## 1 Introduction

Let $N$ be a prime number and let $S_{2}\left(\Gamma_{0}(N), \mathbb{Z}\right)$ denote the modular forms of weight 2 and level $\Gamma_{0}(N)$ with integer coefficients, and for any other ring $R$, we denote $S_{2}\left(\Gamma_{0}(N), R\right)=S_{2}\left(\Gamma_{0}(N), \mathbb{Z}\right) \otimes$ $R$. If $R$ is a characteristic $p$ ring, we define $S_{2}\left(\Gamma_{0}(N), R\right)^{\text {Katz }}$ to be the $R$-module of Katz forms as defined in [Kat73, Section 1.2], and define similar notation for the spaces of weight 1 forms. For $N \nmid n$, let $T_{n}$ denote the $n$th Hecke operator inside $\operatorname{End}\left(S_{2}\left(\Gamma_{0}(N), \overline{\mathbb{Z}}\right)\right.$ ), and let $U_{N}$ denote the $N$ th Hecke operator. We let $\mathbb{T}^{\text {an }}$ denote $\mathbb{Z}\left[T_{3}, T_{5}, \ldots\right]$, the algebra generated by $T_{n}$ for $(2 N, n)=1$, and we denote $\mathbb{T}^{\text {an }}\left[T_{2}, U_{N}\right]$ by $\mathbb{T}$. The goal of this paper is to compute the index of $\mathbb{T}^{\text {an }}$ inside $\mathbb{T}$. Specifically, we prove the following theorem in sections 3 and 4

Theorem 1.1. The quotient $\mathbb{T} / \mathbb{T}^{\text {an }}$ is purely 2 -torsion, and

$$
\operatorname{dim}_{\mathbb{F}_{2}} \mathbb{T} / \mathbb{T}^{\mathrm{an}}=\operatorname{dim}_{\mathbb{F}_{2}} S_{1}\left(\Gamma_{0}(N), \mathbb{F}_{2}\right)^{\mathrm{Katz}}
$$

In other words, if $c=\operatorname{dim}_{\mathbb{F}_{2}} S_{1}\left(\Gamma_{0}(N), \mathbb{F}_{2}\right)^{\text {Katz }}$ is the dimension of the weight 1 level $\Gamma_{0}(N)$ Katz forms over $\mathbb{F}_{2}$, then the index of $\mathbb{T}^{\text {an }}$ in $\mathbb{T}$ is equal to $2^{c}$.

The setup of the paper is as follows. In section 2, we introduce some facts from the literature about modular forms and establish a duality theorem between modular forms and Hecke algebras. In section 3 we prove the first half of the theorem, that $\mathbb{T}^{\text {an }}$ contains $2 \mathbb{T}$ as submodules of $\mathbb{T}$, so the quotient $\mathbb{T} / \mathbb{T}^{\text {an }}$ is purely 2 -torsion. Then in section 4 we use a theorem of Katz to relate the extra elements of $\mathbb{T}$ to weight 1 modular forms using the duality, and finally establish the equality of Theorem 1.1 between dimensions. In section 5 we conclude with some examples, and some theorems and conjectures we propose based on the work of Cohen-Lenstra and Bhargava.

## 2 Preliminaries

### 2.1 From $\mathbb{Z}$ to $\mathbb{Z}_{2}$

We start by proving that $U_{N} \in \mathbb{T}^{\text {an }}$, thereby reducing our work to considering $\mathbb{T}^{\text {an }} \subseteq \mathbb{T}^{\text {an }}\left[T_{2}\right]$.
Theorem 2.1. $U_{N} \in \mathbb{T}^{\mathrm{an}}$.
Proof. It is enough to check that $U_{N} \in \mathbb{T}^{\text {an }} \otimes \mathbb{Z}_{p}$ for every $p$ : if $\mathbb{T}^{\text {an }}$ and $\mathbb{T}^{\text {an }}\left[U_{N}\right]$ have different ranks as $\mathbb{Z}$-modules, then the $\mathbb{Z}_{p}$-ranks of $\mathbb{T}^{\text {an }} \otimes \mathbb{Z}_{p}$ and $\mathbb{T}^{\text {an }}\left[U_{N}\right] \otimes \mathbb{Z}_{p}=\mathbb{T}^{\text {an }} \otimes \mathbb{Z}_{p}\left[U_{N}\right]$ are also

[^0]different for every $p$, contradiction. On the other hand, if $\operatorname{rank}\left(\mathbb{T}^{\mathrm{an}}\right)=\operatorname{rank}\left(\mathbb{T}^{\mathrm{an}}\left[U_{N}\right]\right)$, then the quotient $\mathbb{T}^{\text {an }}\left[U_{N}\right] / \mathbb{T}^{\text {an }}$ is finite. If it's nontrivial, then for any prime $p$ dividing its order, there is a surjective map $\left(\mathbb{T}^{\text {an }}\left[U_{N}\right] \otimes \mathbb{Z}_{p}\right) /\left(\mathbb{T}^{\mathrm{an}} \otimes \mathbb{Z}_{p}\right) \rightarrow\left(\mathbb{T}^{\text {an }}\left[U_{N}\right] / \mathbb{T}^{\mathrm{an}}\right) \otimes \mathbb{Z}_{p}$ with nontrivial image. So for this $p, \mathbb{T}^{\text {an }}\left[U_{N}\right] \otimes \mathbb{Z}_{p} \neq \mathbb{T}^{\text {an }} \otimes \mathbb{Z}_{p}$. Therefore, we will only check whether $\mathbb{T}^{\text {an }} \otimes \mathbb{Z}_{p}$ contains $U_{N}$. Further, as $\mathbb{T}^{\text {an }} \otimes \mathbb{Z}_{p}$ is a complete semi-local ring, it splits as a direct sum of its completions at maximal ideals, so it's further enough to check that $U_{N}$ is in $\mathbb{T}_{\mathfrak{m}}^{\text {an }}$ for the completion $\mathbb{T}_{\mathfrak{m}}^{\text {an }}$ at each maximal ideal $\mathfrak{m}$.

In a previous paper, we proved that $U_{N} \in \mathbb{T}^{\mathrm{an}} \otimes \mathbb{Z}_{2}=\mathbb{T}_{2}^{\text {an }}$ Tay20, Lemma 5.1], so the statement is true for all maximal ideals over 2 . So let $\ell$ be an odd prime, $\mathfrak{m}$ be a maximal ideal of $\mathbb{T}^{\text {an }}$ over $\ell$, and $\mathfrak{a}$ be a maximal ideal of $\mathbb{T}$ containing $\mathfrak{m}$.

Let $\mathbb{T}_{\mathfrak{a}}$ be the completion of $\mathbb{T}$ with respect to $\mathfrak{a}$, and let $A$ be the integral closure of $\mathbb{T}_{\mathfrak{a}}$ over $\mathbb{Z}_{\ell}$, which can be written as $A=\oplus_{i} \mathcal{O}_{i}$ for $\mathcal{O}_{i}$ finite extensions of $\mathbb{Z}_{\ell}$. The maps

$$
\pi_{i}: \mathbb{T} \rightarrow \mathbb{T}_{\mathfrak{a}} \rightarrow A \rightarrow \mathcal{O}_{i}
$$

produce conjugacy classes of eigenforms with coefficients in $\mathcal{O}_{i}$, with the coefficient $a_{i, j}$ of $q^{j}$ equal to $\pi_{i}\left(T_{j}\right)$ if $(j, N)=1$, or $\pi_{i}\left(U_{j}\right)$ if $N \mid j$. These are newforms as $N$ is prime, and there are no weight 2 level 1 forms. By Eichler-Deligne-Shimura-Serre there are representations $\rho_{i}: G_{\mathbb{Q}} \rightarrow \mathrm{GL}_{2}\left(\mathcal{O}_{i}\right)$, unramified away from $\ell N$, so that $\operatorname{Tr}\left(\rho_{i}\left(\mathrm{Frob}_{\ell}\right)\right)=a_{i, p}$ for all primes $p \nmid \ell N$.
[DDT97, Theorem 3.1(e)] describes the shape of the local-at- $N$ representation:

$$
\left.\rho_{i}\right|_{G_{Q_{N}}}=\left(\begin{array}{cc}
\epsilon \chi & * \\
0 & \chi
\end{array}\right)
$$

where $\chi$ is the unramified representation taking $\operatorname{Frob}_{N}$ to $a_{i, N}$ and $\epsilon$ is the $N$-adic cyclotomic character. Additionally, $\operatorname{det} \rho_{i}=\epsilon$, so $\chi^{2}$ is identically 1 and $a_{i, N}$ is equal to 1 or -1 for each $i$. We show that $a_{i, N}$ is equal among all $i$ over all $\mathfrak{a}$ containing $\mathfrak{m}$, so that the image of $U_{N}$ in $\mathbb{T}_{\mathfrak{a}}$ is constantly 1 or -1 over all $\mathfrak{a}$, and hence, in $\mathbb{T}_{\mathfrak{m}}=\oplus_{\mathfrak{m} \subseteq \mathfrak{a}} \mathbb{T}_{\mathfrak{a}}$, is inside $\mathbb{T}_{\mathfrak{m}}^{\text {an }}$.

