Dear Editors,

I am submitting a joint, with Dr. Marianna Pensky and my Ph.D. students, Xing Fan and Feng Yu, paper “ALMA: Alternating Minimization Algorithm for Clustering Mixture Multilayer Network” for publication in the JMLR.

The paper considers a Mixture Multilayer Stochastic Block Model (MMLSBM), where layers can be partitioned into groups of similar networks, and networks in each group are equipped with a distinct Stochastic Block Model. The present paper proposes an alternating minimization algorithm (ALMA) that aims at simultaneous recovery of the layer partition, together with estimation of the matrices of connection probabilities of the distinct layers. Compared to the TWIST method by Jing et al. (2020), ALMA achieves higher accuracy both theoretically and numerically.

This is an original paper which does not significantly overlap with any of our previous submissions and has not been submitted to any conference proceedings or journals. I confirm that all co-authors are aware of the current submission and consent to its review by JMLR. None of us has any conflict of interest with any of the JMLR editors.

We feel that the best matches among the action editors will be Boaz Nadler, Garvesh Raskutti, Prateek Jain, Suvrit Sra or Tong Zhang.

As for the possible reviewers, we suggest Dong Xia (madxia@ust.hk), Jing Lei (jinglei@andrew.cmu.edu), Alessandro Rinaldo (arinaldo@cmu.edu), Moulinath Banerjee (moulib@umich.edu), George Michailidis (gmichail@ufl.edu).

Sincerely yours

Teng Zhang
ALMA: Alternating Minimization Algorithm For Clustering Mixture Multilayer Network

Editor:

Abstract

The paper considers a Mixture Multilayer Stochastic Block Model (MMLSBM), where layers can be partitioned into groups of similar networks, and networks in each group are equipped with a distinct Stochastic Block Model. The goal is to partition the multilayer network into clusters of similar layers, and to identify communities in those layers. Jing et al. (2020) introduced the MMLSBM and developed a clustering methodology, TWIST, based on regularized tensor decomposition.

The present paper proposes a different technique, an alternating minimization algorithm (ALMA), that aims at simultaneous recovery of the layer partition, together with estimation of the matrices of connection probabilities of the distinct layers. Compared to TWIST, ALMA achieves higher accuracy both theoretically and numerically.

Keywords: Stochastic Block Model, Multilayer Network, Alternating Minimization, Clustering

1. Introduction

Stochastic networks arise in many areas of research and applications and are used, for example, to study brain connectivity or gene regulatory mechanisms, to monitor cyber and homeland security, and to evaluate and predict social relationships within groups or between groups, such as countries.

While in the early years of the field of stochastic networks, research mainly focused on studying a single network, in recent years the frontier moved to investigation of collection of networks, the so called multilayer network, which allows to model relationships between nodes with respect to various modalities (e.g., relationships between species based on food or space), or consists of network data collected from different individuals (e.g., brain networks). Although there are many
different ways of modeling a multilayer network (see, e.g., an excellent review article of Kivela et al. (2014)), in this paper we consider the case where all layers have the same set of nodes, and all edges between nodes are drawn within layers, i.e., there are no edges connecting the nodes in different layers. Many authors, who work in a variety of research fields, study this particular version of a multilayer network (see, e.g., Durante et al. (2017), Han and Dunson (2018), Aleta and Moreno (2019), Kao and Porter (2017) among others).

In this paper, we consider a multilayer network where all layers are equipped with the Stochastic Block Models. In this case, the problems of interest are finding groups of layers that are similar in some sense, finding the communities in those groups of layers and estimation of the tensor of connection probabilities. While the scientific community attacked all three of those problems, often in a somewhat ad-hoc manner (see e.g., Brodka et al. (2018), Kao and Porter (2017), Mercado et al. (2018) among others), the theoretically inclined papers in the field of statistics mainly been investigated the case where communities persist throughout all layers of the network. This includes studying the so called “checker board model” in Chi et al. (2020), where the matrices of block probabilities take only finite number of values, as well as the case where community structure persists but the matrix of probabilities of connections can take arbitrary values (see, e.g., Bhattacharyya and Chatterjee (2020), Paul and Chen (2020), Lei et al. (2019), Lei (2020), Paul and Chen (2016) and references therein). In the latter case, the common community structure is usually recovered by clustering of some type of adjusted average of adjacency matrices or their squares.

In many practical situations, however, the assumption of common community structures in all layers of the network may not be justified. Recently, Jing et al. (2020) investigated the so called “Mixture MultiLayer Stochastic Block Model” (MMLSBM), where all layers can be partition into a few different types, with each class of layers equipped with its own community structure and a distinct matrix of connection probabilities. In this paper, we focus on the MMLSBM and suggest a new algorithm for the layer partition and local communities recovery. While the methodology in Jing et al. (2020) is based on a regularized tensor decomposition, our procedure is centered around finding the groups of layers. Specifically, we propose a novel ALternating Minimization Algorithm (ALMA) which utilizes the fact that, for each layer of the network, the matrix of probabilities of connections can be approximated by a low-rank matrix. As a result, for the MMLSBM, our algorithm consistently recovers the layer labels and the memberships of nodes. Unlike the technique in Jing et al. (2020), ALMA does not require the assumption that the number of layers in the network is smaller than the number of nodes. Moreover, as our simulations and theoretical analysis show, ALMA achieves higher accuracy, both theoretically and numerically, than the algorithm of Jing et al. (2020). In addition, since this model is very general, our result can be applied to other commonly used models, such as co-clustering (Chi et al. (2020)).

Note that dynamic network models can be viewed as a particular case of the multilayer network model where there are no edges connecting the nodes in different layers. The difference between those models and the multilayer network is that, in a dynamic network, the layers are ordered according to time instances, while in a multilayer network the enumeration of layers is completely arbitrary. That is why, although there is a multitude of papers that study the change point detection in the dynamic SBMs (see, e.g., Bhattacharjee et al. (2018), Gangrade et al. (2018) and Wang et al. (2017) among others), the techniques and error bounds in those papers are not applicable in the situation of the MMLSBM.
The rest of the paper is organized as follows. Section 2 describes the MMLSBM and presents the necessary concepts and notations. Section 3 introduces the Alternating Minimization Algorithm (ALMA). Section 4 provides theoretical guarantees for between-layer and within-layer clustering errors. Specifically, the section starts with Section 4.1 that investigates the situation where ALMA is applied to the true probability tensor. Based on the results of this analysis, Section 4.2 provides assumptions which, as it is confirmed in Section 4.3, guarantee convergence of our algorithm. Finally, Section 4.4 produces upper bounds for between-layer and within-layer clustering errors. Section 4 is concluded by a discussion of various aspects of ALMA in Section 4.5. Section 5 brings up theoretical and numerical comparisons between the ALMA and the TWIST algorithm, proposed in Jing et al. (2020). The proofs of all statements in the paper are deferred to Section 6, Appendix.

2. Model framework

This work considers an $L$-layer network on the same set of $n$ vertices $\mathcal{V} = \{1, \cdots, n\}$. For any $1 \leq l \leq L$, the observed data is the adjacency matrix $A_l \in \mathbb{R}^{n \times n}$ of the $l$-th network, where $A_l(i,j) = A_l(j,i) = 1$ if a connection between nodes $i$ and $j$ is observed at the $l$-th network, and $A_l(i,j) = A_l(j,i) = 0$ otherwise. Assume that for all $1 \leq i < j \leq n$ and $1 \leq l \leq L$, $A_l(i,j)$ are the Bernoulli random variables with $\Pr(A_l(i,j) = 1) = P_{sl}(i,j)$, and they are independent with each other. The probability matrices $\{P_{sl}\}_{l=1}^L$ take $M$ different values ($M < L$), that is, there exists a partition of $[L] = \{1, \cdots, L\} = \bigcup_{m=1}^M S_m$ such that $P_{sl} = \tilde{Q}_{sm}$ for all $l \in S_m$. This means that there exists a clustering function $\pi : [L] \to [M]$ such that $\pi(l) = m$ if the $l$-th network is of the type $m$, or, equivalently, $l \in S_m$. Consider a set $\mathcal{F}_{LM}$ of the clustering matrices

$$\mathcal{F}_{LM} = \{Z \in \{0,1\}^{L \times M}, \quad Z^T 1 = 1\},$$

and $Z \in \mathcal{F}_{LM}$ such that $Z_i = 1$ if $l \in S_m$ and $Z_{l,m} = 0$ otherwise. It is easy to see that matrix $Z^T Z$ is diagonal, and $W = Z(Z^T Z)^{-1/2}$ satisfies $W^T W = I$.

Furthermore, we assume that each network can be described by a Stochastic Block Model (SBM). Specifically, we assume that, for each $m$ and any $l \in S_m$, $P_{sl} = \tilde{Q}_{sm}$ where $\tilde{Q}_{sm}$ is generated as follows: the nodes $\mathcal{V}$ are grouped into $K_m$ classes $G_{m,1}, \cdots, G_{m,K_m}$, and the probability of a connection $P_{sl}(i,j)$ is entirely determined by the groups to which the nodes $i$ and $j$ belong at $l$. In particular, if $i \in G_{m,k}$ and $j \in G_{m,k'}$, then $P_{sl}(i,j) = B_m(k,k')$, where $B_m \in \mathbb{R}^{K_m \times K_m}$ is the connectivity matrix with $B_m(k,k') = B_m(k',k)$.

In this case, one has

$$P_{sl} = \Theta_m B_m \Theta_m^T, \quad m = \pi(l), \quad \Theta_m \in F_{m,K_m},$$

(1)

where $\Theta_m(i,k) = 1$ if and only if node $i$ belongs to the class $G_{m,k}$ and is zero otherwise.

Denote $Q_{sm} = \sqrt{|S_m|} \tilde{Q}_{sm}$. Denote the three-way tensors with the $l$-th layer $A_l$ and $P_{sl}$ by, respectively, $A, P_s \in \mathbb{R}^{L \times n \times n}$, and the three-way tensor with the $m$-th layer $Q_{sm}$ by $Q_s \in \mathbb{R}^{M \times n \times n}$.

The objective of this work is to partition the multilayer network $\mathcal{A}$ into $M$ similar layers (between-layer clustering) and, furthermore, for each of these sets of layers, to recover communities $G_{m,1}, \cdots, G_{m,K_m}$, $m = 1, \cdots, M$ (within layer clustering). Specifically, we focus on the setting where $M$ and $\{K_m\}_{m=1}^M$ are fixed or grow slowly, while $n$ and $L$ tend to infinity, since usually networks are large but have relatively few similar groups of layers, and the number of communities is also usually small compared to the number of nodes.
2.1 Notations

For any tensor $X \in \mathbb{R}^{n_1 \times n_2 \times n_3}$ and a matrix $A \in \mathbb{R}^{n_1 \times m}$, their product $X \times_1 A$ is a tensor in $\mathbb{R}^{m \times n_2 \times n_3}$ defined by

$$[X \times_1 A](i_1, i_2, i_3) = \sum_{j=1}^{m} A(i_1, j) X(j, i_2, i_3)$$

Let $Y \in \mathbb{R}^{m \times n_2 \times n_3}$ be another tensor, the product between tensors $X$ and $Y$, denoted by $X \times_{1,2} Y$, is a matrix in $\mathbb{R}^{n_1 \times m}$ defined by

$$[X \times_{1,2} Y](i_1, i_2) = \sum_{j_2=1}^{n_2} \sum_{j_3=1}^{n_3} X(i_1, j_2, j_3) Y(i_2, j_2, j_3)$$

The Frobenius norm and the largest singular value of a tensor $X \in \mathbb{R}^{n_1 \times n_2 \times n_3}$ are defined by

$$\|X\|_F = \sqrt{\sum_{i_1, i_2, i_3=1}^{n_1, n_2, n_3} X(i_1, i_2, i_3)^2},$$

$$\sigma_1(X) = \|X\| = \max_{u \in \mathbb{R}^{n_i}, \|u\|=1} \|X \times_1 u\|_2 \times u_1 \times u_2 \times u_3.$$  

In addition, $M_1(X) \in \mathbb{R}^{n_1 \times n_2 \times n_3}$ is a matrix such that $[M_1(X)](l,:) = \text{vec}(X(l,:,:))$.

For any matrix $X$, denote the Frobenius and the operator norm of any matrix $X$ by $\|X\|_F$ and $\|X\|$, respectively, and its $r$-th largest singular value by $\sigma_r(X)$, and denote the projection onto its nearest orthogonal matrix by the operator $\Pi_o$:

$$\Pi_o(X) = X(X^TX)^{-1/2}. \quad (2)$$

Note that $\Pi_o(X)$ is an orthogonal matrix and has the same column space as $X$. Let $K = (K_1, \ldots, K_M)$, and denote

$$K_{\text{max}} = \max_{m=1,\ldots,M} K_m, \quad K_{\text{min}} = \min_{m=1,\ldots,M} K_m, \quad K = \sum_{m=1}^{M} K_m. \quad (3)$$

Denote the size of the smallest cluster in all networks by $g_{\text{min}}$, i.e., $g_{\text{min}} = \min_{1 \leq m \leq M} |G_{m,k}|$.

Next, we introduce a few operators that will be used later in the paper. For any tensor $X \in \mathbb{R}^{M \times n \times n}$, define a projector $\Pi_K : \mathbb{R}^{M \times n \times n} \to \mathbb{R}^{M \times n \times n}$ by

$$[\Pi_K(X)](m,:) = \Pi_{K_m}(X(m,:,:)), \quad m = 1, \ldots, M, \quad (4)$$

where $\Pi_{K_m} : \mathbb{R}^{n \times n} \to \mathbb{R}^{n \times n}$ is the projection onto the nearest rank $K_m$ matrix. Note that $\text{rank}(Q_*(m,:,:)) = K_m$, so if

$$Q_*(m,:,:) = U_m A U_m^T$$

is the SVD of $Q_*(m,:,:)$, then $U_m \in \mathbb{R}^{n \times K_m}$ is an orthogonal matrix that has the same column space as $Q_*(m,:,:)$. Denote $\Pi_{U_m} = I - U_m U_m^T$. Then, the projection onto the tangent plane of the manifold $\{X \in \mathbb{R}^{M \times n \times n} : \text{rank}(X(m,:,:)) = K_m\}$ at $Q_*$ is represented by the operator $\Pi_{T,K}$, which has the explicit formula Absil and Oseledets (2015):

$$[\Pi_{T,K}(X)](m,:) = X(m,:,:) - \Pi_{U_m} X(m,:,:) \Pi_{U_m}, \quad \Pi_{U_m} = I - U_m U_m^T, \quad m = 1, \ldots, M. \quad (5)$$

In addition, let $\Pi_{T,K_m} : \mathbb{R}^{L \times n \times n} \to \mathbb{R}^{L \times n \times n}$ be the projection onto the subspace spanned by $U_m$ for each “slice” of the tensor, i.e.,

$$[\Pi_{T,K_m}(X)](m',,:) = X(m,:,:) - \Pi_{U_{m'}} X(m,:,:) \Pi_{U_{m'}}, \quad m' = 1, \ldots, M,$$
3. Alternating Minimization Algorithm (ALMA)

As we observe the multi-layer networks \(\{A_l\}_{l=1}^L\), our objectives are

- **Between-layer clustering**: recover the network classes \(S_1, \ldots, S_M\) such that \([L] = \cup_{m=1}^M S_m\).
- **Within-layer clustering**: recover the community structures for each network class, i.e., for any \(m \in [M]\), find a partition of the vertices \(G_{m,1}, \ldots, G_{m,K_m}\).

