as that of the virtual protocol 1 for any possibly malicious prover.
Therefore, it suffices to prove \((1 - \frac{\alpha}{N})\)-completeness and \((1 - \frac{\beta}{N})\)-soundness for the virtual protocol \(2\). When \(x \in L\) and \(\pi\) is honestly generated, then \(\rho'_{v}\) is the history state \(\rho_{hist}\), which satisfies \(\text{Tr}(\rho_{hist} \mathcal{H}_{x}) \leq \alpha\), by the correctness of quantum teleportation (Lemma 2.4). For any fixed \(P_{i}\), the probability that \(P_{i}\) is consistent to \((S_{V}, \{W_{j}\}_{j \in S_{V}})\) and the coin tails is \(\frac{1}{N}\). Therefore, by Lemma 2.5 and Lemma 2.8, verifier’s acceptance probability is \(1 - \frac{\beta}{N'}\).

Let \(A\) be an adaptive adversary against soundness of virtual protocol \(2\). That is, \(A\) is given \(k_{p}\) and outputs \((x, \pi)\). We say that \(A\) wins if \(x \notin L\) and \(\text{Verify}(k_{V}, x, \pi) = \top\). For any \(x\), let \(E_{x}\) be the event that the statement output by \(A\) is \(x\), and \(\rho'_{V,x}\) be the state in \(V\) right before the measurement by \(\text{Verify}\) conditioned on \(E_{x}\). Similarly to the analysis for the completeness, by Lemma 2.5 and Lemma 2.8, we have

\[
\Pr[A \text{ wins}] = \sum_{x \notin L} \Pr[E_{x}] \left(1 - \frac{1}{N'} \text{Tr}(\rho'_{V,x} \mathcal{H}_{x})\right) \leq \sum_{x \notin L} \Pr[E_{x}] \left(1 - \frac{\beta}{N'}\right) \leq 1 - \frac{\beta}{N'}.
\]

\(\square\)

**Proof of Lemma 4.3.** We describe the simulator \(\text{Sim}\) below.

\(\text{Sim}(k_{V}, x)\): The simulator parses \((W_{1}, ..., W_{N}, m_{1}, ..., m_{N}, S_{V}, \{\hat{x}_{j}, \hat{z}_{j}\}_{j \in S_{V}}) \leftarrow k_{V}\) and does the following.

1. Generate the classical description of the density matrix \(\rho_{S_{V}} := \text{Sim}_{hist}(x, S_{V})\) where \(\text{Sim}_{hist}\) is as in Lemma 2.8.
2. Sample \(\{x_{j}, z_{j}\}_{j \in S_{V}}\) according to the probability distribution of outcomes of the Bell-basis measurements of the corresponding pairs of qubits of \((\prod_{j \in S_{V}} X_{j}^{\hat{x}_{j}} Z_{j}^{\hat{z}_{j}}) \rho_{S_{V}} (\prod_{j \in S_{V}} Z_{j}^{\hat{z}_{j}} X_{j}^{\hat{x}_{j}})\) and \(\otimes_{j \in S_{V}} (U(W_{j}) | m_{j}\rangle\)). We emphasize that this measurement can be simulated in a classical probabilistic polynomial time since \(|S_{V}| \leq 5\).
3. Choose \((x_{j}, z_{j}) \overset{\$}{\leftarrow} \{0, 1\}^{2}\) for all \(j \in [N] \setminus S_{V}\).
4. Output \(\pi := (x, z)\) where \(x := x_{1}||x_{2}||...||x_{N}\) and \(z := z_{1}||z_{2}||...||z_{N}\).

We prove that the output of this simulator is indistinguishable from the real proof. For proving this, we consider the following sequences of modified simulators. We note that these simulators may perform quantum computations unlike the real simulator.

\(\text{Sim}_{1}(k_{V}, x)\): The simulator parses \((W_{1}, ..., W_{N}, m_{1}, ..., m_{N}, S_{V}, \{\hat{x}_{j}, \hat{z}_{j}\}_{j \in S_{V}}) \leftarrow k_{V}\) and does the following.

1. Generate the classical description of the density matrix \(\rho_{S_{V}} := \text{Sim}_{hist}(x, S_{V})\) where \(\text{Sim}_{hist}\) is as in Lemma 2.8. (This step is the same as the step 1 of \(\text{Sim}(k_{V}, x)\).)
2. Generate \(\tilde{\rho}_{hist} := (\prod_{j \in S_{V}} X_{j}^{\hat{x}_{j}} Z_{j}^{\hat{z}_{j}}) \rho_{S_{V}} (\prod_{j \in S_{V}} Z_{j}^{\hat{z}_{j}} X_{j}^{\hat{x}_{j}}) \otimes \otimes_{j \in S_{V}} (U(W_{j}) | m_{j}\rangle\))) in the Bell basis for \(j \in [N]\), and let \((x_{j}, z_{j})\) be the \(j\)-th measurement result.
3. Output \(\pi := (x, z)\) where \(x := x_{1}||x_{2}||...||x_{N}\) and \(z := z_{1}||z_{2}||...||z_{N}\).

Clearly, the distributions of \(\{x_{j}, z_{j}\}_{j \in S_{V}}\) output by \(\text{Sim}(k_{V}, x)\) and \(\text{Sim}_{1}(k_{V}, x)\) are the same. Moreover, the distributions of \(\{x_{j}, z_{j}\}_{j \in [N] \setminus S_{V}}\) output by \(\text{Sim}(k_{V}, x)\) and \(\text{Sim}_{1}(k_{V}, x)\) are both uniformly and independently random. Therefore, output distributions of \(\text{Sim}(k_{V}, x)\) and \(\text{Sim}_{1}(k_{V}, x)\) are exactly the same.

Next, we consider the following modified simulator that takes a witness \(w \in R_{L}(x)\) as input.
Sim2(kV, x, w): The simulator parses (W1, ..., WN, m1, ..., mN, SV, {x̂j, ẑj}j∈SV) ← kV and does the following.

1. Generate the history state ρ_hist for Hx from w.
2. Generate (x̂j, ẑj) ∈ {0, 1}2 for j ∈ [N] \ SV and let ̂x := ̂x1||...|| ̂xN and ̂z := ̂z1||...|| ̂zN.
3. Compute ρ′_hist := X̂xẐz ρ_hist Ẑ̂x X̂̂z.
4. Measure j-th qubits of ρ′_hist and ρ_P := ⊗N j=1(U(W_j)|m_j)) in the Bell basis for j ∈ [N], and let (x_j, z_j) be the j-th measurement result.
5. Output π := (x, z) where x := x1||x2||...||xN and z := z1||z2||...||zN.

By Lemma 2.3, we have ρ′_hist = (Πj∈SV X̂x_j Ẑz_j) Tr_{N \ SV}[ρ_hist] (Πj∈SV Ẑ̂x_j X̂̂z_j) ⊗ I_{[N] \ SV} from the view of a distinguisher that has no information on {̂x_j, ̂z_j}j∈[N].SV. By Lemma 2.8, we have ||ρSV − Tr_{N \ SV}ρ_hist||tr = negl(λ). Therefore, we have ||ρ′_hist − ρ′_hist||tr = negl(λ). This means that Sim1(kV, x) and Sim2(kV, x, w) are statistically indistinguishable from the view of a distinguisher that makes at most one query.

Finally, noting that the output distribution of Sim2(kV, x, w) is exactly the same as that of Prove(kP, x, w), the proof of Lemma 4.3 is completed.

\square

5 Dual-Mode CV-NIZK with Preprocessing

In this section, we extend the CV-NIZK given in Section 4 to reduce the amount of trust on the setup at the cost of introducing a quantum preprocessing and relying on a computational assumption. In the construction in Section 4, we assume that the trusted setup algorithm honestly generates proving and verification keys, which are correlated with each other, and sends them to the prover and verifier, respectively, without revealing them to the other party. Here, we give a construction of CV-NIZK with preprocessing that consists of generation of common reference string by a trusted party and a single instance-independent quantum message from the verifier to the prover. We call such a model the CRS + (V → P) model. We note this is the same model as is considered in [CVZ20]. Moreover, our construction has a nice feature called the dual-mode property, which has been considered for NIZKs for NP [GS12, GOS12, PS19, HU19, LPWW20]. The dual-mode property requires that there are two computationally indistinguishable modes of generating a common reference string, one of which ensures statistical soundness (and computational zero-knowledge) while the other ensures statistical zero-knowledge (and computational soundness). To the best of our knowledge, ours is the first construction of a dual-mode NIZK for QMA in any kind of model.

5.1 Definition

We give a formal definition of a dual-mode CV-NIZK in the CRS + (V → P) model.

**Definition 5.1** (Dual-Mode CV-NIZK in the CRS + (V → P) Model). A dual-mode CV-NIZK for a QMA language L in the CRS + (V → P) model consists of algorithms \Pi = (CRSGen, Preprocess, Prove, Verify) with the following syntax:
CRSGen($1^\lambda, \text{mode}$): This is a PPT algorithm that takes the security parameter $1^\lambda$ and a mode mode $\in \{\text{binding, hiding}\}$ as input and outputs a classical common reference string $\text{crs}$. We note that $\text{crs}$ can be reused and thus this algorithm is only needed to run once by a trusted third party.

Preprocess($\text{crs}$): This is a QPT algorithm that takes the common reference string $\text{crs}$ as input and outputs a quantum proving key $k_P$ and a classical verification key $k_V$. We note that this algorithm is supposed to be run by the verifier as preprocessing, and $k_P$ is supposed to be sent to the prover while $k_V$ is supposed to be kept on verifier’s side in secret. We also note that they can be used only once and cannot be reused unlike $\text{crs}$.

Prove($\text{crs}, k_P, x, w^\otimes k$): This is a QPT algorithm that takes the common reference string $\text{crs}$, the proving key $k_P$, a statement $x$, and $k = \text{poly}(\lambda)$ copies $w^\otimes k$ of a witness $w \in R_L(x)$ as input and outputs a classical proof $\pi$.

Verify($\text{crs}, k_V, x, \pi$): This is a PPT algorithm that takes the common reference string $\text{crs}$, the verification key $k_V$, a statement $x$, and a proof $\pi$ as input and outputs $\top$ indicating acceptance or $\bot$ indicating rejection.

We require $\Pi$ to satisfy the following properties for some $0 < s < c < 1$ such that $c - s > 1/\text{poly}(\lambda)$. Especially, when we do not specify $c$ and $s$, they are set as $c = 1 - \text{negl}(\lambda)$ and $s = \text{negl}(\lambda)$.

$c$-Completeness. For all mode $\in \{\text{binding, hiding}\}$, $x \in L \cap \{0,1\}^\lambda$, and $w \in R_L(x)$, we have

$$\Pr \left[ \text{Verify}(\text{crs}, k_V, x, \pi) = \top : \ (k_P, k_V) \xleftarrow{\$} \text{Preprocess}(\text{crs}) \quad \pi \xleftarrow{\$} \text{Prove}(\text{crs}, k_P, x, w^\otimes k) \right] \geq c.$$

(Adaptive) Statistical $s$-Soundness in the Binding Mode. For all unbounded-time adversary $A$, we have

$$\Pr \left[ x \notin L \land \text{Verify}(\text{crs}, k_V, x, \pi) = \top : \ (k_P, k_V) \xleftarrow{\$} \text{Preprocess}(\text{crs}) \quad (x, \pi) \xleftarrow{\$} A(\text{crs}, k_P) \right] \leq s.$$

(Adaptive Multi-Theorem) Statistical Zero-Knowledge in the Hiding Mode. There exists a PPT simulator $\text{Sim}_0$ and a QPT simulator $\text{Sim}_1$ such that for any unbounded-time distinguisher $D$, we have

$$\left| \Pr \left[ D^{O_P(\text{crs}, \cdots)}(\text{crs}) = 1 : \text{crs} \xleftarrow{\$} \text{CRSGen}(1^\lambda, \text{binding}) \right] \right| - \Pr \left[ D^{O_S(\text{td}, \cdots)}(\text{crs}) = 1 : \text{crs} \xleftarrow{\$} \text{Sim}_0(1^\lambda) \right] \leq \text{negl}(\lambda)$$

where $D$ can make $\text{poly}(\lambda)$ queries, which should be of the form $(k_P, x, w^\otimes k)$ where $w \in R_L(x)$ and $w^\otimes k$ is unentangled with $D$’s internal registers, $10$ $O_P(\text{crs}, k_P, x, w^\otimes k)$ returns $\text{Prove}(\text{crs}, k_P, x, w^\otimes k)$, and $O_S(\text{td}, k_P, x, w^\otimes k)$ returns $\text{Sim}_1(\text{td}, k_P, x)$.