By the Chebotarev density theorem, a representation is determined up to semisimplification and conjugation by its trace on the Frobenius elements of unramified primes. The $\rho_{i}\left(\mathrm{Frob}_{p}\right)$ have trace equal to $a_{i, p}$, which is the image of $T_{p}$ under $\pi_{i}$. Because $\mathfrak{m}$ is contained in $\mathfrak{a}$ for all $\mathfrak{a}$, the image of $T_{p}$ under reduction of $\mathbb{T}^{\text {an }} \bmod \mathfrak{m}$ is the same as the reduction of $a_{i, p} \bmod \mathfrak{a}$. Therefore, the semisimplifications of the reductions of $\rho_{i}$ over all $i$ and all $\mathfrak{a}$ are all isomorphic. But we can deduce the value of $a_{i, N}$ from the reduction of $\rho_{i} \bmod \mathfrak{a}$, because $\left.\rho_{i}\right|_{G_{\mathbb{Q}_{N}}}$ has an unramified quotient and a ramified subspace, and the same is true for the reduction $\bmod \mathfrak{a}$ as $\ell \neq 2$. So the image of the Frobenius on the unramified quotient is either 1 or -1 for one (and hence every) $\rho_{i}$, and therefore $a_{i, N}$ does not depend on $i$ or $\mathfrak{a}$, only on $\mathfrak{m}$. So $U_{N}$ lies in $\mathbb{T}_{\mathfrak{m}}^{\text {an }}$ for all $\mathfrak{m}$, and we're done.

We can now reduce from forms over $\overline{\mathbb{Z}}$ to forms over $\overline{\mathbb{Z}}_{2}$. To do this, we first recall Wil95, Lemma, pp. 491] which says that if $\mathbb{T}^{1}$ is the Hecke algebra over $\mathbb{Z}$ corresponding to level $\Gamma_{1}(N)$ forms and $\mathbb{T}^{2}$ is the subalgebra of operators relatively prime to 2 , that $\mathbb{T}^{2}$ has 2-power index in $\mathbb{T}^{1}$. As the algebras $\mathbb{T}$ and $\mathbb{T}^{\text {an }}=\mathbb{T}^{\text {an }}\left[U_{N}\right]$ are quotients of $\mathbb{T}^{1}$ and $\mathbb{T}^{2}$ of this lemma, the same is true for $\mathbb{T}$ and $\mathbb{T}^{\text {an }}$. (Alternatively, with a similar argument to the proof of Theorem 2.1, we can check that $T_{2}$ is contained in all completions at maximal ideals of $\mathbb{T}^{\text {an }}\left[\frac{1}{2}\right]$. This is true as 2 is unramified in, and $T_{2}$ is a trace of, the modular representations over primes other than 2 , so Chebotarev and completeness of $\mathbb{T}_{\mathfrak{m}}^{\text {an }}$ show that $T_{2} \in \mathbb{T}_{\mathfrak{m}}^{\mathrm{an}}$.) So we can calculate the index of $\mathbb{T}^{\text {an }} \otimes \mathbb{Z}_{2}$ inside $\mathbb{T} \otimes \mathbb{Z}_{2}$, and by abuse of notation begin to call these $\mathbb{T}^{\text {an }}$ and $\mathbb{T}$ instead. We know that $\mathbb{T}$ and $\mathbb{T}^{\text {an }}$ are semi-local rings, and as such, they can be written as a direct sum of their completions:

$$
\mathbb{T}=\bigoplus_{\mathfrak{a} \subset \mathbb{T}} \mathbb{T}_{\mathfrak{a}}, \quad \text { and } \quad \mathbb{T}^{\mathrm{an}}=\bigoplus_{\mathfrak{m} \subset \mathbb{T}^{\text {an }}} \mathbb{T}_{\mathfrak{m}}^{\mathrm{an}}
$$

Additionally, because the $\mathbb{Z}_{2}$-ranks of $\mathbb{T}$ and $\mathbb{T}^{\text {an }}$ are equal, $T_{2} \in \mathbb{T} \otimes \mathbb{Q}_{2}=\mathbb{T}^{\text {an }} \otimes \mathbb{Q}_{2}=\mathbb{T}^{\text {an }}\left[\frac{1}{2}\right]$, and hence maps $\mathbb{T}^{\text {an }} \rightarrow K$ where $K$ is a finite extension of $\mathbb{Q}_{2}$ can be uniquely extended to maps $\mathbb{T} \rightarrow K$. This means that modular forms are rigid in characteristic 0 : we can determine the image of $T_{2}$ from the image of the remaining operators, and hence from any modular representation $\rho_{f}: G_{\mathbb{Q}} \rightarrow \mathrm{GL}_{2}(K)$ we may determine the entire form $f$. We say that $\rho$ is ordinary if the restriction $\left.\rho\right|_{D_{2}}$ of $\rho$ to the decomposition group at 2 is reducible, and we say that an eigenform is ordinary if $a_{2}$ is a unit mod 2. The next theorem describes the shape of $\rho_{f}$ at 2 :

Theorem 2.2 ( Wil88, Theorem 2]). If $f$ is an ordinary 2-adic form, then $\left.\rho_{f}\right|_{D_{2}}$, the restriction of $\rho_{f}$ to the decomposition group at a prime above 2 , is of the shape

$$
\left.\rho_{f}\right|_{D_{2}} \sim\left(\begin{array}{cc}
\chi \lambda^{-1} & * \\
0 & \lambda
\end{array}\right)
$$

for $\lambda$ the unramified character $G_{\mathbb{Q}_{2}} \rightarrow \overline{\mathbb{Z}}_{2}^{\times}$taking Frob ${ }_{2}$ to the unit root of $X^{2}-a_{2} X+2$, and $\chi$ is the 2-adic cyclotomic character.

### 2.2 A Duality Theorem

In this section, we will compute the Pontryagin dual of one of the summands in $\mathbb{T}$ with the following lemma. Let $\mathfrak{a}$ be any maximal ideal of $\mathbb{T}$ and let

$$
S_{2}\left(\Gamma_{0}(N), \mathbb{Z}_{2}\right)_{\mathfrak{a}}=e \cdot S_{2}\left(\Gamma_{0}(N), \mathbb{Z}_{2}\right)
$$

where $e$ is the projector $\mathbb{T} \rightarrow \mathbb{T}_{\mathfrak{a}}$.
Lemma 2.3. The Pontryagin dual of $\mathbb{T}_{\mathfrak{a}}$ is $M=\lim S_{2}\left(\Gamma_{0}(N), \mathbb{Z}_{2}\right)_{\mathfrak{a}} /\left(2^{n}\right)$ where the transition maps are multiplication by 2 .

Proof. First, we note that $\mathbb{T}_{\mathfrak{a}}$ acts on $M$ because $\mathbb{T}_{\mathfrak{a}}$ acts compatibly on each level. If any element $T \in \mathbb{T}_{\mathfrak{a}}$ acts trivially on $M$, then on any given modular form in $S_{2}\left(\Gamma_{0}(N), \mathbb{Z}_{2}\right)_{\mathfrak{a}}$, it acts by arbitrarily high powers of 2 , and hence acts as 0 . Then $T$ acts trivially on the rest of $S_{2}\left(\Gamma_{0}(N), \mathbb{Z}_{2}\right)$, so $T$ is the 0 endomorphism. Therefore, $M$ is a faithful $\mathbb{T}_{\mathfrak{a}}$-module.