To achieve these goals, we start with the estimation of \(Q_* \in \mathbb{R}^{M \times n \times n}\) and \(W_* \in \mathbb{R}^{L \times M}\) based on \(A\). Then, the between-layer clustering can be carried out by applying \(K\)-means algorithm to the rows of the estimator \(\hat{W}\) of matrix \(W_*\). Subsequently, the within-layer clustering of the \(m\)-th group of networks can be obtained by analyzing estimators \(\hat{Q}_*(m, :, :)\) of \(Q_*(m, :, :)\) for every \(m \in [M]\).

In order to estimate \(Q_*\) and \(W_*\), note that the tensor \(A\) can be considered as a noisy observation of \(P_*\), since \(E(A) = P_*\), where \(P_* = Q_* \times_1 W_*^T\), and \(W_*\) is an orthogonal matrix by definition. For this reason, we propose to find \(Q_*\) and \(W_*\) by solving the following optimization problem

\[
\begin{align*}
\arg\min_{Q,W} & \|A - Q \times_1 W\|_F \\
\text{s.t.} & \quad Q \in \mathbb{R}^{M \times n \times n}, W \in \mathbb{R}^{L \times M}, W^T W = I, \text{ rank}(Q(m, :, :)) \leq K_m \text{ for all } 1 \leq m \leq M.
\end{align*}
\]

We solve (6) by alternatively minimizing the objective function in (6) over \(Q\) and \(W\). When \(W\) is fixed, the solution to \(Q\) is given by \(Q = \Pi_K(A \times_1 W)\). When \(Q\) is fixed, the problem of minimizing \(\|A - Q \times_1 W\|_F\) over \(W\) under the assumption that \(W^T W = I\), is called the orthogonal Procrustes problem in literature (see, e.g., Gower and Dijksterhuis (2004)), and it has an explicit solution. Combining the two steps, we summarize this alternating minimization procedure in Algorithm 1.

**Algorithm 1** Alternating Minimization Algorithm (ALMA)

**Input:** Adjacency tensor \(A \in \mathbb{R}^{L \times n \times n}\); number of different types of networks \(M\); \(\{K_m\}_{m=1}^M\);

Initialization clustering matrix \(W^{(0)} \in \mathbb{R}^{L \times M}\) such that \(W^{(0)T} W^{(0)} = I\)

**Output:** A clustering matrix \(\hat{W} \in \mathbb{R}^{L \times M}\) such that \(\hat{W}^T \hat{W} = I\), and a tensor \(\hat{Q} \in \mathbb{R}^{M \times n \times n}\).

**Steps:**

1. Set iter = 1.
2. Let \(Q^{(iter)} = \Pi_K (A \times_1 W^{(iter-1)})\), where \(\Pi_K\) is a projector defined in (4).
3. Let \(W^{(iter)} = \Pi_o(A \times_2, 3 Q^{(iter)})\) where \(\Pi_o(X)\) is defined in (2).
4. Set iter = iter + 1.
5. Repeat steps 2-4 until \(\|W^{(iter)} - W^{(iter-1)}\|_F \leq \epsilon_{n,L}\) where \(\epsilon_{n,L}\) is a pre-specified threshold, or the number of iterations exceeds the upper limit: iter > \(N^{(iter)}\).
6. Set \(\hat{W} = W^{(iter-1)}, \hat{Q} = Q^{(iter-1)}\).

After obtaining \(\hat{W}\) and \(\hat{Q}\), we recover the groups of similar networks \(S_1, \ldots, S_M\) by clustering the rows of \(\hat{W}\) into \(M\) groups using the \((1 + \epsilon)\) approximate \(K\)-means algorithm. Finally, for clustering the nodes in each type of networks, we apply spectral clustering with \(\hat{Q}(m, :, :)\) being treated as the affinity matrix. Specifically, we first find the orthogonal matrix of size \(n \times K_m\) whose columns are the top \(K_m\) eigenvectors of \(\hat{Q}(m, :, :)\), and then cluster its rows into \(K_m\) groups using the \((1 + \epsilon)\) approximate \(K\)-means. There exist efficient algorithms for solving the \((1 + \epsilon)\) approximate \(K\)-means problem, see, e.g., Kumar et al. (2004).
4. Theoretical guarantees

4.1 Convergence of the iterative algorithm for the true probability tensor

This section studies the convergence of Algorithm 1. As a motivating example, we start with investigating the case where the algorithm is applied to the true probability tensor $P_s$ rather than $A$. Then, the associated optimization problem becomes

$$\arg\min_{Q,W} \|P_s - Q \times_1 W^T\|_F$$

subject to $Q \in \mathbb{R}^{M \times n \times n}$, $W \in \mathbb{R}^{L \times M}$, $W^T W = I$, $\text{rank}(Q(m,:,::)) \leq K_m$ for all $1 \leq m \leq M$.

Algorithm 1 yields

$$Q^{(iter)} = \Pi_K(P_s \times_1 W^{(iter-1)}), \quad W^{(iter)} = W_s \Pi_o(Q_s \times_{2,3} Q^{(iter)})$$

where the latter formula is obtained using $P_s = Q_s \times_1 W_s^T$, so that

$$W^{(iter)} = \Pi_o(P_s \times_{2,3} Q^{(iter)}) = \Pi_o(W_s(Q_s \times_{2,3} Q^{(iter)})) = W_s \Pi_o(Q_s \times_{2,3} Q^{(iter)}).$$

As a result, we can reformulate problem (7) by adding an assumption that $W = W_s V$ for some $V \in \mathbb{R}^{M \times M}$. Then (7) is simplified to

$$\arg\min_{Q,W} \|Q_s - Q \times_1 V^T\|_F$$

subject to $Q \in \mathbb{R}^{M \times n \times n}$, $V \in \mathbb{R}^{M \times M}$, $V^T V = I$, $\text{rank}(Q(m,:,::)) \leq K_m$ for all $1 \leq m \leq M$,

and the iterative relations (8) become

$$Q^{(iter)} = \Pi_K(Q_s \times_1 V^{(iter-1)}), \quad V^{(iter)} = \Pi_o(Q_s \times_{2,3} Q^{(iter)}).$$

The latter implies that, for the sets $S_1$ and $S_2$ in $\mathbb{R}^{M \times n \times n}$ defined by

$$S_1 = \{Q : \text{rank}(Q(m,:,::)) \leq K_m \text{ for all } 1 \leq m \leq M\},$$

$$S_2 = \{Q = Q_s \times_1 V : V \in \mathbb{R}^{M \times M}, V^T V = I\},$$

$Q^{(iter)}$ is the nearest point on $S_1$ to $Q_s \times_1 V^{(iter-1)}$, and $Q_s \times_{2,3} V^{(iter)}$ is the nearest point on $S_2$ to $Q^{(iter)}$. Hence, the update formula (10) can be viewed as an alternating projection between $S_1$ and $S_2$.

Denote the tangent planes to the sets $S_1$ and $S_2$ at $Q_s$ by $Q_s + L_1$ and $Q_s + L_2$, respectively, where $L_1$ and $L_2$ are linear subspaces that pass through the origin:

$$L_1 = \{Q \in \mathbb{R}^{M \times n \times n} : \Pi_{U_m} Q_s(m,:,::) \Pi_{U_m} = 0, \quad m = 1, \ldots, M\},$$

$$L_2 = \{Q = Q_s \times_1 X : X \in \text{Skew}_M\},$$

where Skew$_M$ represents the set of skew-symmetric matrices of size $M \times M$. The explicit formula for $L_1$ follows from Absil and Oseledets (2015), and the explicit formula for $L_2$ follows from the fact that the tangent plane to the set of orthogonal matrices $\{V \in \mathbb{R}^{M \times M} : V^T V = I\}$ at $I$ is the set of skew-symmetric matrices (see, e.g., (Edelman et al., 1998, Section 2.2.1)).

Then, the “alternating projection” viewpoint of (10) shows that it is approximately an alternating projection procedure between the subspaces $L_1$ and $L_2$. Since the projections onto $L_1$ and
$L_2$ are linear operators, the convergence rate of this alternating projection method can be described by the operator norm of the composite operator:

$$\kappa_H = \max_{X \in \mathbb{R}^{M \times n \times n}} \frac{\|P_{L_2}P_{L_1}X\|_F}{\|X\|_F}. \quad (12)$$

Since $P_{L_1}$ and $P_{L_2}$ are projection operators, one has $\|P_{L_1}(X)\|_F \leq \|X\|_F$, $\|P_{L_2}(X)\|_F \leq \|X\|_F$ and, therefore, $\kappa_H \leq 1$.

Note that $\kappa_H$ can be expressed via the smallest principal angle $\theta$ between planes $L_1$ and $L_2$: $\kappa_H = \cos(\theta)$. In particular, $\kappa_H = 0$ if $L_1$ and $L_2$ are perpendicular to each other, and $\kappa_H = 1$ if intersection $L_1 \cap L_2$ is nontrivial. As an example, when $M = 2$, one has $\dim(L_2) = 1$, and $\kappa_H$ can be explicitly written as

$$\kappa_H = \sqrt{\|Q^*_{1,,:} - \Pi_{U_m^\perp}Q^*_{1,,:}\Pi_{U_m^\perp}\|_F^2 + \|Q^*_{2,,:} - \Pi_{U_m^\perp}Q^*_{2,,:}\Pi_{U_m^\perp}\|_F^2}.$$  

Since the algorithm in (10) is approximately an alternating projection procedure between the subspaces $L_1$ and $L_2$, it converges faster for smaller values of $\kappa_H$. Note that $\kappa_H = 1$ if and only if $P_{L_2}P_{L_1}X = X$ for some $X$, i.e., when there is a nontrivial intersection between planes $L_1$ and $L_2$.

4.2 Assumptions

In order to guarantee linear convergence of Algorithm 1 in the noiseless case, we make the following assumption:

**(A1).** The subspaces $L_1$ and $L_2$, defined in (11), have only trivial intersection at the origin.

While Assumption (A1) is somewhat complicated, it is actually not very restrictive. Specifically, the statement below provides two very simple sufficient conditions that guarantee Assumption (A1). We can see that the Assumption (A1) is not too restrictive from the sufficient condition (A1(b)).

**Lemma 1.** Let at least one of the following conditions hold:

**(A1(a)).** For every $1 \leq m \leq M$, the sets of $(M - 1)$ matrices

$$\{\Pi_{U_m^\perp}Q_{s}^{m',,:} \Pi_{U_{m'}^\perp}, m' \neq m, 1 \leq m' \leq M\}$$

are linearly independent. That is, the vectorized versions of those matrices, a matrix of size $n^2 \times M$ with the $m$-th column given by $\text{vec}(\Pi_{U_m^\perp}Q_{s}^{m',,:} \Pi_{U_{m'}^\perp})$, has rank $(M - 1)$.

**(A1(b)).** For all $1 \leq m \leq M$, one has

$$\text{Span}(\Theta_m) \nsubseteq \bigoplus_{1 \leq m' \leq M, m' \neq m} \text{Span}(\Theta_{m'}).$$

where $\Theta_m \in \mathbb{R}^{n \times K_m}$ is the membership matrix for the $m$-th network as defined in (1) and $\oplus$ stands for the direct sum of subspaces.
The proof that these conditions are sufficient is presented in Section 6.4. While conditions in Lemma 1 are sufficient, they are not necessary. A more detailed discussion of assumption (A1) is deferred to Section 4.5.1.

In addition, we impose few other natural assumptions as follows:

\textbf{(A2).} There exist absolute constants \( c_0 > 0 \) such that \( K_{\text{max}} M \leq c_0 \hat{K} \), where \( \hat{K} \) is defined in (3).

\textbf{(A3).} The layers in the network, as well as local communities in each network are balanced, i.e., there exist absolute constants \( c_1, c_2, c_3, c_4 \) such that

\[
\frac{c_1 L}{M} \leq L_m \leq \frac{c_2 L}{M}, \quad \frac{c_3 n}{K_m} \leq |G_{m,k}| \leq \frac{c_4 n}{K_m} \quad \text{for any } 1 \leq m \leq M, 1 \leq k \leq K_m,
\]

where \(|G_{m,k}|\) is the size of the \( k \)-th community in cluster \( m \).

\textbf{(A4).} There exist matrices \( B^0_m \in \mathbb{R}^{K_m \times K_m}, m = 1, \ldots, M \), such that \( B_m = p_{\text{max}} B^0_m \) and \( \|B^0_m\|_\infty \leq 1 \). Here, \( p_{\text{max}} \in (0, 1] \) controls the overall network sparsity. In addition, for some absolute constants \( b_1 > 0 \) and \( b_2 > 0 \), one has

\[
\min_{m=1,\ldots,M} \sigma_{K_m}(B^0_m) \geq b_1, \quad \min_{m=1,\ldots,M} \frac{1}{K_m} \|B^0_m\|_F \geq b_2,
\]

where \( \sigma_{K_m}(B^0_m) \) is the smallest singular value of matrix \( B^0_m \).

4.3 Convergence of ALMA

Denote by \( \kappa_0 \) the condition number of matrix \( Q_{s,2,3} Q_s^* \):

\[
\kappa_0 = \frac{\sigma_1(Q_{s,2,3} Q_s^*)}{\sigma_M(Q_{s,2,3} Q_s^*)}.
\]

Let

\[
\beta_{n,L} = \log^2(n + L) \sqrt{M^3 \kappa_0} \left( \frac{1}{p_{\text{max}} n \min(n, L)} + \frac{\hat{K}^2}{p_{\text{max}} n \min(n, L)} \right)
\]

Then, the following theorem shows that, with a good initialization that satisfies (17), Algorithm 1 converges to a fixed point that is close to \( Q_s^* \) and \( W_s \), as the number of iterations tends to infinity.