Computational Mode Indistinguishability. For any non-uniform QPT distinguisher $D$, we have

$$\left| \Pr \left[ D(\text{crs}) = 1 : \text{crs} \xleftarrow{\$} \text{CRSGen}(1^\lambda, \text{binding}) \right] - \Pr \left[ D(\text{crs}) = 1 : \text{crs} \xleftarrow{\$} \text{CRSGen}(1^\lambda, \text{hiding}) \right] \right| \leq \text{negl}(\lambda).$$

$10$We remark that $k_P$ is allowed to be entangled with $D$’s internal registers unlike $w^\otimes k$. See also footnote 6.
Remark 3 (On definition of zero-knowledge property). By considering a combination of CRSGen (for a fixed mode) and Preprocess as a setup algorithm, (dual-mode) CV-NIZK in the CRS + (V → P) model can be seen as a CV-NIZK in the QSP model in a syntactical sense. However, it seems difficult to prove that this satisfies (even a computational variant of) the zero-knowledge property defined in Definition 2.9 due to the following reasons:

1. In Definition 5.1, Sim1 is quantum, whereas a simulator is required to be classical in Definition 2.9. We observe that this seems unavoidable in the above model: If k_P is quantum, then a classical simulator cannot even take k_P as input. On the other hand, if k_P is classical, then that implies L ∈ AM similarly to the final paragraph of Section 3.

2. A simulator in Definition 5.1 can embed a trapdoor td behind the common reference string crs whereas a simulator in Definition 2.9 just takes an honestly generated verification key k_V as input. We remark that this also seems unavoidable since k_V may be maliciously generated when the verifier is malicious, in which case just taking k_V as input would be useless for the simulation.

On the other hand, the definition in Definition 5.1 allows a distinguisher (that plays the role of a malicious verifier) to maliciously generate k_P, which is a stronger capability than that of a distinguisher in Definition 2.9. Therefore, the zero-knowledge properties in Definition 5.1 and Definition 2.9 are incomparable. We believe that the definition of the zero-knowledge property in Definition 5.1 ensures meaningful security. It roughly means that any malicious verifier cannot learn anything beyond what could be computed in quantum polynomial time by itself even if it is allowed to interact with many sessions of honest provers under maliciously generated proving keys and the reused honestly generated common reference string. While this does not seem very meaningful when L ∈ BQP, we can ensure a meaningful privacy of the witness when L ∈ QMA. Finally we remark that our definition is essentially the same as that in [CVZ20] (except for the dual-mode property).

Remark 4 (Comparison to NIZK in the malicious designated verifier model). A CV-NIZK for QMA in the CRS + (V → P) model as defined above is syntactically very similar to the NIZK for QMA in the malicious designated verifier model as introduced in [Shm20]. However, a crucial difference is that the proving key k_P is a quantum state in our case and cannot be reused whereas that is classical and can be reused for proving multiple statements in [Shm20]. On the other hand, a CV-NIZK in the CRS + (V → P) model has two nice features that the NIZK of [Shm20] does not have: one is that verification can be done classically in the online phase and the other is the dual-mode property.

Though Definition 5.1 does not explicitly require anything on soundness in the hiding mode or the zero-knowledge property in the binding mode, we can easily prove that they are satisfied in a computational sense. Specifically, we have the following lemma.

Lemma 5.2. If a dual-mode CV-NIZK Π = (CRSGen, Preprocess, Prove, Verify) for a QMA language L satisfies statistical s-soundness in the binding mode, statistical zero-knowledge property in the hiding mode, and computational mode indistinguishability, then it also satisfies the following properties.

(Exclusive-Adaptive) Computational \((s + \text{negl}(\lambda))\)-Soundness in the Hiding Mode For all non-uniform QPT adversaries A, we have

\[
\Pr \left[ \text{Verify}(\text{crs}, k_V, x, \pi) = \top : (k_P, k_V) \xleftarrow{\$} \text{Preprocess}(\text{crs}) \right. \\
\left. (x, \pi) \xleftarrow{\$} A(\text{crs}, k_P) \right] \leq s + \text{negl}(\lambda).
\]
where A’s output must always satisfy x \not\in L.

\textbf{(Adaptive Multi-Theorem) Computational Zero-Knowledge in the Binding Mode.} There exists a PPT simulator Sim_0 and QPT simulator Sim_1 such that for any non-uniform QPT distinguisher D, we have

$$\left| \Pr \left[ D^{O_P(\text{crs}, \cdot, \cdot)}(\text{crs}) = 1 : \text{crs} \overset{\$}{\leftarrow} \text{CRSGen}(1^\lambda, \text{binding}) \right] - \Pr \left[ D^{O_S(\text{td}, \cdot, \cdot)}(\text{crs}) = 1 : (\text{crs}, \text{td}) \overset{\$}{\leftarrow} \text{Sim}_0(1^\lambda) \right] \right| \leq \text{negl}(\lambda)$$

where D can make poly(\lambda) queries, which should be of the form (k_P, x, w^\otimes k) where w \in R_L(x) and w^\otimes k is unentangled with D’s internal registers, O_P(\text{crs}, k_P, x, w^\otimes k) returns Prove(\text{crs}, k_P, x, w^\otimes k), and O_S(\text{td}, k_P, x, w^\otimes k) returns Sim_1(\text{td}, k_P, x).

Intuitively, the above lemma holds because soundness and zero-knowledge should transfer from one mode to the other by the mode indistinguishability since otherwise we can distinguish the two modes. Here, security degrades to computational ones as the mode indistinguishability only holds against QPT distinguishers. We omit a formal proof since this is easy and can be proven similarly to a similar statement for dual-mode NIZKs for NP, which has been folklore and formally proven recently [AB20].

\textbf{Remark 5.} Remark that soundness in the hiding mode is defined in the “exclusive style” where A should always output x \not\in L. This is weaker than soundness in the “penalizing style” as in Definition 5.1 where A is allowed to also output x \in L and we add x \not\in L as part of the adversary’s winning condition. This is because the adaptive soundness in the penalizing style does not transfer well through the mode change while the adaptive soundness in the exclusive style does. This was formally proven for NIZK for NP in the common reference string model in [AB20], and easily extends to CV-NIZK for QMA in the CRS + (V \rightarrow P) model. This is justified by the impossibility of penalizing-adaptively (computational) sound and statistically zero-knowledge NIZK for NP in the classical setting (under falsifiable assumptions) [Pas13]. We leave it open to study if a similar impossibility holds for dual-mode CV-NIZK for QMA in the CRS + (V \rightarrow P) model.

Finally, we note that we can amplify the gap between the thresholds for completeness and soundness by parallel repetitions similarly to CV-NIZK in the QSP model as discussed in Section 2.3. As a result, we obtain the following lemma.

\textbf{Lemma 5.3} (Gap amplification for dual-mode CV-NIZK in the CRS + (V \rightarrow P) model). If there exists a dual-mode CV-NIZK for L in the CRS + (V \rightarrow P) model that satisfies c-completeness and s-soundness, for some 0 < s < c < 1 such that c - s > 1/poly(\lambda), then there exists a dual-mode CV-NIZK for L in the CRS + (V \rightarrow P) model (with (1 - \text{negl}(\lambda))-completeness and \text{negl}(\lambda)-soundness).

Since this can be proven similarly to Lemma 2.10, we omit a proof.

\section{5.2 Building Blocks}

We introduce two cryptographic building blocks for our dual-mode CV-NIZK in the CRS + (V \rightarrow P) model.

\textbf{Lossy Encryption} The first building block is lossy encryption [BHY09]. Intuitively, a lossy encryption scheme is a public key encryption scheme with a special property that we can generate a lossy key that is computationally indistinguishable from an honestly generated public key, for which there is no corresponding decryption key.
Definition 5.4 (Lossy Encryption). A lossy encryption scheme over the message space $\mathcal{M}$ and the randomness space $\mathcal{R}$ consists of PPT algorithms $\Pi_{\text{LE}} = (\text{InjGen}, \text{LossyGen}, \text{Enc}, \text{Dec})$ with the following syntax.

$\text{InjGen}(1^\lambda)$: The injective key generation algorithm takes the security parameter $1^\lambda$ as input and outputs an injective public key $pk$ and a secret key $sk$.

$\text{LossyGen}(1^\lambda)$: The lossy key generation algorithm takes the security parameter $1^\lambda$ as input and outputs a lossy public key $pk$.

$\text{Enc}(pk, \mu)$: The encryption algorithm takes the public key $pk$ and a message $\mu \in \mathcal{M}$ as input and outputs a ciphertext $ct$. This algorithm uses a randomness $R \in \mathcal{R}$. We denote by $\text{Enc}(pk, \mu; R)$ to mean that we run $\text{Enc}$ on input $pk$ and $\mu$ and randomness $R$ when we need to clarify the randomness.

$\text{Dec}(sk, ct)$: The decryption algorithm takes the secret key $sk$ and a ciphertext $ct$ as input and outputs a message $\mu$.

We require $\Pi_{\text{LE}}$ to satisfy the following properties.

**Correctness on Injective Keys** For all $\mu \in \mathcal{M}$, we have

$$\Pr \left[ \text{Dec}(sk, ct) = \mu : (pk, sk) \xleftarrow{\$} \text{InjGen}(1^\lambda) \quad ct \xleftarrow{\$} \text{Enc}(pk, \mu) \right] = 1.$$

**Lossiness on Lossy Keys** With overwhelming probability over $pk \xleftarrow{\$} \text{LossyGen}(1^\lambda)$, for all $\mu_0, \mu_1 \in \mathcal{M}$ and all unbounded-time distinguisher $D$, we have

$$\left| \Pr \left[ D(ct) = 1 : ct \xleftarrow{\$} \text{Enc}(pk, \mu_0) \right] - \Pr \left[ D(ct) = 1 : ct \xleftarrow{\$} \text{Enc}(pk, \mu_1) \right] \right| \leq \text{negl}(\lambda).$$

**Computational Mode Indistinguishability** For any non-uniform QPT distinguisher $D$, we have

$$\left| \Pr \left[ D(pk) = 1 : (pk, sk) \xleftarrow{\$} \text{InjGen}(1^\lambda) \right] - \Pr \left[ D(pk) = 1 : pk \xleftarrow{\$} \text{LossyGen}(1^\lambda) \right] \right| \leq \text{negl}(\lambda).$$

It is well-known that Regev’s encryption [Reg09] is lossy encryption under the LWE assumption with a negligible correctness error. We can modify the scheme to achieve perfect correctness by a standard technique. Then we have the following lemma.

Lemma 5.5. If the LWE assumption holds, then there exists a lossy encryption scheme.

**Dual-Mode Oblivious Transfer** The second building block is a $k$-out-of-$n$ dual-mode oblivious transfer. Though this is a newly introduced definition in this paper, 1-out-of-2 case is already implicit in existing works on universally composable (UC-secure) [Can20] oblivious transfers [PVW08, Qua20].

Definition 5.6 (Dual-mode oblivious transfer). A (2-round) $k$-out-of-$n$ dual-mode oblivious transfer with a message space $\mathcal{M}$ consists of PPT algorithms $\Pi_{\text{OT}} = (\text{CRSGen}, \text{Receiver}, \text{Sender}, \text{Derive})$. 

25
CRSGen(1^λ, mode): This is an algorithm supposed to be run by a trusted third party that takes the security parameter 1^λ and a mode mode ∈ {binding, hiding} as input and outputs a common reference string crs.

Receiver(crs, J): This is an algorithm supposed to be run by a receiver that takes the common reference string crs and an ordered set of k indices J ∈ [n]^k as input and outputs a first message ot_1 and a receiver’s state st.

Sender(crs, ot_1, µ): This is an algorithm supposed to be run by a sender that takes the common reference string crs, a first message ot_1 sent from a receiver and a tuple of messages µ ∈ M^n as input and outputs a second message ot_2.

Derive(crs, st, ot_2): This is an algorithm supposed to be run by a receiver that takes a receiver’s state st and a second message ot_2 as input and outputs a tuple of messages µ′ ∈ M^k.

We require the following properties.

