# LEGENDRE TRAJECTORIES OF TRANS- $S$-MANIFOLDS 

ŞABAN GÜVENÇ

#### Abstract

In this paper, we consider Legendre trajectories of trans- $S$-manifolds. We obtain curvature characterizations of these curves and give a classification theorem. We also investigate Legendre curves whose Frenet frame fields are linearly dependent with certain combination of characteristic vector fields of the trans- $S$-manifold.

## 1. Introduction

Let $(M, g)$ be a Riemannian manifold, $F$ a closed 2 -form and let us denote the Lorentz force on $M$ by $\Phi$, which is a (1,1)-type tensor field. If $F$ is associated by the relation

$$
\begin{equation*}
g(\Phi X, Y)=F(X, Y), \quad \forall X, Y \in \chi(M) \tag{1.1}
\end{equation*}
$$

then it is called a magnetic field (1], [2] and [7]). Let $\nabla$ be the Riemannian connection associated to the Riemannian metric $g$ and $\gamma: I \rightarrow M$ a smooth curve. If $\gamma$ satisfies the Lorentz equation

$$
\begin{equation*}
\nabla_{\gamma^{\prime}(t)} \gamma^{\prime}(t)=\Phi\left(\gamma^{\prime}(t)\right) \tag{1.2}
\end{equation*}
$$

then it is called a magnetic curve for the magnetic field $F$. The Lorentz equation is a generalization of the equation for geodesics. Magnetic curves have constant speed. If the speed of the magnetic curve $\gamma$ is equal to 1 , then it is called a normal magnetic curve 8. For extensive information about almost contact metric manifolds and Sasakian manifolds, we refer to Blair's book [3].

Let $\gamma(s)$ be a Frenet curve parametrized by the arc-length parameter $t$ in an almost contact metric manifold $M$. The function $\theta(t)$ defined by $\cos [\theta(t)]=g(T(t), \xi)$ is called the contact angle function. A curve $\gamma$ is called a slant curve if its contact angle is a constant [6]. If a slant curve is with contact angle $\frac{\pi}{2}$, then it is called a Legendre curve 3. Likewise, Cihan Özgür and the present author defined Legendre curves of $S$-manifolds in 15. A curve $\gamma: I \rightarrow M=\left(M^{2 n+s}, f, \xi_{i}, \eta_{i}, g\right)$ is called a Legendre curve if $\eta_{i}(T)=0$, for every $i=1, \ldots s$, where $T$ is the tangent vector field of $\gamma$. This definition can be used in trans- $S$-manifolds.

Let $\gamma$ be a curve in an almost contact metric manifold $(M, \varphi, \xi, \eta, g)$. In [12], Lee, Suh and Lee introduced the notions of $C$-parallel and $C$-proper curves in the tangent and normal bundles. A curve $\gamma$ in an almost contact metric manifold $(M, \varphi, \xi, \eta, g)$ is defined to be $C$-parallel if $\nabla_{T} H=\lambda \xi, C$-proper if $\Delta H=\lambda \xi$, $C$-parallel in the normal bundle if $\nabla_{T}^{\perp} H=\lambda \xi$, C-proper in the normal bundle if $\Delta^{\perp} H=\lambda \xi$, where $T$ is the unit tangent vector field of $\gamma, H$ is the mean curvature vector field, $\Delta$ is the Laplacian, $\lambda$ is a non-zero differentiable function along the

[^0]curve $\gamma, \nabla^{\perp}$ and $\Delta^{\perp}$ denote the normal connection and Laplacian in the normal bundle, respectively [12. The present author and Cihan Ozgür generalized this definition for $S$-manifolds in [10]. In the present study, this definition will be used in trans- $S$-manifolds as well.

An almost contact metric manifold $M$ is called a trans-Sasakian manifold [14] if there exist two functions $\alpha$ and $\beta$ on $M$ such that

$$
\begin{equation*}
\left(\nabla_{X} \varphi\right) Y=\alpha[g(X, Y) \xi-\eta(Y) X]+\beta[g(\varphi X, Y) \xi-\eta(Y) \varphi X] \tag{1.3}
\end{equation*}
$$

for any vector fields $X, Y$ on $M$. $C$-parallel and $C$-proper slant curves of transSasakian manifolds were studied in [16].