\textbf{Theorem 1.} Let Assumptions (A1)-(A4) hold and \( \kappa_H \) be uniformly bounded away from one for any \( n \) and \( L \). Let, for some positive absolute constant \( C_1 \)

\[
p_{\text{max}} n \min(n, L) \geq \left( \frac{C_1 \kappa_0^2 \sqrt{\hat{K}^3 M \log^2(n + L)}}{1 - \kappa_H} \right)^2 + \frac{C_1 \kappa_0^2 \sqrt{\hat{K}^2 M \log^2(n + L)}}{1 - \kappa_H},
\]

and the initialization \( W^{(1)} \) satisfy

\[
\|W^{(1)} - W_s\|_F \leq h(M, \hat{K}, \kappa_0)
\]

for some positive uniformly bounded above function \( h \) of \( M, \hat{K} \) and \( \kappa_0 \). Then, for some absolute constant \( C_2 > 0 \) and \( \text{iter} \geq 1 \), with probability \( 1 - o(1) \) as \( n, L \to \infty \), one has

\[
\|W^{(\text{iter}+1)} - W_s\|_F \leq \frac{1 + \kappa_H}{2} \|W^{(\text{iter})} - W_s\|_F + \frac{C_2}{1 - \kappa_H} \beta_{n,L}
\]

8
Moreover, for any iter > 1, one has
\[ \|W^{(\text{iter})} - W_*\|_F \leq \left( \frac{1 + \kappa H}{2} \right)^{\text{iter}-1} \|W^{(1)} - W_*\|_F + \frac{2C_2}{1 - \kappa H} \beta_{n,L}, \]
with probability \(1 - o(1)\) as \(n, L \to \infty\). Consequently, if \(\bar{W} = \lim_{\text{iter} \to \infty} W^{(\text{iter})}\) and \(\bar{Q} = \lim_{\text{iter} \to \infty} Q^{(\text{iter})}\), then
\[ \|\bar{W} - W_*\|_F \leq \frac{2C_2}{1 - \kappa H} \beta_{n,L} \]  
(19)
In addition, with probability \(1 - o(1)\) as \(n, L \to \infty\), for some absolute constant \(C_3 > 0\) and any \(m = 1, \ldots, M\), one has
\[ \|Q^{(\text{iter})} - Q_*[(m, \ldots, \cdot)]\| \leq 2p_{\max} n \sqrt{L} \|W^{(\text{iter})} - W_*\|_F + C_3 \sqrt{p_{\max}(n + L)} \log(n + L). \]  
(20)

Based on the iterative update formula for the estimation error in (18), we can assess performance of Algorithm 1 with the stopping criterion \(\epsilon_{n,L}\).

**Corollary 1.** Under the assumptions and the notations of Theorem 1, if
\[ \|W^{(\text{iter}+1)} - W^{(\text{iter})}\|_F \leq \epsilon_{n,L}, \]  
(21)
then, with probability \(1 - o(1)\) as \(n, L \to \infty\), one has
\[ \|W^{(\text{iter})} - W_*\|_F \leq \frac{2\epsilon_{n,L}}{1 - \kappa H} + \frac{2C_2}{1 - \kappa H} \beta_{n,L}. \]  
(22)
As a result, if \(\epsilon_{n,L} \geq 6C_2 (1 - \kappa H)^{-1} \beta_{n,L}\), then Algorithm 1 would stop within at most \(T_{n,L}\) iterations, where
\[ T_{n,L} = \log \left( \frac{6 \|W^{(1)} - W_*\|_F}{\epsilon_{n,L}} \right) / \log \left( \frac{2}{1 + \kappa H} \right) \]

**Remark 1. Permutations.** We remark that \(W^{(1)}\) needs to be close to \(W_*\) up to a permutation of columns, but this permutation has no impact on the between-layer and within-layer clustering results, as the outputs of Algorithm 1, \(\bar{W}\) and \(\bar{Q}\), would also be close to \(W_*\) and \(Q_*\) up to permutations of columns and layers, respectively.

**Remark 2. Initialization.** Theorem 1 and Corollary 1 require initialization \(W^{(1)}\) that satisfies condition (17). If \(M, \hat{K}\) and \(\kappa_0\) are uniformly bounded above for any values of \(n\) and \(L\), then (17) is satisfied by any matrix \(W^{(1)}\) since for any \(L \times M\) matrix \(W\) such that \(W^T W = I_M\) one has \(\|W\|^2_F = M\), i.e. condition (17) holds with \(h(M, \hat{K}, \kappa_0) = 2\sqrt{M}\). In order to obtain more precise results, one can first obtain an initial between-layer clustering matrix \(Z^{(1)} \in \{0, 1\}^{L \times M}\) using, e.g., spectral clustering algorithm on vectorized layer matrices \(\{A_l\}_{l=1}^L\), and then set
\[ W^{(1)} = Z^{(1)}((Z^{(1)})^T Z^{(1)})^{-1/2}. \]  
(23)
However, as it follows from Theorem 1 and Corollary 1, the errors are smaller and the convergence of ALMA algorithm is faster when a more accurate initialization $W^{(1)}$ is used. For this reason, in Section 4.5.3 we present a more involved initialization procedure.

**Sketch of the proof.** The proof of Theorem 1 is deferred to Section 6.1. Below we provide some insight into how this theorem can be proved. The proof of the main inequality (18) in Theorem 1 can be divided into four steps.

The first step establishes a deterministic bound on $\|W^{(1)} - W^*\|$ for any given fixed $A$. The second step and the third step establishes a probabilistic bound for a random tensor $A$ under the probabilistic model in Section 2. Finally, the fourth step simplifies this probabilistic bound using Assumptions (A2)-(A4).

As for the proof of (20), it is based on the following chain of inequalities

$$
\|[Q - Q*]_{(m, :)\}} = \|\Pi_{K_m} [A \times_1 \hat{W}] - Q*(m, :)\} \| \leq 2\|A \times_1 \hat{W} - Q*_{(m, :)\}}\| \\
\leq 2\|P* \times_1 (\hat{W} - W*)\| + 2\|\Delta \times_1 \hat{W}(\cdot, m)\| \leq 2\|Q*\|\|\hat{W} - W*\| + 2\|\Delta\| \\
\leq 2\|Q*\|\|\hat{W} - W*\|_F + 2\|\Delta\|, \quad (24)
$$

where $\Delta = A - P*$, and the factor 2 in the first inequality follows from

$$
\|A \times_1 \hat{W} - \Pi_{K_m} [A \times_1 \hat{W}]\| \leq \|A \times_1 \hat{W} - Q*_{(m, :)\}}\|.
$$

Inequality (20) is then obtained by combining (24) with the upper bounds on $\|\Delta\|$ in Lemma 3 (see Appendix) and the fact that $\|Q*\| \leq \|Q*\|_F \leq p_{\max} n \sqrt{L}$.

**4.4 Consistency of between-layer and within-layer clustering**

This section studies the misclassification error rates in network classification and in local community classification. The misclassification error rates are measured by the Hamming distance between clustering partitions. Since the clustering is unique only up to a permutation of clusters, denote the set of permutation functions of $[r] = \{1, \cdots, r\}$ by $\aleph(r)$.

Given the true partition of network layers $[L] = \{1, \cdots, L\} = \cup_{m=1}^M S_m$ and the estimated partition $[\hat{L}] = \cup_{m=1}^M \hat{S}_m$, the misclassification error rate of between-layer clustering is given by

$$
R_{BL} = L^{-1} \min_{\tau \in \aleph(M)} \sum_{m=1}^M |S_m \setminus \hat{S}_{\tau(m)}|. \quad (25)
$$

The misclassification rate of within-layer clustering is defined similarly: given the true partition of vertices $[n] = \{1, \cdots, n\} = \cup_{k=1}^{K_m} G_{m, k}$ and the estimated partition $\cup_{k=1}^{K_m} \hat{G}_{m, k}$, the misclassification error rate of within-layer clustering for the $m$-th group of layers is given by

$$
R_{WL}(m) = n^{-1} \min_{\tau \in \aleph(K_m)} \sum_{k=1}^{K_m} |G_{m, k} \setminus \hat{G}_{m, \tau(k)}|. \quad (26)
$$

The derivations of both misclassification rates are based on the upper bound (20) and Lemma C.1 of Lei (2020). In addition, the analysis of within-layer clustering also applies the Davis-Kahan theorem. Our results on the misclassification errors are as follows, with the proof deferred to Section 6.2.
Theorem 2. (a) [Between-layer clustering error] For an $(1 + \epsilon)$ approximate solution of the $K$-means problem, with probability $1 - o(1)$ as $n, L \to \infty$, the between-layer clustering error is bounded by

$$R_{BL} \leq C\epsilon \frac{\beta_{n,L}}{M^2(1 - \kappa_H)^2}.$$  \hfill (27)

for some constant $C\epsilon$ depending on $\epsilon$.

(b) [Within-layer clustering] With probability $1 - o(1)$ as $n, L \to \infty$, the within-layer clustering error of the $m$-th type of network is bounded by

$$R_{WL}(m) \leq C\epsilon K_{\max} \left( \frac{\beta_{n,L}}{(1 - \kappa_H)^2} + \frac{\log^2(n + L)}{n L p_{\max}} \right), \quad m = 1, \ldots, M.$$ \hfill (28)

Here, $\kappa_H$ and $\beta_{n,L}$ are defined in, respectively, (12) and (15).

4.5 Discussion of theoretical guarantees

4.5.1 Discussion of Assumption (A1)

This section shows that Assumption (A1) is not restrictive, and is usually satisfied in practice. We have already provided, in Lemma 1, sufficient conditions that guarantee Assumption (A1) to hold. Below, we continue the discussion of this assumption.

The fact that Assumption (A1) is not restrictive can also be inferred from counting the dimensions of $L_1$ and $L_2$. Since a symmetric matrix $Q(m, :, :) : \Pi U^\perp_{m} Q(m, :, :) \Pi U^\perp_{m} = 0$ has $n(n - 1)/2 - (n - K_m)(n - K_m - 1)/2 = K_m n - K_m (K_m + 1)/2$ degrees of freedom. Summing those up for $1 \leq m \leq M$, obtain that the dimension of $L_1$ is $\sum_{m=1}^{M} (K_m n - K_m (K_m + 1)/2)$. Since the set $\text{Skew}_M$ has $M(M - 1)/2$ degrees of freedom, $L_2$ has a dimension of $M(M - 1)/2$. Since random subspaces of dimensions $d_1$ and $d_2$ in $\mathbb{R}^D$ do not intersect if $d_1 + d_2 \leq D$, so if

$$\frac{M(M - 1)}{2} + \sum_{m=1}^{M} (K_m n - K_m (K_m + 1)/2) \leq M n^2,$$

(which holds when $n$ is large), then (A1(b)) should usually hold.

We also remark that Assumption (A1) is slightly more restrictive than the local uniqueness of the solution to the problem (6) in the noiseless scenario, which only requires that $S_1$ and $S_2$ intersect only at $Q^*$. However, our goal is to prove the linear convergence of Algorithm 1 and, as it is shown in Figure 1 below, the convergence rate of the alternating method in Algorithm 1 would be slow and nonlinear if $S_1$ and $S_2$ are “tangent” to each other and their tangent planes have nontrivial intersections. On the other hand, the convergence rate is linear if the tangent planes to $S_1$ and $S_2$ have only a trivial intersection.

However, Assumption (A1) fails in the case of the “checker board” model Chi et al. (2020), where all networks have the same community structures, i.e., $\Theta_1 = \Theta_2 = \cdots = \Theta_M$. This is due to the uniqueness issues of the optimization problem in (6). We will discuss the “checker board” model in the next section.

4.5.2 Uniqueness of the solution and the “checker board” model

Similar to many clustering problems, the solution of the optimization problem (7) is unique only up to permutations of clusters. The non-uniqueness due to permutation of clusters, however, does not
cause difficulty for Algorithm 1, and Theorem 1 still applies: if the initialization $W^{(1)}$ is reasonably close to $W^*$, then Algorithm 1 converges to the true solution.

However, if the model satisfies the “checker board” setting of Chi et al. (2020) where $\Theta_1 = \Theta_2 = \cdots = \Theta_M$, then the solution is only unique up to orthogonal transformations. Indeed, $(Q_s \times_1 O, W_s O)$ is another solution to (7) for any orthogonal matrix $O \in \mathbb{R}^{M \times M}$. Unlike the non-uniqueness due to permutations, in this case $(Q_s, W_s)$ is not the unique solution of (7) in its neighborhood, and the “good initialization” assumption is not sufficient for Theorem 1 to be true. For example, if Algorithm 1 is initialized at $(Q_s \times_1 O, W_s O)$ with $O \approx I$, then the algorithm gets stuck at this point as it is a fixed point of the algorithm. That is, the algorithm does not converge to $(Q_s, W_s)$, even though the initialization is close to the true values. The latter explains why Theorem 1 does not apply to the “checker board” model, where Assumption (A1) fails.

Nevertheless, even though Theorem 3 does not apply, we remark that $(Q_s \times_1 O, W_s O)$ with orthogonal matrix $O$, the alternate solutions to (7), still gives correct between-layer clustering and within-layer clustering. In this sense, Algorithm 1 is still successful under the “checker board” setting.

4.5.3 Initialization

We remark that Theorem 1 and Corollary 1 require a good initialization such that (17) holds. Also, as Remark 2 states, the errors in Theorem 1 and Corollary 1 are smaller, and the convergence of Algorithm 1 is faster when a more accurate initialization $W^{(1)}$ is used. For this reason, in this section we present a more involved initialization procedure, Algorithm 2, which can be viewed as a modification of the initialization strategy in Jing et al. (2020). Denote

$$\deg_j = \sum_{i=1}^{L} \sum_{k=1}^{n} A(i,j,k), \quad \delta = 2 \sqrt{K} \left( \frac{\max_{1 \leq j \leq n} \deg_j}{\sum_{j=1}^{n} \deg_j^2} \right)^{-1/2}$$

Theoretical guarantees on this initialization are given by the statement below. Its proof is deferred to Section 6.4.