We also know that $M[\mathfrak{a}]$, the elements of $M$ killed by all of $\mathfrak{a}$, is a subspace of $S_{2}\left(\Gamma_{0}(N), \mathbb{Z}_{2}\right)_{\mathfrak{a}} /(2)=$ $S_{2}\left(\Gamma_{0}(N), \mathbb{F}_{2}\right)_{\mathfrak{a}}$. It is a vector space over $\mathbb{T} / \mathfrak{a}$, although through the action of $\mathbb{T}$, not by multiplication on the coefficients. We explain why it's a 1 -dimensional $\mathbb{T} / \mathfrak{a}$-vector space. The map

$$
S_{2}\left(\Gamma_{0}(N), \mathbb{F}_{2}\right) \rightarrow \operatorname{Hom}\left(\mathbb{T}, \mathbb{F}_{2}\right), \quad f \mapsto \phi_{f}: T_{n} \rightarrow a_{n}
$$

is injective by the $q$-expansion principle. The forms killed by $\mathfrak{a}$ must correspond to maps factoring through $\mathbb{T} / \mathfrak{a}$, so the space of forms is at most the dimension of $\operatorname{Hom}\left(\mathbb{T} / \mathfrak{a}, \mathbb{F}_{2}\right)=\operatorname{dim}_{\mathbb{F}_{2}} \mathbb{T} / \mathfrak{a}$. So the dimension as a $\mathbb{T} / \mathfrak{a}$-vector space is at most 1 .

On the other hand, there is at least 1 form in $M[\mathfrak{a}]$, because we may take the form $T_{1} q+T_{2} q^{2}+$ $T_{3} q^{3}+\ldots \in S_{2}\left(\Gamma_{0}(N), \mathbb{T} / \mathfrak{a}\right)$ and consider its image under the trace map $\mathbb{T} / \mathfrak{a} \rightarrow \mathbb{F}_{2}$. This is nonzero because the trace map is nondegenerate, and because the Hecke operators generate $\mathbb{T}$ additively. This is in the kernel of $\mathfrak{a}$ because the trace of a form is just the sum of its conjugates, and for any expression in $\mathfrak{a}$ in terms of the Hecke operators with coefficients in $\mathbb{F}_{2}$, because its application to the original form is 0 by definition, its application to any of the form's conjugates must also be 0 (because the Hecke operators act $\mathbb{F}_{2}$-linearly on a form's coefficients and hence commute with Galois conjugation), and so too must its application to the sum. Because the trace form has coefficients in $\mathbb{F}_{2}$, we've found a nontrivial form in $M[\mathfrak{a}]$, and this must be dimension 1 as required.

We consider the Pontryagin dual of $M$ : as $M$ is a $\mathbb{Z}_{2}$-module, the image of any map $M \rightarrow \mathbb{Q} / \mathbb{Z}$ must land in $\mathbb{Q}_{2} / \mathbb{Z}_{2}$. So let $M^{\vee}=\operatorname{Hom}_{\mathbb{Z}_{2}}\left(M, \mathbb{Q}_{2} / \mathbb{Z}_{2}\right)$. We endow this with a $\mathbb{T}_{\mathfrak{a}}$-module structure by letting $(T \phi)(f)=\phi(T f)$. Because $S_{2}\left(\Gamma_{0}(N), \mathbb{Z}_{2}\right)_{\mathfrak{a}} \simeq \mathbb{Z}_{2}^{k}$ for some $k$ because it is torsion free, $M \simeq\left(\mathbb{Q}_{2} / \mathbb{Z}_{2}\right)^{k}$ as a $\mathbb{Z}_{2}$ module. So if $\phi(f)=0$ for all $\phi \in M^{\vee}$, we know that $f=0$. If $T \phi=0$ for all $\phi$, then $\phi(T f)=0$ for all $\phi$ and $f$, and so $T f=0$ for all $f$, and $T=0$. So $M^{\vee}$ is also a faithful $\mathbb{T}_{\mathfrak{a}}$-module.

Further, $\mathbb{T}_{\mathfrak{a}}$ injects into $M^{\vee}$ : we can rewrite

$$
M=\underset{\longrightarrow}{\lim } \frac{1}{2^{n}} S_{2}\left(\Gamma_{0}(N), \mathbb{Z}_{2}\right)_{\mathfrak{a}} / S_{2}\left(\Gamma_{0}(N), \mathbb{Z}_{2}\right)_{\mathfrak{a}}
$$

where the transition maps are inclusion. Then the $\mathbb{T}_{\mathfrak{a}} \times M \rightarrow \mathbb{Q}_{2} / \mathbb{Z}_{2}$ as $(T, f) \rightarrow a_{1}(T f)$ defines the injection. By Nakayama's lemma and the duality of $M[\mathfrak{a}]$ and $M^{\vee} / \mathfrak{a}$, the minimal number of generators of $M^{\vee}$ as a $\mathbb{T}_{\mathfrak{a}}$-module is 1 . So we've proven that $M^{\vee} \simeq \mathbb{T}_{\mathfrak{a}}$.

We may use Pontryagin Duality to find that the dual to $T_{\mathfrak{a}} / 2=M^{\vee} / 2$ is $M[2]$, which is exactly $S_{2}\left(\Gamma_{0}(N), \mathbb{Z}_{2}\right)_{\mathfrak{a}} /(2)=S_{2}\left(\Gamma_{0}(N), \mathbb{F}_{2}\right)_{\mathfrak{a}}$. Thus we obtain a perfect pairing

$$
T_{\mathfrak{a}} / 2 \times S_{2}\left(\Gamma_{0}(N), \mathbb{F}_{2}\right)_{\mathfrak{a}} \rightarrow \mathbb{F}_{2}, \quad(T, f) \rightarrow a_{1}(T f)
$$

We may sum these pairings over all $\mathfrak{a}$, because Hecke operators and forms with incompatible maximal ideals annihilate each other. Therefore we obtain a perfect pairing $\mathbb{T} / 2 \times S_{2}\left(\Gamma_{0}(N), \mathbb{F}_{2}\right) \rightarrow$ $\mathbb{F}_{2}$.

## $32 T_{2}$ is integral

In this section we prove the following lemma:
Lemma 3.1. For any element $T \in \mathbb{T}$, the element $2 T \in \mathbb{T}$ lies inside $\mathbb{T}^{\text {an }}$.
First we prove a lemma describing the image of the representation corresponding to a nonEisenstein ideal.

Lemma 3.2. Suppose $\mathfrak{m}$ does not contain the Eisenstein ideal. Then there is a representation

$$
\rho: G_{\mathbb{Q}} \rightarrow \mathrm{GL}_{2}\left(\mathbb{T}_{\mathfrak{m}}^{\mathrm{an}}\right)
$$

that is unramified outside $2 N$, and which satisfies $\operatorname{Tr}\left(\rho\left(\operatorname{Frob}_{\ell}\right)\right)=T_{\ell}$ for $\ell \nmid 2 N$.
Proof. Let $A=\mathbb{T}_{\mathfrak{m}}^{\text {an }}$ and $A^{\prime}$ is its integral closure over $\mathbb{Z}_{2}$, which can be written as the product $\prod_{i} \mathcal{O}_{i}$ of a collection of integer rings. We know that there exist representations $\rho_{i}^{\prime}: G_{\mathbb{Q}} \rightarrow \prod_{i} \mathrm{GL}_{2}\left(\mathcal{O}_{i}\right)$, by Eichler-Shimura-Deligne-Serre. The image is $\mathrm{GL}_{2}\left(\mathcal{O}_{i}\right)$, because $G_{\mathbb{Q}}$ is compact, and we may choose an invariant lattice on which it acts. These $\rho_{i}^{\prime}$ combine to give a representation

$$
\rho^{\prime}=\prod_{i} \rho_{i}^{\prime}: G_{\mathbb{Q}} \rightarrow \prod_{i} \mathrm{GL}_{2}\left(\mathcal{O}_{i}\right) .
$$

We know that the traces of the representations at $\mathrm{Frob}_{\ell}$ are the images of $T_{\ell}$ for all $\ell \nmid p N$, so the trace of $\rho^{\prime}$ by Chebotarev Density always lands in $\mathbb{T}_{\mathfrak{m}}^{\text {an }}$. We assumed $\mathfrak{m}$ did not contain the Eisenstein ideal, so we know that each $\rho_{i}^{\prime}$, and therefore the full $\rho^{\prime}$, is residually irreducible. By Car94, Theorem 2] we find that $\rho^{\prime}$ is similar to a representation

$$
\rho: G_{\mathbb{Q}} \rightarrow \mathrm{GL}_{2}\left(\mathbb{T}_{\mathfrak{m}}^{\mathrm{an}}\right)
$$

To prove Lemma 3.1, we look at the three different possible cases and deduce that the projection of $2 T_{2}$ to $\mathbb{T}_{\mathfrak{a}}$ lies in $\mathbb{T}_{\mathfrak{m}}^{\mathrm{an}}$ for each $\mathfrak{m} \subseteq \mathfrak{a}$. Further, we prove that $T_{2}^{2}$ lies in $\mathbb{T}_{\mathfrak{m}}^{\text {an }} \cdot T_{2}+\mathbb{T}_{\mathfrak{m}}^{\text {an }}$, so that any $T \in \mathbb{T}$, being an element in $\mathbb{T}^{\text {an }}\left[T_{2}\right]$, lies in $\mathbb{T}_{\mathfrak{m}}^{\text {an }} \cdot T_{2}+\mathbb{T}_{\mathfrak{m}}^{\text {an }}$ also, and hence is half of an element in $\mathbb{T}_{\mathfrak{m}}^{\mathrm{an}}$.

