Abstract

We present the fundamental solutions for the spin-\(\frac{1}{2}\) fields propagating in the spacetimes with power type expansion/contraction and the fundamental solution of the Cauchy problem for the Dirac equation. The derivation of these fundamental solutions is based on formulas for the solutions to the generalized Euler-Poisson-Darboux equation, which are obtained by the integral transform approach.

Keywords

Dirac equation · Einstein & de Sitter model · FLRW models · non-Fuchsian equations · Euler-Poisson-Darboux equation

1 Introduction. Main results

The Dirac equation is one of the important equations of relativistic quantum mechanics, quantum electrodynamics, and quantum field theory. The Dirac equation and its quantization in curved spacetime is of great interest due to the role of spin-\(\frac{1}{2}\) particles in astrophysics and cosmology. Recent observational confirmation of the expansion of the universe and the quantum field theory demand a detailed investigation of the solutions of the Dirac equation in the curved spacetime (see, e.g., [3, 23] and bibliography therein). The construction of a quantum field theory in curved spacetime is heavily relying on the detailed description of the solutions of the Dirac equation in curved background. The standard models of Cosmology provide such backgrounds, which form a family of curved backgrounds under name Friedmann-Lemaître-Robertson-Walker (FLRW) models. For the FLRW spacetime with accelerated expansion/contraction, more exactly, for the de Sitter spacetime in [33] a fundamental solution of the Dirac operator and an explicit formula for the solution of the Cauchy problem are obtained. In [34] examination of these explicit formulas gave the answer to such an interesting question in the physics of fundamental particles as a validity of the Huygens principle. Must be noted that several exact solutions of the Dirac equation in the FLRW spacetime, which is the base of the standard cosmological model, obtained by separation of variables approach answer to some very interesting questions of physics (see, e.g., [1, 6, 12, 15, 16, 17, 20, 27, 36] and bibliography therein). On the other hand, the fundamental solutions to the Dirac operator can provide an information, which is impossible to obtain by numerical solutions of differential equations, as well as new solutions, which are not among exact solutions obtained by the separation of variables approach.

In the present paper we construct the fundamental solution of the Dirac operator and obtain the explicit formulas for the solution of the Cauchy problem for the FLRW spacetime with both accelerating and decelerating expansion or contraction. The spatially flat FLRW models considered in this paper have the metric tensor in Cartesian coordinates written as follows

\[
(g_{\mu\nu}) = \begin{pmatrix}
  1 & 0 & 0 & 0 \\
  0 & -a^2(t) & 0 & 0 \\
  0 & 0 & -a^2(t) & 0 \\
  0 & 0 & 0 & -a^2(t)
\end{pmatrix}, \quad \mu, \nu = 0, 1, 2, 3
\] (1)
where the scale factor $a(t) = a_0 t^\ell$, $\ell \in \mathbb{R}$, $t > 0$, and $x \in \mathbb{R}^3$, $x_0 = t$. If $\ell < 0$ the spacetime is contracting. In the case of $\ell > 1$ the expansion is accelerating (with horizon), while for $0 < \ell < 1$ the expansion is decelerating. In the case of the Milne spacetime $[7, 13, 25] \ell = 1$. The FLRW spacetime with the scale factors $a(t) = a_0 t^{2/3}$ and $a(t) = a_0 t^{1/2}$ (see, e.g., [18, 19]) are modeling the matter dominated universe (Einstein & de Sitter model [11]) and the radiation dominated universe, respectively. The Dirac equation in the spacetime with the metric tensor (1) is (see, e.g., [1])

$$
(i\gamma^0 \partial_0 + i\frac{1}{a(t)}\gamma^1 \partial_{x_1} + i\frac{1}{a(t)}\gamma^2 \partial_{x_2} + i\frac{1}{a(t)}\gamma^3 \partial_{x_3} + i\frac{3\dot{a}(t)}{2a(t)}\gamma^0 - m\mathbb{I}_4) \Psi = F,
$$

where the contravariant gamma matrices are (see, e.g., [5, p. 61])

$$
\gamma^0 = \begin{pmatrix} \mathbb{I}_2 & \mathbb{O}_2 \\ \mathbb{O}_2 & -\mathbb{I}_2 \end{pmatrix}, \quad \gamma^k = \begin{pmatrix} \mathbb{O}_2 & \sigma^k \\ -\sigma^k & \mathbb{O}_2 \end{pmatrix}, \quad k = 1, 2, 3.
$$

Here $\sigma^k$ are the Pauli matrices

$$
\sigma^1 = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \quad \sigma^2 = \begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix}, \quad \sigma^3 = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix},
$$

and $\mathbb{I}_n$, $\mathbb{O}_n$ denote the $n \times n$ identity and zero matrices, respectively.

We consider the fundamental solutions and the Cauchy problem with the initial time $t = \varepsilon > 0$. Furthermore, we admit that the mass of the field (particle) can be changing in time and vanishing at infinity. More exactly, the model that we choose is determined by the Dirac operator

$$
\mathcal{D}(t, \partial_t, \partial_x) := i\gamma^0 \partial_0 + i\frac{1}{a(t)}\gamma^1 \partial_{x_1} + i\frac{1}{a(t)}\gamma^2 \partial_{x_2} + i\frac{1}{a(t)}\gamma^3 \partial_{x_3} + i\frac{3\dot{a}(t)}{2a(t)}\gamma^0 - m t^{-1}\mathbb{I}_4,
$$

where $m \in \mathbb{C}$. This model includes equation of neutrino with $m = 0$ as well as massive spin-$\frac{1}{2}$ particle undergoing a redshifting of its wavelength as the universe expands.

We start with the fundamental solution to the Dirac operator. Recall that a retarded fundamental solution (a retarded inverse) for the Dirac operator (3) is a four dimensional matrix with the operator-valued entries $\mathcal{E}^{ret} = \mathcal{E}^{ret}(x, t; x_0, t_0; m)$ that solves the equation

$$
\mathcal{D}(t, \partial_t, \partial_x)\mathcal{E}(x, t; x_0, t_0; m) = \delta(x - x_0)\delta(t - t_0)\mathbb{I}_4, \quad (x, t), (x_0, t_0) \in \mathbb{R}^3 \times \mathbb{R}_+,
$$

and with the support in the chronological future (causal future) $D_+(x_0, t_0)$ of the point $(x_0, t_0) \in \mathbb{R}^3 \times \mathbb{R}_+$. The advanced fundamental solution (propagator) $\mathcal{E}^{adv} = \mathcal{E}^{adv}(x, t; x_0, t_0; m)$ solves the equation (4) and has a support in the chronological past (causal past) $D_-(x_0, t_0)$. The forward and backward light cones are defined as the boundaries of

$$
D_{\pm} (x_0, t_0) := \left\{ (x, t) \in \mathbb{R}^3 \times \mathbb{R}_+; |x - x_0| \leq \pm (\phi(t) - \phi(t_0)) \right\},
$$

where $\phi(t) := \frac{1}{1-t^\ell}$ if $\ell \neq 1$, and $\phi(t) := \ln(t + 1)$ if $\ell = 1$, is a distance function when $\ell < 1$. In fact, any intersection of $D_-(x_0, t_0)$ with the hyperplane $0 < t = const < t_0$ determines the so-called dependence domain for the point $(x_0, t_0)$, while the intersection of $D_+(x_0, t_0)$ with the hyperplane $t = const > t_0 > 0$ is the so-called domain of influence of the point $(x_0, t_0)$. The Dirac equation (2) is non-invariant with respect to time inversion and its solutions have different properties in different direction of time.