**Correctness** For all mode ∈ {binding, hiding}, J = (j_1, ..., j_k) ∈ [n]^k, and µ = (µ_1, ..., µ_n) ∈ M^n, we have

\[
\Pr \left[ \text{Derive(crs, st, ot_2)} = (\mu_{j_1}, ..., \mu_{j_k}) : \\
\text{crs} \xleftarrow{\$} \text{CRSGen}(1^\lambda, \text{mode}) \\
\text{ot}_1 \xleftarrow{\$} \text{Receiver(crs, J)} \\
\text{ot}_2 \xleftarrow{\$} \text{Sender(crs, ot}_1, \mu) \right] \geq 1 - \text{negl}(\lambda).
\]

**Statistical Receiver’s Security in the Binding Mode** Intuitively, this security requires that the indices chosen by a receiver are hidden from a sender. Formally, we require that there is a PPT algorithm Sim_rec such that for any unbounded-time distinguisher D and J ∈ [n]^k, we have

\[
\left| \Pr \left[ D(\text{crs, ot}_1) = 1 : \\
\text{crs} \xleftarrow{\$} \text{CRSGen}(1^\lambda, \text{binding}) \\
\text{ot}_1 \xleftarrow{\$} \text{Receiver(crs, J)} \right] - \Pr \left[ D(\text{crs, ot}_1) = 1 : \\
\text{crs} \xleftarrow{\$} \text{CRSGen}(1^\lambda, \text{binding}) \\
\text{ot}_1 \xleftarrow{\$} \text{Sim_{CRS}(crs)} \right] \right| \leq \text{negl}(\lambda).
\]

**Statistical Sender’s Security in the Hiding Mode** Intuitively, this security requires that we can extract the indices of messages which a (possibly malicious) receiver tries to learn by using a trapdoor in the hiding mode. Formally, there are PPT algorithms Sim_{CRS} and Sim_{sen} and a deterministic classical polynomial-time algorithm Open_rec such that the following two properties are satisfied.

- For any unbounded-time distinguisher D, we have

\[
\left| \Pr \left[ D(\text{crs}) = 1 : \text{crs} \xleftarrow{\$} \text{CRSGen}(1^\lambda, \text{hiding}) \right] - \Pr \left[ D(\text{crs}) = 1 : (\text{crs, td}) \xleftarrow{\$} \text{Sim_{CRS}(1^\lambda)} \right] \right| \leq \text{negl}(\lambda).
\]

- For any unbounded-time adversary A = (A_0, A_1) (that plays the role of a malicious receiver)
and \( \mu = (\mu_1, ..., \mu_n) \), we have

\[
\Pr \left[ A_1(st_{A}, ot_2) = 1 : (crs, td) \xleftarrow{\$} \text{Sim}_{\text{CRS}}(1^\lambda) \right.
\]

\[
\left. (ot_1, st_{A}) \xleftarrow{\$} A_0(crs, td) \right.
\]

\[
\left. ot_2 \xleftarrow{\$} \text{Sender}(crs, ot_1, \mu) \right] \leq \text{negl}(\lambda)
\]

where the output of \( \text{Open}_{\text{rec}} \) always satisfies \( J \in [n]^k \) and \( \mu_J := (\mu_{j_1}, ..., \mu_{j_k}) \) for \( J = (j_1, ..., j_k) \).

**Computational Mode Indistinguishability.** For any non-uniform QPT distinguisher \( D \), we have

\[
\Pr \left[ D(crs) = 1 : crs \xleftarrow{\$} \text{CRSGen}(1^\lambda, \text{binding}) \right] - \Pr \left[ D(crs) = 1 : crs \xleftarrow{\$} \text{CRSGen}(1^\lambda, \text{hiding}) \right] \leq \text{negl}(\lambda).
\]

**Remark 6** (On security definition of dual-mode oblivious transfer). We remark that security of a \( k \)-out-of-\( n \) dual-mode oblivious transfer as defined in Definition 5.6 does not imply UC-security [Can20, PVW08, Qua20] or even full-simulation security in the standard stand-alone simulation-based definition [Lin08]. This is because the receiver’s security in Definition 5.6 only ensures privacy of \( J \) and does not prevent a malicious sender from generating \( ot_2 \) so that he can manipulate the message derived on the receiver’s side depending on \( J \). The security with such a weaker receiver’s security is often referred to as half-simulation security [CNs07]. We define the security in this way due to the following reasons:

1. This definition is sufficient for constructing a dual-mode CV-NIZK in the CRS + (V → P) model given in Section 5.3 by additionally relying on lossy encryption.

2. We are not aware of an efficient construction of a \( k \)-out-of-\( n \) oblivious transfer that satisfies full-simulation security under a post-quantum assumption (even if we ignore the dual-mode property). We note that Quach [Qua20] gave a construction of a 1-out-of-2 oblivious transfer with full-simulation security based on LWE and we can extend it to 1-out-of-\( n \) one. However, we are not aware of an efficient way to convert this into \( k \)-out-of-\( n \) one without losing the full-simulation security. We note that a conversion from 1-out-of-\( n \) to \( k \)-out-of-\( n \) oblivious transfer by a simple \( k \)-parallel repetition does not work if we require the full-simulation security since a malicious sender can send different inconsistent messages in different sessions, which should be considered as an attack against full-simulation security. One possible way to prevent such an inconsistent message attack is to let the sender prove that the messages in all sessions are consistent by using (post-quantum) NIZK for NP in the common reference string model [PS19]. However, such a construction is very inefficient since it uses the underlying 1-out-of-\( n \) oblivious transfer in a non-black-box manner. On the other hand, the half-simulation security is preserved under parallel repetitions as shown in Appendix D, and thus we can achieve this much more efficiently.

**Lemma 5.7.** If the LWE assumption holds, then there exists \( k \)-out-of-\( n \) dual-mode oblivious transfer for arbitrary \( 0 < k < n \) that are polynomial in \( \lambda \).

\[\text{His construction further satisfies UC-security, which is stronger than full-simulation security.}\]
Proof (sketch). First, we can see that the LWE-based UC-secure OT by Quach [Qua20] can be seen as a 1-out-of-2 dual-mode oblivious transfer. This construction can be converted into 1-out-of-$n$ dual-mode oblivious transfer by using the generic conversion for an ordinary oblivious transfer given in [BCR86] observing that the conversion preserves the dual-mode property.\footnote{Alternatively, it may be possible to directly construct 1-out-of-$n$ dual-mode oblivious transfer by appropriately modifying the construction by Quach [Qua20].} By $k$-parallel repetition of the 1-out-of-$n$ dual-mode oblivious transfer, we obtain $k$-out-of-$n$ dual-mode oblivious transfer. The full proof can be found in Appendix D.

5.3 Construction

In this section, we construct a dual-mode CV-NIZK in the CRS + $(V \rightarrow P)$ model. As a result, we obtain the following theorem.

Theorem 5.8. If the LWE assumption holds, then there exists a dual-mode CV-NIZK in the CRS + $(V \rightarrow P)$ model.

Let $L$ be a QMA language, and $H_x, N, M, p_i, s_i, P_i, \alpha, \beta$, and $\rho_{\text{hist}}$ be as in Lemma 2.8 for the language $L$. We let $N' := \sum_{i=1}^{5} \binom{N}{i}$ similarly to Lemma 4.2. Let $\Pi_{\text{LE}} = (\text{InjGen}_{\text{LE}}, \text{LossyGen}_{\text{LE}}, \text{Enc}_{\text{LE}}, \text{Dec}_{\text{LE}})$ be a lossy encryption scheme over the message space $M_{\text{LE}} = \{0, 1\}^2$ and the randomness space $R_{\text{LE}}$ as defined in Definition 5.4. Let $\Pi_{\text{OT}} = (\text{CRSGen}_{\text{OT}}, \text{Receiver}_{\text{OT}}, \text{Sender}_{\text{OT}}, \text{Derive}_{\text{OT}})$ be a 5-out-of-$N$ dual-mode oblivious transfer over the message space $M_{\text{OT}} = M_{\text{LE}} \times R_{\text{LE}}$ as defined in Definition 5.6. Then our dual-mode CV-NIZK $\Pi_{\text{DM}} = (\text{CRSGen}_{\text{DM}}, \text{Preprocess}_{\text{DM}}, \text{Prove}_{\text{DM}}, \text{Verify}_{\text{DM}})$ for $L$ is described in Figure 7.

Then we prove the following lemmas.

Lemma 5.9. $\Pi_{\text{DM}}$ satisfies $(1 - \frac{\alpha}{N'} - \text{negl}(\lambda))$-completeness.

Proof. By the correctness of $\Pi_{\text{OT}}$, it is easy to see that the probability that an honestly generated proof passes the verification differs from that in $\Pi_{\text{NIZK}}$ in Figure 4 only by $\text{negl}(\lambda)$. Since $\Pi_{\text{NIZK}}$ satisfies $(1 - \frac{\alpha}{N'})$-completeness as shown in Lemma 4.2, $\Pi_{\text{DM}}$ satisfies $(1 - \frac{\alpha}{N'} - \text{negl}(\lambda))$-completeness.

Lemma 5.10. $\Pi_{\text{DM}}$ satisfies the computational mode indistinguishability.

Proof. This can be reduced to the computational mode indistinguishability of $\Pi_{\text{OT}}$ and $\Pi_{\text{LE}}$ in a straightforward manner.

Lemma 5.11. $\Pi_{\text{DM}}$ satisfies statistical $(1 - \frac{\beta}{N'} + \text{negl}(\lambda))$-soundness in the binding mode.

Lemma 5.12. $\Pi_{\text{DM}}$ satisfies the statistical zero-knowledge property in the hiding mode.

By combining Lemmas 5.3, 5.5, 5.7 and 5.9 to 5.12 and

$$\left(1 - \frac{\alpha}{N'} - \text{negl}(\lambda)\right) - \left(1 - \frac{\beta}{N'} + \text{negl}(\lambda)\right) = \frac{\beta - \alpha}{N'} - \text{negl}(\lambda) = \frac{1}{\text{poly}(\lambda)},$$

we obtain Theorem 5.8.

In the following, we prove Lemmas 5.11 and 5.12.

Proof of Lemma 5.11 (Soundness). For any adversary $A$, we consider the following sequence of games between $A$ and the challenger where we denote by $\text{Win}_i$ the event that the challenger returns $\top$ in Game$_i$. 

28
CRSGenDM(1^\lambda, \text{mode}): The CRS generation algorithm generates crs_{OT} \xleftarrow{\$} CRSGen_{OT}(1^\lambda, \text{mode}).

- If mode = binding, then it generates (pk, sk) \xleftarrow{\$} \text{InjGen}_{LE}(1^\lambda).
- If mode = hiding, then it generates pk \xleftarrow{\$} \text{LossyGen}_{LE}(1^\lambda).

Then it outputs crs_{DM} := (crs_{OT}, pk).

Preprocess_{DM}(crs_{DM}): The preprocessing algorithm parses (crs_{OT}, pk) \xleftarrow{\$} crs_{DM} and chooses
(W_1, ..., W_N) \xleftarrow{\$} \{X, Y, Z\}^N, (m_1, ..., m_N) \xleftarrow{\$} \{0, 1\}^N, and a uniformly random subset S_V \subseteq [N] such that 1 \leq |S_V| \leq 5. Let J = (j_1, ..., j_5) \in [N]^5 be the elements of S_V in the ascending order where we append arbitrary indices when |S_V| < 5. It generates (ot_1, st) \xleftarrow{\$}
Receiver_{OT}(crs_{OT}, J) and outputs a proving key k_P := \left(\rho_P := \bigotimes_{j=1}^N (U(W_j)|m_j\rangle\langle m_j|), ot_1\right) and a verification key k_V := (W_1, ..., W_N, m_1, ..., m_N, S_V, st).

Prove_{DM}(crs_{DM}, k_P, x, w): The proving algorithm parses (crs_{OT}, pk) \xleftarrow{\$} crs_{DM} and (\rho_P, ot_1) \xleftarrow{\$} k_P,
generates (\hat{x}, \hat{z}) \xleftarrow{\$} \{0, 1\}^N \times \{0, 1\}^N, generates the history state \rho_{hist} for H_x from w, and computes \rho'_{hist} := X^\hat{x} Z^\hat{z} \rho_{hist} Z^\hat{z} X^\hat{x}. It measures j-th qubits of \rho'_{hist} and \rho_P in the Bell basis for j \in [N]. Let x := x_1, x_2, ..., x_N, and z := z_1, z_2, ..., z_N where (x_j, z_j) denotes the outcome of j-th measurement. For j \in [N], it generates ct_j := Enc_{LE}(pk, (\tilde{x}_j, \tilde{z}_j); R_j) where R_j \xleftarrow{\$} R_{LE} and \tilde{x}_j and \tilde{z}_j denote the j-th bits of \hat{x} and \hat{z}, respectively. It sets \mu_j := ((\tilde{x}_j, \tilde{z}_j), R_j) for j \in [N] and generates ot_2 \xleftarrow{\$} Sender_{OT}(crs_{OT}, ot_1, (\mu_1, ..., \mu_N)). It outputs a proof \pi := (x, z, \{ct_j\}_{j \in [N]}, ot_2).