## $3.1 \bar{\rho}$ ordinary irreducible

We first assume that the residual representation $G_{\mathbb{Q}} \rightarrow \mathrm{GL}_{2}\left(\mathbb{T}_{\mathfrak{m}}^{\mathrm{an}} / \mathfrak{m}\right)$ is irreducible but the local residual representation at 2 is reducible. We will show that $2 T_{2}$, as an element of $\mathbb{T}_{\mathfrak{m}}^{\text {an }}\left[T_{2}\right]$, actually lies in $\mathbb{T}_{\mathfrak{m}}^{\mathrm{an}}$. This will be done by proving it is in the ring generated over $\mathbb{Z}_{2}$ by the traces of $\rho$. Equivalently, we will look at the traces of $\rho \otimes_{\mathbb{Z}_{2}} \mathbb{Q}_{2}$. This breaks the representation into a direct sum $\bigoplus_{i} \rho_{i}^{\prime} \otimes \mathbb{Q}_{2}: G_{\mathbb{Q}} \rightarrow \prod_{i} \mathrm{GL}_{2}\left(E_{i}\right)$. Each of the $\rho_{i}^{\prime}$ themselves have the same residual representation which is reducible when restricted to the decomposition group, so all these representations are ordinary.

Looking at a given $\rho_{i}^{\prime}$, we may apply Theorem 2.2 to it to obtain a shape of $\left.\rho_{i}^{\prime}\right|_{D_{2}}$. In particular, the trace of an element $\rho(g)$ is equal to $\chi(g) \lambda^{-1}(g)+\lambda(g)$ with $\lambda$ the unramified character whose image of Frobenius is the unit root of $X^{2}-T_{2} X+2$, and $\chi$ is the cyclotomic character. If $\alpha$ denotes the unit root of $x^{2}-a_{2, i} x+2=0$, then letting $g$ be an element of $\operatorname{Gal}\left(\mathbb{Q}_{2}^{\text {ab }} / \mathbb{Q}_{2}\right)$ which both is a lift of Frobenius and acts trivially on the 2-power roots of unity (so $\chi(g)=1$ ), then we know $\operatorname{Tr}(g)=\alpha+\alpha^{-1}$. If we let $h$ be a lift of Frobenius with $\chi(h)=-1$, we find that $\operatorname{Tr}(h)=\alpha-\alpha^{-1}$. And by definition, we know $\alpha+\frac{2}{\alpha}=a_{2, i}$, so $2 a_{2, i}=2 \alpha+4 \alpha^{-1}=3 \operatorname{Tr}(g)-\operatorname{Tr}(h)$.

We now look at the product of representations. The elements $g$ and $h$ were independent of the coefficient field, so we know that the element of $\mathbb{T}_{\mathfrak{m}}^{\text {an }} \otimes \mathbb{Q}_{2}$ that is $2 a_{2, i}$ in each coordinate, namely $2 T_{2} \otimes 1$, is equal to $3 \operatorname{Tr}(g)-\operatorname{Tr}(h)$. So $2 T_{2}$ is in the ring generated by the traces of elements, and thus in $\mathbb{T}_{\mathfrak{m}}^{\text {an }}$.

Similarly, we can prove that $T_{2}^{2}$ is in $\mathbb{T}_{\mathfrak{m}}^{\text {an }}+T_{2} \cdot \mathbb{T}_{\mathfrak{m}}^{a n}$ : in each coordinate, we can calculate that

$$
a_{2, i}^{2}=\operatorname{Tr}(g) a_{2, i}+\left(\operatorname{Tr}(g h)-\operatorname{Tr}\left(g^{2}\right)-1\right) .
$$

So in $\mathbb{T}_{\mathfrak{m}}^{\text {an }}\left[T_{2}\right]$, we find that $T_{2}^{2}=\operatorname{Tr}(g) T_{2}+\left(\operatorname{Tr}(g h)-\operatorname{Tr}\left(g^{2}\right)-1\right)$. So $T_{2}^{2} \subseteq \mathbb{T}_{\mathfrak{m}}^{\text {an }}+T_{2} \cdot \mathbb{T}_{\mathfrak{m}}^{\text {an }}$, and therefore so is every power of $T_{2}$. So we know that $2 \mathbb{T}_{\mathfrak{m}}^{\text {an }}\left[T_{2}\right] \subseteq \mathbb{T}_{\mathfrak{m}}^{\text {an }}$, and the $\mathbb{T}_{\mathfrak{m}}^{\text {an }}$-module quotient $\mathbb{T}_{\mathfrak{m}}^{\mathrm{an}}\left[T_{2}\right] / \mathbb{T}_{\mathfrak{m}}^{\mathrm{an}}$ is an $\mathbb{F}_{2}$ vector space. In section 4 we will calculate its dimension.

## $3.2 \quad \bar{\rho}$ reducible

We now suppose $\mathbb{T}_{\mathfrak{m}}^{\text {an }}$ corresponds to a reducible residual representation, so that $\mathfrak{m}$ is the Eisenstein ideal generated by 2 and $T_{\ell}$ for $\ell \nmid N$ (including $\ell=2$ ). We claim that $T_{2}$ is already in $\mathbb{T}_{\mathfrak{m}}^{\text {an }}$. This is because by [Maz77, Proposition 17.1], the Eisenstein ideal of the full Hecke algebra is generated by $1+\ell-T_{\ell}$ for any good prime. So by completeness, $T_{2}-3$ and therefore $T_{2}$ can be written as a power series in $T_{\ell}-\ell-1$.

## $3.3 \bar{\rho}$ non-ordinary

We now assume that the residual local representation at 2 is irreducible, or equivalently that in $\mathbb{T}_{\mathfrak{a}}, T_{2}$ is not a unit, where $\mathfrak{a}$ is some ideal of $\mathbb{T}$ above $\mathfrak{m}$ corresponding to $\rho$. We claim that $T_{2}$ is already in $\mathbb{T}_{\mathfrak{m}}^{a n}$, so that $\mathfrak{a}=\mathfrak{m}$ is actually unique, and the index is 1 .

Theorem 3.3. If $\rho$ is non-ordinary with corresponding map $\mathbb{T}^{\text {an }} \rightarrow \mathbb{F}$ with maximal ideal $\mathfrak{m}$, then for any $\mathfrak{a} \subseteq \mathbb{T}$ containing $\mathfrak{m}$, $T_{2} \in \mathbb{T}_{\mathfrak{a}}$ is already contained in the image of $\mathbb{T}_{\mathfrak{m}}^{\text {an }}$.

Proof. The $\mathbb{T}_{\mathfrak{m}}^{\text {an }}$-module $\mathbb{T}_{\mathfrak{m}}^{\text {an }}\left[T_{2}\right]$ requires the same generators as the $\mathbb{T}^{\text {an }} / \mathfrak{m}$-vector space $\mathbb{T} / \mathfrak{m} \mathbb{T}$ by Nakayama's Lemma, so it's enough to prove that $\mathbb{T} / \mathfrak{m} \mathbb{T}$ is one-dimensional over $\mathbb{T}^{\text {an }} / \mathfrak{m}$. If it's not, then all of $\mathbb{T}^{\mathrm{an}} / \mathfrak{m}$ and $T_{2}$ are independent over $\mathbb{F}_{2}$, so there is a homomorphism $\phi \in \operatorname{Hom}\left(\mathbb{T} / \mathfrak{m} \mathbb{T}, \mathbb{F}_{2}\right)$ sending all of $\mathbb{T}^{\text {an }} / \mathfrak{m}$ to 0 , and $T_{2}$ to 1 . Recalling the perfect pairing after Lemma 2.3, we find a nonzero modular form $g \in S_{2}\left(\Gamma_{0}(N), \mathbb{F}_{2}\right)[\mathfrak{m}]$ with all odd coefficients equal to 0 .