In order to distinguish upper and lower 2-spinors we introduce two more $\gamma$-matrices (projection operators), the upper left corner and lower right corner matrices,

$$
\gamma^U = \begin{pmatrix} \mathbb{I}_2 & 0 \\ 0 & \mathbb{O}_2 \end{pmatrix} = \frac{1}{2}(\mathbb{I}_4 + \gamma^0), \quad \gamma^L = \begin{pmatrix} \mathbb{O}_2 & 0 \\ 0 & \mathbb{I}_2 \end{pmatrix} = \frac{1}{2}(\mathbb{I}_4 - \gamma^0).
$$

Next we define the right co-factor

$$
\mathcal{D}^{co}(t, \partial_t, \partial_x) := it^{-\frac{3}{2}}\gamma^0(t^{im}\gamma^U + t^{-im}\gamma^L)\frac{\partial}{\partial t} + it^{-\frac{3}{2}}\sum_{k=1}^{3}\gamma^k(t^{im}\gamma^U + t^{-im}\gamma^L)\frac{\partial}{\partial x_k}
$$

(6)
of the Dirac operator $\mathcal{D}(t, \partial_t, \partial_x)$ of (3), which is chosen in the way that the composition $\mathcal{D}(t, \partial_t, \partial_x) \mathcal{D}^{co}(t, \partial_t, \partial_x)$ is a diagonal matrix of operators. In fact, the complementary operator $\mathcal{D}^{co}(t, \partial_t, \partial_x)$ is not unique. For the Dirac equation in the de Sitter spacetime such complementary operators were first suggested in [33].

Denote $\mathcal{E}^w(x,t)$ the distribution that is the fundamental solution to the Cauchy problem for the wave equation in the Minkowski spacetime

$$\mathcal{E}^w_\mu - \Delta \mathcal{E}^w = 0, \quad \mathcal{E}^w(x,0) = \delta(x), \quad \mathcal{E}^w_\mu(x,0) = 0.$$  \hspace{1cm} (7)

Here $\Delta$ is the Laplace operator in $\mathbb{R}^3$. Henceforth, $F(\alpha, \beta; \gamma; z)$ is the hypergeometric function (see, e.g., [2]). Our first main theorem gives for the Dirac operator the fundamental solution (retarded propagator) with support in the forward cone.

**Theorem 1.1** For every $x_0 \in \mathbb{R}^3$, $t,t_0 \in \mathbb{R}_+$, the fundamental solution $\mathcal{E}_+(x,t; x_0,t_0; m)$ with support in the forward cone $D_+(x_0,t_0)$, that is, a distribution satisfying

$$\begin{cases}
\mathcal{D}(t, \partial_t, \partial_x) \mathcal{E}_+(x,t; x_0,t_0; m) = \delta(x-x_0)\delta(t-t_0)\mathbb{I}_4, \\
\text{supp} \mathcal{E}_+ \subseteq D_+(x_0,t_0).
\end{cases}$$  

is given as follows

$$\mathcal{E}_+(x,t; x_0,t_0; m) = -2^{\frac{\nu}{2}+im} \mathcal{D}^{co}(t, \partial_t, \partial_x) \int_0^{\nu(t) - \phi(t_0)} \left( E(r,t; t_0; m) \mathbb{I}_2 \quad E(r,t; t_0; -m) \mathbb{I}_2 \right) \mathcal{E}^w(x-x_0,r) dr,$$

where

$$E(r,t; t_0; m) = 2^{\frac{2im}{1-\ell}} (1-\ell)^{-\frac{im}{1-\ell}} \phi(t_0)^{1-\ell} m^{-\ell} \left( \frac{\phi(t) + \phi(t_0)}{\phi(t_0)^2} \right)^2 - \frac{im}{1-\ell},$$

$$\times F \left( \frac{i}{1-\ell}, \frac{m}{1-\ell}; 1; \frac{r^2}{(\phi(t) + \phi(t_0))^2 - r^2} \right).$$

The fundamental solution to the Cauchy problem is given by the next theorem.

**Theorem 1.2** For every positive $\varepsilon > 0$ and $t > \varepsilon$ the fundamental solution $\mathcal{E}_+(x,t; x_0,t_0; m; \varepsilon)$ to the Cauchy problem, that is, a distribution satisfying

$$\begin{cases}
\mathcal{D}(t, \partial_t, \partial_x) \mathcal{E}_+(x,t; x_0,t_0; m; \varepsilon) = \mathbb{I}_4, \\
\mathcal{E}_+(x,t; x_0,t_0; m; \varepsilon) = \delta(x-x_0)\mathbb{I}_4,
\end{cases}$$

is given as follows

$$\mathcal{E}_+(x,t; x_0,t_0; m; \varepsilon) = -i\varepsilon^{\frac{\nu}{2}-im} \mathcal{D}^{co}(x,t, \partial_t, \partial_x) \gamma^0 \times \int_0^{\phi(t)-\phi(\varepsilon)} \left( K_1 \left( r, \frac{\phi(t) - \phi(\varepsilon)}{\phi(\varepsilon)} ; m; \varepsilon \right) \mathbb{I}_2 \quad K_1 \left( r, \frac{\phi(t) - \phi(\varepsilon)}{\phi(\varepsilon)} ; -m; \varepsilon \right) \mathbb{I}_2 \right) \mathcal{E}^w(x-x_0,r) dr,$$

where

$$K_1 \left( r, \frac{\phi(t) - \phi(\varepsilon)}{\phi(\varepsilon)} ; m; \varepsilon \right) = 2^{\frac{2im}{1-\ell}} \phi(\varepsilon)^{\frac{im}{1-\ell}} \left( \frac{\phi(t) + \phi(\varepsilon)}{\phi(\varepsilon)^2} \right)^{-m} \times F \left( \frac{i}{1-\ell}, \frac{im}{1-\ell}; 1; \frac{\phi(t) + \phi(\varepsilon)^2 - \phi(\varepsilon)^2 r^2}{\phi(t) - \phi(\varepsilon)^2 r^2} \right).$$

$$\text{im}$$
In order to write solution to the Cauchy problem we introduce the operator
\[
\mathcal{G}(x, t, D_x; m)[f](x, t)
\]
\[
:= -2 \int_{\varepsilon}^{t} b^{\frac{t-s}{m}} db \int_{0}^{\phi(t) - \phi(b)} E(r, t; b; m) \int_{\mathbb{R}^3} \mathcal{E}^w(x - y, r) f(y, b) dy dr, \quad f \in C_0^\infty(\mathbb{R}^{n+1}),
\]
and the operator \( K_1(x, t, D_x; m; \varepsilon) \) as follows:
\[
K_1(x, t, D_x; m; \varepsilon)[\varphi](x, t)
\]
\[
:= -i\varepsilon^{\frac{t-s}{m}} \int_{0}^{\phi(t) - \phi(\varepsilon)} K_1 \left( r, \frac{\phi(t) - \phi(\varepsilon)}{\varepsilon}; m \right) \int_{\mathbb{R}^3} \mathcal{E}^w(x - y, r)\varphi(y) dy dr, \quad \varphi \in C_0^\infty(\mathbb{R}^n).
\]

**Theorem 1.3** The solution to the Cauchy problem
\[
\begin{align*}
\mathcal{D}(t, \partial_t, \partial_x) \Psi(x, t) &= F(x, t), \quad t > \varepsilon > 0, \\
\Psi(x, \varepsilon) &= \Psi_\varepsilon(x),
\end{align*}
\]
with \( m \in \mathbb{C} \), is given as follows
\[
\Psi(x, t) = \mathcal{D}^{\infty}(t, \partial_t, \partial_x) \left\{ \begin{array}{c}
\mathcal{G}(x, t, D_x; m)I_2 \\
\mathcal{G}(x, t, D_x; -m)I_2
\end{array} \right\} \left[ F(x, t) \right] + \gamma^0 \left( \begin{array}{c}
K_1(x, t, D_x; m; \varepsilon)I_2 \\
K_1(x, t, D_x; -m; \varepsilon)I_2
\end{array} \right) \left[ \Psi_\varepsilon(x) \right], \quad t > \varepsilon > 0.
\]

For the case of \( \ell = 0 \) see [33].