Verify_{DM}(crs_{DM}, k_V, x, \pi): The verification algorithm parses (crs_{OT}, pk) \xleftarrow{\$} crs_{DM}, (W_1, ..., W_N, m_1, ..., m_N, S_V, st) \xleftarrow{\$} k_V, and (x, z, \{ct_j\}_{j \in [N]}, ot_2) \xleftarrow{\$} \pi. It runs \mu' \xleftarrow{\$} Derive_{OT}(crs_{OT}, st, ot_2) and parses (((\tilde{x}_j', \tilde{z}_j'), R_j')) \xleftarrow{\$} \mu'. If Enc_{LE}(pk, (\tilde{x}_i', \tilde{z}_i'); R_i') \neq ct_{j_i} for some i \in [5], it outputs \bot. Otherwise, it recovers \{\tilde{x}_j, \tilde{z}_j\}_{j \in S_V} by setting (\tilde{x}_{j_i}, \tilde{z}_{j_i}) := (\tilde{x}_i', \tilde{z}_i') for i \in [S_V]. It chooses i \in [M] according to the probability distribution defined by \{p_i\}_{i \in [M]} (i.e., chooses i with probability p_i). Let
S_i := \{j \in [N] \mid j\text{th Pauli operator of } P_i \text{ is not } I\}.

We note that we have 1 \leq |S_i| \leq 5 by the 5-locality of H_x. We say that P_i is consistent to (S_V, \{W_j\}_{j \in S_V}) if and only if S_V = S_V and the j-th Pauli operator of P_i is W_j for all j \in S_i. If P_i is not consistent to (S_V, \{W_j\}_{j \in S_V}), it outputs \top. If P_i is consistent to (S_V, \{W_j\}_{j \in S_V}), it flips a biased coin that heads with probability 1 - 3|S_i|^{-5}. If heads, it outputs \top. If tails, it defines
\[ m'_j := \begin{cases} 
  m_j \oplus x_j \oplus \hat{x}_j & (W_j = Z), \\
  m_j \oplus z_j \oplus \hat{z}_j & (W_j = X), \\
  m_j \oplus x_j \oplus \hat{x}_j \oplus z_j \oplus \hat{z}_j & (W_j = Y)
\end{cases} \]
for j \in S_i, and outputs \top if \((-1)^{\sum_{j \in S_i} m'_j} = -s_i\) and \bot otherwise.

Figure 7: Our Dual-Mode CV-NIZK \Pi_{DM}
Game 1: This game is the original soundness game in the binding game. That is, it works as follows:

1. The challenger generates \( \text{crs}_{\text{OT}} \leftarrow \text{CRSGen}_{\text{OT}}(1^\lambda, \text{binding}) \) and \( (\text{pk}, \text{sk}) \leftarrow \text{InjGen}_{\text{LE}}(1^\lambda) \).
2. The challenger generates \( (W_1, \ldots, W_N) \leftarrow \{X, Y, Z\}^N \), \( (m_1, \ldots, m_N) \leftarrow \{0, 1\}^N \), and \( \rho_P := \otimes_{j=1}^N (U(W_j)|m_j) \).
3. The challenger generates \( S_V \) and \( J = (j_1, \ldots, j_5) \) similarly to \( \text{Preprocess}_{\text{DM}} \).
4. The challenger generates \( (\text{ot}_1, \text{st}) \leftarrow \text{Receiver}_{\text{OT}}(\text{crs}_{\text{OT}}, J) \).
5. The challenger gives \( \text{crs}_{\text{DM}} \) and a proving key \( k_P := (\rho_P, \text{ot}_1) \) to \( A \), and \( A \) outputs \( (x, \pi = (x, z, \{ct_j\}_{j \in [N]}, \text{ot}_2)) \). If \( x \in L \), the challenger outputs \( \perp \) and immediately halts.
6. The challenger runs \( \mu' \leftarrow \text{Derive}_{\text{OT}}(\text{crs}_{\text{OT}}, \text{st}, \text{ot}_2) \) and parses \( ((\bar{x}'_1, \bar{z}'_1), \bar{R}'_1), \ldots, ((\bar{x}'_5, \bar{z}'_5), \bar{R}'_5)) \leftarrow \mu' \). If \( \text{Enc}_{\text{LE}}(\text{pk}, (\bar{x}'_i, \bar{z}'_i); \bar{R}'_i) \neq \text{ct}_{j_i} \) for some \( i \in [5] \), it outputs \( \perp \) and immediately halts. Otherwise, it recovers \( \{\bar{x}_j, \bar{z}_j\}_{j \in S_V} \) by setting \( (\bar{x}_j, \bar{z}_j) := (\bar{x}'_j, \bar{z}'_j) \) for \( i \in \{|S_V|\} \).
7. The challenger samples \( i \) and defines \( S_i \) and \( P_i \) similarly to \( \text{Verify}_{\text{DM}} \). If \( P_i \) is not consistent to \( (S_V, \{W_j\}_{j \in S_V}) \), it outputs \( \top \). If \( P_i \) is consistent to \( (S_V, \{W_j\}_{j \in S_V}) \), it flips a biased coin that heads with probability \( 1 - 3^{|S_i|} - 5 \). If heads, it outputs \( \top \). If tails, it defines \( m'_{j} \) for \( j \in S_i \) similarly to \( \text{Verify}_{\text{DM}} \) and outputs \( \top \) if \( (-1)^{\oplus_{j \in S_i} m'_{j}} = -s_i \) and \( \perp \) otherwise.

Our goal is to prove \( \Pr[\text{Win}_1] \leq 1 - \frac{\beta}{N^2} + \text{negl}(\lambda) \).

Game 2: This game is identical to the previous game except that Step 6 is replaced with Step 6’ as follows.

6’. The challenger computes \( (\bar{x}_j, \bar{z}_j) \leftarrow \text{Dec}_{\text{LE}}(\text{sk}, \text{ct}_j) \) for \( j \in [N] \).

If the challenger does not output \( \perp \) in Step 6, then we have \( \text{Enc}_{\text{LE}}(\text{pk}, (\bar{x}'_i, \bar{z}'_i); \bar{R}'_i) = \text{ct}_{j_i} \) for all \( i \in [5] \). In this case, we have \( \text{Dec}_{\text{LE}}(\text{sk}, \text{ct}_{j_i}) = (\bar{x}'_i, \bar{z}'_i) \) by correctness of \( \Pi_{\text{LE}} \). Therefore, the values of \( \{\bar{x}_j, \bar{z}_j\}_{j \in S_V} \) computed in Step 6 and 6’ are identical conditioned on that the challenger does not output \( \perp \) in Step 6. Noting that Step 7 only uses the values of \( (\bar{x}_j, \bar{z}_j) \) for \( j \in S_V \), we have \( \Pr[\text{Win}_1] \leq \Pr[\text{Win}_2] \).

Game 3: This game is identical to the previous game except that Step 4 is replaced with Step 4’ as follows.

4’ The challenger generates \( \text{ot}_1 \leftarrow \text{Sim}_{\text{rec}}(\text{crs}_{\text{OT}}) \).

By statistical receiver’s security in the binding mode of \( \Pi_{\text{OT}} \), it is clear that we have \( |\Pr[\text{Win}_3] - \Pr[\text{Win}_2]| \leq \text{negl}(\lambda) \).

Game 4: This game is identical to the previous game except that Step 2 is replaced with Step 2’ described below.

2’. The challenger generates \( N \) Bell-pairs between registers \( \text{P} \) and \( \text{V} \) and lets \( \rho_P \) and \( \rho_V \) be quantum states in registers \( \text{P} \) and \( \text{V} \), respectively. Then it chooses \( (W_1, \ldots, W_N) \leftarrow \{X, Y, Z\}^N \), and measures \( j \)-th qubit of \( \rho_V \) in the \( W_j \) basis for all \( j \in [N] \), and lets \( (m_1, \ldots, m_N) \) be the measurement outcomes.

By Lemma 2.1, the joint distributions of \( (\rho_P, (W_1, \ldots, W_N, m_1, \ldots, m_N)) \) in \( \text{Game}_3 \) and \( \text{Game}_4 \) are identical, and thus we have \( \Pr[\text{Win}_4] = \Pr[\text{Win}_3] \).
We consider the following sequence of modified versions of additional input.

- The challenger computes \( \rho'_V := X^z \otimes \tilde{Z}^z \otimes \rho_V Z^z \otimes X^z \). For all \( j \in S_i \), it measures \( j \)-th qubit of \( \rho'_V \) in \( W_j \) basis, and lets \( m'_j \) be the measurement outcome.

By Lemma 2.2, this does not change the distribution of \( \{m'_j\}_{j \in S_i} \). Therefore, we have \( \Pr[\text{Win}_5] = \Pr[\text{Win}_4] \).

Let \( E_x \) be the event that the statement output by \( \mathcal{A} \) is \( x \), and \( \rho'_{V,x} \) be the state in \( \mathcal{V} \) right before the measurement in the modified Step 7 conditioned on \( E_x \). For any fixed \( P_i \), the probability that \( P_i \) is consistent to \( (S_V, \{W_j\}_{j \in S_V}) \) and the coin tails is \( \frac{1}{N} \). Therefore, by Lemma 2.5, we have

\[
\Pr[\text{Win}_5|E_x] = 1 - \frac{1}{N'} \text{Tr}(\rho'_{V,x} \mathcal{H}_x).
\]

Then we have

\[
\Pr[\text{Win}_5] = \sum_{x \notin L} \Pr[E_x] \left( 1 - \frac{1}{N'} \text{Tr}(\rho'_{V,x} \mathcal{H}_x) \right) \leq \sum_{x \notin L} \Pr[E_x] \left( 1 - \frac{\beta}{N'} \right) \leq 1 - \frac{\beta}{N'}
\]

where the first inequality follows from Lemma 2.8.

By combining the above, we obtain \( \Pr[\text{Win}_1] \leq 1 - \frac{\beta}{N'} + \text{negl}(\lambda) \).

This completes the proof of Lemma 5.11. \( \Box \)

**Proof of Lemma 5.12 (Zero-Knowledge).** Let \( \text{Sim}_{\text{CRS}}, \text{Sim}_{\text{sen}}, \) and \( \text{Open}_{\text{rec}} \) be the corresponding algorithms for statistical sender's security in the hiding mode of \( \Pi_{\text{OT}} \). The simulator \( \text{Sim} = (\text{Sim}_0, \text{Sim}_1) \) for \( \Pi_{\text{DM}} \) is described below.

\( \text{Sim}_0(1^\lambda) \): It generates \( (\text{crs}_{\text{OT}}, \text{td}_{\text{OT}}) \xleftarrow{\$} \text{Sim}_{\text{CRS}}(1^\lambda) \) and \( \text{pk} \xleftarrow{\$} \text{LossyGen}_{\text{LE}}(1^\lambda) \) and outputs \( \text{crs}_{\text{DM}} := (\text{crs}_{\text{OT}}, \text{pk}) \) and \( \text{td}_{\text{DM}} := (\text{crs}_{\text{OT}}, \text{td}_{\text{OT}}, \text{pk}) \).

\( \text{Sim}_1(\text{td}_{\text{DM}}, k_P, x) \): The simulator parses \( (\text{crs}_{\text{OT}}, \text{td}_{\text{OT}}, \text{pk}) \xleftarrow{\$} \text{td}_{\text{DM}} \) and \( (\rho_P, \text{ot}_1) \xleftarrow{\$} k_P \) and does the following.

1. Compute \( J := \text{Open}_{\text{rec}}(\text{td}_{\text{OT}}, \text{ot}_1) \). Let \( S_V := \{j_1, ..., j_5\} \subseteq [N] \) where \( J = (j_1, ..., j_5) \).
2. Generate \( (\tilde{x}, \tilde{z}) \xleftarrow{\$} \{0, 1\}^N \times \{0, 1\}^N \) and \( R_j \xleftarrow{\$} \mathcal{R}_{\text{LE}} \) for \( j \in [N] \), \( \text{ct}_j := \text{Enc}_{\text{LE}}(\text{pk}, (\tilde{x}, \tilde{z}); R_j) \) for all \( j \in [N] \), and \( \text{ot}_2 \xleftarrow{\$} \text{Sim}_{\text{sen}}(\text{crs}_{\text{OT}}, \text{ot}_1, J, \mu, J) \) where \( \mu := (\mu_{j_1}, ..., \mu_{j_5}) \) and \( \mu_j := ((\tilde{x}_{j_i}, \tilde{z}_{j_i}), R_{j_i}) \) for \( i \in [5] \).
3. Generate the classical description of the density matrix \( \rho_{S_V} := \text{Sim}_{\text{hist}}(x, S_V) \) where \( \text{Sim}_{\text{hist}} \) is as in Lemma 2.8.
4. Generate \( \tilde{\rho}_{\text{hist}} := \left( \prod_{j \in S_V} X_j \tilde{Z}_j Z_j \right) \rho_{S_V} \left( \prod_{j \in S_V} Z_j \tilde{X}_j X_j \right) \otimes \frac{I_{[N] \setminus S_V}}{2^{([N] \setminus S_V)}} \).
5. Measure \( j \)-th qubits of \( \tilde{\rho}_{\text{hist}} \) and \( \rho_P \) in the Bell basis for \( j \in [N] \), and let \( (x_j, z_j) \) be the \( j \)-th measurement result.
6. Output \( \pi := (x, z, \{\text{ct}_j\}_{j \in [N]}, \text{ot}_2) \) where \( x := x_1 \parallel x_2 \parallel ... \parallel x_N \) and \( z := z_1 \parallel z_2 \parallel ... \parallel z_N \).