## 2. Preliminaries

Firstly, let us recall framed $f$-manifolds. Let $(M, g)$ be a $(2 n+s)$-dimensional Riemann manifold. It is called framed metric $f$-manifold with a framed metric $f$-structure $\left(f, \xi_{i}, \eta_{i}, g\right), \alpha \in\{1, \ldots, s\}$, if it satisfies the following equations:

$$
\begin{gather*}
\varphi^{2}=-I+\sum_{\alpha=1}^{s} \eta^{\alpha} \otimes \xi_{\alpha}, \quad \eta_{i}\left(\xi_{j}\right)=\delta_{i j}, \quad f\left(\xi_{i}\right)=0, \quad \eta_{i} \circ f=0  \tag{2.1}\\
g(f X, f Y)=g(X, Y)-\sum_{i=1}^{s} \eta_{i}(X) \eta_{i}(Y)  \tag{2.2}\\
\eta^{\alpha}(X)=g(X, \xi) \tag{2.3}
\end{gather*}
$$

Here, $f$ is a $(1,1)$ tensor field of rank $2 n ; \xi_{1}, \ldots, \xi_{s}$ are vector fields; $\eta_{1}, \ldots, \eta_{s}$ are 1 -forms and $g$ is a Riemannian metric on $M ; X, Y \in \chi(M)$ and $i, j \in\{1, \ldots, s\}$ [13]. $\left(f, \xi_{i}, \eta_{i}, g\right)$ is called $S$-structure, when the Nijenhuis tensor of $\varphi$ is equal to $-2 d \eta^{\alpha} \otimes \xi_{\alpha}$, for all $\alpha \in\{1, \ldots, s\}$ [3].

Secondly, the concept of trans- $S$-manifolds is as follows:
A $(2 n+s)$-dimensional metric $f$-manifold M is called an almost trans- $S$ manifold if it satisfies

$$
\left(\nabla_{X} f\right) Y=\sum_{i=1}^{s}\left[\begin{array}{c}
\alpha_{i}\left\{g(f X, f Y) \xi_{i}+\eta(Y) f^{2} X\right\}  \tag{2.4}\\
+\beta_{i}\left\{g(f X, Y) \xi_{i}-\eta_{i}(Y) f X\right\}
\end{array}\right]
$$

where $\alpha_{i}, \beta_{i}(i=1, \ldots, s)$ are smooth functions and $X, Y \in \chi(M) 4$. If M is normal, then it is called a trans-S-manifold. If $s=1$, a trans- $S$-manifold becomes a transSasakian manifold. In trans-Sasakian case, the above condition implies normality. But, for $s \geq 2$, this statement is no longer valid 4]. Since

$$
\begin{equation*}
[f, f](X, Y)+2 \sum_{i=1}^{s} d \eta_{i}(X, Y) \xi_{i}=\sum_{i, j=1}^{s}\left[\eta_{j}\left(\nabla_{X} \xi_{i}\right) \eta_{j}(Y)-\eta_{j}\left(\nabla_{Y} \xi_{i}\right) \eta_{j}(X)\right] \xi_{i} \tag{2.5}
\end{equation*}
$$

and $\left\{\xi_{i}\right\}_{i=1}^{s}$ is $g$-orthonormal, it is found that

$$
\sum_{j=1}^{s}\left[\eta_{j}\left(\nabla_{X} \xi_{i}\right) \eta_{j}(Y)-\eta_{j}\left(\nabla_{Y} \xi_{i}\right) \eta_{j}(X)\right]=0
$$

for all $i=1, \ldots, s$. After calculations, one obtains

$$
\begin{equation*}
\nabla_{X} \xi_{i}=-\alpha_{i} f X-\beta_{i} f^{2} X \tag{2.6}
\end{equation*}
$$

for $i=1, \ldots, s$ [4].