**Proposition 1.** Let Assumption of Theorem 1 hold and $M, K, \tilde{K}$ and $\kappa_0$ be uniformly bounded above for all values of $n$ and $L$. Then, with probability $1 - o(1)$ as $n, L \to \infty$, one has for some absolute constant $C_4 > 0$

$$\|W^{(1)} - W_s\|_F \leq C_4 \kappa_0^{-2} \tilde{K}^{-2} \sqrt{M}$$

12
Algorithm 2 Initialization of Algorithm 1

Input: Adjacency matrices $A_l \in \mathbb{R}^{n \times n}$, $1 \leq l \leq L$; number of different layers $M$; $\hat{K}$.
Output: $W^{(1)}$.
Steps:

1: Find $\tilde{U}^{(0)} \in \mathbb{R}^{n \times \hat{K}}$ comprised of the top $\hat{K}$ left singular vectors of $\sum_{l=1}^{L} A_l$.
2: Set $\tilde{U}^{(0)} = P_{\delta,K}(\tilde{U}^{(0)})$, where $P_{\delta}$ is a regularization operator defined in formula (33) and $\delta$ is given by (29).
3: Set $\tilde{W}^{(0)}$ to be composed of the top $M$ left singular vectors of $M \times (A \times_2 \tilde{U}^{(0)} \times_3 \tilde{U}^{(0)})$.
4: Apply the $K$-means algorithms to the rows of $\tilde{W}^{(0)}$ to obtain an initial estimator of the between-layer clustering $[L] = \cup_{m=1}^{M} \tilde{S}_m$.
5: Apply (23) to obtain $W^{(1)}$ from $[L] = \cup_{m=1}^{M} \tilde{S}_m$.

5. Comparison with existing results

To the best of our knowledge, the only paper that studied the model considered in this paper is Jing et al. (2020) where the authors use methodology based on regularized tensor decomposition algorithm TWIST. In this section, we provide theoretical and numerical comparisons with their results.

5.1 Description of TWIST

While Jing et al. (2020) consider the model described in this paper, their methodology and their assumptions are somewhat different. Specifically, TWIST iterates Tucker decomposition with regularization step on the observation tensor $A$ to obtain a low-rank approximation of $A$, where the intention of the regularization is to dampen the stochastic errors. The Tucker structure of the approximation is used to cluster the nodes and the layers. Jing et al. (2020) start with compiling a collection of all clustering matrices $\Theta_m$, $m = 1, \ldots, M$, in (1) into one matrix $\Theta \in \mathbb{R}^{n \times \hat{K}}$ defined as $\Theta = [\Theta_1, \ldots, \Theta_M]$. With this notation, they obtain the Tucker decomposition of the true probability tensor $P_\ast$ as

$$P_\ast = B \times_2 \Theta \times_3 \Theta \times_1 Z, \quad C \in \mathbb{R}^{K \times K \times M}, \quad (31)$$

where $Z \in \{0, 1\}^{L \times M}$ is the clustering matrix of layers such that $Z(Z^TZ)^{-1/2} = W_\ast$ and $B$ is defined as

$$B(:, :, m) = \text{diag}(0, \ldots, 0, B_m, 0, \ldots, 0), \quad m = 1, \ldots, M. \quad (32)$$

Furthermore, they obtain the SVD $\Theta = \bar{U}D\bar{R}$ of $\Theta$ where matrices $\bar{U} \in \mathbb{R}^{n \times r}$ and $\bar{R} \in \mathbb{R}^{K \times r}$ have orthonormal columns, $r$ is the rank of $\Theta$ and $D$ is the diagonal matrix of nonzero singular values. The objective of the technique is to recover matrix $W_\ast$ as well as $\bar{U}$.

The TWIST algorithm is based on iterative updates of matrices $\tilde{U}^{(iter)}$ and $\tilde{W}^{(iter)}$. Specifically, given $\tilde{U}^{(iter)}$ and $\tilde{W}^{(iter)}$, TWIST sets

$$\tilde{U}^{(iter)} = P_{\delta_1, r}(\tilde{U}^{(iter)}), \quad \tilde{W}^{(iter)} = P_{\delta_2, M}(\tilde{W}^{(iter)}),$$

where, for matrix $V$, any $\delta > 0$ and positive integer $s$, one has

$$P_{\delta, s}(V) = SVD_s(V), \quad \text{with} \quad V_\ast(:, :, i) = V(:, :, i) \frac{\min(\delta, ||V(:, :, i)||)}{||V(:, :, i)||}. \quad (33)$$
and $SVD_s$ returns the top $s$ left singular vectors. Subsequently, the new iterations $\hat{U}^{(\text{iter}+1)}$ and $\hat{W}^{(\text{iter}+1)}$ are obtained as, respectively, the top $r$ left singular vectors of $\mathcal{M}_3(A \times_1 (\hat{U}^{(\text{iter})})^T \times_2 (\hat{W}^{(\text{iter})})^T$, and the top $M$ left singular vectors of $\mathcal{M}_1(A \times_2 (\hat{U}^{(\text{iter})})^T \times_3 (\hat{U}^{(\text{iter})})^T$. The process is carried out till the number of iterations reaches the pre-specified value $\text{iter}_{\text{max}}$.

5.2 Theoretical comparisons of TWIST and ALMA

Note that TWIST aims at revealing both global/local memberships of nodes together with the memberships of layers. Since Algorithm 1 (ALMA) does not deal with the concept of global communities, in the context of this paper, we use the terms “within-layer” and “between-layer” clustering to stand for the local memberships and memberships of layers, respectively. The global communities, defined in Jing et al. (2020), are related to but not identical to the persistence of the local ones in all layers.

Since Jing et al. (2020) apply a different technique, their assumptions, theoretical analysis and final results differ from ours. We start with the comparison of the assumptions.

Specifically, Jing et al. (2020) impose the following conditions:

1. Denote $\sigma_{\text{min}}(B) = \min\{\sigma_{\text{min}}(\mathcal{M}_1(B)), \sigma_{\text{min}}(\mathcal{M}_2(B)), \sigma_{\text{min}}(\mathcal{M}_3(B))\}$. Then, for the tensor $B$, defined in (32), one has $\sigma_{\text{min}}(B) \geq \hat{c}_1 p_{\text{max}}$. Note that

$$\sigma_{\text{min}}(B) \leq \sigma_{\text{min}}(\mathcal{M}_1(B)) = \min_{m=1,\ldots,M} \sigma_{K_m} B_m = p_{\text{max}} \min_{m=1,\ldots,M} \sigma_{K_m} B_m^0.$$ 

Hence, the assumption on $\sigma_{\text{min}}(\mathcal{M}_1(B))$ is equivalent to the first part of Assumption (A4) in (14). While the assumption on $\sigma_{\text{min}}(\mathcal{M}_j(B))$ for $j = 2, 3$ is not directly comparable to the second part of Assumption (A4) in (14), both serve a similar purpose that $B$ is not too small.

2. Matrix $\Theta$ in (31), for some $\tilde{\kappa}_0 < \infty$, is assumed to satisfy the condition $\sigma_{\text{max}}(\Theta) \leq \tilde{\kappa}_0 \sigma_r(\Theta)$ where $r = \text{rank}(\Theta)$. This assumption implicitly implies our assumption (A2) and the “balanced local community” assumption in (A3), i.e., the second condition in (13).

3. Layer sizes and community sizes in the layers are assumed to be similar. This is equivalent to the assumption (A3).

4. Network sparsity assumption $Ln p_{\text{max}} \geq C(\hat{K} + \tilde{\kappa}_0^2 r^2 \log^2 n)M^{-1} \tilde{\kappa}_0^2 r^2 \log^2 (r \tilde{\kappa}_0) \log^2 n$. In comparison, we have a similar assumption in (16).

5. Theoretical analysis of TWIST is carried out under the condition that $L \leq n$. We do not impose this assumption.

Under these assumptions, the error rate of the between-layer clustering of TWIST is

$$R_{BL}^{TWIST} = O\left(\tilde{\kappa}_0^4 \frac{r^2 \log n}{ML n p_{\text{max}}} \right).$$
Under the additional assumption $\sqrt{Tn p_{\text{max}}} \geq CM^{-1}r_0^{-5/2} \log(r_0) \log^{5/2} n$, the error rate of within-layer clustering for the $m$-th type of network is

$$R^{(TWIST)}_{WL}(m) = O\left(\frac{\tilde{\kappa}_0^4 K_m^2 \log n}{ML n p_{\text{max}}}\right).$$

We remark that the comparison with $\kappa_0$ and $\tilde{\kappa}_0$ is not straightforward, as they are defined very differently (even though both measure how “well-conditioned” the model is). In order to compare the clustering errors of ALMA and TWIST, we assume that $M, K_m, \kappa_0$ and $\kappa_H$ are uniformly bounded by constants independent of $n$ and $L$, so that, as a result, the same is true for $\tilde{K}, r$ and $\tilde{\kappa}_0$. Then the clustering error rates are more comparable since they depend only on $n, L$, and $p_{\text{max}}$.

Specifically, the error rates of the between-layer clustering are

$$R^{(ALMA)}_{BL} = O\left(\frac{\log^4(n + L)}{n^2 p_{\text{max}}} + \frac{\log^4(n + L)}{n^2 \min(n, L) p_{\text{max}}}\right), \quad R^{(TWIST)}_{BL} = O\left(\frac{\log n}{L n p_{\text{max}}}\right). \quad (34)$$

The error rates of the within-layer clustering for the $m$-th type of network are

$$R^{(ALMA)}_{WL}(m) = O\left(\frac{\log^4(n + L)}{n \min(n, L) p_{\text{max}}}\right), \quad R^{(TWIST)}_{WL}(m) = O\left(\frac{\log n}{L n p_{\text{max}}}\right). \quad (35)$$

Recall that, for both the between-layer clustering and the within-layer clustering, the error rates of TWIST are derived under the assumption that $L \leq n$.

In comparison, the error rates of the between-layer clustering of ALMA are better in two aspects. First, they hold in the case of $L > n$. Second, since both methods require that the quantity $n L p_{\text{max}}$ grows with $n$ and $L$, it is easy to see that, up to the logarithmic factors,

$$R^{(ALMA)}_{BL} = o\left(R^{(TWIST)}_{BL}\right) \quad \text{if} \quad n \to \infty, \quad L/n \to 0.$$  

Also, up to the logarithmic factors, the within-layer clustering error rates are equivalent.

However, Jing et al. (2020) do not have anything similar to Assumption (A1) imposed in the present paper. This assumption is due to the fact that Theorem 1 attempts to achieve something more than clustering: it aims at recovering $Q_*$ and $W_*$ directly. In addition, we have somewhat stronger assumption on sparsity, requiring that $n p_{\text{max}} > O(\log L + \log n)$, instead of $n L p_{\text{max}} > O(\log n)$ in Jing et al. (2020). We suspect that the difference in the assumptions is due to the technicalities in our analysis, rather than the inherent drawbacks of our algorithm.

### 5.3 Numerical comparisons

As it is evident from the previous section, the theoretical comparison between ALMA and TWIST is very difficult due to the differences between assumptions.

In order to test the performance of Algorithm 1 (ALMA) and subsequent within-layer clustering, and to provide a fair comparison of the clustering precisions with the TWIST technique of Jing et al. (2020), we carry out a limited simulation study with various choices of parameters $p_{\text{max}}, L$ and $n$. We use the misclassification rates as measures of the performance of our algorithm. Specifically, we characterize the between layer clustering precision by (25). For the error of the within-layer clustering, we average the rates in (26) over the $M$ layers and use

$$R_{WL} = M^{-1} \sum_{m=1}^{M} R_{WL}(m). \quad (36)$$
We choose $M$ and fix $K_1 = \cdots = K_M = K$, so that in each cluster, network follows SBM with $K$ communities. The underlying class for each layer, and the membership for each node in every class of layers are randomly sampled using the multinomial distributions with equal class probabilities $1/M$ for the layers of the networks, and $1/K$ for the nodes in each of the layer clusters. In each of the layers, we use identical connectivity matrices $B_m \equiv B$ where the diagonal values are set to $p = p_{max}$ while the off-diagonal entries are equal to $q = \alpha p_{max}$ with $\alpha < 1$. The constant $\alpha$ controls the ratio of the probability of connection of a node outside its own community versus inside it. Consequently, the within layer clustering is easier when $\alpha$ is small and harder when it is large.

We investigate the performances of ALMA (Algorithm 1) and compare it with the performances of the TWIST in four simulation scenarios. In our simulations, we set $M = 3$, $K = 3$ and $r = 7$, since $r = \text{rank}([\Theta_1, \cdots, \Theta_M]) \leq \sum_{m=1}^{M} K_m - (M - 1)$, with inequality occurring in degenerate setting. Since our approach does not involve the concept of global membership, we only compare ALMA with TWIST in terms of “within–layer” and “between–layer clustering”. Furthermore, we
choose the stopping criterion $\|W^{(\text{iter})} - W^{(\text{iter}-1)}\| \leq 10^{-4}$ for both of ALMA and TWIST to make a fair comparison between the algorithms. Below we describe the simulation schemes.

In Simulation 1, we investigate the effect of the network sparsity on the precision of the algorithms. For this purpose, we choose the number of vertices $n = 100$, the number of layers $L = 40$, the number of network clusters $M = 3$, the number of communities in each cluster of layers $K = 3$ and $\alpha = 0.9$. The variable $p_{\text{max}}$, which controls the overall network sparsity, varies from 0.3 to 1. Fig. 2 shows that both between-layer and within-layer clustering errors decrease as $p_{\text{max}}$ is increasing.

In Simulation 2, the settings are the same as Simulation 1 except that $p_{\text{max}} = 0.6$ is fixed, and the number of vertices varies from 30 to 300. As $n$ increases, the between-layer and within-layer clustering error rates decrease to zero, as predicted by Theorem 2.
In Simulations 3 and 4, we study the effect of the numbers of layers in the network, when $L > n$ and $L < n$, respectively. Specifically, in Simulation 3, we set $n = 40, M = 3, K = 3, \alpha = 0.8, p_{\text{max}} = 0.6$ and vary the number of layers $L$ between 40 and 140. The settings in Simulation 4 are the same as Simulation 3, except $n = 100$ is larger, and $L$ varies from 50 to 100.

For both algorithms, in each of the simulation scenarios, we report the between-layer and the within-layer clustering errors (25) and (26), respectively, averaged over 30 independent simulation runs. The results are summarized in Figures 2–5.

As it is evident from Figures 2–5, for all four scenarios, ALMA has smaller both the between-layer and the within-layer clustering error rates. Note also that ALMA has better precision not only in the case of $L > n$ that violates the assumptions of TWIST but also in the case of $L \leq n$.

6. Appendix

6.1 Proof of Theorem 1

The organization of this section follows from the sketch of the proof after Theorem 1 in four steps: the first step establishes a deterministic bound of $W(\text{iter}) - W_*$, the second and the third steps establish a probabilistic bound, and the fourth step simplifies the probabilistic bound using Assumptions (A2)-(A4).