We consider the following sequence of modified versions of \( \text{Sim}_1 \), which take \( \nu \in R_L(x) \) as an additional input.
Sim$_1^{(1)}$(td$_{DM}$, kp, x, w): This simulator works similarly to Sim$_1$ except that it generates the history state $\rho_{\text{hist}}$ for $H_x$ from w instead of $\rho_{S_V}$ in Step 3, defines $\rho'_{\text{hist}} := X^{\tilde{x}}Z^{\tilde{z}}\rho_{\text{hist}}Z^{\tilde{x}}X^{\tilde{x}}$ in Step 4, and uses $\rho'_{\text{hist}}$ instead of $\tilde{\rho}'_{\text{hist}}$ in Step 5.

Sim$_1^{(2)}$(td$_{DM}$, kp, x, w): This simulator works similarly to Sim$_1^{(1)}$ except that in Step 2, it generates $\tilde{\rho}_2 \leftarrow \text{Sender}_O(crs$_{OT}$, ot$_1$, (\mu$_1$, ..., \mu$_N$)) instead of $\tilde{\rho}_2 \leftarrow \text{Sim}_s(crs$_{OT}$, ot$_1$, J, \mu, j)$ where $\mu_j := ((\tilde{x}_j, \tilde{z}_j), R_j)$ for $j \in [N]$. We note that Sim$_1^{(2)}$ needs not run Step 1 since it does not use J in later steps and thus it does not use td$_{OT}$.

Let $O_P(crs$_{DM}, \cdot, \cdot)$ and $O_S(td$_{DM}, \cdot, \cdot)$ be as in Definition 5.1 and $O_S^{(i)}(td$_{DM}, \cdot, \cdot)$ be the oracle that works similarly to $O_S(td$_{DM}, \cdot, \cdot)$ except that it uses Sim$_1^{(i)}$ instead of Sim$_1$ for $i = 1, 2$.

Then we prove the following claims.

**Claim 5.13.** If $\Pi_{LE}$ satisfies lossiness on lossy keys, we have

$$\Pr \left[ D^{O_S(td_{DM}, \cdot, \cdot)}(crs$_{DM}$) = 1 \right] - \Pr \left[ D^{O_S^{(1)}(td_{DM}, \cdot, \cdot)}(crs$_{DM}$) = 1 \right] \leq \text{negl}(\lambda)$$

where $(crs$_{DM}, td_{DM}) \leftarrow \text{Sim}_0(1^\lambda)$ for any distinguisher $D$ that makes poly($\lambda$) queries of the form $(kp, ot_1, x, w)$ for some $w \in R_L(x)$.

**Proof of Claim 5.13.** Let $\tilde{O}_S(td_{DM}, \cdot, \cdot)$ and $\tilde{O}_S^{(1)}(td_{DM}, \cdot, \cdot)$ be oracles that work similarly to $O_S(td_{DM}, \cdot, \cdot)$ and $O_S^{(1)}(td_{DM}, \cdot, \cdot)$ except that they generate $ct_j := \text{Enc}_L(pk, (0,0); R_j)$ instead of $ct_j := \text{Enc}_L(pk, (\tilde{x}_j, \tilde{z}_j); R_j)$ for $j \not\in S_V$, respectively. By lossiness on lossy keys of $\Pi_{LE}$, $D$ cannot distinguish $\tilde{O}_S(td_{DM}, \cdot, \cdot)$ and $\tilde{O}_S^{(1)}(td_{DM}, \cdot, \cdot)$ from $O_S(td_{DM}, \cdot, \cdot)$ and $O_S^{(1)}(td_{DM}, \cdot, \cdot)$ with non-negligible advantage, respectively, noting that no information of $\{R_j\}_{j \not\in S_V}$ is given to $D$.

When $D$ is given either of $\tilde{O}_S(td_{DM}, \cdot, \cdot)$ or $\tilde{O}_S^{(1)}(td_{DM}, \cdot, \cdot)$, it has no information on $\{\tilde{x}_j, \tilde{z}_j\}_{j \not\in S_V}$. Therefore, by Lemma 2.3, we have

$$\rho'_\text{hist} = \left( \prod_{j \in S_V} X^{\tilde{x}_j}Z^{\tilde{z}_j} \right) \text{Tr}_{N \setminus S_V} \left[ \rho_{\text{hist}} \right] \left( \prod_{j \in S_V} Z^{\tilde{x}_j}X^{\tilde{x}_j} \right) \otimes \frac{I_{[N] \setminus S_V}}{2^{[N] \setminus S_V}}$$

from the view of $D$. By Lemma 2.8, we have $\|\rho_{S_V} - \text{Tr}_{[N] \setminus S_V} \rho_{\text{hist}}\|_{tr} \leq \text{negl}(\lambda)$. Therefore, we have $\|\rho'_\text{hist} - \rho'_\text{hist}\|_{tr} \leq \text{negl}(\lambda)$. This means that it cannot distinguish $\tilde{O}_S(td_{DM}, \cdot, \cdot)$ and $\tilde{O}_S^{(1)}(td_{DM}, \cdot, \cdot)$ with non-negligible advantage. By combining the above, Claim 5.13 follows.

**Claim 5.14.** If $\Pi_{OT}$ satisfies the second item of statistical sender’s security in the hiding mode, we have

$$\Pr \left[ D^{O_S^{(1)}(td_{DM}, \cdot, \cdot)}(crs$_{DM}$) = 1 \right] - \Pr \left[ D^{O_S^{(2)}(td_{DM}, \cdot, \cdot)}(crs$_{DM}$) = 1 \right] \leq \text{negl}(\lambda)$$

where $(crs$_{DM}, td_{DM}) \leftarrow \text{Sim}_0(1^\lambda)$ for any distinguisher $D$ that makes poly($\lambda$) queries.

**Proof of Claim 5.14.** Let $Q = \text{poly}(\lambda)$ be the maximum number of $D$’s queries. For $i = 0, ..., Q$, let $O_S^{(i)}(td_{DM}, \cdot, \cdot)$ be the hybrid oracle that works similarly to $O_S^{(2)}(td_{DM}, \cdot, \cdot)$ for the first $i$ queries and works similarly to $O_S^{(1)}(td_{DM}, \cdot, \cdot)$ for the rest. By a standard hybrid argument, it suffices to prove

$$\Pr \left[ D^{O_S^{(i)}(td_{DM}, \cdot, \cdot)}(crs$_{DM}$) = 1 \right] - \Pr \left[ D^{O_S^{(i+1)}(td_{DM}, \cdot, \cdot)}(crs$_{DM}$) = 1 \right] \leq \text{negl}(\lambda) \quad (1)$$

32
where \((\text{crs}_\text{DM}, \text{td}_\text{DM}) \xrightarrow{*} \text{Sim}_0(1^\lambda))\) for all \(i = 0, \ldots, Q - 1\). For proving this, for any fixed \((\tilde{x}, \tilde{z}) \in \{0, 1\}^N \times \{0, 1\}^N\) and \(\{R_j\}_{j \in [N]} \in \mathcal{R}_{\text{LE}}^N\), we consider the following adversary \(A = (A_0, A_1)\) against the second item of statistical sender’s security in the hiding mode of \(\Pi_{\text{OT}}\).

\(A_0(\text{crs}_\text{OT}, \text{td}_\text{OT})\): It generates \(pk \xrightarrow{*} \text{LossyGen}(1^\lambda)\), gives \(\text{crs}_\text{DM} := (\text{crs}_\text{OT}, pk)\) to \(D\) as input and runs it until it makes \((i + 1)\)-th query where \(A_0\) simulates responses to the first \(i\) queries similarly to \(O_S^<(\text{td}_\text{DM}, \cdots, \cdot)\) where \(\text{td}_\text{DM} = (\text{crs}_\text{OT}, \text{td}_\text{OT}, pk)\). Let \((kp, x, w)\) be \(D\)’s \((i + 1)\)-th query. \(A_0\) parses \((kp, ot_1) \leftarrow kp\) and computes the history state \(\rho_{\text{hist}}\) for \(H_x\) from \(w\). It outputs \(ot_1\) and \(st_A := (kp, \rho_{\text{hist}})\).

\(A_1(\text{st}_A = (kp, \rho_{\text{hist}}), ot_2)\): It generates \(ct_j := \text{Enc}_E(pk, (\tilde{x}_j, \tilde{z}_j); R_j)\) for all \(j \in [N]\) and \(\rho_{\text{hist}} := X^\tilde{x}_jZ^\tilde{z}_j\rho_{\text{hist}}Z^\tilde{z}_jX^\tilde{x}_j\), measures \(j\)-th qubits of \(\rho_{\text{hist}}\) and \(kp\) in the Bell basis for \(j \in [N]\), lets \((x_j, z_j)\) be the \(j\)-th measurement result, and returns \(\pi := (x, z, \{ct_j\}_{j \in [N]}, ot_2)\) to \(D\) as the response of the oracle to the \((i + 1)\)-th query where \(x := x_1 \cdots x_N\) and \(z := z_1 \cdots z_N\). \(A_1\) runs the rest of the execution of \(D\) by simulating the oracle similarly to \(O_S^<(\text{td}_\text{DM}, \cdots, \cdot)\). Finally, \(A_1\) outputs whatever \(D\) outputs.

Let \(\mu := (((\tilde{x}_1, \tilde{z}_1), R_1), \ldots, ((\tilde{x}_N, \tilde{z}_N), R_N))\). If \(ot_2\) is generated as \(ot_2 \xrightarrow{*} \text{Sender}(\text{crs}_\text{OT}, ot_1, \mu)\), then \(A\) perfectly simulates the execution of \(D^<(\text{td}_\text{DM}, \cdots, \cdot)(\text{crs}_\text{DM})\) conditioned on the fixed \((\tilde{x}, \tilde{z})\) and \(\{R_j\}_{j \in [N]}\). On the other hand, if \(ot_2\) is generated as \(J := \text{Open}_{\text{rec}}(\text{td}_\text{OT}, ot_1)\) and \(ot_2 \xrightarrow{*} \text{Sim}_{\text{sen}}(\text{crs}_\text{OT}, ot_1, J, \mu_j)\), then \(A\) perfectly simulates the execution of \(D^<(\text{td}_\text{DM}, \cdots, \cdot)(\text{crs}_\text{DM})\) conditioned on the fixed \((\tilde{x}, \tilde{z})\) and \(\{R_j\}_{j \in [N]}\). Therefore, averaging over the random choice of \((\tilde{x}, \tilde{z})\) and \(\{R_j\}_{j \in [N]}\), the l.h.s. of Equation (1) can be upper bounded by the average of the advantage of \(A\) to distinguish the two cases, which is negligible by the assumption. This completes the proof of Claim 5.14.

\(\Box\)

**Claim 5.15.** If \(\Pi_{\text{OT}}\) satisfies the first item of statistical sender’s security in the hiding mode, We have

\[
\Pr \left[ D^<(\text{crs}_\text{DM}, \text{td}_\text{DM}, \cdots, \cdot)(\text{crs}_\text{DM}) = 1 : (\text{crs}_\text{DM}, \text{td}_\text{DM}) \xrightarrow{*} \text{Sim}_0(1^\lambda) \right] - \Pr \left[ D^P(\text{crs}_\text{DM}, \text{td}_\text{DM}, \cdots, \cdot)(\text{crs}_\text{DM}) = 1 : \text{crs}_\text{DM} \xrightarrow{*} \text{CRSGen}_\text{DM}(1^\lambda, \text{hiding}) \right] \leq \text{negl}(\lambda)
\]

**Proof of Claim 5.15.** For any \((\text{crs}_\text{DM}, \text{td}_\text{DM}) \xrightarrow{*} \text{Sim}_0(1^\lambda), kp, x, \text{and } w\), we have

\[O_S^<(\text{td}_\text{DM}, kp, x, w) = O_P(\text{crs}_\text{DM}, kp, x, w)\]

observing that \(\text{Sim}_1^{(2)}\) works in the exactly the same way as the honest proving algorithm. Moreover, we can see that the distributions of \(\text{crs}_\text{DM}\) generated by \(\text{Sim}_0(1^\lambda)\) and \(\text{CRSGen}_\text{DM}(1^\lambda, \text{hiding})\) are statistically indistinguishable by the first item of statistical sender’s security in the hiding mode of \(\Pi_{\text{OT}}\). Therefore Claim 5.15 follows.