By part (3) of the main result of Kat77, we know that there is some nonzero form $f \in$ $S_{1}\left(\Gamma_{0}(N), \mathbb{F}_{2}\right)^{\text {Katz }}$ with $f^{2}=g$. (Here, we're considering weight 1 Katz forms, and so the weight 2 forms we construct may be Katz forms as well. So if necessary we enlarge the spaces we're considering, but it doesn't affect the conclusion.) As forms with coefficients in $\mathbb{F}_{2}$ commute with the Frobenius endomorphism, $f\left(q^{2}\right)$ has the same $q$-expansion as $g$. If $\mathbb{T}^{1}$ and $\mathbb{T}^{1, \text { an }}$ are the weight 1 Hecke algebras, it is quick to check that the corresponding Hecke actions on $q$-expansions of $\mathbb{T}^{1, \text { an }}$ are identical to those of $\mathbb{T}^{\text {an }}$. Therefore $f \in S_{1}\left(\Gamma_{0}(N), \mathbb{F}_{2}\right)^{\mathrm{Katz}}[\mathfrak{m}]$. Further, we know that $f$ is alone in this space, by part (2) of Kat77: any other form in $S_{1}\left(\Gamma_{0}(N), \mathbb{F}_{2}\right)^{\text {Katz }}[\mathfrak{m}]$ has the same odd coefficients, so the difference between it and $f$ has only even-power coefficients, and hence must be 0 by Katz's theorem. So $f$ is also an eigenform for $T_{2}$ in weight 1 , say with eigenvalue $b_{2}$.

So we've discovered that $S_{2}\left(\Gamma_{0}(N), \mathbb{F}_{2}\right)^{\mathrm{Katz}}[\mathfrak{m}]$ is at most 2 dimensional, spanned by $V f$ and $A f$. Here, $V$ acts as $V\left(\sum_{n=1}^{\infty} a_{n} q^{n}\right)=\sum_{n=1}^{\infty} a_{n} q^{2 n}$ on power series, so that $V f=g$, and can either be a weight-doubling operator, as used in Kat77, or a level-doubling operator. Additionally, $A f$ is the multiplication of $f$ with the Hasse invariant $A$, which preserves $q$-expansions. We can hence calculate the action of $T_{2}$ on this space: we know that $T_{2}$ acts in weight 2 via $U+2 V$, where $U\left(\sum_{n=1}^{\infty} a_{n} q^{n}\right)=\sum_{n=1}^{\infty} a_{2 n} q^{n}$, and in weight 1 as $U+\langle 2\rangle V$ with $\langle 2\rangle$ the diamond operator, which is identically 1 on $\bmod 2$ forms. Further, we can compute that $U V f=A f$, as $V$ doubles each exponent and $U$ halves it.

So we find

$$
\begin{aligned}
& T_{2}(V f)=U V f=A f \\
& T_{2}(A f)=U(A f)=A(U f)=A\left(T_{2} f-\langle 2\rangle V f\right)=A\left(b_{2} f\right)-\langle 2\rangle V f
\end{aligned}
$$

and the matrix for the $T_{2}$ action is $\left(\begin{array}{cc}b_{2} & -\langle 2\rangle \\ 1 & 0\end{array}\right)$. (In these computations, the distinction between the level-raising $V$ and the weight-raising $V$ has been blurred, because on $q$-expansions they are equal; we view both lines as equalities of weight 2 level $\Gamma_{0}(N)$ forms.) As $\langle 2\rangle$ is trivial, the determinant of this matrix is 1 , so $T_{2}$ is invertible. This is impossible because the form was non-ordinary. So there cannot be such a form $g$, and $\mathbb{T}_{\mathfrak{m}}^{\text {an }}\left[T_{2}\right]$ requires only one generator as a $\mathbb{T}_{\mathfrak{m}}^{\text {an }}$-module, as required.

## 4 Dimension of $\mathbb{T} / \mathbb{T}^{\text {an }}$

In this section we prove the second half of Theorem 1.1. It is enough to look locally, so we will localize at a maximal ideal $\mathfrak{m}$ of $\mathbb{T}^{\text {an }}$. Because completion at only ordinary non-Eisenstein ideals have $T_{2}$ not immediately in $\mathbb{T}_{\mathfrak{m}}^{\text {an }}$, we assume that $\mathfrak{m}$ is such an ideal.

### 4.1 Relating $\mathbb{T} / \mathbb{T}^{\text {an }}$ to $S_{2}$

We first recall the perfect pairing $S_{2}\left(\Gamma_{0}(N), \mathbb{F}_{2}\right) \times \mathbb{T} / 2 \rightarrow \mathbb{F}_{2}$, given by $(f, T) \rightarrow a_{1}(T f)$. While proving this, we proved perfect pairings $S_{2}\left(\Gamma_{0}(N), \mathbb{F}_{2}\right)_{\mathfrak{a}} \times \mathbb{T}_{\mathfrak{a}} / 2 \rightarrow \mathbb{F}_{2}$, and we now combine all $\mathfrak{a}$ that contain $\mathfrak{m}$, to get a perfect pairing $S_{2}\left(\Gamma_{0}(N), \mathbb{F}_{2}\right)_{\mathfrak{m}} \times \mathbb{T}_{\mathfrak{m}} / 2 \rightarrow \mathbb{F}_{2}$ where we denote $\mathbb{T}_{\mathfrak{m}}$ as the localization of $\mathbb{T}$ at the (not necessarily maximal) ideal $\mathfrak{m} \mathbb{T}$, and $S_{2}\left(\Gamma_{0}(N), \mathbb{F}_{2}\right)_{\mathfrak{m}}=e \cdot S_{2}\left(\Gamma_{0}(N), \mathbb{F}_{2}\right)$ for $e$ the projection from $\mathbb{T}$ to $\mathbb{T}_{\mathfrak{m}}$. Considering the subspace of forms killed by $A \theta$, the operator
defined in Kat77] which acts as $q \frac{d}{d q}$ on $q$-expansions and raises the weight by 3 , it's clear that the entirety of $\mathbb{T}_{\mathfrak{m}}^{a n}$ annihilates it under the pairing, and we wish to prove that this is the full annihilator. For ease of notation, let us write $V=\mathbb{T}_{\mathfrak{m}} / 2 \mathbb{T}_{\mathfrak{m}}, W=S_{2}\left(\Gamma_{0}(N), \mathbb{F}_{2}\right)_{\mathfrak{m}}$, and $V^{\prime}=\mathbb{T}_{\mathfrak{m}}^{\mathrm{an}} / 2 \mathbb{T}_{\mathfrak{m}}$.
Lemma 4.1. $S_{2}\left(\Gamma_{0}(N), \mathbb{F}_{2}\right)_{\mathfrak{m}} \cap \operatorname{Ker} A \theta$ and $\mathbb{T}_{\mathfrak{m}}^{\text {an }} / 2 \mathbb{T}_{\mathfrak{m}}$ are mutual annihilators in this perfect pairing.
Proof. We've seen that they annihilate each other. Now suppose $f=\sum_{i=1}^{\infty} a_{i} q^{i} \in W$ is annihilated by all of $V^{\prime}$. By the usual formula for the Hecke action on $q$-expansions, the coefficient of $q^{1}$ in $T_{n} f$ is $a_{n}$, so $a_{n}=0$ for all odd $n$. Therefore $f \in S_{2}\left(\Gamma_{0}(N), \mathbb{F}_{2}\right)_{\mathfrak{m}} \cap \operatorname{Ker} A \theta$, and we can call this space Ann $\left(V^{\prime}\right)$. This is enough to show they are mutual annihilators by dimension count, but we'll prove the other direction as well.

The space $W / \operatorname{Ann}\left(V^{\prime}\right)$ is represented by sequences of odd-power coefficients that appear in forms in $W$. We first prove that the map $V^{\prime} \rightarrow \operatorname{Hom}\left(W / \operatorname{Ann}\left(V^{\prime}\right), \mathbb{F}_{2}\right)$ induced by the pairing is surjective. Given a map $\varphi \in \operatorname{Hom}\left(W / \operatorname{Ann}\left(V^{\prime}\right), \mathbb{F}_{2}\right)$ whose input is sequences of odd-power coefficients, we can define a map $\varphi^{\prime}$ in the double dual of $V^{\prime}$ taking maps

$$
\chi: V^{\prime} \rightarrow \mathbb{F}_{2} \text { to } \varphi\left(\chi\left(T_{1}\right), \chi\left(T_{3}\right), \chi\left(T_{5}\right), \ldots\right) .
$$

This is the definition of $\varphi^{\prime}$ when $\left(\chi\left(T_{1}\right), \chi\left(T_{3}\right), \ldots\right)$ appears as the odd-power coefficients of a form. And then if we've not defined $\varphi^{\prime}$ on all of the dual of $V^{\prime}$, we can just extend it any way we want. But because $V^{\prime}$ is finite dimensional, this $\varphi^{\prime}$ determines an element $T_{\varphi} \in V^{\prime}$ for which

$$
\chi\left(T_{\varphi}\right)=\varphi^{\prime}(\chi)=\varphi\left(\chi\left(T_{1}\right), \chi\left(T_{3}\right), \ldots\right) .
$$

Then because any sequence of coefficients $\left(a_{1}, a_{3}, \ldots\right)$ is given by a character $\chi_{\left(a_{i}\right)}: T_{n} \rightarrow a_{n}$ (the restriction of such a $\chi$ from $\mathbb{T}_{\mathfrak{a}}$, for example), the pairing truly does send $T_{\varphi}$ to $\varphi$.