The derivation of the formulas for the fundamental solutions and for the solution of the Cauchy problem is carried out in three steps. The first step (Section 2) is the finding of a complementary operator that reduces the 4 × 4 system of the first order operators to the system of the diagonal operator-valued matrix with two pairs of the coinciding non-Fuchsian second-order hyperbolic partial differential operators. The second step (Section 4) is a reduction of such second-order hyperbolic partial differential operators to the generalized Euler-Poisson-Darboux equation
\[
\partial_t^2 u - A(x, \partial_x)u + \frac{2im}{t} \partial_t u = f, \quad (10)
\]
where \( m \in \mathbb{C}, t \in \mathbb{R}_+ \) and \( A(x, \partial_x) \) can be a pseudo-differential operator with the symbol \( A(x, \xi) \) defined for \( (x, \xi) \in \Omega \times \mathbb{R}^n \) and \( \Omega \) is a domain in \( \mathbb{R}^n \). The reduction is done by the change to the co-moving coordinates.

The last, the third step (Section 5), is devoted to solving of the Cauchy problem for the generalized Euler-Poisson-Darboux equation (10) (Theorems 5.3-5.5). In the equation (10) higher order derivatives with respect to spatial variables may appear. To solve the last equation the integral transform approach from [30, 31, 32, 35] is employed. In the last two steps it is supposed that \( x \in \mathbb{R}^n \) with an arbitrary dimension \( n \).

## 2 The complementary operator

The non-Fuchsian Type Dirac operator \( \mathcal{D}(t, \partial_t, \partial_x) \) in the FLRW spacetime is defined by
\[
\mathcal{D}(t, \partial_t, \partial_x) := i\gamma^0 \frac{\partial}{\partial t} + it^{-\ell} \gamma^1 \frac{\partial}{\partial x_1} + it^{-\ell} \gamma^2 \frac{\partial}{\partial x_2} + it^{-\ell} \gamma^3 \frac{\partial}{\partial x_3} + i\frac{3}{2} t^{-1} \gamma^0 - mt^{-1} \mathbb{I}_4.
\]
With the aid of the matrices \( \gamma^U \) and \( \gamma^L \) (5) we calculate
\[
t^{\ell} \gamma^U + \gamma^L = \begin{pmatrix} t^\ell \mathbb{I}_2 & \mathbb{I}_2 \\ \mathbb{I}_2 & -\mathbb{I}_2 \end{pmatrix}, \quad (t^{\ell} \gamma^U + \gamma^L)\gamma^0 (t^{\ell} \gamma^U + \gamma^L) = \begin{pmatrix} t^{\ell+\gamma} \mathbb{I}_2 & \mathbb{I}_2 \\ \mathbb{I}_2 & -\mathbb{I}_2 \end{pmatrix},
\]
\[
(t^{\ell} \gamma^U + \gamma^L)\gamma^k (t^{\ell} \gamma^U + \gamma^L) = \begin{pmatrix} \mathbb{I}_2 & t^{\ell} \sigma^k \\ -t^{\ell} \sigma^k & \mathbb{I}_2 \end{pmatrix}, \quad k = 1, 2, 3.
\]
Next we use them to define a family of complementary factors \( \mathcal{D}^{co}(t, \partial_t, \partial_x) \). For the Dirac operator an auxiliary right complementary factors to the diagonal matrix with operator-valued entries form a family of operators, which contains the following operators

\[
\mathcal{D}^{co}(t, \partial_t, \partial_x) := it^b(t^c \gamma U + \gamma L) \frac{\partial}{\partial t}(t^c \gamma U + \gamma L) + it^{-t} t^b(t^c \gamma U + \gamma L) \gamma^1 (t^c \gamma U + \gamma L) \frac{\partial}{\partial x_1} + it^{-t} t^b(t^c \gamma U + \gamma L) \gamma^2 (t^c \gamma U + \gamma L) \frac{\partial}{\partial x_2} + it^{-t} t^b(t^c \gamma U + \gamma L) \gamma^3 (t^c \gamma U + \gamma L) \frac{\partial}{\partial x_3} +
\]

These operators depend on parameters \( b_0, b, c, n, r \in \mathbb{C} \). We need also a matrix

\[
\ell^a \gamma^U + \ell^b \gamma^L = \left( \begin{array}{cc} t^a \mathbb{I}_2 & 0 \\ 0 & t^{-a} \mathbb{I}_2 \end{array} \right).
\]

Then for the parameters \( a, b, c, n \) chosen as follows

\[
a := \frac{\ell}{2} - im, \quad \omega := \frac{\ell}{2} + im, \quad b_0 = - \frac{4im}{3}, \quad b = -im - \frac{\ell}{2}, \quad r = 2im, \quad c = 0, \quad n = m,
\]

since \( \gamma^U + \gamma^L = \mathbb{I}_4 \), we obtain the operator of (6) and the following identity

\[
\mathcal{D}(t, \partial_t, \partial_x) \mathcal{D}^{co}(t, \partial_t, \partial_x) = (-t^{-a} \gamma^U + t^{-\omega} \gamma^L) \left( \begin{array}{cc} -2(t^{-2} - t^{-2} + (t+2im) \frac{\partial}{t} & \mathbb{O}_2 \\ \mathbb{O}_2 & -2(t^{-2} - t^{-2} + (t+2im) \partial) \end{array} \right).
\]

If we denote the second-order scalar hyperbolic operator

\[
P(t, \partial_t, \partial_x; m) := \partial^2 - t^{-2} \Delta + t^{-1} (\ell + 2im) \partial_t,
\]

then we obtain the identity with the diagonal right-hand side

\[
\mathcal{D}(t, \partial_t, \partial_x) \mathcal{D}^{co}(t, \partial_t, \partial_x) = - (t^{-a} \gamma^U + t^{-\omega} \gamma^L) (\gamma^U P(t, \partial_t, \partial_x; m) + \gamma^L P(t, \partial_t, \partial_x; -m))
\]

The complementary operator \( \mathcal{D}^{co}(t, \partial_t, \partial_x) \) is not unique. An advantage of the choice of parameters \( b_0, b, c, n, r \) (11) is that the diagonal entries of (13) are the scalar operators: two operators \( t^{-a} P(t, \partial_t, \partial_x; m) \) and two operators \( t^{-\omega} P(t, \partial_t, \partial_x; -m) \), which differ only by the sign of the mass \( m \) and the factors \( t^{-a} \) and \( t^{-\omega} \).

In order to consider the Dirac equation in curvilinear coordinates as well as to enlarge class of the partial differential equations, we follow the arguments which have been specified in [33, Sec1]. More exactly, consider operator

\[
\mathcal{D}(x, t, \partial_t, \partial_x) := i \gamma^0 \frac{\partial}{\partial t} + it^{-t} \sum_{k=1}^{3} \gamma^b A_k(x, \partial_x) + it^{-t} (t^{-1} \gamma^0 - mt^{-1} \mathbb{I}_4),
\]

where the operators \( A_k(x, \partial_x), k = 1, 2, 3 \), in general, are the scalar pseudo-differential operators \( A_k(x, \partial_x) \) with symbols depending on the spatial variables too. Following [33] we define the generalized Dirac operator as an operator (14) satisfying the condition

\[
(t^{-im} \gamma^U + t^{im} \gamma^L) \gamma^a \gamma^b (t^{-im} \gamma^U + t^{im} \gamma^L) A_k(x, \partial_x) A_b(x, \partial) = -A(x, \partial_x; m) \mathbb{I}_4 \quad \text{for all } t > 0,
\]

where \( A(x, \partial_x; m) \) is the scalar pseudo-differential operator independent of \( t \). For \( m = 0 \) this condition coincides with condition (1.17) [33]. We note that for the pairwise commuting operators this condition is satisfied with \( A(x, \partial_x; m) = - \sum_{k=1,2,3} A^2_k(x, \partial) \). From now on we omit \( m \) in the notation \( A(x, \partial_x; m) \) and write just \( A(x, \partial_x) \).