The notion of a Frenet curve is well-known as below:
Let us consider a unit-speed curve $\gamma: I \rightarrow M$ in an $n$-dimensional Riemannian manifold $(M, g)$. If there exists orthonormal vector fields $E_{1}, E_{2}, \ldots, E_{r}$ along $\gamma$ satisfying

$$
\begin{align*}
E_{1} & =\gamma^{\prime}=T \\
\nabla_{T} E_{1} & =\kappa_{1} E_{2} \\
\nabla_{T} E_{2}= & -\kappa_{1} E_{1}+\kappa_{2} E_{3}  \tag{2.7}\\
& \cdots \\
\nabla_{T} E_{r}= & -\kappa_{r-1} E_{r-1},
\end{align*}
$$

then $\gamma$ is called a Frenet curve of osculating order $r$, where $\kappa_{1}, \ldots, \kappa_{r-1}$ are positive functions on $I$ and $1 \leq r \leq n$.

A Frenet curve of osculating order 1 is a called geodesic. A Frenet curve of osculating order 2 is a circle if $\kappa_{1}$ is a non-zero positive constant. A Frenet curve of osculating order $r \geq 3$ is called a helix of order $r$, when $\kappa_{1}, \ldots, \kappa_{r-1}$ are non-zero positive constants; a helix of order 3 is simply called a helix.

Finally, we can define Legendre curves in trans- $S$-manifolds like:
Definition 1. Let $M=\left(M^{2 n+s}, f, \xi_{i}, \eta_{i}, g\right)$ be a trans-S-manifold. Consider a unit-speed smooth curve $\gamma: I \rightarrow M$ and its unit tangential vector field $T=\gamma^{\prime}$. If $\eta_{i}(T)=0$ for all $i=1,2, \ldots, s$, then it is called a Legendre curve.

Here are the direct results from the definition:

$$
\begin{gather*}
f^{2} T=-T \\
\kappa_{1} \eta_{i}\left(E_{2}\right)+\beta_{i}=0  \tag{2.8}\\
\left(\nabla_{T} f\right) T=\sum_{i=1}^{s} \alpha_{i} \xi_{i}
\end{gather*}
$$

which gives us

$$
\begin{equation*}
\nabla_{T} f T=\sum_{i=1}^{s} \alpha_{i} \xi_{i}+\kappa_{1} f E_{2} \tag{2.9}
\end{equation*}
$$

Let us recall what a magnetic curve is and what we mean by trajectory:
Let $M^{2 n+s}=\left(M^{2 n+s}, f, \xi_{\alpha}, \eta^{\alpha}, g\right)$ be an trans- $S$-manifold and $\Omega$ the fundamental 2 -form of $M^{2 n+s}$ defined by

$$
\begin{equation*}
\Omega(X, Y)=g(X, f Y) \tag{2.10}
\end{equation*}
$$

(see [13]). From Proposition 3.1 (i) in [4], for a trans- $S$-manifold,

$$
\begin{equation*}
d \Omega=2 \Omega \wedge \sum_{i=1}^{s} \beta_{i} \eta_{i} \tag{2.11}
\end{equation*}
$$

If the fundamental 2-form $\Omega$ on $M^{2 n+s}$ is closed, then M becomes a $K$-manifold. Moreover, $F=d \eta_{i}$, it becomes an $S$-manifold. If $d \eta_{i}=0$, it becomes a $C$-manifold. When $\Omega$ is closed, the magnetic field $F_{q}$ on $M^{2 n+s}$ can be defined by

$$
F_{q}(X, Y)=q \Omega(X, Y)
$$

where $X$ and $Y$ are vector fields on $M^{2 n+s}$ and $q$ is a real constant. $F_{q}$ is called the contact magnetic field with strength $q$ [11. If $q=0$ then the magnetic curves
are geodesics of $M^{2 n+s}$. Because of this reason one can consider $q \neq 0$ (see [5] and [8]).