Now given $T$ that sends all of $\operatorname{Ann}\left(V^{\prime}\right)$ to $0, T f$ must only depend on the odd coefficients of $f$. But then $\varphi: f \rightarrow a_{1}(T f)$ is an element of $\operatorname{Hom}\left(W / \operatorname{Ann}\left(V^{\prime}\right), \mathbb{F}_{2}\right)$. So by surjectivity there is some element $T^{\prime}$ of $V^{\prime}$ with $a_{1}(T f)=\varphi(f)=a_{1}\left(T^{\prime} f\right)$ for all $f \in W / \operatorname{Ann}\left(V^{\prime}\right)$. Then $a_{1}\left(\left(T-T^{\prime}\right) f\right)$ is 0 for all $f$ either in $\operatorname{Ann}\left(V^{\prime}\right)$ or a lift of an element of $W / \operatorname{Ann}\left(V^{\prime}\right)$, and so in all of $W$. Because the pairing is perfect, $T=T^{\prime} \in V^{\prime}$ as we needed.

Now that we know these are mutual annihilators, we obtain an isomorphism

$$
V / V^{\prime} \rightarrow \operatorname{Hom}\left(\operatorname{Ann}\left(V^{\prime}\right), \mathbb{F}_{2}\right),
$$

and taking dimensions and reinterpreting, we've proven that

$$
\operatorname{dim} \mathbb{T}_{\mathfrak{m}} / \mathbb{T}_{\mathfrak{m}}^{\mathrm{an}}=\operatorname{dim} S_{2}\left(\Gamma_{0}(N), \mathbb{F}_{2}\right)_{\mathfrak{m}} \cap \operatorname{Ker} A \theta
$$

So we have proven the following.
Lemma 4.2. The index of $\mathbb{T}_{\mathfrak{m}}^{\text {an }}$ in $\mathbb{T}_{\mathfrak{m}}$ equals 2 raised to the dimension of $S_{2}\left(\Gamma_{0}(N), \mathbb{F}_{2}\right)_{\mathfrak{m}} \cap \operatorname{Ker} A \theta$.

### 4.2 Lifting from weight 1 to weight 2

Now we use the main theorem of Kat77] to find a subspace of $S_{1}\left(\Gamma_{0}(N), \mathbb{F}_{2}\right)^{\text {Katz }}$ that maps under $V$ to $S_{2}\left(\Gamma_{0}(N), \mathbb{F}_{2}\right)_{\mathfrak{m}} \cap \operatorname{Ker} A \theta$. As in Section 3.3, we have $\mathbb{T}^{\text {an }}$-equivariance, and so the maximal ideal $\mathfrak{m}$ has an exact analogue in $\mathbb{T}^{1, \text { an }}$ and we land in the subspace $S_{1}\left(\Gamma_{0}(N), \mathbb{F}_{2}\right)_{\mathfrak{m}}^{\text {Katz }}$. We may not obtain the whole subspace because, while $V f$ is in the kernel of $A \theta$ for all $f \in S_{1}\left(\Gamma_{0}(N), \mathbb{F}_{2}\right)_{\mathfrak{m}}^{\mathrm{Katz}}$, we don't know that it's a form that is the reduction of a $\mathbb{Z}_{2}$ form, which is what $\mathbb{T}_{\mathfrak{m}}^{\text {an }}$ parametrizes. In this section we will prove that the space of Katz forms of weight 2 actually are all standard forms.

The first case is $N \equiv 3 \bmod 4$, which was taken care of Edixhoven:

Theorem 4.3 ([Edi06, Theorem 5.6]). Let $N \geq 5$ be odd and divisible by a prime number $q \equiv-1$ modulo 4 (hence the stabilizers of the group $\Gamma_{0}(N) /\{1,-1\}$ acting on the upper half plane have odd order $)$. Then $S_{2}\left(\Gamma_{0}(N), \mathbb{F}_{2}\right)^{\text {Katz }}$ and $\mathbb{F}_{2} \otimes S_{2}\left(\Gamma_{0}(N), \mathbb{Z}\right)$ are equal, and the localizations at non-Eisenstein maximal ideals of the algebras of endomorphisms of $S_{2}\left(\Gamma_{0}(N), \mathbb{F}_{2}\right)^{\text {Katz }}$ and $H_{\mathrm{par}}^{1}\left(\Gamma_{0}(N), \mathbb{F}_{2}\right)$ generated by all $T_{n}(n \geq 1)$ coincide: both are equal to that of $S_{2}\left(\Gamma_{0}(N), \mathbb{Z}\right)$ tensored with $\mathbb{F}_{2}$.

So for primes $N \equiv 3 \bmod 4$, we've proven the equality in Theorem 1.1. For the remainder of this section we therefore assume $N \equiv 1 \bmod 4$. Further, up until this point we've only worked with $\mathbb{F}_{2}$-forms, but we change coefficients to $\overline{\mathbb{F}}_{2}$ so that we can find eigenforms associated to each maximal ideal. Theorem 4.3 still applies as its proof in Edi06 can be extended to all finite extensions of $\mathbb{F}_{2}$.

Theorem 4.4. There are no Katz forms that are not the reduction of a form in $S_{2}\left(\Gamma_{0}(N), \overline{\mathbb{Z}}_{2}\right)$. That is,

$$
S_{2}\left(\Gamma_{0}(N), \overline{\mathbb{F}}_{2}\right)^{\mathrm{Katz}}=S_{2}\left(\Gamma_{0}(N), \overline{\mathbb{F}}_{2}\right) .
$$

Proof. Let $\ell$ be an arbitrary prime that is $3 \bmod 4$, and we will look at $S_{2}\left(\Gamma_{0}(N \ell), \bar{F}_{2}\right)^{\text {Katz }}$. We can apply Theorem 4.3 to it and conclude that this space is exactly the characteristic 0 forms tensored with $\overline{\mathbb{F}}_{2}$, so we may drop the Katz superscript. Further, we know that all Katz forms of level $\Gamma_{0}(N)$ lie in this space. So we just need to know there are no extra level $\Gamma_{0}(N)$ forms within this space.

As $\mathbb{T}^{\text {Katz }} \otimes \overline{\mathbb{F}}_{2}$ can be broken into a direct sum of $\overline{\mathbb{F}}_{2}$-vector spaces on which the semi-simple action of each operator is by multiplication by a constant, $S_{2}\left(\Gamma_{0}(N), \bar{F}_{2}\right)^{\text {Katz }}$ can be written as a direct sum of generalized eigenspaces. If we show every generalized eigenform in $S_{2}\left(\Gamma_{0}(N), \overline{\mathbb{F}}_{2}\right)^{\text {Katz }}$ is the reduction of a modular form from $S_{2}\left(\Gamma_{0}(N), \overline{\mathbb{Z}}_{2}\right)$, then we're done. So suppose $f$ is a generalized Katz eigenform for all $T_{n}$, including $T_{2}$. Let the eigenvalue corresponding to $T_{\ell}$ equal $a_{\ell}$; we will prove that if $f \notin S_{2}\left(\Gamma_{0}(N), \overline{\mathbb{F}}_{2}\right)$, then $a_{\ell}=0$.