6.1.1 Step 1: Deterministic analysis of Algorithm 1

In this step, we aim to find a metric $\| \cdot \|_{d}$ on $\mathbb{R}^{L \times M}$ such that $\{\|W(\text{iter}) - W_*\|_{d}\}_{\text{iter}=1}^{\infty}$ should be monotonically decreasing approximately. While it is natural to consider the Frobenius norm, the previous analysis of the noiseless case in algorithm (10) does not support the monotonicity of $\{\|W(\text{iter}) - W_*\|_{F}\}_{\text{iter}=1}^{\infty}$. Instead, it establishes the “approximate” monotonicity of $\|Q_\ast \times_1 (V(\text{iter}) - I)\|_{F}$ of

$$
\|Q_\ast \times_1 (V(\text{iter}+1) - I)\|_{F} \lesssim \kappa_H \|Q_\ast \times_1 (V(\text{iter}) - I)\|_{F}.
$$

Recall that in the noiseless case, $W(\text{iter}) = W_* V(\text{iter})$, we expect that $\| \cdot \|_{d}$ should be defined such that when $V$ is orthogonal and close to $I$,

$$
\|W_*(V - I)\|_{d} \approx \|Q_\ast \times_1 (V - I)\|_{F}.
$$

(37)

Since the tangent plane of the set of orthogonal matrices at $I$ is the set of skew-symmetric matrices (add citation), the tangent space of $\{W_* V : V^T V = I\}$ at $V = I$ is $L_0 = \{W_* Y : Y \in \text{Skew}(M)\} \subset \mathbb{R}^{L \times M}$, (37) implies that for any $W_* Y \in L_0$, $\| \cdot \|_{d}$ should be defined such that

$$
\|W_* Y\|_{d} = \|Q_\ast \times_1 Y\|_{F} = \|P_\ast \times_1 W_* Y\|_{F}.
$$

(38)

Combining this metric on $L_0$ and the standard Euclidean/Frobenius metric on the orthogonal subspace $L_0^\perp$, we define the metric $\| \cdot \|_{d} : \mathbb{R}^{L \times M} \to \mathbb{R}$ by

$$
\|W\|_{d} = \sqrt{(\lambda \|P_\ast \times_1 P_{L_0} W\|_{F})^2 + \|P_{L_0^\perp} W\|_{F}^2},
$$

(38)
where $\lambda$ balances the weights from the two components such that $\lambda = 1/\min_{Y \in \text{Skew}(M)} \|Q_\ast \times_1 Y\|_F$. By the definition of the metric $\| \cdot \|_d$ in (38), we have the following equivalence between $\| \cdot \|_d$ and $\| \cdot \|_F$:

$$
\| W \|_d \geq \sqrt{\|P_{L0}W\|_F^2 + \|L_0^+W\|_F^2} = \| W \|_F
$$

and for $C_H = \max_{Y \in \text{Skew}(M)} \|Q_\ast \times_1 Y\|_F / \min_{Y \in \text{Skew}(M)} \|Q_\ast \times_1 Y\|_F$,

$$
\| W \|_d \leq \sqrt{C_H^2 \|P_{L0}W\|_F^2 + C_H^2 \|L_0^+W\|_F^2} = C_H \| W \|_F.
$$

We remark that in (38), the projection operators can be explicitly written as $P_{L0}W = W_\ast (W_\ast^T W_\ast^{(iter)} - W_\ast^{(iter)T} W_\ast) / 2$ and $L_0^+W = W_\ast (W_\ast^T W_\ast^{(iter)} + W_\ast^{(iter)} T W_\ast) / 2 + (I - W_\ast W_\ast^T) W_\ast^{(iter)}$.

Before stating our main result, we introduce two additional parameters:

$$
\kappa_1 = \frac{p_{\max}^2 n^2 L}{\|Q_\ast\|_F^2}, \quad \kappa_2 = \sqrt{\frac{K}{\min_{m=1,\ldots,M} \sigma_M(Q_\ast(m,\cdot,::))}}.
$$

Both parameters are greater than 1, and describe how “well-conditioned” $Q_\ast$ is, and when $Q_\ast$ is well-conditioned, then all parameters are close to 1. In particular, $\kappa_1 \geq 1$ because $\|Q_\ast\|_F = \|P_\ast\|_F$ and all elements of $P_\ast$ are bounded by $p_{\max}$, and $\kappa_2 \geq 1$ because

$$
\hat{K} \min_{m=1,\ldots,M} \sigma_M(Q_\ast(m,\cdot,::)) \leq \sum_{m=1}^M \sum_{k=1}^K \sigma_k(Q_\ast(m,\cdot,::))^2 = \|Q_\ast\|_F^2 \leq \min_{m=1,\ldots,M} \sigma_M(Q_\ast(m,\cdot,::)).
$$

When $Q_\ast(m,\cdot,::)$ is “degenerate” in the sense that $\sigma_M(Q_\ast(m,\cdot,::)) \approx 0$, then $\kappa_2$ is large.

The main result in this step states that, if the noise $\Delta$ is small and when Algorithm 1 is applied to the observed adjacency tensor $A$ with a good initialization $W^{(0)}$, the estimations are likely to improve over each iteration, and Algorithm 1 converges to $W_\ast$ approximately. The statement is as follows, and its proof is rather complicated and deferred to Section 6.3.

**Lemma 2 (Step 1: A deterministic result on Algorithm 1).** For

$$
a_1 = \min_{m=1,\ldots,M} \|\Pi_T K_\ast(m,\cdot,::)\|_2 \| \Pi_T K_\ast(m,\cdot,::) \|_2 \Pi_T K_\ast(m,\cdot,::) \|_2 \Pi_T K_\ast(m,\cdot,::) \|_2 + 2 \max_{m=1,\ldots,M} \|\Pi_T K_\ast(m,\cdot,::)\|_2 \| \Pi_T K_\ast(m,\cdot,::) \|_2 \Pi_T K_\ast(m,\cdot,::) \|_2
$$

$$
\sigma_M(Q_\ast \times_2,3 Q_\ast)
$$

and the initialization satisfies

$$
\|W^{(1)} - W_\ast\|_d \leq \frac{1 - \kappa_H}{2} \min_{m=1,\ldots,M} \sigma_M(Q_\ast(m,\cdot,::)) / \|Q_\ast\|_2,
$$

then for all $\iter \geq 1$,

$$
\|W^{(\iter+1)} - W_\ast\|_d \leq \frac{1 + \kappa_H}{2} \|W^{(\iter)} - W_\ast\|_d + C_H a_1,
$$

which implies

$$
\lim_{\iter \to \infty} \|W^{(\iter)} - W_\ast\|_d \leq \frac{2C_H a_1}{1 - \kappa_H}.
$$
6.1.2 Step 2: Probabilistic estimation

Since \(Q_*\) is deterministic in our model, we only need to estimate the terms that depend on \(\Delta\) in Lemma 2. The estimations are summarized as follows, and the proof is deferred to the Appendix.

**Lemma 3** (Step 2: Probabilistic estimation). (a) [Restatement of Zhou and Zhu, 2019, Theorem 2.1] If \(p_{\text{max}} \geq \frac{c \log(\max(n, L))}{\max(n, L)}\) for some constant \(c > 0\), then for any \(r > 0\), there exists a constant \(C > 0\) depending only on \(r, c\) such that with probability at least \(1 - n^{-r}\), \(\|\Delta\| = \sup_{u \in \mathbb{R}^t, v \in \mathbb{R}^n} \frac{\Delta \times u \times v \times y}{\|u\|\|v\|} \) satisfies \(\|\Delta\| \leq C \sqrt{p_{\text{max}} n L} \log(\max(n, L))\).

(b) \[
\Pr \left( \|\Pi_{T, K_n}(Q) \times_{2, 3} \Pi_{T, K_m}(\Delta)\|_F > 3nL \sqrt{p_{\text{max}}^3} \right) \leq 2KL \exp \left( -\frac{1}{2} \frac{t^2}{1 + \frac{1}{3 \sqrt{p_{\text{max}} n L}} } \right). \tag{42}
\]

(c) \[
\Pr \left( \max_{1 \leq m \leq M} \|\Pi_{T, K_n}(\Delta) \times_{2, 3} \Pi_{T, K_m}(\Delta)\|_F \geq 9K^2t^2 p_{\text{max}} n L \right) \leq 2K(L + n) \exp \left( -\frac{t^2/2}{1 + \frac{1}{\sqrt{p_{\text{max}} n L}} } \right). \tag{43}
\]

6.1.3 Step 3: A probabilistic result on Algorithm 1 without Assumptions (A2)-(A4)

From the definition of \(\kappa_0 = \frac{\sigma_1(Q_* \times_{2, 3} Q_*)}{\sigma_M(Q_* \times_{2, 3} Q_*)}\) and the fact \(Q_* \times_{2, 3} Q_* = M_1(Q_*)M_1(Q_*)^T\), we have

\[
\kappa_0 = \left( \frac{\sigma_1(Q_* \times_{2, 3} Q_*)}{\sigma_M(Q_* \times_{2, 3} Q_*)} \right)^2 \left( \frac{\sigma_1(M_1(Q_*))}{\sigma_M(M_1(Q_*))} \right)^2,
\]

\[
\|Q_* \times Y\|_F = \|M_1(Q_*)Y\|_F \leq \sigma_1(M_1(Q_*)) \|Y\|_F, \text{ and } \|Q_* \times Y\|_F = \|M_1(Q_*)Y\|_F \geq \sigma_M(M_1(Q_*)) \|Y\|_F.
\]

As a result, \(C_H \leq \sqrt{\kappa_0}\).

Combining \(C_H \leq \sqrt{\kappa_0}\) with \(\|Q_*\| \leq \|Q_*\|_F \leq p_{\text{max}} n \sqrt{r}\), the estimation that

\[
\sigma_M(Q_* \times_{2, 3} Q_*) \geq \frac{1}{\kappa_0} \sigma_1(Q_* \times_{2, 3} Q_*) = \frac{1}{\kappa_0} \|M_1(Q_*)\|^2 \geq \frac{1}{M \kappa_0} \|M_1(Q_*)\|^2 = \frac{1}{M \kappa_0} \|Q_*\|_F^2 \geq \frac{p_{\text{max}} n^2 L}{M \kappa_0 \kappa_1},
\]

Lemma 2 and Lemma 3 imply

**Theorem 3** (Step 3: A generic result on Algorithm 1 without Assumptions (A2)-(A4)). If \(p_{\text{max}} \geq \frac{c \log(\max(n, L))}{\max(n, L)}\) for some constant \(c > 0\), then for any \(r > 0\), there exists \(C > 0\) that depending only on \(r, c\) such that for

\[
a_1 = C \kappa_0 \kappa_1 \sqrt{M^3 \left( \frac{t}{n \sqrt{p_{\text{max}}}} + \frac{\hat{K}^2 t^2}{p_{\text{max}} n \min(n, L)} \right)} + C \kappa_0 \kappa_1 \kappa_2 \sqrt{M K} \frac{\log(\max(n, L))}{p_{\text{max}} n \min(n, L)}
\]

\[
a_2 = C \kappa_0 \kappa_1 \kappa_2 \sqrt{MK} \left( 1 + \frac{\log(\max(n, L))}{p_{\text{max}} n \min(n, L)} \right),
\]

if

\[
C \kappa_2 \sqrt{K} \leq \sqrt{p_{\text{max}} n \min(n, L)}, \quad \sqrt{4a_1 \kappa_0 (a_2 + 112 \kappa_0^2)} \leq 1 - \kappa, \quad 2 \kappa_0 \kappa_2 a_1 \sqrt{K} \leq (1 - \kappa) \tag{44}
\]
and the initialization satisfies
\[ \|W^{(1)} - W_*\|_F \leq \min \left( \frac{1 - \kappa_H}{2\kappa_0(a_2 + 112k_0^3)}, \frac{1}{4\kappa_2\sqrt{\kappa_0K}} \right) \] (45)
then with probability at least
\[ 1 - n^{-r} - 2KL \exp \left( \frac{-\frac{1}{2} \frac{t^2}{1 + \frac{t}{\sqrt{n}}} - \frac{t^2/2}{1 + \sqrt{\max(n,L) \min}} \right), \]
\[ \|W^{(\text{iter+1})} - W_*\|_d \leq \frac{1 + \kappa_H}{2\kappa_0} \|W^{(\text{iter})} - W_*\|_d + a_1 \sqrt{\kappa_0}, \] (46)
holds for all \( i \geq 1 \), which implies
\[ \lim_{\text{iter} \to \infty} \|W^{(\text{iter})} - W_*\|_F \leq \lim_{\text{iter} \to \infty} \|W^{(\text{iter})} - W_*\|_d \leq \frac{2a_1 \sqrt{\kappa_0}}{1 - \kappa_H}. \]

6.1.4 Step 4: Simplification under Assumptions (A2)-(A4)
We will need to estimate the parameters \( \kappa_1, \kappa_2 \) under Assumptions (A2)-(A4). Since \( Q_*(m, \ldots) = \sqrt{L_m} \Theta_m \Theta_m^* \), and \( \Theta_m^* = \text{diag}(G_m,1,|G_m,2|, \ldots, |G_m,K_m|) \), we have \( \sigma_k(m, \ldots) = \sqrt{L_m} \sigma_k(B_m) \sigma_k(m, \Theta_m)^2 \geq c_1 \sqrt{c_3} \max \frac{\sqrt{M}}{K_m \sqrt{M}} \min m=1, \ldots, M \sigma_k(B_m), \) which suggests
\[ \kappa_2 \leq \frac{K_{\max} \sqrt{M}}{c_1 \sqrt{c_3} b_2}. \]