The complementary operator \( \mathcal{D}^{co}(x, t, \partial_t, \partial_x) \) for operator (14) is given by the following theorem.
Theorem 2.1 Assume that for operator (14) condition (15) is fulfilled. Then the following operator

\[ D^{co}(x, t, \partial_t, \partial_x) := it^{-\frac{\mu}{2}} \gamma^0 (t^{im} \gamma^U + t^{-im} \gamma^L) \frac{\partial}{\partial t} + it^{-\frac{\mu}{2}} \sum_{k=1}^{3} \gamma^k (t^{im} \gamma^U + t^{-im} \gamma^L) A_k(x, \partial) \]

is a complementary operator \( D^{co}(x, t, \partial_t, \partial_x) \) for (14), that is,

\[ D(x, t, \partial_t, \partial_x) D^{co}(x, t, \partial_t, \partial_x) = -t^{-\frac{\mu}{2}} (t^{im} \gamma^U + t^{-im} \gamma^L) \left\{ \|L\|^2 \frac{d^2}{dt^2} - t^{-2\mu} A(x, \partial_\times) \|L\| + t^{-1} (\|L\|^2 + 2im\gamma^0) \frac{\partial}{\partial t} \right\}. \]

**Proof.** Indeed, it is easy to see that

\[ D(x, t, \partial_t, \partial_x) D^{co}(x, t, \partial_t, \partial_x) = I_1 + I_2 + I_3 + I_4, \]

where we have denoted

\[ I_1 = it^{-\frac{\mu}{2}} \gamma^0 (t^{im} \gamma^U + t^{-im} \gamma^L) \frac{\partial}{\partial t} \left\{ t^{-\frac{\mu}{2}} \gamma^0 (t^{im} \gamma^U + t^{-im} \gamma^L) \frac{\partial}{\partial t} + it^{-\frac{\mu}{2}} \sum_{k=1}^{3} \gamma^k (t^{im} \gamma^U + t^{-im} \gamma^L) A_k(x, \partial) \right\}, \]

\[ I_2 = it^{-\frac{\mu}{2}} \gamma^0 (t^{im} \gamma^U + t^{-im} \gamma^L) \frac{\partial}{\partial t} \left\{ it^{-\frac{\mu}{2}} \gamma^0 (t^{im} \gamma^U + t^{-im} \gamma^L) \frac{\partial}{\partial t} + it^{-\frac{\mu}{2}} \sum_{b=1}^{3} \gamma^b (t^{im} \gamma^U + t^{-im} \gamma^L) A_b(x, \partial) \right\}, \]

\[ I_3 = -mt^{-\frac{\mu}{2}} \gamma^0 (t^{im} \gamma^U + t^{-im} \gamma^L) \frac{\partial}{\partial t} - mt^{-\frac{\mu}{2}} \gamma^0 (t^{im} \gamma^U + t^{-im} \gamma^L) \frac{\partial}{\partial t} - mt^{-\frac{\mu}{2}} \gamma^0 (t^{im} \gamma^U + t^{-im} \gamma^L) A_b(x, \partial), \]

\[ I_4 = mt^{-\frac{\mu}{2}} \gamma^0 (t^{im} \gamma^U + t^{-im} \gamma^L) \frac{\partial}{\partial t} - mt^{-\frac{\mu}{2}} \gamma^0 (t^{im} \gamma^U + t^{-im} \gamma^L) A_b(x, \partial). \]

Then it is easy to derive

\[ I_1 = -t^{-\frac{\mu}{2}} (t^{im} \gamma^U + t^{-im} \gamma^L) \frac{\partial^2}{\partial t^2} - t^{-\frac{\mu}{2}} \sum_{b=1}^{3} \gamma^0 \gamma^b (t^{im} \gamma^U + t^{-im} \gamma^L) A_b(x, \partial) \frac{\partial}{\partial t} \]

\[ + t^{-\frac{\mu}{2}} (t^{im} \gamma^U + t^{-im} \gamma^L) \frac{\partial}{\partial t} - mt^{-\frac{\mu}{2}} (t^{im} \gamma^U - t^{-im} \gamma^L) \frac{\partial}{\partial t} \]

\[ + \frac{3\mu}{2} t^{-\frac{\mu}{2} - 1} \sum_{b=1}^{3} \gamma^0 \gamma^b (t^{im} \gamma^U + t^{-im} \gamma^L) A_b(x, \partial), \]

\[ I_2 = -t^{-\frac{\mu}{2}} \sum_{a=1}^{3} \gamma^a \gamma^0 (t^{im} \gamma^U + t^{-im} \gamma^L) \frac{\partial}{\partial t} \]

\[ - t^{-\frac{\mu}{2}} \sum_{a=1}^{3} \gamma^a \gamma^b (t^{im} \gamma^U + t^{-im} \gamma^L) A_b(x, \partial), \]

\[ I_3 = \frac{3}{2} t^{-\frac{\mu}{2} - 1} (t^{im} \gamma^U + t^{-im} \gamma^L) \frac{\partial}{\partial t} - \frac{3}{2} t^{-\frac{\mu}{2} - 1} \sum_{b=1}^{3} \gamma^0 \gamma^b (t^{im} \gamma^U + t^{-im} \gamma^L) A_b(x, \partial), \]

\[ I_4 = -mt^{-\frac{\mu}{2}} \gamma^0 (t^{im} \gamma^U + t^{-im} \gamma^L) \frac{\partial}{\partial t} - mt^{-\frac{\mu}{2}} \gamma^0 (t^{im} \gamma^U + t^{-im} \gamma^L) A_b(x, \partial). \]
After substitution of all these expressions in \( \mathcal{D}(x,t,\partial_x) \mathcal{D}^\gamma(x,t,\partial_x) \) we obtain operator with the coefficients as follows. The coefficient of \( \partial_t^2 / \partial t^2 \) is

\[
-t^{-\frac{\ell}{2}}(t^{im} \gamma U + t^{-im} \gamma L).
\]

The coefficient of the operator \( \partial_t / \partial t \) is

\[
-\frac{\ell}{2} t^{-\frac{\ell}{2} - 1}(t^{im} \gamma U + t^{-im} \gamma L) - \text{imm} t^{-\frac{\ell}{2} - 1}(t^{im} \gamma U - t^{-im} \gamma L) - \frac{3}{2} \ell t^{-\frac{\ell}{2} - 1}(t^{im} \gamma U + t^{-im} \gamma L) - \text{imm} t^{-\frac{\ell}{2} - 1}(t^{im} \gamma U + t^{-im} \gamma L)
\]

\[
= t^{-\frac{\ell}{2} - 1}(t^{im} \gamma U + t^{-im} \gamma L) (-\ell - 2\text{imm}^0).
\]

For the terms with \( \frac{\partial}{\partial t} A_a(x, \partial) \) we obtain

\[
-t^{-\frac{3\ell}{2}} \sum_{b=1}^{3} \gamma^0 \gamma^b(t^{im} \gamma U + t^{-im} \gamma L) A_b(x, \partial) \frac{\partial}{\partial t}
\]

\[
-t^{-\frac{3\ell}{2}} \sum_{a=1}^{3} \gamma^a \gamma^0(t^{im} \gamma U + t^{-im} \gamma L) A_a(x, \partial) \frac{\partial}{\partial t} = 0.
\]