There are two maps from $S_{2}\left(\Gamma_{0}(N), \overline{\mathbb{F}}_{2}\right)^{\text {Katz }}$ to $S_{2}\left(\Gamma_{0}(N \ell), \overline{\mathbb{F}}_{2}\right)$ : the plain embedding with equality on $q$-expansions, and the map $V_{\ell}$ sending $f(q)$ to $f\left(q^{\ell}\right)$. We know $T_{\ell}=U_{\ell}+\ell V_{\ell}$ on $q$-expansions, so we find that

$$
U_{\ell}\left(T_{\ell}-a_{\ell}\right)=U_{\ell}\left(U_{\ell}+\ell V_{\ell}-a_{\ell}\right)=U_{\ell}^{2}-a_{\ell} U_{\ell}+\ell U_{\ell} V_{\ell}=U_{\ell}^{2}-a_{\ell} U_{\ell}+\ell
$$

as operators from $S_{2}\left(\Gamma_{0}(N), \overline{\mathbb{F}}_{2}\right)^{\mathrm{Katz}}$ to $S_{2}\left(\Gamma_{0}(N \ell), \overline{\mathbb{F}}_{2}\right)$. Then because $f$ is a generalized eigenform, we find

$$
0=\left(U_{\ell}^{k}\left(T_{\ell}-a_{\ell}\right)^{k}\right) f=U_{\ell}^{k-1}\left(U_{\ell}^{2}-a_{\ell} U_{\ell}+\ell\right)\left(T_{\ell}-a_{\ell}\right)^{k-1} f=\ldots=\left(U_{\ell}^{2}-a_{\ell} U_{\ell}+\ell\right)^{k} f
$$

If we factor $X^{2}-a_{\ell} X+\ell$ as $(X-\alpha)(X-\beta)$ for some lift of $a_{\ell}$, we've proven that $\left(U_{\ell}-\alpha\right)\left(U_{\ell}-\beta\right)$ acts topologically nilpotently on any lift of $f$ (which exists by Theorem 4.4). This will eventually be used to prove that one of $\alpha$ or $\beta$, and hence both, reduce to $1 \bmod$ the maximal ideal of $\overline{\mathbb{Z}}_{2}$.
Lemma 4.5. For any characteristic 0 newform $g$ of level $N \ell, U_{\ell}-1$ acts topologically nilpotently.
Proof. The eigenform $g$ gives us a representation $\rho: G_{\mathbb{Q}} \rightarrow \mathrm{GL}_{2}\left(\overline{\mathbb{Q}}_{2}\right)$. The shape of this representation at the decomposition group at $\ell$ is given by [DDT97, Theorem 3.1(e)], as we recalled in the proof of Theorem 2.1, which says that

$$
\left.\rho\right|_{D_{\ell}}=\left(\begin{array}{cc}
\chi \varepsilon & * \\
0 & \chi
\end{array}\right)
$$

where $\chi$ is the unramified representation that sends $\mathrm{Frob}_{\ell}$ to the $U_{\ell}$-eigenvalue of $g$, and $\varepsilon$ is the 2-adic cyclotomic character. Because the determinant is the 2-adic cyclotomic character as well, we know that $\chi^{2}=1$, so the $U_{\ell}$-eigenvalue of $g$ is $\pm 1$. So $U_{\ell}-1$ is either 0 or -2 , which both act nilpotently.

If $\alpha-1$ and $\beta-1$ have valuation 0 , then $\left(U_{\ell}-\alpha\right)\left(U_{\ell}-\beta\right)$ will not act nilpotently on any linear combination of eigenforms which includes at least one newform, by Lemma 4.5. As $\left(U_{\ell}-\alpha\right)\left(U_{\ell}-\beta\right)$ acts nilpotently on a lift of $f$, we know that this lift is a linear combinaton of only oldforms, and hence $f$ lifts to $S_{2}\left(\Gamma_{0}(N), \overline{\mathbb{Z}}_{2}\right)$. Otherwise, one of $\alpha$ and $\beta$, and hence both, are $1 \bmod$ the maximal ideal of $\overline{\mathbb{Z}}_{2}$, and so $\alpha+\beta \equiv 0 \equiv a_{\ell}$.

Therefore, we have proven that if $f$ is a generalized eigenform in $S_{2}\left(\Gamma_{0}(N), \overline{\mathbb{F}}_{2}\right)^{\text {Katz }}$ that has no lift to characteristic 0 , then $a_{\ell}=0$ for any prime $\ell \equiv 3 \bmod 4$, as our choice of $\ell$ was arbitrary. Letting $g$ be a true eigenform in the same eigenspace as $f$, we obtain a representation $\bar{\rho}_{g}: G_{\mathbb{Q}} \rightarrow$ $\mathrm{GL}_{2}\left(\overline{\mathbb{F}}_{2}\right)$ with $\operatorname{Tr}\left(\rho_{g}\left(\operatorname{Frob}_{p}\right)\right)=a_{p}$. We showed that $\bar{\rho}_{g}$ has trace 0 on all Frob $\ell$, so it must be the induction of a character from $G_{\mathbb{Q}(i)}$ to $G_{\mathbb{Q}}$. But such a representation is dihedral in the terminology of KM19, and KM19, Theorem 12(1)] proves that it's impossible for a dihedral representation on $G_{\mathbb{Q}(i)}$ to give rise to a form of level $\Gamma_{0}(N)$. So there can be no Katz eigenforms of level $\Gamma_{0}(N)$ that don't lift, and hence no generalized eigenforms and therefore no forms at all.

From this, we conclude that all the forms $V_{2} f$, where $f$ is a weight 1 form of level $N$, are classical forms, and so the dimension of the space $S_{2}\left(\Gamma_{0}(N), \mathbb{F}_{2}\right)_{\mathfrak{m}} \cap \operatorname{Ker} A \theta$ is exactly the dimension $S_{1}\left(\Gamma_{0}(N), \mathbb{F}_{2}\right)_{\mathfrak{m}}^{\text {Katz }}$. And so from Lemma 4.2, taking a direct sum over all $\mathfrak{m}$, we obtain Theorem 1.1.

## 5 Examples

In this section we use Theorem 1.1 to make nontrivial observations about the index of $\mathbb{T}^{\text {an }}$ inside $\mathbb{T}$.

## 5.1 $N \equiv 3 \bmod 4$

Lemma 5.1. If $N \equiv 3 \bmod 4$ is prime, the anemic Hecke algebra $\mathbb{T}^{\text {an }}$ is equal to the full algebra $\mathbb{T}$ if and only if the class group $\operatorname{Cl}(\mathbb{Q}(\sqrt{-N}))$ is trivial.

Proof. If $K=\mathbb{Q}(\sqrt{-N})$ has class number greater than 1 , by genus theory, since the discriminant of $K$ is $-N$ which is divisible by only a single prime, the 2 -part of the class group of $K$ is trivial, so $\mathrm{Cl}(K)$ has a nontrivial mod 2 multiplicative character which translates to an unramified mod 2 character $\chi$ of $\operatorname{Gal}(\overline{\mathbb{Q}} / K)$. Inducing this to $\operatorname{Gal}(\overline{\mathbb{Q}} / \mathbb{Q})$, we get a dihedral representation with Artin conductor equal to $N$. Wiese proves in Wie04 that all dihedral representations give rise to Katz modular forms, and so the space $S_{1}\left(\Gamma_{0}(N), \mathbb{F}_{2}\right)^{\text {Katz }}$ is nontrivial, and hence $\mathbb{T}^{\text {an }} \subsetneq \mathbb{T}$.

This shows that if $N$ is not $3,7,11,19,43,67$ or 163 (and is still a $3 \bmod 4 \operatorname{prime}$ ), $\mathbb{T}^{\text {an }}(N) \subsetneq$ $\mathbb{T}(N)$. On the other hand, for $N=3$ and $N=7$ there are no modular forms of weight 2 , and for the other $N$, computer verification using the techniques of modular symbols, such as described in [Ste07], provides the following table:

| $N$ | $T_{2}$ |
| :---: | :---: |
| 11 | $-2 T_{1}$ |
| 19 | 0 |
| 43 | $-2 T_{1}-2 T_{3}+T_{5}$ |
| 67 | $T_{3}-T_{11}$ |
| 163 | $30 T_{1}-16 T_{3}-23 T_{5}-9 T_{7}+18 T_{9}+3 T_{11}-24 T_{13}$ |
|  | $+12 T_{15}+40 T_{17}-16 T_{19}-14 T_{21}-9 T_{23}+2 T_{25}+32 T_{27}$ |

These each prove that there are no Katz eigenforms of weight 1 and level $N$ for any of these $N$, and in turn that there are no Galois representations that could provide such forms. Of course, we knew a priori there were no dihedral representations, as they would need to arise from the class group, but we now know that there are no larger-image representations.

## $5.2 \quad N \equiv 1 \bmod 4$

Question 5.2. Is it true that for a positive proportion of prime $N \equiv 1 \bmod 4$, the anemic Hecke algebra $\mathbb{T}^{\text {an }}$ is not equal to the full algebra $\mathbb{T}$, and for a positive proportion of $N, \mathbb{T}^{\text {an }}$ is equal to $\mathbb{T}$ ?