\(\Box\)

By combining Claims 5.13 to 5.15, We can complete the proof of Lemma 5.12.

\(\Box\)

A More Explanation on Lemma 2.8

Here, we explain how to obtain Lemma 2.8 based on [BG20]. Let \( L \) be any \( \text{QMA} \) language, and \( V = U_T \ldots U_1 \) be its verification circuit, where each \( U_i \) is an elementary gate taken from a universal gate set. For \( x \in L \), there exists a witness state \( |\psi\rangle \) such that \( V \) accepts with probability exponentially close to 1, whereas for \( x \notin L \), any state makes \( V \) accept with probability exponentially small.

As is explained in [BG20], we consider the encoded version of the verification circuit \( V' \) with a certain quantum error correcting code. The circuit \( V' \) consists of gates from the universal gate set \( \{\text{CNOT}, T, H, X, Z\} \). From the standard circuit-to-Hamiltonian construction technique, we can construct a local Hamiltonian \( H_x := \sum_i H_i \) corresponding to \( V' \). If there is a witness state \( |\psi\rangle \) that makes \( V' \) accept with probability \( 1 - \text{negl}(|x|) \), then the history state

\[
\frac{1}{\sqrt{T+1}} \sum_{t \in [T+1]} |0^{T-t+1}\rangle \otimes U_t \ldots U_1 (\text{Enc}(|\psi\rangle) \otimes |0^4\rangle)
\]

has exponentially small energy. Due to the local simulatability, there is an efficient deterministic algorithm that outputs the classical description of a state that is close to the reduced density matrix of the history state on at most five qubits [BG20, GSY19]. If every quantum state \( |\psi\rangle \) makes \( V' \) reject with probability at least \( \epsilon \), then the ground energy of \( H \) is at least \( \Omega(\frac{1}{\epsilon^2}) \).

Let \( H_x = \sum_{i=1}^M c_i P_i \) be the local Hamiltonian, where \( M = \text{poly}(|x|) \), \( c_i \) is real, and \( P_i \) is a tensor product of Pauli operators \( (I, X, Y, Z) \). In the standard circuit-to-Hamiltonian construction, each \( P_i \) is a tensor product of at most five non-trivial Pauli operators \( (X, Y, Z) \). As is shown in [MNS18], this Hamiltonian can be changed to the form of \( \sum_{i=1}^M p_i \frac{I + s_i P_i}{2} \) with \( M = \text{poly}(|x|) \), \( s_i \in \{+1, -1\} \), \( p_i > 0 \), \( \sum_{i=1}^M p_i = 1 \), and \( P_i \) is a tensor product of Pauli operators \( (X, Y, Z) \) with at most five non-trivial Pauli operators \( (X, Y, Z) \). In fact, define the normalized Hamiltonian

\[
H'_x := \frac{1}{2} \left( I + \frac{H_x}{\sum_{i=1}^M |c_i|} \right) = \sum_{i=1}^M \frac{|c_i|}{\sum_{i=1}^M |c_i|} \left( I + \text{sign}(c_i) P_i \right),
\]

and we have only to take \( p_i := \frac{|c_i|}{\sum_{i=1}^M |c_i|} \) and \( s_i := \text{sign}(c_i) \).

B Proofs of Lemmas 3.2 and 4.2

Here, we give an alternative direct proof of Lemma 3.2, and more details for the proof of Lemma 4.2.
B.1 Alternative Proof of Lemma 3.2

We first show the soundness. Let us define $H^h = \prod_{j=1}^N H^h_j$ and $|m\rangle := \bigotimes_{j=1}^N |m_j\rangle$. Let $\{\Lambda_{x,z,x}\}_{x,z,x}$ be the POVM that the adversary $A$ does on $k_P$. Then,

$$\Pr \left[ x \notin L \wedge \text{Verify}(k_V, x, \pi) = \top : (k_P, k_V) \xleftarrow{\$} \text{Setup}(1^\lambda), (x, \pi) \xleftarrow{\$} A(k_P) \right]$$

$$= \frac{1}{2} \sum_{h \in \{0, 1\}} \frac{1}{2N} \sum_{m \in \{0, 1\}^N} \sum_{x, z \notin L} \sum_{x' \notin L} \frac{\langle m | H^h \Lambda_{x,z,x} H^h | m \rangle}{\sum_{j_1, j_2} p_{x_1, j_2} \frac{1 - s_{x_1, j_2}(-1)^{m_{j_1} \oplus m_{j_2}}}{2}}$$

$$= \frac{1}{2} \sum_{h \in \{0, 1\}} \frac{1}{2N} \sum_{m \in \{0, 1\}^N} \sum_{x, z \notin L} \sum_{x' \notin L} \sum_{j_1, j_2} p_{x_1, j_2} \frac{\langle m | H^h \Lambda_{x,z,x} H^h | m \rangle}{2}$$

$$= \frac{1}{2} \sum_{h \in \{0, 1\}} \frac{1}{2N} \sum_{x, z \notin L} \sum_{x' \notin L} \frac{\sum_{j_1, j_2} p_{x_1, j_2} \text{Tr} \left[ H^h \Lambda_{x,z,x} H^h H^h X^z Z^z H^h \frac{I - s_{x_1, j_2} Z^z j_2}{2} H^h Z^x X^h | m \rangle \right]}{2}$$

$$\leq \frac{1}{2} \sum_{x, z \notin L} \sum_{x' \notin L} \frac{\sum_{j_1, j_2} p_{x_1, j_2} \text{Tr} \left[ Z^x X^z \Lambda_{x,z,x} X^z Z^z (I - H_X) \right]}{2}$$

$$\leq 1 - \frac{\sigma}{\text{Tr} \sigma} (1 - H_X)$$

$$\leq 1 - \frac{\sigma}{\text{Tr} \sigma} H_X$$

where $\sigma := \frac{1}{2N} \sum_{x, z} \sum_{x' \notin L} Z^z X^z \Lambda_{x,z,x} X^z Z^z$. Note that $\frac{\sigma}{\text{Tr} \sigma}$ is a quantum state for any POVM $\{\Lambda_{x,z,x}\}_{x,z,x}$.

Next we show the completeness. The POVM corresponding to Prove is $\{\Lambda_{x,z} = \frac{1}{2N} Z^x X^z \rho_{\text{hist}} X^x Z^x \}_x$. Note that this is a POVM, because $\Lambda_{x,z} \geq 0$, and

$$\sum_{x, z} \Lambda_{x,z} = 2^N \times \frac{1}{2N} \sum_{x, z} Z^x X^z \rho_{\text{hist}} X^x Z^x Z^z = 2^N \frac{I}{2^N} = I.$$

The reason why such $\{\Lambda_{x,z}\}_{x,z}$ is the POVM done by Prove algorithm is as follows. The Prove algorithm first prepares $\rho_{\text{hist}} \otimes H^h |m\rangle \langle m | H^h$, and then measures $j$th qubit of the history state and the $j$th qubit of $H^h |m\rangle$ in the Bell basis for all $j = 1, 2, ..., N$. Then,

$$\Pr \left[ \text{Verify}(k_V, x, \pi) = \top : (k_P, k_V) \xleftarrow{\$} \text{Setup}(1^\lambda), (x, \pi) \xleftarrow{\$} \text{Prove}(k_P, x, \omega^{\otimes k}) \right]$$

$$= \frac{1}{2N} \sum_{x, z} \text{Tr} \left[ Z^x X^x \left( \frac{1}{2N} Z^x X^x \rho_{\text{hist}} X^x Z^x \right) X^x Z^x (I - H_X) \right]$$

$$= \Pr \left[ \rho_{\text{hist}} (I - H_X) \right]$$

$$\geq 1 - \alpha.$$
B.2 More details for the proof of Lemma 4.2

Here we give more details of the completeness and the soundness of the virtual protocol 2. In the virtual protocol 2, $i \in [M]$ is chosen after $S_V$ and $(W_1, ..., W_N)$ are chosen, but we can assume that $i$ is chosen before $S_V$ and $(W_1, ..., W_N)$ are chosen, because they are independent. When $P_i$ is not consistent to $(S_V, \{W_j\}_{j \in S_V})$ or the coin heads, the measurement result on $\rho'_V$ is not used. The probability that such cases happen is

$$\sum_{i=1}^{M} p_i \left( \Pr[\text{not consistent}|i] + \Pr[\text{consistent}|i](1 - 3^{S_i-5}) \right)$$

$$= \sum_{i=1}^{M} p_i \left( 3^N \sum_{j=1}^{5} \binom{N}{j} - 3^N - |S_i| \right) \frac{3^N - |S_i|}{3^N \sum_{j=1}^{5} \binom{N}{j} \left( 1 - 3^{S_i-5} \right)}$$

$$= \sum_{i=1}^{M} p_i \left( 1 - \frac{1}{3^5 \sum_{j=1}^{5} \binom{N}{j}} \right)$$

$$= 1 - \frac{1}{3^5 \sum_{j=1}^{5} \binom{N}{j}}$$

$$= 1 - \frac{1}{N'}.$$

The probability that it is consistent and the coin tails is therefore $\frac{1}{N'}$. In this case, the measurement result on $\rho'_V$ is used. The probability that the measurement result satisfies $(-1)^{\bigoplus_{j \in S_i} m'_j} = -s_i$ is from Lemma 2.5,

$$\sum_{i=1}^{M} p_i \text{Tr}\left[ \left( I - \frac{I + s_i P_i}{2} \right) \rho'_V \right] = 1 - \text{Tr}(H_x \rho'_V).$$

The total acceptance probability is therefore

$$1 - \frac{1}{N'} + \frac{1}{N'} \left[ 1 - \text{Tr}(H_x \rho'_V) \right] = 1 - \frac{\text{Tr}(H_x \rho'_V)}{N'}.$$

C Alternative Simpler Construction of CV-NIZK in the Secret Parameter Model.

Here, we give an alternative construction of a CV-NIZK for QMA, which is slightly simpler than the construction given in Section 4.

Our construction of a CV-NIZK for a QMA language $L$ is given in Figure 8 where $H_x$, $N$, $M$, $p_i$, $s_i$, $P_i$, $\alpha$, $\beta$, and $\rho_{\text{hist}}$ are as in Lemma 2.7 for the language $L$.

We have the following lemmas.

**Lemma C.1** (Completeness and Soundness). $\Pi'_{\text{NIZK}}$ satisfies $(1 - \frac{\alpha}{N'})$-completeness and $(1 - \frac{\beta}{N'})$-soundness where $N' := 3^5 \sum_{i=1}^{5} \binom{N}{i'}$.

**Lemma C.2** (Zero-Knowledge). $\Pi'_{\text{NIZK}}$ satisfies the zero-knowledge property.

They can be proven similarly to Lemmas 4.2 and 4.3, respectively.
Setup(1^λ): The setup algorithm chooses \((W_1, \ldots, W_N, m_1, \ldots, m_N) \leftarrow \ast (X, Y, Z)^N \times \{0, 1\}^N\) and a uniformly random subset \(S_V \subseteq [N]\) such that \(1 \leq |S_V| \leq 5\), and outputs a proving key \(k_P := \bigotimes_{j=1}^N (U(W_j)|m_j))\) and a verification key \(k_V := (S_V, \{W_j, m_j\}_{j \in S_V})\).

Prove\((k_P, x, w)\): The proving algorithm generates the history state \(\rho_{\text{hist}}\) for \(\mathcal{H}_x\) from \(w\) and measures \(j\)-th qubits of \(\rho_{\text{hist}}\) and \(k_P\) in the Bell basis for \(j \in [N]\). Let \(x := x_1\|x_2\| \ldots\|x_N\), and \(z := z_1\|z_2\| \ldots\|z_N\) where \(x_j, z_j\) denotes the outcome of \(j\)-th measurement. It outputs a proof \(\pi := (x, z)\).