For the terms with \( A_a(x, \partial) \) we obtain

\[
+\frac{3\ell}{2} t^{-\frac{3\ell}{2} - 1} \sum_{b=1}^{3} \gamma^0 \gamma^b(t^{im} \gamma U + t^{-im} \gamma L) A_b(x, \partial) - \text{imm} t^{-\frac{3\ell}{2} - 1} \sum_{b=1}^{3} \gamma^0 \gamma^b(t^{im} \gamma U - t^{-im} \gamma L) A_b(x, \partial)
\]

\[
-\frac{3}{2} \ell t^{-\frac{3\ell}{2} - 1} \sum_{b=1}^{3} \gamma^0 \gamma^b(t^{im} \gamma U + t^{-im} \gamma L) A_b(x, \partial) - \text{imm} t^{-\frac{3\ell}{2} - 1} \sum_{b=1}^{3} \gamma^b(t^{im} \gamma U + t^{-im} \gamma L) A_b(x, \partial)
\]

\[
= 0.
\]

The remaining terms are

\[
-t^{-\frac{3\ell}{2}} \sum_{a=1}^{3} \sum_{b=1}^{3} \gamma^a \gamma^b(t^{im} \gamma U + t^{-im} \gamma L) A_a(x, \partial) A_b(x, \partial)
\]

\[
= - (t^{im} \gamma U + t^{-im} \gamma L) (t^{-im} \gamma U + t^{im} \gamma L) t^{-\frac{3\ell}{2}} \sum_{a=1}^{3} \gamma^a \gamma^b(t^{im} \gamma U + t^{-im} \gamma L) A_a(x, \partial) A_b(x, \partial)
\]

\[
= t^{-\frac{3\ell}{2}} (t^{im} \gamma U + t^{-im} \gamma L) A(x, \partial_x) \mathbb{I}_4.
\]

Theorem is proved. \(\square\)

**Remark 2.2** More general choice of the family of operators was suggested in [33, Sec.1], which in the case of \( a(t) = \alpha_0 t^\ell \) leads to

\[
(t^{-im} \gamma U + t^{im} \gamma L) \gamma^a \gamma^b(t^{im} \gamma U + t^{-im} \gamma L) A_a(x, \partial) A_b(x, \partial)
\]

\[
= -A(x, \partial_x; m) \mathbb{I}_4 + B(x, \partial_x; m) \gamma^0 + C(x, \partial_x; m) \gamma^1 \gamma^2 + D(x, \partial_x; m) \gamma^3 \gamma^0 \gamma^1 \gamma^2 \forall t > 0,
\]

where \( A_k(x, \partial_x), A(x, \partial_x; m), B(x, \partial_x; m), C(x, \partial_x; m), \) and \( D(x, \partial_x; m) \) are scalar pseudo-differential operators. For the purpose of the present paper it suffices to consider the case of (15), that is, \( B(x, \partial_x; m) = C(x, \partial_x; m) = D(x, \partial_x; m) = 0.\)

In order to find a complementary operator for the Dirac operator in the FLRW spacetime in the spherical coordinates, we appeal to the spherical coordinates in \( \mathbb{R}^3 \)

\[
x(r, \theta, \phi) := r \cos(\phi) \sin(\theta), \quad y(r, \theta, \phi) := r \sin(\phi) \sin(\theta), \quad z(r, \theta, \phi) := r \cos(\theta)
\]
and choose a family of operators with the property (15) containing the operators with coefficients

$$A_1(x, \partial) = \cos(\phi) \sin(\theta) \partial_r + \frac{\cos(\phi) \cos(\theta)}{r} \partial_\theta - \frac{\sin(\phi)}{r \sin(\theta)} \partial_\phi,$$

$$A_2(x, \partial) = \sin(\phi) \sin(\theta) \partial_r + \frac{\sin(\phi) \cos(\theta)}{r} \partial_\theta + \frac{\cos(\phi)}{r \sin(\theta)} \partial_\phi,$$

$$A_3(x, \partial) = \cos(\theta) (\partial_\tau + V(r)) - \frac{\sin(\theta)}{r} \partial_\phi,$$

$$A(x, \partial_x) = \partial^2_x + 2 \frac{1}{r} (1 + rV(r)) \partial_r + \frac{1}{r} \left( rV'(r) + 2V(r) + rV^2(r) \right)$$

$$+ \frac{1}{r^2} \left( \partial^2_\theta + \cot(\theta) \partial_\theta + \csc^2(\theta) \partial^2_\phi \right).$$

Here $x = (r, \theta, \phi)$ and $V = V(r)$ is a smooth function defined in $\mathbb{R}_+.$

We can write the Dirac equation (2) as follows

$$\left( i \gamma^0 \partial_0 + \frac{1}{a(t)} \left( \gamma^r \partial_r + \gamma^\phi \partial_\phi + \gamma^\theta \partial_\theta \right) + i \frac{3 \dot{a}(t)}{2a(t)} \gamma^0 - mt^{-1} \mathbb{1}_4 \right) \Psi(x, t) = F(x, t),$$

where in this Cartesian tetrad gauge the gamma matrices will be given by (see, e.g., [24])

$$\gamma^r_c = \gamma^1 \cos(\phi) \sin(\theta) + \gamma^2 \sin(\theta) \sin(\phi) + \gamma^3 \cos(\theta),$$

$$\gamma^\phi_c = -\gamma^1 \sin(\phi) + \frac{\gamma^2 \cos(\phi)}{r \sin(\theta)} = \frac{1}{r \sin(\theta)} \left( -\gamma^1 \sin(\phi) + \gamma^2 \cos(\phi) \right),$$

$$\gamma^\theta_c = \frac{1}{r} \left( \gamma^1 \cos(\theta) \cos(\phi) + \gamma^2 \sin(\phi) \cos(\theta) - \gamma^3 \sin(\theta) \right).$$

We have used the subscript $c$ for Cartesian. We can also write

$$\left( i \gamma^0 \partial_0 + i \frac{1}{a(t)} \left( \tilde{\gamma}^r_c \partial_r + \tilde{\gamma}^\phi_c \frac{1}{r \sin(\theta)} \partial_\phi + \tilde{\gamma}^\theta_c \frac{1}{r} \partial_\theta \right) + i \frac{3 \dot{a}(t)}{2a(t)} \gamma^0 - mt^{-1} \mathbb{1}_4 \right) \Psi(x, t) = F(x, t),$$

where \( \tilde{\gamma}^r_c = \gamma^0 \) and

$$\tilde{\gamma}^r_c = \gamma^r_c \quad \text{and} \quad \tilde{\gamma}^\phi_c = \gamma^\phi_c \quad \text{and} \quad \tilde{\gamma}^\theta_c = \gamma^\theta_c,$$

and with the Lorentzian metric $\eta$ in the Minkowski spacetime we have

$$\{ \gamma^\mu_c, \gamma^\nu_c \} = 2 \eta^{\mu\nu}, \quad \mu, \nu = t, r, \theta, \phi, \quad \eta^{rr} = \eta^{\theta\theta} = \eta^{\phi\phi} = -1, \quad \eta^{\mu\nu} = 0 \quad \text{if} \quad \mu \neq \nu.$$