From (1.1) and (2.10), the Lorentz force $\Phi$ associated to the contact magnetic field $F_{q}$ can be written as

$$
\Phi_{q}=-q f
$$

So the Lorentz equation (1.2) can be written as

$$
\begin{equation*}
\nabla_{T} T=-q f T \tag{2.12}
\end{equation*}
$$

where $\gamma: I \subseteq R \rightarrow M^{2 n+s}$ is a smooth unit-speed curve and $T=\gamma^{\prime}$ (see [8] and [11).

From 2.11, for trans- $S$-manifolds, notice that $\Omega$ does not need to be closed in general. But, we can still look for curves satisfying $\nabla_{T} T=-q \varphi T$ in a trans-$S$-manifold, calling them trajectories. In this paper, for sake of computations, Legendre trajectories will be considered. The general solution of the problem is in progress.

For the last part of this study, it is necessary to define $C$-parallel $C$-proper curves as below:

We can generalize the definition from [10] to trans- $S$-manifolds:
Definition 2. 10 Let $\gamma: I \rightarrow\left(M^{2 n+s}, f, \xi_{i}, \eta_{i}, g\right)$ be a unit speed curve in an trans-S-manifold. Then $\gamma$ is called
i) $C$-parallel (in the tangent bundle) if

$$
\nabla_{T} H=\lambda \sum_{i=1}^{s} \xi_{i}
$$

ii) C-parallel in the normal bundle if

$$
\nabla_{T}^{\perp} H=\lambda \sum_{i=1}^{s} \xi_{i}
$$

iii) C-proper (in the tangent bundle) if

$$
\Delta H=\lambda \sum_{i=1}^{s} \xi_{i}
$$

iv) $C$-proper in the normal bundle if

$$
\Delta^{\perp} H=\lambda \sum_{i=1}^{s} \xi_{i}
$$

where $H$ is the mean curvature field of $\gamma, \lambda$ is a real-valued non-zero differentiable function, $\nabla$ is the Levi-Civita connection, $\nabla^{\perp}$ is the Levi-Civita connection in the normal bundle, $\Delta$ is the Laplacian and $\Delta^{\perp}$ is the Laplacian in the normal bundle.

From the definition, same direct proposition as in [10] is obtained:
Proposition 1. 10 Let $\gamma: I \rightarrow\left(M^{2 n+s}, f, \xi_{i}, \eta_{i}, g\right)$ be a unit speed curve in an $S$-manifold. Then
i) $\gamma$ is $C$-parallel (in the tangent bundle) if and only if

$$
\begin{equation*}
-\kappa_{1}^{2} T+\kappa_{1}^{\prime} E_{2}+\kappa_{1} \kappa_{2} E_{3}=\lambda \sum_{i=1}^{s} \xi_{i} \tag{2.13}
\end{equation*}
$$

ii) $\gamma$ is $C$-parallel in the normal bundle if and only if

$$
\begin{equation*}
\kappa_{1}^{\prime} E_{2}+\kappa_{1} \kappa_{2} E_{3}=\lambda \sum_{i=1}^{s} \xi_{i} \tag{2.14}
\end{equation*}
$$

iii) $\gamma$ is $C$-proper (in the tangent bundle) if and only if

$$
\begin{equation*}
3 \kappa_{1} \kappa_{1}^{\prime} T+\left(\kappa_{1}^{3}+\kappa_{1} \kappa_{2}^{2}-\kappa_{1}^{\prime \prime}\right) E_{2}-\left(2 \kappa_{1}^{\prime} \kappa_{2}+\kappa_{1} \kappa_{2}^{\prime}\right) E_{3}-\kappa_{1} \kappa_{2} \kappa_{3} E_{4}=\lambda \sum_{i=1}^{s} \xi_{i} \tag{2.15}
\end{equation*}
$$

iv) $\gamma$ is C-proper in the normal bundle if and only if

$$
\begin{equation*}
\left(\kappa_{1} \kappa_{2}^{2}-\kappa_{1}^{\prime \prime}\right) E_{2}-\left(2 \kappa_{1}^{\prime} \kappa_{2}+\kappa_{1} \kappa_{2}^{\prime}\right) E_{3}-\kappa_{1} \kappa_{2} \kappa_{3} E_{4}=\lambda \sum_{i=1}^{s} \xi_{i} \tag{2.16}
\end{equation*}
$$