Similarly, we have the estimation
\[ \kappa_1 \leq \frac{1}{c_1 \sqrt{c_3} b_2}. \]
Let \( p^* = \max(n, L) \) and \( t = \log(n + L) \), then we have the estimation that
\[ a_1 = \frac{C\kappa_0 \sqrt{M^3}}{c_1 \sqrt{c_3} b_2} \left( \frac{t}{\sqrt{p_{\max}}} + \frac{\sqrt{M^3}}{p_{\max} n \min(n, L)} \right) + C\kappa_0 \frac{\sqrt{K_{\max} M \log^2(\max(n, L))}}{c_1 \sqrt{c_3} b_2 \sqrt{\max(n, L)}} \]
\[ \leq C\kappa_0 \log^2(n + L) \left( \frac{1}{\sqrt{p^*} c_1 \sqrt{c_3} b_2} + \frac{1}{p^*} \left( \frac{\sqrt{M^3}}{c_1 \sqrt{c_3} b_2} + \frac{\sqrt{K_{\max} M}}{c_1 \sqrt{c_3} b_2} \right) \right) \]
\[ \leq C\kappa_0 \log^2(n + L) \sqrt{M^3} \left( \frac{1}{\sqrt{p^*}} + \frac{\sqrt{K_{\max} M}}{p^*} \right) \]
\[ a_2 = C\kappa_0 \frac{\sqrt{K_{\max} M}}{c_1 \sqrt{c_3} b_2} \left( 1 + \log(\max(n, L)) \right) \leq C\kappa_0 \log(n + L) \frac{1}{\sqrt{p^*} c_1 \sqrt{c_3} b_2 \sqrt{\max(n, L)}} \frac{\sqrt{K_{\max} M}}{p^*} \]
\[ \leq C\kappa_0 \log(n + L) \sqrt{\kappa^3}, \]
By calculation, a sufficient condition for the requirement in (44) becomes (16).
With (16), we have
\[ \frac{p^t(1-\kappa_H)}{\kappa_2^3 \log(n+L) \kappa^3} \geq \frac{\sqrt{M}}{K^2}, \]
so the assumption on the initialization (45) can be guaranteed by (17). Then (18) is proved by applying Theorem 3, and (19) follows from (18). The proof of (20) is presented in (24) at the end of Section 4.3.
6.2 Proof of Theorem 2

Proof of Theorem 2. (a) For completeness, we will first write down the statement from (Lei, 2020, Lemma C.1):

Let \( U \) be an \( n \times d \) matrix with \( K \) distinct rows with minimum pairwise Euclidean norm separation \( \gamma \). Let \( \hat{U} \) be another \( n \times d \) matrix and \( (\hat{\Theta}, \hat{X}) \) be an \( (1+\epsilon) \)-approximate solution to \( K \)-means problem with input \( \hat{U} \), then the number of errors in \( \hat{\Theta} \) as an estimate of the row clusters of \( U \) is no larger than \( C_\epsilon \| U - \hat{U} \|_F^2 \gamma^{-2} \) for some constant \( C_\epsilon \) depending only on \( \epsilon \).

Note that \( W_\ast \) is an \( L \times M \) matrix with \( M \) distinct rows with minimum pairwise Euclidean norm separation larger than \( 2/\max_{m=1,\ldots, M} \sqrt{L_m} \), the misclassification rate is not larger than

\[
\max_{m=1,\ldots, M} \sqrt{L_m} C_\epsilon \| W_\ast - \hat{W} \|_F^2.
\]

Combining it with the estimation of \( \| W_\ast - \hat{W} \|_F^2 \) and assumption (A3) on \( \max_{m=1,\ldots, M} \sqrt{L_m} \), part (a) is proved.

(b) Denote the orthogonal matrix of size \( n \times K_m \) whose columns are the top \( K_m \) eigenvectors of \( \hat{Q}(m,::) \) by \( \hat{U}_m \) and the orthogonal matrix of size \( n \times K_m \) whose columns are the top \( K_m \) eigenvectors of \( Q_\ast(m,::) \) by \( U_m \), then the Davis-Kahan theorem implies that

\[
\| \hat{U}_m - U_m \|_F \leq \frac{\| \hat{Q}(m,::) - Q_\ast(m,::) \|_F}{\sigma_{K_m}(Q_\ast(m,::))}.
\]

In addition, \( U_m \) has \( K_m \) distinct rows with minimum pairwise Euclidean norm separation at least \( 2/\sqrt{g_{m,\max}} \), where \( g_{m,\max} = \max_{1 \leq k \leq K_m} |G_{m,k}| \). As a result, (20) implies that the misclassification rate is bounded by

\[
\frac{g_{m,\max}}{4n} C_\epsilon \frac{\| \hat{Q}(m,::) - Q_\ast(m,::) \|_F^2}{\sigma_{K_m}(Q_\ast(m,::))^2} \leq \frac{1}{4K_m} C_\epsilon \frac{\| \hat{Q}(m,::) - Q_\ast(m,::) \|_F^2}{\sigma_{K_m}(Q_\ast(m,::))^2} \leq C_\epsilon \frac{\| \hat{Q}(m,::) - Q_\ast(m,::) \|_F^2}{\sigma_{K_m}(Q_\ast(m,::))^2} \leq C_\epsilon \frac{2\| \hat{Q}(m,::) - Q_\ast(m,::) \|_F^2}{\sigma_{K_m}(Q_\ast(m,::))^2} \leq C_\epsilon \frac{K^2}{K} \left( \| \hat{W} - W_\ast \|_F^2 + \left( \frac{\sqrt{\max n \log(n \log(n,L))}}{p_{\max} \sqrt{L}} \right)^2 \right) \leq C_\epsilon \frac{K^2}{K} \left( \| \hat{W} - W_\ast \|_F^2 + \left( \frac{\sqrt{\max n \log(n \log(n,L))}}{p_{\max} \sqrt{L}} \right)^2 \right) \leq C_\epsilon \frac{K^2}{K} \left( \log^4(n+L)M^3 \frac{\kappa_0}{1 - \kappa_H} \left( \sqrt{\frac{1}{p_{\max} n^2}} + \frac{\hat{K}^4}{p_{\max} n^2 \min(n,L)} \right)^2 \right) \leq C_\epsilon K_{\max} \log^4(n+L)M^3 \frac{\kappa_0}{1 - \kappa_H} \left( \sqrt{\frac{1}{p_{\max} n^2}} + \frac{\hat{K}^4}{p_{\max} n^2 \min(n,L)} \right)^2 + \frac{(n+L) \log(n+L)^2}{n^2 p_{\max} L} \]

\( \square \)
6.3 Proof of Lemma 2

**Proof of Lemma 2.** The main idea of the proof of Lemma 2 is as follows. Assumption (A1) implies that, when the observation is noise-free in the sense that $A = P_*$, Algorithm 1 converges linearly. As a result, we only need to show that the output of the algorithm does not change much if we replace $A$ with $P_*$ and Algorithm 1 with its linear approximation $P_{L_2} P_{L_1}$.

Given $W^{\text{(iter)}}$, we construct a skew-symmetric matrix $W^{(\text{iter})} \in \mathbb{R}^{M \times M}$ by

$$
Y^{(\text{iter})} = \frac{1}{2}(W^*_T W^{(\text{iter})} - W^{(\text{iter})} T W^*_s),
$$

and then the update formula for the “clean” version of the algorithm is the solution to the equation

$$
Q_* \times_1 \hat{Y}^{(\text{iter} + 1)} = P_{L_2} P_{L_1} (Q_* \times_1 Y^{(\text{iter})}).
$$

(48)

Intuitively, $\hat{Y}^{(\text{iter} + 1)}$ is the algorithmic update when $A_*$ is replaced by $P_*$, and Algorithm 1 is replaced by its linear approximation $P_{L_2} P_{L_1}$. By the definition of $\kappa_H$ in (12), we have

$$
\|W_* \hat{Y}^{(\text{iter} + 1)}\|_d \leq \kappa_H \|W_* Y^{(\text{iter})}\|_d.
$$

(49)

We will bound $\|W^{(\text{iter} + 1)} - W_*\|_d$ as a function of $\|W^{\text{(iter)}} - W_*\|_d$ by (49) and the following perturbation bounds in Lemma 4, with its proof deferred to Section 6.3.1.

**Lemma 4.** For any $W^{\text{iter}}$, let $Y^{\text{iter}}$ and $\hat{Y}^{(\text{iter} + 1)}$ be defined as in (47) and (48), then

1. $\|W_* Y^{(\text{iter})}\|_d \leq \|W^{\text{iter}} - W_*\|_d$.

(50)

2. For

$$
\hat{W}^{(\text{iter} + 1)} = \Pi_0(P_* \times_2 \Pi_{T,K}(Q_* \times_1 (I + Y^{(\text{iter})}))),
$$

we have

$$
\|\hat{W}^{(\text{iter} + 1)} - W_* \hat{Y}^{(\text{iter} + 1)}\|_F \leq \frac{32 \kappa_0^2 \|Y^{\text{iter}}\|^2}{2 - 8 \kappa_0^2 \|Y^{\text{iter}}\|_F - 4 \kappa_0 \|Y^{\text{iter}}\|_F (2 + 4 \kappa_0 \|Y^{\text{iter}}\|_F)}.
$$

(51)

3. If

$$
\|W_* - W^{\text{iter}}\|_F \leq \min_{m=1,\ldots,M} \sigma_{K_m}(Q_*(m,\ldots)),
$$

(53)

then for

$$
\beta = \frac{\|Q_* \times_2 Q_*\|}{6} (a_1 + a_2 \|W^T W^{\text{iter}} - I\|_2),
$$

$$
\|W^{\text{iter} + 1} - \hat{W}^{(\text{iter} + 1)}\|_F \leq \frac{\beta}{\sigma_M(Q_* \times_2 Q_*) - 2 \|Q_* \times_2 Q_*\| \|Y^{\text{iter}}\|_F - \beta}.
$$

(54)

With the perturbation bounds in Lemma 4, we have

$$
\|W^{(\text{iter} + 1)} - W_* (\hat{Y}^{(\text{iter} + 1)} + I)\|_F
$$

\leq \frac{\beta}{\sigma_M(Q_* \times_2 Q_*) - 2 \|Q_* \times_2 Q_*\| \|Y^{\text{iter}}\|_F - \beta} \frac{32 \kappa_0^2 \|Y^{\text{iter}}\|^2}{2 - 8 \kappa_0^2 \|Y^{\text{iter}}\|_F - 4 \kappa_0 \|Y^{\text{iter}}\|_F (2 + 4 \kappa_0 \|Y^{\text{iter}}\|_F)} + \frac{2 \kappa_0 + 8 \kappa_0 \|Y^{\text{iter}}\|_F}{2 - 8 \kappa_0 \|Y^{\text{iter}}\|_F - \kappa_0 (1 + 4 \kappa_0 \|Y^{\text{iter}}\|_F) 4 \kappa_0 \|Y^{\text{iter}}\|_F} (4 \kappa_0 \|Y^{\text{iter}}\|_F)^2.
$$
When
\[ \|W^{(\text{iter})} - W_*\|_F \leq \min\left(\frac{1}{32\kappa_0^2}, \frac{1}{6a_2}\right), \]  
(55)
we have (using \(\|W^{(\text{iter})}\|_F \leq \|W^{(\text{iter})} - W_*\|_F + 4\kappa_0\|Y^{\text{iter}}\|_F \leq 1, 8\kappa_0\|Y^{\text{iter}}\|_F + \kappa_0(1 + 4\kappa_0)\|Y^{\text{iter}}\|_F 4\kappa_0\|Y^{\text{iter}}\|_F < 1\), which imply

\[ \|W^{(\text{iter}+1)} - W_*\|_F = \|\tilde{W}_* Y^{(\text{iter}+1)} + I\|_F \leq \frac{\beta_1}{\sigma_M(Q_s \times 2,3 Q_s)/2 - \beta_1} + 32\kappa_0^2\|Y^{\text{iter}}\|_F^2 + (1 + 2\kappa_0 + 8\kappa_0\|Y^{\text{iter}}\|_F)(4\kappa_0\|Y^{\text{iter}}\|_F)^2 \]
\[ = \frac{\beta_1}{\sigma_M(Q_s \times 2,3 Q_s)/2 - \beta_1} + (3 + 2\kappa_0 + 8\kappa_0\|Y^{\text{iter}}\|_F)(4\kappa_0\|Y^{\text{iter}}\|_F)^2 \]
\[ \leq \frac{6\beta_1}{\sigma_M(Q_s \times 2,3 Q_s)/2 - \beta_1} + (5 + 2\kappa_0)(4\kappa_0\|Y^{\text{iter}}\|_F)^2 \]
\[ = a_1 + a_2\|W_*^T W^{(\text{iter})} - I\|_F^2 + (5 + 2\kappa_0)(4\kappa_0\|Y^{\text{iter}}\|_F)^2. \]

Recall that
\[ \|W^{(\text{iter}+1)} - W_*\|_d \leq \|W_*\tilde{Y}^{(\text{iter}+1)}\|_d - \|W^{(\text{iter}+1)} - W_*\tilde{Y}^{(\text{iter}+1)} + I\|_d \]
\[ \leq \kappa_H\|W_* Y^{(\text{iter})}\|_d - \|W^{(\text{iter}+1)} - W_*\tilde{Y}^{(\text{iter}+1)} + I\|_d \]
\[ \leq \kappa_H\|W_* - W^{(\text{iter})}\|_d - \|W^{(\text{iter}+1)} - W_*\tilde{Y}^{(\text{iter}+1)} + I\|_d, \]
so we have

\[ \|W^{(\text{iter}+1)} - W_*\|_d \leq \kappa_H\|W^{(\text{iter})} - W_*\|_d + C_H\left(a_1 + a_2\|W_*^T W^{(\text{iter})} - I\|_F + (5 + 2\kappa_0)(4\kappa_0\|Y^{\text{iter}}\|_F)^2\right) \leq \kappa_H\|W^{(\text{iter})} - W_*\|_d + C_H\left(a_1 + a_2\|W_*^T W^{(\text{iter})} - I\|_F^2 + 16(5 + 2\kappa_0)\kappa_0^2\|W^{(\text{iter})} - W_*\|_d^2\right) \leq \kappa_H\|W^{(\text{iter})} - W_*\|_d + C_H\left(a_1 + (a_2 + 80\kappa_0^2 + 32\kappa_0^3)\|W^{(\text{iter})} - W_*\|_d^2\right) \]
\[ \]
As a result, if in addition we have
\[ C_H(a_2 + 80\kappa_0^2 + 32\kappa_0^3)\|W^{(\text{iter})} - W_*\|_d \leq (1 - \kappa_H)/2, \]  
(56)
then
\[ \|W^{(\text{iter}+1)} - W_*\|_d \leq \frac{1 + \kappa_H}{2}\|W^{(\text{iter})} - W_*\|_d + C_H a_1. \]  
(57)

By assumptions in (39) and (40) and the argument of induction, (53), (55), and (56) hold for all iter \( \geq 1 \). Therefore, (57) holds for all iter \( \geq 1 \) and the theorem is proved.