**Proposition 2.1** In the spherical coordinates the complementary operator for the Dirac operator in the FLRW spacetime is

$$\mathcal{D}^{ca}(x, t, \partial_t, \partial_x)$$

$$:= it^{-\frac{4}{3}} \gamma^0 \left( t^{im} \gamma^U + t^{-im} \gamma^L \right) \partial_t + it^{-\frac{4}{3}} \left( \gamma^r_c \partial_r + \gamma^\phi_c \frac{1}{r \sin(\theta)} \partial_\phi + \gamma^\theta_c \frac{1}{r} \partial_\theta \right) \left( t^{im} \gamma^U + t^{-im} \gamma^L \right),$$

that is,

$$\mathcal{D}(x, t, \partial_t, \partial_x) \mathcal{D}^{ca}(x, t, \partial_t, \partial_x)$$

$$= \left( \gamma^r_0 \frac{\partial}{\partial t} + it^{-t} \left( \gamma^r_c \partial_r + \gamma^\phi_c \frac{1}{r \sin(\theta)} \partial_\phi + \gamma^\theta_c \frac{1}{r} \partial_\theta \right) \right) \left( t^{im} \gamma^U + t^{-im} \gamma^L \right) \left( \gamma^0 - mt^{-1} \mathbb{1}_4 \right)$$

$$\times \left( \gamma^r_0 \frac{\partial}{\partial t} + it^{-t} \left( \gamma^r_c \partial_r + \gamma^\phi_c \frac{1}{r \sin(\theta)} \partial_\phi + \gamma^\theta_c \frac{1}{r} \partial_\theta \right) \right) \left( t^{im} \gamma^U + t^{-im} \gamma^L \right)$$

8
Indeed, if we look for the solution in the form

\[ \Phi(x, \varepsilon) = \Psi(x) \]

order equations, that is, \( \Phi(x, \varepsilon) \) vanishing initial data. For the case of \( \varepsilon > 0 \) then (20) implies

\[ A \]

For \( A(x, \partial_{x}) \) is given by (14), then it suffices to solve the scalar equations given by the operator

\[ P(t, \partial_{t}, \partial_{x}; m) := \partial_{t}^{2} - t^{-2\delta} A(x, \partial_{x}) + t^{-1}(\delta + 2im) \partial_{t} . \]

For \( A(x, \partial_{x}) = \Delta \) the operator \( P(t, \partial_{t}, \partial_{x}; m) \) coincides with the second-order scalar hyperbolic operator (12). Indeed, if we look for the solution in the form

\[ \Psi(x, t) = \mathcal{D}^{(x, t, \partial_{t}, \partial_{x})} \Phi(x, t), \]

then (20) implies

\[ \mathcal{D}^{\varepsilon(x, \partial_{t}, \partial_{x})} \Phi(x, \varepsilon) = \Psi_{\varepsilon}(x), \]

where

\[ F(x, t) = \begin{pmatrix} F_{U}(x, t) \\ F_{L}(x, t) \end{pmatrix}, \quad \Phi(x, t) = \begin{pmatrix} \Phi_{U}(x, t) \\ \Phi_{L}(x, t) \end{pmatrix}. \]

Hence,

\[ P(x, t, \partial_{t}, \partial_{x}; m) \Phi_{U}(x, t) = -t^{\delta} F_{U}(x, t), \quad t \geq \varepsilon > 0, \]

\[ P(x, t, \partial_{t}, \partial_{x}; -m) \Phi_{L}(x, t) = -t^{\delta} F_{L}(x, t), \quad t \geq \varepsilon > 0, \]

\[ \mathcal{D}^{\varepsilon(x, \partial_{t}, \partial_{x})} \Phi(x, \varepsilon) \] is given by Theorem 4.1 with vanishing initial data. For the case of \( F(x, t) = 0 \) we choose the zero for the first initial data for the second order equations, that is, \( \Phi(x, \varepsilon) = 0 \). Then

\[ \mathcal{D}^{\varepsilon(x, t, \partial_{t}, \partial_{x})} \Phi(x, t) \bigg|_{t=\varepsilon} = \begin{pmatrix} -i \varepsilon^{-im} \gamma_{0}^{(\varepsilon 2im \gamma U + \gamma L)} \frac{\partial}{\partial t} \Phi(x, t) \bigg|_{t=\varepsilon} \\ \end{pmatrix} \]

Thus, we have obtained initial conditions for the solutions of the Klein-Gordon equations:

\[ \mathcal{D}^{\varepsilon(x, \partial_{t}, \partial_{x})} \Phi(x, \varepsilon) \bigg|_{t=\varepsilon} = \begin{pmatrix} -i \varepsilon^{-im} \Psi_{\varepsilon U}(x, \varepsilon) \\ i \varepsilon^{+im} \Psi_{\varepsilon L}(x, \varepsilon) \end{pmatrix}. \]
The solution to the last problem is given by Theorem 4.1. Let \( A(x, \partial_x) = \sum_{|\alpha| \leq d} a_\alpha(x) \partial^{\alpha} \) be a differential operator with the smooth coefficients \( a_\alpha(x) \). According to Theorem 4.1 if the function \( v = v_f(x, r; b) \) solves the problem

\[
\begin{align*}
&\left\{ u_r(x, r; b) - A(x, \partial_x) u(x, r; b) = 0, \\
&v(x, 0; b) = f(x, b), \quad v_r(x, 0; b) = 0,
\end{align*}
\]

while the function \( v = v_\varphi(x, r) \) solves the problem

\[
\begin{align*}
&\left\{ u_r(x, r) - A(x, \partial_x) v(x, r) = 0, \\
&v(x, 0) = \varphi(x), \quad v(x, 0) = 0,
\end{align*}
\]

then the function \( u = u(x, t) \) defined by

\[
u(x, t) = 2 \int_{\varepsilon}^{t} db \int_{0}^{|\phi(t) - \phi(b)|} E(r, t; b; m)v_f(x, r; b) dr + \int_{0}^{|\phi(t) - \phi(b)|} K_1 \left( r, \frac{\phi(t) - \phi(b)}{\phi(b)}; m \right) v_\varphi(x, r) dr,
\]

where the kernels \( E(r, t; b; m) \) and \( K_1 \left( r, \frac{\phi(t) - \phi(b)}{\phi(b)}; m \right) \) are defined by (8) and (9), respectively, is a solution to the Cauchy problem

\[
\begin{align*}
&\{ u_{tt} - t^{-2t} A(x, \partial_x) u + t^{-1}(t + 2im)u_t = f(x, t), \\
&u(x, \varepsilon) = 0, \quad u_t(x, \varepsilon) = \varphi_1(x).
\end{align*}
\]

Here and henceforth in the notations \( v = v_f(x, r; b) \) and \( v = v_\varphi(x, r) \) the subindexes \( f \) and \( \varphi \) do not denote a partial derivative.

Thus, for the 2-spinor solution \( \Phi_U = \Phi_U(x, t) \) of the problem

\[
\begin{align*}
&\{ P(x, t, \partial_t, \partial_x; m)\Phi_U(x, t) = -t^a F_U(x, t), \quad t \geq \varepsilon > 0, \\
&\Phi_U(x, \varepsilon) = 0, \quad (\partial_t \Phi_U)(x, \varepsilon) = -i\varepsilon^{-im} \Psi_\varepsilon U(x),
\end{align*}
\]

we obtain

\[
\Phi_U(x, t) = -2 \int_{\varepsilon}^{t} db \int_{0}^{|\phi(t) - \phi(b)|} E(r, t; b; m) \int_{\mathbb{R}^3} \mathcal{E}^w(x - y, r) F_U(y, b) dy dr + i\varepsilon^{-im} \int_{0}^{|\phi(t) - \phi(b)|} K_1 \left( r, \frac{\phi(t) - \phi(b)}{\phi(b)}; m \right) \int_{\mathbb{R}^3} \mathcal{E}^w(x - y, r) \Psi_\varepsilon U(y) dy dr, \quad t > \varepsilon > 0.
\]