Verify\((k_V, x, \pi)\): The verification algorithm parses \((S_V, \{W_j, m_j\}_{j \in S_V}) \leftarrow k_V\) and \((x, z) \leftarrow \pi\), chooses \(i \in [M]\) according to the probability distribution defined by \([p_i]_{i \in [M]}\) (i.e., chooses \(i\) with probability \(p_i\)). Let

\[
S_i := \{j \in [N] \mid j\text{th Pauli operator of } P_i \text{ is not } I\}.
\]

We note that we have \(1 \leq |S_i| \leq 5\) by the 5-locality of \(\mathcal{H}_x\). We say that \(P_i\) is consistent to \((S_V, \{W_j\}_{j \in S_V})\) if and only if \(S_i = S_V\) and the \(j\)th Pauli operator of \(P_i\) is \(W_j\) for all \(j \in S_i\). If \(P_i\) is not consistent to \((S_V, \{W_j\}_{j \in S_V})\), it outputs \(\top\). If \(P_i\) is consistent to \((S_V, \{W_j\}_{j \in S_V})\), it flips a biased coin that heads with probability \(1 - 3^{1|S_i|} - 5\). If heads, it outputs \(\top\). If tails, it defines

\[
m'_j := \begin{cases} m_j \oplus x_j & (W_j = Z), \\ m_j \oplus z_j & (W_j = X), \\ m_j \oplus x_j \oplus z_j & (W_j = Y) \end{cases}
\]

for \(j \in S_i\), and outputs \(\top\) if \((-1)^{\bigoplus_{j \in S_i} m'_j} = -s_i\) and \(\bot\) otherwise.

---

**D Construction of Dual-Mode k-out-of-n Oblivious Transfer**

In this section, we prove Lemma 5.7. That is, we give a construction of a dual-mode \(k\)-out-of-\(n\) oblivious transfer defined in Definition 5.6 based on the LWE assumption.

**D.1 Building Block**

We introduce dual-mode encryption that is used as a building block for our construction. We refer to [PVW08] for the intuition of this primitive.

**Definition D.1 (Dual-Mode Encryption [PVW08, Qua20]^{13}).** A dual-mode encryption scheme over the message space \(\mathcal{M}\) consists of PPT algorithms \(\Pi_{\text{Enc}} = (\text{Setup}, \text{KeyGen}, \text{Enc}, \text{Dec}, \text{FindMessy}, \text{TrapKeyGen})\) with the following syntax.

Setup(\(1^\lambda, \text{mode}\)): The setup algorithm takes the security parameter \(1^\lambda\) and a mode \(\text{mode} \in \{\text{messy, dec}\}\) as input, and outputs a common reference string \(\text{crs}\) and a trapdoor \(\text{td}_\text{mode}\).

---

\(^{13}\)This definition is based on the definition in [Qua20], which has several minor differences from that in [PVW08].
KeyGen(crs, σ): The key generation algorithm takes the common reference string crs and a branch value σ ∈ \{0, 1\} as input, and outputs a public key pk and a secret key sk.

Enc(crs, pk, b, µ): The encryption algorithm takes the common reference string crs, a public key pk, a branch value b ∈ \{0, 1\}, and a message µ ∈ M as input, and outputs a ciphertext ct.

Dec(crs, sk, ct): The decryption algorithm takes the common reference string crs, a secret key sk, and a ciphertext ct as input, and outputs a message µ ∈ M.

FindMessy(crs, td\text{messy}, pk): The messy branch finding algorithm takes the common reference string crs, a trapdoor td\text{messy} in the messy mode, and a public key pk as input, and outputs a branch value b ∈ \{0, 1\}.

TrapKeyGen(crs, td\text{dec}): The trapdoor key generation algorithm takes the common reference string crs and a trapdoor td\text{dec} in the decryption mode as input, and outputs a public key pk₀ and two secret keys sk₀ and sk₁ that correspond to branches 0 and 1, respectively.

We require $\Pi_{\text{Dec}}$ to satisfy the following properties.

**Correctness for Decryptable Branch** For all mode ∈ \{messy, dec\}, σ ∈ \{0, 1\}, and µ ∈ M, we have

$$\Pr \left[ \text{Dec}(\text{crs}, \text{sk}_{\sigma}, \text{ct}, \mu) = \mu : (\text{pk}, \text{sk}_{\sigma}) \leftarrow \text{Setup}(\lambda, \text{mode}) \right] \geq 1 - \operatorname{negl}(\lambda).$$

**Statistical Security in the Messy Mode** With overwhelming probability over (crs, td\text{messy}) \leftarrow \text{Setup}(\lambda, \text{messy}), for all possibly malformed pk, all messages µ₀, µ₁ ∈ \{0, 1\}^\ell, and all unbounded-time distinguisher D, we have

$$\Pr \left[ D(\text{ct}) = 1 : b \leftarrow \text{FindMessy}(\text{crs}, \text{td}_{\text{messy}}, \text{pk}) \right] - \Pr \left[ D(\text{ct}) = 1 : b \leftarrow \text{Enc}(\text{crs}, \text{pk}, b, \mu_0) \right] \leq \operatorname{negl}(\lambda).$$

**Statistical Security in the Decryption Mode** With overwhelming probability over (crs, td\text{dec}) \leftarrow \text{Setup}(\lambda, \text{dec}), for all σ ∈ \{0, 1\} and all unbounded-time distinguisher D, we have

$$\Pr \left[ D(\text{pk}, \text{sk}_{\sigma}) = 1 : (\text{pk}, \text{sk}_{\sigma}) \leftarrow \text{KeyGen}(\text{crs}, \sigma) \right] - \Pr \left[ D(\text{pk}, \text{sk}_{\sigma}) = 1 : (\text{pk}, \text{sk}_0, \text{sk}_1) \leftarrow \text{TrapKeyGen}(\text{crs}, \text{td}_{\text{dec}}) \right] \leq \operatorname{negl}(\lambda).$$

**Computational Mode Indistinguishability** For any non-uniform QPT distinguisher D, we have

$$\Pr \left[ D(\text{crs}) = 1 : (\text{crs}, \text{td}_{\text{messy}}) \leftarrow \text{CRSGen}(\lambda, \text{messy}) \right] - \Pr \left[ D(\text{crs}) = 1 : (\text{crs}, \text{td}_{\text{dec}}) \leftarrow \text{CRSGen}(\lambda, \text{dec}) \right] \leq \operatorname{negl}(\lambda).$$
CRSGen\(_{1\rightarrow n}(1^\lambda, \text{mode})\): Let mode\(_'\) := dec if mode = binding and mode\(_'\) := messy if mode = hiding. Then it generates (crs, td\(_{\text{mode'}}\)) \(\leftarrow\) Setup\((1^\lambda, \text{mode'})\) and outputs crs.

Receiver\(_{1\rightarrow n}(\text{crs}, j)\): It generates \((pk_i, sk_{i, \sigma_i}) \leftarrow\) KeyGen(crs, \(\sigma_i\)) for all \(i \in [N]\) where \(\sigma_j := 1\) and \(\sigma_i := 0\) for all \(i \in [n] \setminus \{j\}\). It outputs \(ot_1 := \{pk_i\}_{i \in [n]}\) and \(st := (j, \{\sigma_i, sk_{i, \sigma_i}\}_{i \in [n]}\).

Sender\(_{1\rightarrow n}(\text{crs}, \ot_1, \mu)\): It parses \(\{pk_i\}_{i \in [n]} \leftarrow\) \(ot_1\) and \((\mu_1, ..., \mu_n) \leftarrow\) \(\mu\), generates \((r_1, ..., r_{N-1}) \leftarrow\) \(\{0, 1\}^{\ell \times (N-1)}\), sets \(\mu_{i,0}' := \mu_i \oplus r_{i-1}\) and \(\mu_{i,1}' := r_i \oplus r_{i-1}\) for all \(i \in [n]\) where \(r_0\) is defined to be 0\(\ell\). Then it generates \(ct_{i,b} \leftarrow\) Enc\((pk_i, b, \mu_{i,b}'\)) for all \(i \in [n]\) and \(b \in \{0, 1\}\), and outputs \(ot_2 := \{ct_i, b\}_{i \in [n], b \in \{0, 1\}}\).

Derive\(_{1\rightarrow n}(st, ot_2)\): It parses \((j, \{\sigma_i, sk_{i, \sigma_i}\}_{i \in [n]}\) \(\leftarrow\) \(st\) and \(\{ct_{i, b}\}_{i \in [n], b \in \{0, 1\}} \leftarrow\) \(ot_2\), computes \(\mu_{i, \sigma_i}' \leftarrow\) Dec\((sk_{i, \sigma_i}, ct_{i, \sigma_i}\)) for all \(i \in [j]\) and outputs \(\mu_j := \bigoplus_{i=1}^j \mu_{i, \sigma_i}'\).

Figure 9: Our 1-out-of-\(n\) oblivious transfer \(\Pi_{1\rightarrow n}\)

Quach \cite{Quach20} gave a construction of a dual-mode encryption scheme based on the LWE assumption.

Lemma D.2 (\cite{Quach20}). If the LWE assumption holds, then there exists a dual-mode encryption scheme.

Remark 7. Peikert, Vaikuntanathan, and Waters \cite{PVW08} gave a construction of a relaxed variant of dual-mode encryption scheme based on the LWE assumption. Their construction is more efficient than that of Quach \cite{Quach20} since they only rely on LWE with polynomial size modulus whereas Quach’s construction relies on LWE with super-polynomial modulus. However, their scheme does not suffice for our purpose due to the following two reasons.

1. The security in the decryption mode holds only against computationally bounded adversaries.
2. crs can be reused only for bounded number of times.

D.2 1-out-of-\(n\) Oblivious Transfer

In this section, we construct a dual-mode 1-out-of-\(n\) oblivious transfer based on dual-mode encryption. That is, we prove the following lemma.

Lemma D.3. If there exists a dual-mode encryption scheme, then there exists a dual-mode 1-out-of-\(n\) oblivious transfer.

Let \(\Pi_{\text{Enc}} = (\text{Setup, KeyGen, Enc, Dec, FindMessy, TrapKeyGen})\) be a dual-mode encryption scheme over the message space \(\mathcal{M} = \{0, 1\}^\ell\). Then our construction of a dual-mode 1-out-of-\(n\) oblivious transfer \(\text{OT}_{1\rightarrow n} = (\text{CRSGen}_{1\rightarrow n}, \text{Receiver}_{1\rightarrow n}, \text{Sender}_{1\rightarrow n}, \text{Derive}_{1\rightarrow n})\) over the message space \(\mathcal{M}\) is given in Figure 9. This can be seen as a protocol obtained by applying the conversion of \cite{BCR86} to the dual-mode 1-out-of-2 oblivious transfer of \cite{Quach20}.

Then we prove the following lemmas.

Lemma D.4. \(\Pi_{1\rightarrow n}\) satisfies correctness
Proof. This easily follows from correctness of $\Pi_{DEnc}$.

Lemma D.5. $\Pi_{1-n}$ satisfies the computational mode indistinguishability.

Proof. This can be reduced to the computational mode indistinguishability of $\Pi_{DEnc}$ in a straightforward manner.

Lemma D.6. $\Pi_{1-n}$ satisfies statistical receiver’s security in the binding mode.

Proof. We construct $\text{Sim}_{rec}$ as follows.

$\text{Sim}_{rec}(\text{crs})$: It generates $(\text{pk}_i, \text{sk}_i, 0) \xleftarrow{\$} \text{KeyGen}(\text{crs}, 0)$ for all $i \in [n]$, and outputs $\ot_1 := \{\text{pk}_i\}_{i \in [n]}$.

By statistical security in the decryption mode of $\Pi_{DEnc}$, with overwhelming probability over $(\text{crs}, \text{td}_{dec}) \xleftarrow{\$} \text{Setup}(1^\lambda, \text{dec})$, the distribution of $\text{pk}$ generated as $(\text{pk}, \text{sk}_\sigma) \xleftarrow{\$} \text{KeyGen}(\text{crs}, \sigma)$ for any fixed $\sigma \in \{0, 1\}$ is statistically close to that generated as $(\text{pk}, \text{sk}_0, \text{sk}_1) \xleftarrow{\$} \text{TrapKeyGen}(\text{crs}, \text{td}_{dec})$, which does not depend on $\sigma$. Therefore, the distributions of $\text{pk}_i$ generated by $\text{Sim}_{rec}(\text{crs})$ and $\text{Receiver}(\text{crs}, j)$ are statistically close for any $j \in [n]$. Then statistical receiver’s security in the binding mode of $\Pi_{1-n}$ follows by a standard hybrid argument.

Lemma D.7. $\Pi_{1-n}$ satisfies the statistical sender’s security in the hiding mode.

Proof. We construct $\text{Sim}_{CRS}$, $\text{Open}_{rec}$, and $\text{Sim}_{sen}$ as follows.

$\text{Sim}_{CRS}(1^\lambda)$: It generates $(\text{crs}, \text{td}_{messy}) \xleftarrow{\$} \text{Setup}(1^\lambda, \text{messy})$ and outputs $\text{crs}$ and $\text{td} := \text{td}_{messy}$.