We cannot immediately claim anything about the class group, because the Cohen-Lenstra heuristics [CL84, C11] claim that approximately $75.446 \%$ of positive prime-discriminant quadratic extensions have trivial class group, so that there can be no dihedral modular forms.

The strong form of Serre's conjecture due to Edixhoven [Edi97, Conjecture 1.8] is not known, where the strong form differs from the form proven by Khare and Wintenberger in [KW09] in this weight 1 case. A result of Wiese for dihedral representations Wie04 is known, and a converse (that the corresponding representation $\bar{\rho}$ is unramified at 2) has been proven Wie14, Corollary 1.3]. We may also use Theorem 1.1 to construct weight 1 forms in the case that the eigenvalues of $\mathrm{Frob}_{2}$ in the characteristic 2 representation are distinct, because there are two possible values for $a_{2}$, implying that $\mathbb{T}_{\mathfrak{m}} \neq \mathbb{T}_{\mathfrak{m}}^{\text {an }}$.

We also know the subgroups of $\mathrm{SL}_{2}\left(\overline{\mathbb{F}}_{2}\right)$, by Dickson, of four types: cyclic, upper-triangular, dihedral, and full-image (see [Suz77, Chapter 3, Theorem 6.17]). We know a modular representation must be absolutely irreducible: if not, say $f$ is a weight 1 form for which $\bar{\rho}_{f}$ is reducible. Then $A f$ is a weight 2 form with the same representation, along with $V f$ in the same generalized eigenspace. But in Section 3.2 we proved that $T_{2}$ is already contained in the Hecke algebra corresponding to any eigenform with reducible representation, meaning that the dimension of $S_{2}\left(\Gamma_{0}(N), \mathbb{F}_{2}\right)_{\mathfrak{m}}$ is dimension 1 , not 2 . Therefore only absolutely irreducible representations can be modular, so only dihedral and full-image representations can exist. So assuming the strong version of Serre's conjecture, we know that for any weight 1 forms to exist at level $N$, we need either a dihedral extension of $\mathbb{Q}$, which must arise from inducing from the class group of $\mathbb{Q}(\sqrt{N})$, or we need an extension of $\mathbb{Q}$ unramified outside $N$ with Galois group isomorphic to $\mathrm{SL}_{2}\left(\mathbb{F}_{2^{k}}\right)$ for some $k$.

Work has been done by Lipnowski Lip16 to interpret Bhargava's heuristics for the Galois group $\mathrm{GL}_{2}\left(\mathbb{F}_{p}\right)$ for $p$ a prime, in order to count elliptic curves by their conductors through their $p$-adic representations. Although not done in this current note, it appears tractable to similarly analyze the groups $\mathrm{SL}_{2}\left(\mathbb{F}_{2^{k}}\right)$ and obtain a heuristic, explicit or not, on how many primes $p$ have an elsewhere-unramified extension with each of these as their Galois groups. Because of the CohenLenstra heuristics, it appears likely that infinitely many, even a positive proportion, of primes $1 \bmod 4$ have no weight 1 forms, so $\mathbb{T}=\mathbb{T}^{\text {an }}$, and a positive proportion of primes have some weight 1 form so $\mathbb{T}^{\text {an }} \subsetneq \mathbb{T}$.

### 5.2.1 Explicit example: $N=653$

An instructive example is that of $N=653$. Of course this is $1 \bmod 4$, and so any dihedral representation that would give a weight 1 form would have to come from an induction of the class group of $\mathbb{Q}(\sqrt{653})$, but the Minkowski bound is $\frac{1}{2} \sqrt{653} \approx 12.77$, and $2,3,5$ are inert and $7=230^{2}-653 \cdot 9^{2}$ and $-11=51^{2}-653 \cdot 2^{2}$ are norms of principal ideals. So $\mathbb{Q}(\sqrt{653})$ has class number 1. But the Galois closure $L$ of the field $\mathbb{Q}[x] /\left(x^{5}+3 x^{3}-6 x^{2}+2 x-1\right)$ has Galois group $A_{5}=\mathrm{SL}_{2}\left(\mathbb{F}_{4}\right)$, and is ramified only at 653 with ramification degree 2 and inertial degree 2. Therefore, Edixhoven predicts that the tautological Galois representation gives rise to a weight 1 level $\Gamma_{0}(653)$ modular form. This is not a classical form, as $\mathrm{SL}_{2}\left(\mathbb{F}_{4}\right)$ does not embed into $\mathrm{GL}_{2}(\mathbb{C})$, where all weight 1 characteristic 0 eigenforms must arise from.

On the other hand, $\mathrm{SL}_{2}\left(\mathbb{F}_{4}\right)$ does embed into $\mathrm{PGL}_{2}(\mathbb{C})$, and by a theorem of Tate, all projective Galois representations lift. We can follow the proof given by Serre in Ser77 to obtain a lift, unramified away from 653, and with Artin conductor $653^{2}$. The fixed field of the kernel of this representation is a quadratic extension of $L[x] /\left(x^{4}-x^{3}+82 x^{2}-1102 x+13537\right)$, which is itself the compositum of $L$ and the quartic subfield of the 653 rd roots of unity. Locally at 653 it is a faithful representation of $\operatorname{Gal}\left(\mathbb{Q}_{653}(\sqrt[8]{653}, \sqrt{2}) / \mathbb{Q}_{653}\right)$, a Galois group isomorphic to $\langle x, y| x^{8}=y^{2}=e, y x=$ $\left.x^{5} y\right\rangle$.

We therefore find that, as the Artin conjecture for odd representations has been proven in [KW09], an eigenform of weight 1 and level $653^{2}$ that reduces to the characteristic 2 form of level 653 we found above. We can additionally twist by the nontrivial character of $\mathbb{Q}(\sqrt{653}) / \mathbb{Q}$, not changing the determinant or level, to get a second Artin representation, and hence a second modular form of the same weight and nebentypus. These two eigenforms are congruent mod 2, so their average is also an integral form, and there is therefore a nilpotent element of the weight 1 $\bmod 2$ Hecke algebra, in a similar sense to [CE09, Lemma 3.8]. And conjugating the $\mathbb{F}_{4}$-forms, we obtain 2 more weight 1 forms of level 653 . So the index of $\mathbb{T}^{\text {an }}$ in $\mathbb{T}$ must be at least 16 .

Indeed, we can find the following four (non-eigen)forms of weight 2 and level 653:
$f_{1}=0 q^{1}+1 q^{2}+2 q^{3}-4 q^{4}+0 q^{5}+2 q^{6}+0 q^{7}+4 q^{8}+0 q^{9}+4 q^{10}+0 q^{11}+1 q^{12}-6 q^{13}+\ldots$
$f_{2}=0 q^{1}+0 q^{2}+2 q^{3}-3 q^{4}+0 q^{5}+2 q^{6}+2 q^{7}+2 q^{8}+4 q^{9}-3 q^{10}+4 q^{11}-6 q^{12}+0 q^{13}+\ldots$
$f_{3}=0 q^{1}+0 q^{2}+0 q^{3}+4 q^{4}+0 q^{5}+1 q^{6}+2 q^{7}+2 q^{8}+4 q^{9}+5 q^{10}+2 q^{11}+0 q^{12}+4 q^{13}+\ldots$
$f_{4}=0 q^{1}-2 q^{2}-6 q^{3}+2 q^{4}+0 q^{5}+2 q^{6}+2 q^{7}-5 q^{8}+0 q^{9}+0 q^{10}-2 q^{11}-6 q^{12}-2 q^{13}+\ldots$
each of whose odd-power coefficients are all even, proving that none of $T_{2}, T_{4}, T_{6}$ or $T_{8}$ are in $\mathbb{T}^{\text {an }}$ plus the other 3. But a calculation up to the Sturm bound of 109 proves that there are no other modular forms with all odd-power coefficients and coefficients of $q^{2}, q^{4}, q^{6}, q^{8}$ all even but some other coefficient is odd. Therefore $\mathbb{T}=2 \mathbb{T}+\left\langle T_{2}, T_{4}, T_{6}, T_{8}\right\rangle$, so $\mathbb{T} / 2 \mathbb{T}$ is generated as an $\mathbb{F}_{2}$-vector space by $T_{2}, T_{4}, T_{6}, T_{8}$. By Lemma $3.1, \mathbb{T} / \mathbb{T}^{\text {an }}$ is a quotient of $\mathbb{T} / 2 \mathbb{T}$, but from the above forms $T_{2}, T_{4}, T_{6}, T_{8}$ are independent in $\mathbb{T} / \mathbb{T}^{\text {an }}$ so the index of $\mathbb{T}^{\text {an }}$ in $\mathbb{T}$ must be exactly $2^{4}=16$.