Similarly, for the 2-spinor function \( \Phi_L = \Phi_L(x, t) \) we obtain

\[
\Phi_L(x, t) = -2 \int_{\varepsilon}^{t} db \int_{0}^{|\phi(t) - \phi(b)|} E(r, t; b; -m) \int_{\mathbb{R}^3} \mathcal{E}^w(x - y, r) F_L(y, b) dy dr + i\varepsilon^{-im} \int_{0}^{|\phi(t) - \phi(b)|} K_1 \left( r, \frac{\phi(t) - \phi(b)}{\phi(b)}; -m \right) \int_{\mathbb{R}^3} \mathcal{E}^w(x - y, r) \Psi_\varepsilon L(y) dy dr, \quad t > \varepsilon > 0.
\]

Hence, according to (21), the solution to the Cauchy problem

\[
\begin{align*}
&\{ \mathcal{D}(x, t, \partial_t, \partial_x) \Psi(x, t) = F(x, t), \quad t \geq \varepsilon > 0, \\
&\Psi(x, \varepsilon) = \Psi_\varepsilon(x),
\end{align*}
\]

for \( t > \varepsilon > 0 \) is given as follows

\[
\Psi(x, t) = \left\{ it^{-2} \eta^0 (t^{im_a} U + t^{im_a} L) \frac{\partial}{\partial t} + it^{-2} \sum_{i=1}^{3} \gamma^i (t^{im_a} U + t^{im_a} L) \frac{\partial}{\partial x_i} \right\}
\]
Thus, we have proved main Theorem 1.3.

In terms of (7), the retarded fundamental solution (propagator) $\mathcal{E}_+(x; t; x_0, t_0; m) = \mathcal{E}_+(x-x_0, t; 0; t_0; m)$ with support in the forward cone $D_+(x_0, t_0)$, $x_0 \in \mathbb{R}^n$, $t_0 \in \mathbb{R}_+$, $\text{supp} \mathcal{E}_+ \subseteq D_+(x_0, t_0)$, is given by

$$\mathcal{E}_+(x, t; x_0, t_0; m) = \mathcal{G}(x, t, D_x; m) \left( \begin{array}{c} \mathcal{G}(x,t,D_x;m) \varepsilon_2 \\ \mathcal{G}(x,t,D_x;-m) \varepsilon_2 \end{array} \right) \left[ \begin{array}{c} \mathcal{G}(x,t,D_x; m) \varepsilon_2 \\ \mathcal{G}(x,t,D_x; -m) \varepsilon_2 \end{array} \right] [\mathcal{E}_+](x,t), \quad t > \varepsilon > 0.$$
In this and remaining sections we assume that

\[ 4.1 \text{ Change to the proper time} \]

We set \( 0 < \varepsilon < t_0 \) in the definition of the operator \( \mathcal{G}(x, t, D_x; m) \). Hence, for the upper 2-spinor we have

\[ \mathcal{G}(x, t, D_x; m)[\delta_{x_0} \delta_{t_0}](x, t) = -2t_0^{\ell + im} \int_0^{\phi(t) - \phi(t_0)} E(r, t; t_0; m) \bar{E}(r, t; t_0; -m) \mathcal{E}^u(x - x_0, r) dr. \]

Similarly, for the lower 2-spinor we obtain

\[ \mathcal{G}(x, t, D_x; -m)[\delta_{x_0} \delta_{t_0}](x, t) = -2t_0^{\ell + im} \int_0^{\phi(t) - \phi(t_0)} E(r, t; t_0; -m) \mathcal{E}^u(x - x_0, r) dr, \quad t > \varepsilon > 0. \]

Thus, we have proved Theorem 1.1.

4 Solution to non-Fuchsian type hyperbolic partial differential equations

4.1 Change to the proper time

In this and remaining sections we assume that \( x \in \mathbb{R}^n \) with \( n \geq 1 \). Hence, we have to solve non-Fuchsian type hyperbolic partial differential equation

\[ u_{tt} - t^{-2\ell} \Delta u + t^{-1}(\ell + 2im)u_t = f, \quad (22) \]

where \( \Delta \) is Laplacian in \( \mathbb{R}^n \). After change to comoving frame with the inverse function \( \phi^{-1}(\varepsilon) \) if \( \ell \neq 1 \),

\[ \phi(t) = \frac{1}{1 - \ell t^{1 - \ell}}, \quad \phi^{-1}(\varepsilon) = |1 - \ell|^{\frac{1}{1 - \ell}} \varepsilon^{\frac{1}{1 - \ell}}, \quad \ell \neq 1. \]

We consider the case of \( \ell < 1 \) since the corresponding modifications for the case of \( \ell > 1 \) are evident. If we want to solve problem with the initial data prescribed on \( t = \varepsilon \), we introduce a new variable \( s \), make change

\[ s = \frac{\phi(t)}{\phi(\varepsilon)} = \left( \frac{t}{\varepsilon} \right)^{1 - \ell}, \quad t = (1 - \ell)^{-\frac{1}{1 - \ell}} \varepsilon \phi^{-1}(s) = \varepsilon s^{\frac{1}{1 - \ell}}, \]

and obtain for the derivatives following:

\[ \frac{d}{dt} = \frac{\phi'(t)}{\phi(\varepsilon)} \frac{d}{ds}, \quad \frac{d'}{dt} = \frac{\phi'(t)}{\phi(\varepsilon)} \frac{d'}{ds} = \frac{(1 - \ell)^{-\frac{1}{1 - \ell}}}{\phi(\varepsilon)} \left( \phi(t) \right)^{-\frac{1}{1 - \ell}}, \]

\[ \frac{d^2}{dt^2} = \left( \frac{\phi'(t)}{\phi(\varepsilon)} \right)^2 \frac{d^2}{ds^2} + \left( \frac{\phi''(t)}{\phi(\varepsilon)} \right) \frac{d}{ds} = \frac{1}{\phi^2(\varepsilon)} t^{-2\ell} \frac{d^2}{ds^2} - \frac{\ell}{\phi(\varepsilon)} t^{-\ell - 1} \frac{d}{ds}. \]

The time \( t = \varepsilon \) corresponds to \( s = 1 \). Then the equation (22) for the function \( u = u(x, s) \) reads

\[ \frac{d^2}{ds^2} u(x, s) - \phi^2(\varepsilon) \Delta u(x, s) + \frac{2im}{(1 - \ell)s} \frac{d}{ds} u(x, s) = \varepsilon^{2\ell} \phi^2(\varepsilon) \frac{d}{ds} f(x, \varepsilon s^{1/(1 - \ell)}). \]

Thus, we arrive at the generalized Fuchsian type partial differential equations (or generalized Euler-Poisson-Darboux equation)

\[ \tilde{u}_{\tau \tau}(x, \tau) - A(x, \partial_x) \tilde{u}(x, \tau) + \frac{2im}{(1 - \ell) \tau + 1} \tilde{u}(x, \tau) = \tilde{f}(x, \tau) \quad (23) \]

\[ 12 \]
that will be discussed in the next sections. Here \( s = \tau + 1 \), and for the case of (22) we have \( A(x, \partial_x) = \Delta \), while in general,

\[
\begin{align*}
\tilde{A}(x, \partial_x) &= \phi^2(\varepsilon)A(x, \partial_x), \\
\tilde{f}(x, \tau) &= \left( \frac{\phi(\varepsilon)}{\phi(t)} \right)^2 f(x, \varepsilon(\tau + 1)^{1/(1-\ell)}), \\
\tilde{f}(x, \tau) &= (1 - \ell)^{-i\imath} \phi^{2\imath}(\varepsilon) (\tau + 1)^{2\imath} f(x, \varepsilon(\tau + 1)^{1/(1-\ell)}), \\
t &= \varepsilon(\tau + 1)^{1/(1-\ell)}, \quad \tau = \frac{\phi(t) - \phi(\varepsilon)}{\phi(\varepsilon)} ,
\end{align*}
\]

where \( A(x, \partial_x) \) is a pseudo-differential operator of order \( d \). For the Dirac operator written in the Cartesian coordinates \( A(x, \partial_x) = \Delta \). On the other hand, the Dirac operator written in other orthogonal coordinate systems is rather complicated partial differential operator with the variable coefficients depending not only on time variable (16) (see, also, [24, 33]). Having this in mind, in what follows, we discuss more general case (24) of the operator \( A(x, \partial_x) \) that can be an operator of order \( d \) higher than two.