$\text{Open}_{rec}(\text{td, ot}_1)$: It parses $\text{td}_{messy} \leftarrow \text{td}$ and $\{\text{pk}_i\}_{i \in [n]} \leftarrow \text{ot}_1$, computes $\sigma_i \xleftarrow{\$} \text{FindMessy}$(\text{td}_{messy}, \text{pk}_i)$ for all $i \in [n]$, and outputs the minimal $j \in [n]$ such that $\sigma_j = 1$.

$\text{Sim}_{sen}(\text{crs, ot}_1, j, \mu)$: It generates $\mu_i \xleftarrow{\$} \mathcal{M}$ for $i \in [n] \setminus \{j\}$, and outputs $\ot_2 \xleftarrow{\$} \text{Sender}_{1-n}(\text{crs, ot}_1, (\mu_1, ..., \mu_n))$.

The first item of statistical sender’s security in the hiding mode is clear because $\text{Sim}_{CRS}(1^\lambda)$ generates $\text{crs}$ in exactly the same manner as $\text{CRSGenerate}(1^\lambda, \text{hiding})$. In the following, we prove the second item is also satisfied. For any unbounded-time adversary $A = (A_0, A_1)$ and fixed $\mu = (\mu_1, ..., \mu_n)$, we consider the following sequence of games between $A$ and the challenger. We denote by $E_i$ the event that $A_i$ returns 1 in Game$_i$.

Game$_1$: This game works as follows.

1. The challenger generates $(\text{crs}, \text{td}_{messy}) \xleftarrow{\$} \text{Setup}(1^\lambda, \text{messy})$ and sets $\text{td} := \text{td}_{messy}$.
2. $A_0$ takes $(\text{crs}, \text{td})$ as input and outputs $\ot_1 := \{\text{pk}_i\}_{i \in [n]}$ and $\text{st}_A$.
3. The challenger computes $j := \text{Open}_{rec}(\text{td, ot}_1)$. That is, it computes $\sigma_i \xleftarrow{\$} \text{FindMessy}(\text{td}_{messy}, \text{pk}_i)$ for all $i \in [n]$ and let $j$ be the minimal value such that $\sigma_j = 1$.
4. The challenger sets $\tilde{\mu}_j := \mu_j$, generates $\tilde{\mu}_i \xleftarrow{\$} \mathcal{M}$ for $i \in [n] \setminus \{j\}$ and $(r_1, ..., r_{N-1}) \xleftarrow{\$} \{0, 1\}^{(N-1)}$, and sets $\mu'_{i, 0} := \tilde{\mu}_i \oplus r_{i-1}$ and $\mu'_{i, 1} := r_i \oplus r_{i-1}$ for all $i \in [n]$ where $r_0$ is defined to be 0. Then it generates $\text{ct}_{i, b} := \text{Enc}(\text{pk}_i, b, \mu'_{i, b})$ for all $i \in [n]$ and $b \in \{0, 1\}$ and sets $\ot_2 := \{\text{ct}_{i, b}\}_{i \in [n], b \in \{0, 1\}}$.
5. $A_1$ takes $\text{st}_A$ and $\ot_2$ as input and outputs a bit $\beta$. 

43
CRSGen_{k,n}(1^\lambda, \text{mode}): It generates crs \leftarrow CRSGen_{1,n}(1^\lambda, \text{mode}) and outputs crs.

Receiver_{k,n}(crs, J): It parses \( (j_1, \ldots, j_k) \leftarrow J \), generates \( (ot_{1,i}, st_i) \leftarrow \text{Receiver}_{1,n}(crs, j_i) \) for all \( i \in [k] \), and outputs \( ot_1 := \{ot_{1,i}\}_{i \in [k]} \) and \( st := \{st_i\}_{i \in [k]} \).

Sender_{k,n}(crs, ot_1, \mu): It parses \( \{ot_{1,i}\}_{i \in [k]} \leftarrow ot_1 \), generates \( ot_{2,i} \leftarrow \text{Sender}_{1,n}(crs, ot_{1,i}, \mu) \) for all \( i \in [k] \), and outputs \( ot_2 := \{ot_{2,i}\}_{i \in [k]} \).

Derive_{k,n}(crs, st, ot_2): It parses \( \{st_i\}_{i \in [k]} \leftarrow st \), computes \( \mu_{j_i} \leftarrow \text{Derive}_{1,n}(crs, st_i, ot_{2,i}) \) for \( i \in [k] \), and outputs \( (\mu_{j_1}, \ldots, \mu_{j_k}) \).

---

**Figure 10: Our k-out-of-n oblivious transfer \( \Pi_{k,n} \)**

**Game_2:** This game is identical to the previous game except that \( \mu'_{i,\sigma_i} \) is replaced with \( 0^\ell \) for all \( i \in [n] \).

By the statistical security in the messy mode of \( \Pi_{\text{DEnc}} \), it is easy to see that we have \( \Pr[\mathbb{E}_2] - \Pr[\mathbb{E}_1] \leq \text{negl}(\lambda) \).

**Game_3:** This game is identical to the previous game except that \( \mu'_{i,0} \) is replaced with an independently and uniformly random element of \( \mathcal{M} \) for all \( i > j \). We note that this game does not use \( \{\tilde{\mu}_i\}_{i \neq j} \) at all.

By an easy information theoretical argument, we can see that the distribution of \( \{\mu'_{i,b}\}_{i \in [n], b \in \{0,1\}} \) does not change from the previous game, and thus we have \( \Pr[\mathbb{E}_3] = \Pr[\mathbb{E}_2] \).

**Game_4:** This game is identical to the \( \text{Game}_1 \) except that the challenger uses \( \mu \) instead of \( \tilde{\mu} \).

By considering similar game hops to those from \( \text{Game}_1 \) to \( \text{Game}_2 \) in the reversed order, by the statistical security in the messy mode of \( \Pi_{\text{DEnc}} \), we have \( \Pr[\mathbb{E}_4] - \Pr[\mathbb{E}_3] \leq \text{negl}(\lambda) \).

Combining the above, we have \( \Pr[\mathbb{E}_4] - \Pr[\mathbb{E}_1] \leq \text{negl}(\lambda) \). This is exactly the second item of statistical sender’s security in the hiding mode. \( \square \)

By combining Lemmas D.4 to D.7, we obtain Lemma D.3.

### D.3 k-out-of-n Oblivious Transfer

In this section, we construct a dual-mode k-out-of-n oblivious transfer based on dual-mode 1-out-of-n oblivious transfer by \( k \) parallel repetitions. That is, we prove the following lemma.

**Lemma D.8.** If there exists a dual-mode 1-out-of-n oblivious transfer, then there exists a dual-mode k-out-of-n oblivious transfer.

By combining Lemmas D.2, D.3 and D.8, we obtain Lemma 5.7.

What is left is to prove Lemma D.8. Let \( \Pi_{1,n} = (\text{CRSGen}_{1,n}, \text{Receiver}_{1,n}, \text{Sender}_{1,n}, \text{Derive}_{1,n}) \) be a dual-mode 1-out-of-n oblivious transfer over the message space \( \mathcal{M} \). Then our dual-mode k-out-of-n oblivious transfer \( \Pi_{k,n} = (\text{CRSGen}_{k,n}, \text{Receiver}_{k,n}, \text{Sender}_{k,n}, \text{Derive}_{k,n}) \) is described in Figure 10.

Then we prove the following lemmas.
Lemma D.9. \( \Pi_{k,n} \) satisfies correctness.

Proof. This can be reduced to correctness of \( \Pi_{1,n} \) in a straightforward manner. \( \square \)

Lemma D.10. \( \Pi_{k,n} \) satisfies the computational mode indistinguishability.

Proof. This can be reduced to the computational mode indistinguishability of \( \Pi_{1,n} \) in a straightforward manner. \( \square \)

Lemma D.11. \( \Pi_{k,n} \) satisfies statistical receiver’s security in the binding mode.

Proof. Let \( \text{Sim}_{\text{rec},1,n} \) be the corresponding algorithm for statistical receiver’s security in the binding mode of \( \Pi_{1,n} \). Then We construct \( \text{Sim}_{\text{rec},k,n} \) for \( \Pi_{k,n} \) as follows.

\( \text{Sim}_{\text{rec},k,n}(\text{crs}): \) It parses \( (\text{crs}, \text{pk}) \leftarrow \text{crs} \), computes \( \text{ot}_{1,i} \leftarrow \text{Sim}_{\text{rec},1,n}(\text{crs}) \) for all \( i \in [k] \), and outputs \( \text{ot}_1 := \{\text{ot}_{1,i}\}_{i \in [k]} \).

Statistical receiver’s security in the binding mode of \( \Pi_{k,n} \) follows from that of \( \Pi_{1,n} \) by a straightforward hybrid argument. \( \square \)

Lemma D.12. Let \( \Pi_{k,n} \) satisfies the statistical sender’s security in the hiding mode.

Proof. Let \( \text{Sim}_{\text{CRS},1,n}, \text{Open}_{\text{rec},1,n}, \) and \( \text{Sim}_{\text{sen},1,n} \) be the corresponding algorithms for statistical sender’s security in the hiding mode of \( \Pi_{1,n} \). Then We construct \( \text{Sim}_{\text{CRS},k,n}, \text{Open}_{\text{rec},k,n}, \) and \( \text{Sim}_{\text{sen},k,n} \) for \( \Pi_{k,n} \) as follows.

\( \text{Sim}_{\text{CRS},k,n}(1^\lambda): \) This is exactly the same as \( \text{Sim}_{\text{CRS},1,n}(1^\lambda) \).

\( \text{Open}_{\text{rec}}(\text{td}, \text{ot}_1): \) It parses \( \{\text{ot}_{1,i}\}_{i \in [k]} \leftarrow \text{ot}_1 \), computes \( j_i := \text{Open}(\text{td}, \text{ot}_{1,i}) \) for all \( i \in [k] \), and outputs \( J = (j_1, ..., j_k) \).

\( \text{Sim}_{\text{sen}}(\text{crs}, \text{ot}_1, J, \mu_j): \) It parses \( (j_1, ..., j_k) \leftarrow J \) and \( (\mu_{j_1}, ..., \mu_{j_k}) \leftarrow \mu_j \), generates \( \mu_i \leftarrow \mathcal{M} \) for \( i \in [n] \setminus \{j_1, ..., j_k\} \), and outputs \( \text{ot}_2 \leftarrow \text{Sender}_{k,n}(\text{crs}, \text{ot}_1, (\mu_1, ..., \mu_n)) \).

The first item of statistical sender’s security in the hiding mode of \( \Pi_{k,n} \) immediately follows from that of \( \Pi_{1,n} \). In the following, we prove the second item. For any unbounded-time adversary \( \mathcal{A} = (\mathcal{A}_0, \mathcal{A}_1) \) and fixed \( \mu = (\mu_1, ..., \mu_n) \), we consider the following sequence of games between \( \mathcal{A} \) and the challenger. We denote by \( E_i \) the event that \( \mathcal{A}_1 \) returns 1 in Game\(_i\).

Game\(_i\): This game works as follows.

1. The challenger generates \( (\text{crs}, \text{td}) \leftarrow \text{Sim}_{\text{CRS},k,n}(1^\lambda) \).
2. \( \mathcal{A}_0 \) takes \( (\text{crs}, \text{td}) \) as input and outputs \( \text{ot}_1 = \{\text{ot}_{1,i}\}_{i \in [k]} \) and \( \text{st}_A \).
3. The challenger computes \( J := \text{Open}_{\text{rec},k,n}(\text{td}, \text{ot}_1) \). That is, it computes \( j_i := \text{Open}_{\text{rec},1,n}(\text{td}, \text{ot}_{1,i}) \) for all \( i \in [k] \) and lets \( J := (j_1, ..., j_k) \).
4. The challenger generates \( \text{ot}_{2,i} \leftarrow \text{Sim}_{\text{sen},1,n}(\text{crs}, \text{ot}_{1,i}, j_i, \mu_{j_i}) \) for \( i \in [k] \) and sets \( \text{ot}_2 := \{\text{ot}_{2,i}\}_{i \in [k]} \).
5. \( \mathcal{A}_1 \) takes \( \text{st}_A \) and \( \text{ot}_2 \) as input and outputs a bit \( \beta \).
**Game$_2$:** This game is identical to the previous game except that $\mathbf{ot}_{2,i}$ is generated as $\mathbf{ot}_{2,i} \leftarrow \text{Sender}(\text{crs}, \mathbf{ot}_{1,i}, \mu)$ for $i \in [k]$.

By the second item of statistical sender’s security in the hiding mode of $\Pi_{1,n}$, we have $|\Pr[E_2] - \Pr[E_1]| \leq \text{negl}(\lambda)$ by a standard hybrid argument. This is exactly the second item of statistical sender’s security in the hiding mode.

$\square$

By combining Lemmas D.9 to D.12, we obtain Lemma D.8.