## 3. Main results on Legendre Trajectories

Let $M=\left(M, f, \xi_{i}, \eta_{i}, g\right)$ be a trans- $S$-manifold and $\gamma: I \rightarrow M$ a unit-speed Legendre curve with arc-length parameter $t$. Assume that $\gamma$ satisfies $\nabla_{T} T=-q f T$. Then, we have

$$
\nabla_{T} T=-q f T=\kappa_{1} E_{2}
$$

and

$$
g(f T, f T)=1
$$

So,

$$
f T \neq 0
$$

Using the norm of both sides gives us

$$
\begin{equation*}
\kappa_{1}=|q| . \tag{3.1}
\end{equation*}
$$

Thus

$$
|q| E_{2}=-q f T
$$

and

$$
\begin{equation*}
f T=\delta E_{2} \tag{3.2}
\end{equation*}
$$

where $\delta=\operatorname{sgn}(-q)$. From (2.8) and (3.2), we have

$$
\left.\beta_{i}\right|_{\gamma}=0
$$

(3.2) gives us

$$
\begin{equation*}
f E_{2}=-\delta T \tag{3.3}
\end{equation*}
$$

From (2.9) and (3.3), we can write

$$
\begin{aligned}
\nabla_{T} f T & =\delta \nabla_{T} E_{2}=\delta\left(-\kappa_{1} T+\kappa_{2} E_{3}\right) \\
& =\sum_{i=1}^{s} \alpha_{i} \xi_{i}-\kappa_{1} \delta T
\end{aligned}
$$

As a result, we find

$$
\begin{equation*}
\kappa_{2} E_{3}=\delta \sum_{i=1}^{s} \alpha_{i} \xi_{i} \tag{3.4}
\end{equation*}
$$

which gives us

$$
\begin{equation*}
\kappa_{2}=\sqrt{\sum_{i=1}^{s} \alpha_{i}^{2}} \tag{3.5}
\end{equation*}
$$

Then

$$
\kappa_{2}=\left.0 \Leftrightarrow \alpha_{i}\right|_{\gamma}=0 .
$$

Let $\kappa_{2} \neq 0$. Notice that $\operatorname{sgn}\left(g\left(E_{3}, \sum_{i=1}^{s} \alpha_{i} \xi_{i}\right)\right)=\delta$. Using (3.4) and (3.5), we find

$$
\begin{equation*}
E_{3}=\frac{\delta}{\sqrt{\sum_{i=1}^{s} \alpha_{i}^{2}}} \sum_{i=1}^{s} \alpha_{i} \xi_{i} \tag{3.6}
\end{equation*}
$$

If we differentiate $E_{3}$, we obtain

$$
\begin{gather*}
\kappa_{3} E_{4}=\delta \sum_{i=1}^{s}\left(\frac{\alpha_{i}}{\sqrt{\sum_{i=1}^{s} \alpha_{i}^{2}}}\right)^{\prime} \xi_{i} .  \tag{3.7}\\
\kappa_{3}=\sqrt{\sum_{i=1}^{s}\left[\left(\frac{\alpha_{i}}{\sqrt{\sum_{i=1}^{s} \alpha_{i}^{2}}}\right)^{\prime}\right]^{2}} . \tag{3.8}
\end{gather*}
$$

Moreover, if $\kappa_{3}=0$, then

$$
\frac{\alpha_{i}}{\sqrt{\sum_{i=1}^{s} \alpha_{i}^{2}}}=c_{i}=\text { constant }, \forall i .
$$