### 6.3.1 Proof of Lemma 4

The proof of Lemma 4 is based on Lemma 5-8. Among these lemmas, the proofs of Lemmas 5, 7, 8 will be presented in Section 6.4, and Lemma 6 is a restatement of Theorem VII.5.1 in Bhatia (1997). We shall prove the three perturbation bounds (50), (52), and (54) separately.
Lemma 5. Given any symmetric matrix $Q \in \mathbb{R}^{M \times M}$, if $QY - X = S$ holds for a symmetric matrix $S \in \mathbb{R}^{M \times M}$ and a skew symmetric matrix $Y \in \text{Skew}(M)$, then we have
\[ \|QY\|_F, \|S\|_F \leq 2\|X\|_F. \]

Lemma 6. For any square matrices $A$ and $B$,
\[ \|\Pi_o(A) - \Pi_o(B)\|_F \leq 2\frac{\|A - B\|_F}{\sigma_{\min}(A) + \sigma_{\min}(B)}. \]

The inequality also holds if the operator norm is replaced with Frobenius norm.

Lemma 7. For any positive definite matrix $Q$, symmetric matrix $S \in \mathbb{R}^{M \times M}$ and skew symmetric matrix $Y \in \text{Skew}(M)$ with $\|Y\| \leq 1$, we have
\[ \|\Pi_o(Q(I + Y) - (I + Y))\|_F \leq (1 + \frac{2\|Q\|}{2\sigma_{\min}(Q) - e\|Q\|\|Y\|})(e - 2)\|Y\|^2_F. \]

Lemma 8. Let $\Pi_o$ be defined in (2). Then
\[ \|\Pi_o(X + Y) - \Pi_o(X)\|_F \leq (1 + \sqrt{2})\frac{\|Y\|_F}{\sigma_M(X) - \|Y\|}, \]
where $\sigma_M(X)$ represents the $M$-th singular value of $X$.

Lemma 9. For a symmetric matrix $X_0 \in \mathbb{R}^{n \times n}$ with rank $r$, let $\Pi_T : \mathbb{R}^{n \times n} \rightarrow \mathbb{R}^{n \times n}$ be projection onto the tangent space of $\{X : \text{rank}(X) = r\}$ at $X_0$ and $\Pi_{T,\perp}$ be the remainder of the projection, then for any symmetric matrix $\Delta$,
\[ \|\Pi_{T,\perp}(\Delta)\|_F \leq \frac{\|\Pi_T(\Delta)\|_F^2}{\sigma_r(X_0) - \|\Delta\|}. \]

Proof of bound 1 in (50)

It follows from the observation that $W_*Y_{(iter)} = P_{L_0}(W^{(iter)} - W_*)$ and from the definition (38), $\|W_*Y_{(iter)}\|_d = \lambda\|P_* \times W_*Y_{(iter)}\|_F$ and
\[ \|W^{(iter)} - W_*\|_d = \sqrt{\lambda}\|P_* \times W_*Y_{(iter)}\|_F^2 + \|P_{L_0}^+(W^{(iter)} - W_*)\|_F^2. \]

Proof of bound 2 in (52)

By the definition of (48), we have that for any $\Delta \in \text{Skew}(M)$,
\[ 0 = (Q_* \times_{1,2} \tilde{Y}_{(iter+1)} - P_{L_1}(Q_* \times_{1,2} Y_{(iter)}), Q_* \times_{1,2} \Delta) \]
\[ = (Q_* \times_{1,2} (Q_* \times_{1,2} \tilde{Y}_{(iter+1)} - P_{L_1}(Q_* \times_{1,2} Y_{(iter)})), \Delta). \]

As a result, $Q_* \times_{1,2} (Q_* \times_{1,2} \tilde{Y}_{(iter+1)} - P_{L_1}(Q_* \times_{1,2} Y_{(iter)})) = (Q_* \times_{1,2} Q_* \tilde{Y}_{(iter+1)} - Q_* \times_{1,2} P_{L_1}(Q_* \times_{1,2} Y_{(iter)}))$ is a symmetric matrix. Denoting it by $S$, Lemma 5 implies that
\[ \max(\|Q_* \times_{1,2} S\|_F), \|S\|_F \leq 2\|Q_* \times_{1,2} \Pi_{T,\perp}(Q_* \times_{1,2} Y_{(iter)})\|_F, \]
\[ \leq 2\max_{1 \leq m \leq M} \|Q_* \times_{1,2} \Pi_{T,K_m}(Q_* \times_{1,2} Y_{(iter)})\|_F \leq 4\|Q_* \times_{1,2} Q_* \|_F \|Y_{(iter)}\|_F, \quad (58) \]
where the last inequality is due to
\[ Q_* \times_{2,3} Q_* = \|M_1(Q_*)\|^2, \|Q_* \times_{2,3} \Pi_{T,K_m}(Q_*)\| \leq \|M_1(Q_*)\| \|M_1(\Pi_{T,K_m}(Q_*))\|, \]
\[ M_1(\Pi_{T,K_m}(Q_*)) = M_1(Q_*)(\Pi_{U_m} \otimes I) + M_1(Q_*)(\Pi_{U_m} \otimes \Pi_{U_m}), \]
where \( \otimes \) represents the Kronecker product, and \( \|A \otimes B\| \leq \|A\|\|B\| \).

As a result,
\[ \|\tilde{Y}^{(\text{iter}+1)}\|_F \leq 4\kappa_0\|Y^{(\text{iter})}\|_F. \tag{59} \]

By the definition of \( \hat{W}^{(\text{iter}+1)}\hat{W}^{(\text{iter}+1)} \), we have \( W, \hat{W}^{(\text{iter}+1)} = \Pi_o(Q_* \times_{2,3} \Pi_{T,K}(Q_* \times_1 \hat{W}^{(\text{iter})})) = \Pi_o((Q_* \times_{2,3} Q_*)((\tilde{Y}^{(\text{iter}+1)} + I) - S)). \) Lemma 6, the upper bounds of \( \|S\|_F \) in (58), and \( \|Y^{(\text{iter}+1)}\|_F \) in (59) imply
\[
\|W, \hat{W}^{(\text{iter}+1)} - \Pi_o((Q_* \times_{2,3} Q_* - S)(\tilde{Y}^{(\text{iter}+1)} + I))\|_F \\
= \|\Pi_o((Q_* \times_{2,3} Q_*)((\tilde{Y}^{(\text{iter}+1)} + I) - S) - \Pi_o((Q_* \times_{2,3} Q_* - S)(\tilde{Y}^{(\text{iter}+1)} + I))\|_F \\
\leq \frac{2\|SY^{(\text{iter}+1)}\|_F}{2\sigma_{\text{min}}((Q_* \times_{2,3} Q_*)((\tilde{Y}^{(\text{iter}+1)} + I)) - \|S\|(2 + \|Y^{(\text{iter}+1)}\|)) \\
\leq \frac{2\|SY^{(\text{iter}+1)}\|_F}{2\sigma_{\text{min}}((Q_* \times_{2,3} Q_*)((\tilde{Y}^{(\text{iter}+1)} + I)) - \|S\|(2 + \|Y^{(\text{iter}+1)}\|)) \\
\leq \frac{2\sigma_{\text{min}}(Q_* \times_{2,3} Q_*) - 2\|Q_* \times_{2,3} Q_*\|\|Y^{(\text{iter}+1)}\|_F - \|S\|(2 + \|Y^{(\text{iter}+1)}\|))}{2(4\|Q_* \times_{2,3} Q_*\|\|Y^{(\text{iter}+1)}\|_F)(4\kappa_0\|Y^{(\text{iter}+1)}\|_F)} \\
\leq \frac{2\sigma_{\text{min}}(Q_* \times_{2,3} Q_*) - 2\|Q_* \times_{2,3} Q_*\|\|Y^{(\text{iter}+1)}\|_F - (4\|Q_* \times_{2,3} Q_*\|\|Y^{(\text{iter}+1)}\|_F)(4\kappa_0\|Y^{(\text{iter}+1)}\|_F)}{32\kappa_0^2\|Y^{(\text{iter}+1)}\|_F} \\
\leq 2 - 8\kappa_0^2\|Y^{(\text{iter}+1)}\|_F - 4\kappa_0\|Y^{(\text{iter}+1)}\|_F(2 + 4\kappa_0\|Y^{(\text{iter}+1)}\|_F). \\
\]

In addition, Lemma 7 implies
\[
\|\Pi_o((Q_* \times_{2,3} Q_* - S)((\tilde{Y}^{(\text{iter}+1)} + I)) - (\tilde{Y}^{(\text{iter}+1)} + I)\|_F \\
\leq 1 + \frac{2\|Q_* \times_{2,3} Q_* - S\|}{2\sigma_{\text{min}}(Q_* \times_{2,3} Q_* - S) - e\|Q_* \times_{2,3} Q_* - S\||\|\tilde{Y}^{(\text{iter}+1)}\|_F|} (e - 2)|\|\tilde{Y}^{(\text{iter}+1)}\|_F^2 \\
\leq 1 + \frac{2\|Q_* \times_{2,3} Q_*\| + 2\|S\|_F}{2\sigma_{\text{min}}(Q_* \times_{2,3} Q_*) - 2\|S\|_F - (\|Q_* \times_{2,3} Q_*\| + \|S\|_F)|\|\tilde{Y}^{(\text{iter}+1)}\|_F|} |\|\tilde{Y}^{(\text{iter}+1)}\|_F^2 \\
\leq 1 - 8\kappa_0\|Y^{(\text{iter}+1)}\|_F(4\kappa_0\|Y^{(\text{iter}+1)}\|_F) - 4\kappa_0(1 + 4\kappa_0\|Y^{(\text{iter}+1)}\|_F)\|Y^{(\text{iter}+1)}\|_F^2. \\
\]

Combining the previous two estimations, part 2 is proved.

**Proof of bound 3 in (54)**

By the definition of \( \hat{W}^{(\text{iter}+1)} \) in (51) and \( W^{(\text{iter}+1)} = \Pi_o(A \times_{2,3} \Pi_K(A \times_1 W^{(\text{iter})})) \), Lemma 8 implies that
\[
\|\hat{W}^{(\text{iter}+1)} - W^{(\text{iter}+1)}\|_F \leq \frac{\beta_1}{\sigma_M(P_* \times_{2,3} \Pi_{T,K}(Q_* \times_1 (I + Y^{(\text{iter}+1)})))) - \beta_1} \leq \frac{\beta_1}{\sigma_M(Q_* \times_{2,3} Q_*) - \beta_2 - \beta_1}. \\
\]
for \( \beta_1 = \|A \times_{2,3} \Pi_K(A \times_1 W^{(\text{iter})}) - P_\ast \times_{2,3} \Pi_T(K(Q_\ast \times_1 (I + Y^{(\text{iter})})))\|_F \) and \( \beta_2 = \|P_\ast \times_{2,3} \Pi_T(K(Q_\ast \times_1 Y^{(\text{iter})}))\|_F \). By the same calculation as in (58), we have

\[
\beta_2 \leq \max_{1 \leq m \leq M} \|Q_\ast \times_{2,3} \Pi_{T,K_m}(Q_\ast)\|_F \|Y^{(\text{iter})}\|_F \leq 2 \|Q_\ast \times_{2,3} Q_\ast\|_F \|Y^{(\text{iter})}\|_F. \tag{60}
\]

To estimate the upper bound of \( \beta_1 \), we note that \( \beta_1 \leq \beta_3 + \beta_4 \), where

\[
\beta_3 = \|A \times_{2,3} \Pi_K(A \times_1 W^{(\text{iter})}) - A \times_{2,3} (Q_\ast + \Pi_T(K(A \times_1 W^{(\text{iter})}) - Q_\ast))\|_F \tag{61}
\]

and

\[
\beta_4 = \|A \times_{2,3} (Q_\ast + \Pi_T(K(A \times_1 W^{(\text{iter})}) - Q_\ast)) - P_\ast \times_{2,3} (Q_\ast + \Pi_T(K(P_\ast \times_1 (W^{(\text{iter})} - W_\ast))))\|_F \tag{62}
\]

\[
= \|\Delta \times_{2,3} \Pi_T(K[P_\ast \times_1 W^{(\text{iter})}] + \Delta \times_{2,3} \Pi_T(K[\Delta \times_1 W^{(\text{iter})}] + P_\ast \times_{2,3} \Pi_T(K[\Delta \times_1 W^{(\text{iter})}])\|_F.
\]

To estimate the upper bound of \( \beta_3 \) in (61), let \( \Pi_{T,K,\perp} \in \mathbb{R}^{M \times n \times n} \) be \( \Pi_K(A \times_1 W^{(\text{iter})}) - (Q_\ast + \Pi_T(K(A \times_1 W^{(\text{iter})}) - Q_\ast)) \), then by Lemma 9 and

\[
A \times_1 W^{(\text{iter})} - Q = \Delta \times_1 W^{(\text{iter})} + P_\ast \times_1 (W^{(\text{iter})} - W),
\]

we have \( \text{rank}(\Pi_{T,K,\perp}(m,:,\cdot)) \leq K_m \) and

\[
\|\Pi_{T,K,\perp}(m,:,\cdot)\| \leq \frac{\|\Pi_{T,K_m}[A \times_1 W^{(\text{iter})} - Q](m,:,\cdot)\|^2}{\sigma_{K_m}(Q_\ast(m,:,\cdot)) - \|Q_\ast\|_F \|W_\ast - W^{(\text{iter})}\| - \|\Delta\|} \leq \frac{4\|\|A \times_1 W^{(\text{iter})} - Q\|(m,:,\cdot)\|^2}{\sigma_{K_m}(Q_\ast(m,:,\cdot)) - \|Q_\ast\|_F \|W_\ast - W^{(\text{iter})}\| - \|\Delta\|} \leq \frac{4\|\|W_\ast W^{(\text{iter})} - I\|(m,:,\cdot)\|_F^2}{\sigma_{K_m}(Q_\ast(m,:,\cdot))} \leq \frac{16\|\|Q_\ast\|_F^2 \|W_\ast W^{(\text{iter})} - I\|(m,:,\cdot)\|_F^2}{\sigma_{K_m}(Q_\ast(m,:,\cdot))} \leq 2K_m \|A\| \|\Pi_{T,K,\perp}(m,:,\cdot)\|. \tag{63}
\]

Since \( \text{rank}(\Pi_{T,K,\perp}(m,:,\cdot)) \leq 2K_m \), we have

\[
\beta_3 \leq \|A \times_{2,3} \Pi_{T,K,\perp}(m,:,\cdot)\| \leq 2K_m \|A\| \|\Pi_{T,K,\perp}(m,:,\cdot)\|.
\]