Hence

$$
\sum_{i=1}^{s} \alpha_{i}^{2}\left(\sum_{i=1}^{s} c_{i}^{2}-1\right)=0
$$

So,
or

$$
\sum_{i=1}^{s} \alpha_{i}^{2}=0 \Leftrightarrow \kappa_{2}=0
$$

$$
\sum_{i=1}^{s} c_{i}^{2}=1
$$

To sum up, if $\kappa_{3}=0$ and $\kappa_{2} \neq 0$, we have

$$
\begin{gathered}
E_{2}=\delta f T \\
E_{3}=\delta \sum_{i=1}^{s} c_{i} \xi_{i}
\end{gathered}
$$

where

$$
\begin{gather*}
\alpha_{i}=c_{i} \sum_{i=1}^{s} \alpha_{i}^{2}, \forall i  \tag{3.9}\\
c_{i}=\text { constant such that } \sum_{i=1}^{s} c_{i}^{2}=1 \tag{3.10}
\end{gather*}
$$

Now we can state the following theorem:

Theorem 1. Let $\gamma: I \rightarrow M$ be a Legendre trajectory. Then $\gamma$ is one of the following:

1) a Legendre circle with $\kappa_{1}=|q|$ and the Frenet frame field $\{T, \delta f T\}$, where $\delta=\operatorname{sgn}(-q)$. In this case, $\alpha_{i}=0, \beta_{i}=0, \forall i$.
2) a Legendre curve of osculating order $r \geq 3$ with

$$
\kappa_{1}=|q|, \kappa_{2}=\sqrt{\sum_{i=1}^{s} \alpha_{i}^{2}}
$$

$\kappa_{3}$ given in (3.8) and the Frenet frame field

$$
\left\{T, \delta f T, E_{3}, E_{4}, \ldots, E_{r}\right\}
$$

where $\delta=\operatorname{sgn}(-q) ; E_{3}, E_{4}$ are given in (3.6) and (3.7), respectively. In this case, $\alpha_{i} \neq 0, \exists i, \beta_{i}=0, \forall i$. Moreover, if $r=3$, equations (3.9) and (3.10) are also satisfied and its Frenet frame field is

$$
\left\{T, \delta f T, E_{3}\right\}
$$

## 4. Main results of $C$-parallel and $C$-proper Legendre Curves

Let $M^{2 n+s}$ be $a$ trans-S-manifold and $\gamma: I \rightarrow M$ a Legendre curve in $M$.
i) $C$-parallel in the tangent bundle:

$$
-\kappa_{1}^{2} T+\kappa_{1}^{\prime} E_{2}+\kappa_{1} \kappa_{2} E_{3}=\lambda \sum_{i=1}^{s} \xi_{i}
$$

If we apply $T$ to both sides, we have the following result:
Theorem 2. There does not exist a C-parallel Legendre curve (in the tangent bundle) in a trans-S-manifold.
ii) $C$-parallel in the normal bundle:

$$
\kappa_{1}^{\prime} E_{2}+\kappa_{1} \kappa_{2} E_{3}=\lambda \sum_{i=1}^{s} \xi_{i}
$$

a) $r=2$.

$$
\kappa_{1}^{\prime} E_{2}=\lambda \sum_{i=1}^{s} \xi_{i}
$$

Theorem 3. Let $r=2$. Then $\gamma$ is $C$-parallel in the normal bundle iff

$$
\begin{gathered}
\kappa_{1}=\mp \sqrt{s} \beta \\
\lambda=-\beta^{\prime} \\
\sum_{i=1}^{s} \xi_{i}= \pm \sqrt{s} E_{2} .
\end{gathered}
$$

In this case, $\beta_{1}=\beta_{2}=\ldots=\beta_{s}=\beta$.
b) $r \geq 3$.

In this case, for a smooth function $w=w(t)$, we have

$$
\begin{equation*}
\sum_{i=1}^{s} \xi_{i}=\sqrt{s}\left(\cos w E_{2}+\sin w E_{3}\right) \tag{4.1}
\end{equation*}
$$

If we differentiate the above equation, we have

$$
\begin{equation*}
\sum_{i=1}^{s} \beta_{i}=-\sqrt{s} \kappa_{1} \cos w \tag{4.2}
\end{equation*}
$$

and

$$
\begin{equation*}
\kappa_{2}= \pm \frac{1}{\sqrt{s}} \sum_{i=1}^{s} \alpha_{i}-w^{\prime} \tag{4.3}
\end{equation*}
$$

We also have

$$
\begin{equation*}
\lambda=\frac{-\kappa_{1} \kappa_{1}^{\prime}}{\sum_{i=1}^{s} \beta_{i}} \tag{4.4}
\end{equation*}
$$

Since $f T \perp E_{2}$, we can write

$$
\begin{equation*}
f T= \pm\left(\sin w E_{2}-\cos w E_{3}\right) \tag{4.5}
\end{equation*}
$$

Theorem 4. Let $r \geq 3$. Then $\gamma$ is $C$-parallel in the normal bundle iff equations (4.1), (4.2), (4.3), (4.4) and (4.5) are satisfied.
iii) $C$-proper in the tangent bundle:

$$
3 \kappa_{1} \kappa_{1}^{\prime} T+\left(\kappa_{1}^{3}+\kappa_{1} \kappa_{2}^{2}-\kappa_{1}^{\prime \prime}\right) E_{2}-\left(2 \kappa_{1}^{\prime} \kappa_{2}+\kappa_{1} \kappa_{2}^{\prime}\right) E_{3}-\kappa_{1} \kappa_{2} \kappa_{3} E_{4}=\lambda \sum_{i=1}^{s} \xi_{i}
$$

If we apply $T$, we directly have $\kappa_{1}=$ constant. Then the equation reduces to

$$
\kappa_{1}\left(\kappa_{1}^{2}+\kappa_{2}^{2}\right) E_{2}-\kappa_{1} \kappa_{2}^{\prime} E_{3}-\kappa_{1} \kappa_{2} \kappa_{3} E_{4}=\lambda \sum_{i=1}^{s} \xi_{i}
$$

Applying $E_{2}$, we get

$$
\kappa_{1}^{2}\left(\kappa_{1}^{2}+\kappa_{2}^{2}\right)=-\lambda \sum_{i=1}^{s} \beta_{i}
$$

a) $r=2$.

In this case, we have

$$
\begin{equation*}
\kappa_{1}^{3} E_{2}=\lambda \sum_{i=1}^{s} \xi_{i} \tag{4.6}
\end{equation*}
$$

If we apply $\xi_{j}$, we find

$$
\kappa_{1}^{3} \eta_{j}\left(E_{2}\right)=\lambda, \forall j
$$

If we denote

$$
\beta_{1}=\beta_{2}=\ldots=\beta_{s}=\beta
$$

we get

$$
\lambda=-s \beta^{3}=\text { constant }
$$

If we differentiate (4.6), it is easy to see that

$$
\sum_{i=1}^{s} \alpha_{i}=0
$$

As a result, we have

$$
\kappa_{1}=\mp \sqrt{s} \beta=\text { constant }
$$

i.e., $\gamma$ is a circle.

Theorem 5. Let $r=2$. Then $\gamma$ is $C$-proper in the tangent bundle iff it is a circle with

$$
\kappa_{1}=\mp \sqrt{s} \beta=\text { constant }
$$

and the Frenet frame field

$$
\left\{T, \frac{ \pm 1}{\sqrt{s}} \sum_{i=1}^{s} \xi_{i}\right\}
$$

In this case, $\beta_{1}=\beta_{2}=\ldots=\beta_{s}=\beta, \lambda=-s \beta^{3}=$ constant and $\sum_{i=1}^{s} \alpha_{i}=0$.
b) $r=3$.

$$
\kappa_{1}\left(\kappa_{1}^{2}+\kappa_{2}^{2}\right) E_{2}-\kappa_{1} \kappa_{2}^{\prime} E_{3}=\lambda \sum_{i=1}^{s} \xi_{i}
$$

So, $\sum_{i=1}^{s} \xi_{i} \in \operatorname{sp}\left\{E_{2}, E_{3}\right\}$. It can be written as

$$
\begin{equation*}
\sum_{i=1}^{s} \xi_{i}=\sqrt{s}\left(\cos w E_{2}+\sin w E_{3}\right) \tag{4.7}
\end{equation*}
$$

for a smooth function $w=w(t)$. If we differentiate this equation and apply $T$, we find

$$
\begin{equation*}
\sum_{i=1}^{s} \beta_{i}=-\sqrt{s} \kappa_{1} \cos w \tag{4.8}
\end{equation*}
$$

and

$$
\begin{equation*}
\kappa_{2}= \pm \frac{1}{\sqrt{s}} \sum_{i=1}^{s} \alpha_{i}-w^{\prime} \tag{4.9}
\end{equation*}
$$