Summing \( 1 \leq m \leq M \), (63) implies

\[
\beta_3 = \|A \times_{2,3} \Pi_{T,K,\perp}\|_F \leq 16 \|A\| \sqrt{\sum_{m=1}^{M} \frac{K_m(\|Q_\ast\|_F^2 \|W_\ast W^{(\text{iter})} - I\|(m,:,\cdot)\|_F^2 + \|\Delta\|_F^2)}{\sigma_{K_m}(Q_\ast(m,:,\cdot)) - \|Q_\ast\|_F \|W_\ast - W^{(\text{iter})}\| - \|\Delta\|}} \]

\[
\leq 16 \|A\| \sum_{m=1}^{M} \frac{K_m(\|Q_\ast\|_F^2 \|W_\ast W^{(\text{iter})} - I\|(m,:,\cdot)\|_F^2 + \|\Delta\|_F^2)}{\sqrt{M} \sigma_{K_m}(Q_\ast(m,:,\cdot)) - \|Q_\ast\|_F \|W_\ast - W^{(\text{iter})}\| - \|\Delta\|}} \leq 16 \|A\| \sqrt{\frac{\hat{K}(\|Q_\ast\|_F^2 \|W_\ast W^{(\text{iter})} - I\|_2^2 + \|\Delta\|_2^2)}{\sqrt{M} \min_{k=1}^{M} \sigma_{K_m}(Q_\ast(m,:,\cdot))}} \]

\[
\leq 32 \sqrt{\frac{\hat{K}(\|Q_\ast\|_F^2 \|W_\ast W^{(\text{iter})} - I\|_2^2 + \|\Delta\|_2^2)}{\sqrt{M} \min_{k=1}^{M} \sigma_{K_m}(Q_\ast(m,:,\cdot))}} \]

where \( \hat{K} \) is the bound of the eigenvalue of the perturbation matrix.
To estimate the upper bound of $\beta_4$ in (62), note that
\[
\|[\Delta \times_{2,3} \Pi_{T,K}(\Delta \times_1 W^{(iter)})](i,:)\| = \|\Delta \times_{2,3} \Pi_{T,K_m}(\Delta)\|W^{(iter)}(i,:)\|
\]
\[
= \|\Pi_{T,K_m}(\Delta) \times_{2,3} \Pi_{T,K_m}(\Delta)\|W^{(iter)}(i,:)\| \leq \|\Pi_{T,K_m}(\Delta)\| \times_{2,3} \Pi_{T,K_m}(\Delta)\|
\]
which implies
\[
\|\Delta \times_{2,3} \Pi_{T,K}(\Delta \times_1 W^{(iter)})\|_F \leq \max_{1 \leq m \leq M} \|\Pi_{T,K_m}(\Delta)\| \sqrt{M}. \tag{64}
\]

Similarly,
\[
\|P \times_{2,3} \Pi_{T,K}(\Delta \times_1 W^{(iter)})\|_F \leq \max_{1 \leq m \leq M} \|\Pi_{T,K_m}(P)\| \times_{2,3} \Pi_{T,K_m}(\Delta)\| \sqrt{M},
\]
\[
\|\Delta \times_{2,3} \Pi_{T,K}(P \times_1 W^{(iter)})\|_F \leq \max_{1 \leq m \leq M} \|\Pi_{T,K_m}(P)\| \times_{2,3} \Pi_{T,K_m}(\Delta)\| \sqrt{M}. \tag{65}
\]
As a result,
\[
\beta_4 \leq \sqrt{M} \left( \max_{1 \leq m \leq M} \|\Pi_{T,K_m}(\Delta)\| \times_{2,3} \Pi_{T,K_m}(\Delta)\| + 2 \max_{1 \leq m \leq M} \|\Pi_{T,K_m}(P)\| \times_{2,3} \Pi_{T,K_m}(\Delta)\| \right).
\]
Combining the estimations of $\beta_1$, $\beta_2$, $\beta_3$, and $\beta_4$, part 3 is proved. \hfill \Box

6.4 Proofs of auxiliary Lemmas and Propositions

Proof of Lemma 1. For any $X \in \text{Skew}_m$ such that $Q_* \times_1 X \in L_1$, due to
\[
[Q_* \times_1 X](m,:) = \sum_{m' = 1}^M X(m,m')Q_*(m',:) = \sum_{m = 1, m' \neq m}^M X(m,m')Q_*(m',:),
\]
one has $\sum_{m' = 1}^M X(m,m')\Pi_{U_m^\perp} Q_*(m',:)\Pi_{U_m^\perp} = 0$. When the first sufficient condition holds, then $X(m,m') = 0$ for all $1 \leq m' \leq M$. Combining the analysis for all $1 \leq m \leq M$, we have $X = 0$. As a result, $L_1 \cap L_2 = \{0\}$ and (A1) holds.

The second sufficient condition follows from the first sufficient condition directly. \hfill \Box

Proof of Lemma 3. We first summarize a special case of (Lei, 2020, Theorem 2.1) as follows:

Lemma 10. If $X_l \in \mathbb{R}^{n \times r}$, $l = 1, \cdots, L$ are i.i.d. elementwise sampled from a centered Bernoulli distribution with parameter not larger than $p$, then
\[
\Pr \left( \left\| \sum_{l=1}^L X_l \right\| \geq t \right) \leq 2(r + n) \exp \left( - \frac{t^2 / 2}{pL \max(n,r) + t} \right)
\]

Since $U_m$ is a matrix of size $n \times K_m$ such that the $i$-th column is the normalized indicator vector of the set $G_{m,i}$, i.e., the indicator vector with scale $1 / \sqrt{|G_{m,i}|}$. As a result,
\[
\langle Q(m_1,:), \Delta(l,:) U_m(k,:) \rangle = \sum_{j_1=1}^n \sum_{j_2 \in G_{m,i}} \Delta(l, j_1, j_2) \frac{Q(m_1, j_1, j_2)}{|G_{m,i}|},
\]
\[28\]
and by Bernstein’s inequality (each term is not larger than $\sqrt{L_m p_{\text{max}}}$ and
\[
\text{Expect} \left[ (\Delta(l,j_1,j_2) \sum_{j_2' \in G(m,k)} Q(m_1,j_1,j_2')^2) \right] \leq L_m p_{\text{max}}^3,
\]
\[
\Pr \left( \left| \sum_{j_2 \in G(m,k)} Q(m_1,j_1,j_2) \right| \geq t \sqrt{L_m p_{\text{max}}^3 n |G(m,k)|} \right) \leq 2 \exp \left( \frac{-t^2}{3 \sqrt{L_m p_{\text{max}}^3 n |G(m,k)|}} \right).
\]
Summing it over $1 \leq i \leq K_m$, $1 \leq l \leq L$, and $1 \leq m_1 \leq M$, we proved (42).

By definition, $\|M_1(\Pi_{T,K_m}(\Delta))\| \leq 3 \sum_{k=1}^{K_m} \frac{1}{\sqrt{G_m,k}} \sum_{i \in G_m,k} \Delta(\cdot,i)$, and Lemma 10 implies that
\[
\Pr \left( \left\| \sum_{i \in G_m,k} \Delta(\cdot,i) \right\| \geq t \sqrt{\text{max}(n,L)|G_m,k|} \right) \leq 2(L + n) \exp \left( \frac{-t^2/2}{1 + \frac{t^2}{\sqrt{\text{max}(n,L)|G_m,k|}}} \right).
\]
As a result,
\[
\Pr \left( \left\| M_1(\Pi_{T,K_m}(\Delta)) \right\| \leq 3K_m t \sqrt{\text{max}(n,L)} \right) \geq 2K_m(L + n) \exp \left( \frac{-t^2/2}{1 + \frac{t^2}{\sqrt{\text{max}(n,L)|G_m,k|}}} \right)
\]
and (43) is then proved.

\textbf{Proof of Lemma 5.} Without loss of generality, assume that $Q$ is a diagonal matrix with $Q = \text{diag}(q_1, \ldots, q_M)$. Then for each $1 \leq i, j \leq M$, $q_i Y_{i,j} - X_{i,j} = S_{i,j}$ and $q_j Y_{j,i} - X_{j,i} = S_{j,i}$. Since $S_{i,j} = S_{j,i}$ and $Y_{i,j} = -Y_{j,i}$, we have
\[
Y_{i,j} = \frac{X_{i,j} - X_{j,i}}{q_i + q_j}, \quad S_{i,j} = \frac{q_j X_{i,j} - q_i X_{j,i}}{q_i + q_j}.
\]
Since $\{q_i\}_{i=1}^M$ are positive, the lemma is proved.

\textbf{Proof of Lemma 7.} Let $U = \exp(Y)$, then it is an orthogonal matrix. In addition, $\|U - I\| = \left\| \sum_{k=1}^{\infty} \frac{1}{k!} Y^k \right\| \leq \sum_{k=1}^{\infty} \frac{1}{k!} \|Y\|^k \leq (e - 1)\|Y\|$ and $\|U - (I + Y)\|_F = \|U - (I + Y)\|_F \leq \sum_{k=2}^{\infty} \frac{1}{k!} \|Y\|^{k-2} \leq (e - 2)\|Y\|_F$. As a result, Lemma 6 implies
\[
\|\Pi_0(Q(I + Y) - (I + Y))\|_F \leq \|\Pi_0(Q(I + Y)) - \Pi_0(QU)\|_F + \|\Pi_0(QU) - (I + Y)\|_F \leq \frac{2}{\sigma_{\text{min}}(Q(I + Y)) + \sigma_{\text{min}}(QU)} \|Q(U - I - Y)\|_F + \|U - I - Y\|_F \leq (1 + \frac{2\|Q\|}{\sigma_{\text{min}}(Q(I + Y)) + \sigma_{\text{min}}(QU)}) (e - 2)\|Y\|_F \leq (1 + \frac{2\|Q\|}{2\sigma_{\text{min}}(Q) - e\|Q\|\|Y\|_F}) (e - 2)\|Y\|_F^2.
\]
Proof of Lemma 8.

\[ \|\Pi_o(X + Y) - \Pi_o(X)\|_F = \|Y[(X + Y)^T(X + Y)]^{-0.5} - X[X^TX]^{-0.5}\|_F \]

\[ \leq \frac{\|Y\|_F}{\sigma_M(X)} + \|X[X^TX]^{-0.5}[(X + Y)^T(X + Y)]^{-0.5} - [X^TX]^{-0.5}\|_F \]

Here the first and the second inequalities follows from \(\|AB\|_F \leq \|A\|_F \|B\|\), and the third inequality follows from (Bhatia, 1997, (VII.39)).

\[ \square \]

Proof of Lemma 9. Let \(U \in \mathbb{R}^{n \times r}\) be the orthogonal matrix that has the same column space as \(X_0\), then

\[ \|\Pi_{T,\perp} \Delta\|_F = \|\Pi_{U,\perp} \Delta\|_F \geq \|\Pi_{U,\perp} \Delta\|_F = \|\Pi_{U,\perp} \Delta\|_F, \]

and

\[ \Pi_{T,\perp} \Delta = \Pi_{U,\perp} \Delta (U^T(X_0 + \Delta)U)^{-1}U^T \Delta U^T \Pi_{U,\perp}. \]

As a result,

\[ \|\Pi_{T,\perp} \Delta\|_F \leq \frac{\|\Pi_{U,\perp} \Delta\|_F^2}{\sigma_r(U^T(X_0 + \Delta)U)} \leq \frac{\|\Pi_{T,\perp} \Delta\|_F^2}{\sigma_r(X_0) - \|\Delta\|}. \]

\[ \square \]

Proof of Proposition 1. For \(W^{(0)}\), Lemma 5 of Jing et al. (2020) gives the following theoretical guarantees. Let \(P_*\) have Tucker ranks \((M, r, r)\) with decomposition \(P_* = C_{\times 1}W_{\times 2}U_{\times 3}\), where \(C \in \mathbb{R}^{M \times r}, W \in \mathbb{R}^{L \times M}\) and \(U \in \mathbb{R}^{n \times r}\) are orthogonal matrices, and \(L = (L_1, \ldots, L_M) \in \mathbb{R}^M\). Then, if \(\delta = \max_{1 \leq j \leq L} (e_j^T)\) is such that \(\delta = O(\sqrt{r/n})\), and \(\sigma_r(C_{\times 3} (L/L)^1/2) \geq C \sqrt{np_{\max} \log^2 n}\), then, with probability at least \(1 - 3n^{-2}\),

\[ \min_{O \in \mathbb{R}^{M \times M}, OO^T = I} \|W^{(0)} - W_*\|_F^2 \leq \min \left( \frac{C \sqrt{Mnp_{\max} \log^2 n \log^2 r}}{\sigma_{\min}(C)} \right), \quad (66) \]

where \(\sigma_{\min}(C) = \min\{\sigma_{\min}(M_j(C)), j = 1, 2, 3\}\). In addition, (Lei, 2020, Lemma C.1) shows that if \((1 + \epsilon)\) K-means is applied, the number of misclassified layers in the initial between-class clustering \(\cup_{m=1}^{M} \hat{S}_m\) is bounded by \(C \min_{O \in \mathbb{R}^{M \times M}, OO^T = I} \|W^{(0)} - W_*\|_F^2 \max_{1 \leq m \leq M} \|S_m\|\), which implies that with a permutation of the columns of \(W^{(1)}\),

\[ \|W^{(1)} - W_*\|_F^2 \leq C \min_{O \in \mathbb{R}^{M \times M}, OO^T = I} \|W^{(0)} - W_*\|_F^2 \max_{1 \leq m \leq M} \|L_m \|. \quad (67) \]

Here \(C\) represents a constant that depends on \(\epsilon\) that might be different in different equations. Combining (67) with the upper bound on \(\|W^{(0)} - W_*\|_F\) in (66), we obtain

\[ \|W^{(1)} - W_*\| \leq C \sqrt{M} \min \left( \frac{C \sqrt{Mnp_{\max} \log^2 n \log^2 r}}{\sigma_{\min}(C)} \right) \max_{1 \leq m \leq M} \|L_m \|. \quad (68) \]
Due to the assumption that $M, K_m, K$ and $\kappa_0$ are uniformly bounded above for all values of $n$ and $L$, one has $r = O(1)$, $\sigma_r(C \times_3 (L/L)^{1/2}) = O(p_{\text{max}}n\sqrt{L})$, and $\sigma_{\text{min}}(C = O(p_{\text{max}}n\sqrt{L}))$. As a result, if $p_{\text{max}}nL \to \infty$, then $\|W^{(1)} - W^*_r\|_F = O(\frac{1}{\sqrt{p_{\text{max}}nL}})$ and converges to zero. Also, the RHS of (30) is in the order of $O(1)$. As a result, the assumption on initialization (30) is satisfied with high probability.