We also have

$$
\begin{equation*}
f T= \pm\left(\sin w E_{2}-\cos w E_{3}\right) \tag{4.10}
\end{equation*}
$$

and

$$
\begin{equation*}
\lambda=\frac{-\kappa_{1}^{2}\left(\kappa_{1}^{2}+\kappa_{2}^{2}\right)}{\sum_{i=1}^{s} \beta_{i}} \tag{4.11}
\end{equation*}
$$

Theorem 6. Let $r=3$. Then $\gamma$ is $C$-proper in the tangent bundle iff equations (4.7), (4.8), (4.9), (4.10) and (4.11) are satisfied.
c) $\mathbf{r} \geq 4$.

In this case, $\sum_{i=1}^{s} \xi_{i} \in s p\left\{E_{2}, E_{3}, E_{4}\right\}$, consequently, $f T \in s p\left\{E_{2}, E_{3}, E_{4}, E_{5}\right\}$. Let us write

$$
\begin{equation*}
\sum_{i=1}^{s} \xi_{i}=\sqrt{s}\left(\cos w E_{2}+\sin w \cos \varphi E_{3}+\sin w \sin \varphi E_{4}\right) \tag{4.12}
\end{equation*}
$$

for some smooth functions $w=w(t), \varphi=\varphi(t)$. As a result, the curve must satisfy

$$
\begin{gathered}
\kappa_{1}=\text { constant, } \\
\sum_{i=1}^{s} \beta_{i}=-\sqrt{s} \kappa_{1} \cos w, \\
\lambda \sqrt{s} \cos w=\kappa_{1}^{2}\left(\kappa_{1}^{2}+\kappa_{2}^{2}\right), \\
\lambda \sqrt{s} \sin w \cos \varphi=-\kappa_{1} \kappa_{2}^{\prime}, \\
\lambda \sqrt{s} \sin w \sin \varphi=-\kappa_{1} \kappa_{2} \kappa_{3} .
\end{gathered}
$$

Differentiating (4.12), we also have

$$
\kappa_{4}=\frac{-\left(\sum_{i=1}^{s} \alpha_{i}\right) \cdot g\left(f T, E_{5}\right)}{\sin w \sin \varphi} .
$$

Theorem 7. Let $r \geq 4$. Then $\gamma$ is $C$-proper in the tangent bundle iff it satisfies the last six equations.
iv) $C$-proper in the normal bundle:

$$
\left(\kappa_{1} \kappa_{2}^{2}-\kappa_{1}^{\prime \prime}\right) E_{2}-\left(2 \kappa_{1}^{\prime} \kappa_{2}+\kappa_{1} \kappa_{2}^{\prime}\right) E_{3}-\kappa_{1} \kappa_{2} \kappa_{3} E_{4}=\lambda \sum_{i=1}^{s} \xi_{i}
$$

In this case, again $\sum_{i=1}^{s} \xi_{i} \in s p\left\{E_{2}\right\}, \sum_{i=1}^{s} \xi_{i} \in s p\left\{E_{2}, E_{3}\right\}$ or $\sum_{i=1}^{s} \xi_{i} \in s p\left\{E_{2}, E_{3}, E_{4}\right\}$ depending on the osculating order $r$. We can follow the above procedure to get results for $r=2$ and $r=3$. The case $r \geq 4$ is similar to case iii) c) with minor changes in equations.

Remark. For sake of shortness, $\left.\alpha_{i}\right|_{\gamma}$ and $\left.\beta_{i}\right|_{\gamma}$ are written as $\alpha_{i}$ and $\beta_{i}$ where possible. This means the equations are not necessarily satisfied globally. But instead, they are satisfied along the curve $\gamma$.