### 4.2 Solution in the original time

To write a solution to the Cauchy problem for the operator \( P(t, \partial_t, \partial_t; m) \) we need one more kernel function that is defined as follows

\[
K_0(r, \tau; m) := -2^{i\imath} \frac{m}{1 - \ell} \left( (\tau + 2)^2 - r^2 \right)^{-i\imath} \times \left( 2i (r^2 - \tau(\tau + 1)) F \left( i \frac{m}{1 - \ell}, i \frac{m}{1 - \ell}; 1; \frac{\tau^2 - r^2}{(\tau + 2)^2 - r^2} \right) - 4i(\tau + 1) \frac{(\tau + 2 - r^2)}{(\tau - r^2)((\tau + 2)^2 - r^2)} \right)
\]

and, consequently,

\[
K_0 \left( r, \frac{\phi(t) - \phi(\varepsilon)}{\phi(\varepsilon)} ; m \right) = -2^{i\imath} \frac{m}{1 - \ell} \phi^{i\imath}(\varepsilon) \left( (\phi(t) + \phi(\varepsilon))^2 - \phi^2(\varepsilon) r^2 \right)^{-i\imath} \times \left\{ 2i \frac{(\phi^2(\varepsilon) r^2 - (\phi^2(t) - \phi^2(\varepsilon)))}{\phi^2(\varepsilon) r^2 - (\phi(t) - \phi(\varepsilon))^2} F \left( i \frac{m}{1 - \ell}, i \frac{m}{1 - \ell}; 1; (\phi(t) - \phi(\varepsilon))^2 - \phi^2(\varepsilon) r^2 \right) - \frac{4i(\phi(t) (\phi^2(\varepsilon) - \phi(t) - \phi(\varepsilon))^2)}{(\phi(t) - \phi(\varepsilon))^2 - \phi^2(\varepsilon) r^2} \right\}. 
\]

In the following text we have to specify smoothness property of the given functions and solutions. Since the following results cover a wide class of pseudo-differential operators \( A(x, \partial_x) \) and even abstract linear operators, we will not specify Sobolev spaces or distributions, and just assume that these functions possess continuous partial derivatives in time variable up to second order.

**Theorem 4.1** Assume that the function \( v = v_f(x, r; b) \in C_{x, r, b}^{d, 2.0} \) solves the problem

\[
\begin{align*}
v_{rr}(x, r; b) - A(x, \partial_x) v(x, r; b) &= 0 , \\
v(x, 0; b) &= f(x, b), \quad v_r(x, 0; b) = 0 ,
\end{align*}
\]
while the function \( v = v_\varphi(x, r) \in C_{x, r}^{d, 2} \) solves the problem
\[
\begin{aligned}
&v_{rr}(x, r) - A(x, \partial_x)v(x, r) = 0, \\
v(x, 0) = \varphi(x), &\quad v_r(x, 0) = 0.
\end{aligned}
\]

Then the function \( u = u(x, t) \) defined by
\[
\begin{aligned}
u(x, t) &= 2 \int_{-\tau}^{t} db \int_{0}^{\phi(t) - \phi(b)} E(r, t; b; m) v_f (x, r; b) \, dr + \int_{0}^{\phi(t) - \phi(b)} K_1 \left( r, \frac{\phi(t) - \phi(\varepsilon)}{\phi(\varepsilon)}; m \right) v_{\varphi_1}(r, t) \, dr \\
&+ \left( \frac{\phi(t)}{\phi(\varepsilon)} \right) ^{-im} v_{\varphi_0}(x, \frac{\phi(t) - \phi(\varepsilon)}{\phi(\varepsilon)}) + \int_{0}^{\phi(t) - \phi(b)} \left[ K_0 \left( r, \frac{\phi(t) - \phi(\varepsilon)}{\phi(\varepsilon)}; m \right) + 2im K_1 \left( r, \frac{\phi(t) - \phi(\varepsilon)}{\phi(\varepsilon)}; m; \varepsilon \right) \right] v_{\varphi_0}(r, t) \, dr,
\end{aligned}
\]
where the kernels \( E(r, t; b; m), K_1 \left( r, \frac{\phi(t) - \phi(\varepsilon)}{\phi(\varepsilon)}; m; \varepsilon \right) \) and \( K_0 \left( r, \frac{\phi(t) - \phi(\varepsilon)}{\phi(\varepsilon)}; m; \varepsilon \right) \) are defined by (8), (9), and (28), respectively, is a solution to the Cauchy problem
\[
\begin{aligned}
u_{tt} - t^{-2\ell} A(x, \partial_x)u + t^{-1}(\ell + 2im)u_t = f(x, t), &\quad t > \varepsilon, \\
u(x, \varepsilon) = \varphi_0(x), &\quad u_t(x, \varepsilon) = \varphi_1(x).
\end{aligned}
\]

In order to prove this theorem we consider separately three cases, which correspond to three functions \( f(x, t), \varphi_1(x) \), and \( \varphi_0(x) \).

### 4.3 Proof of Theorem 4.1 with \( f \). Case of \( \varphi_0 = \varphi_1 = 0 \)

We set
\[
\bar{m} = \frac{m}{1 - \ell},
\]
then the equation (23) reads
\[
\frac{d^2}{dt^2} \bar{u} - \bar{A}(x, \partial_x)\bar{u} + \frac{2i\bar{m}}{1 + 1/\bar{r}} \frac{d}{dr} \bar{u} = \bar{f}.
\]

According to Theorem 5.3 the function
\[
\bar{u}(x, \tau) = \int_{0}^{\tau} db \int_{0}^{\bar{b}} E(r, \tau; b; \bar{m}) \bar{v}_f (x, r; b) \, dr,
\]
where
\[
\bar{E}(r, \tau; b; \bar{m}) = 2^{2i\bar{m}} (1 + b) 2^{i\bar{m}} \left( (\tau + b + 2)^2 - r^2 \right) ^{-i\bar{m}} F \left( i\bar{m}, i\bar{m}; 1; \frac{(\tau - b)^2 - r^2}{(\tau + b + 2)^2 - r^2} \right)
\]
and the function \( \bar{v} = \bar{v}_f (x, r; b) \in C_{x, r, b}^{d, 2, 0} \) is defined by
\[
\begin{aligned}
&\bar{v}_{rr}(x, r; b) - \bar{A}(x, \partial_x)\bar{v}(x, r; b) = 0, \\
&\bar{v}(x, 0; b) = \bar{f}(x, b), \quad \bar{v}_r(x, 0; b) = 0
\end{aligned}
\]
solves the Cauchy problem
\[
\begin{aligned}
&\bar{u}_{rr}(x, \tau) - \bar{A}(x, \partial_x)\bar{u}(x, \tau) + \frac{2i\bar{m}}{1 + 1/\bar{r}} \bar{u}_r(x, \tau) = \bar{f}(x, \tau), \\
&\bar{u}(x, 0) = 0, \quad \bar{u}_r(x, 0) = 0.
\end{aligned}
\]
Lemma 4.2 Assume that the function $z = z_f(x, r; b) \in C^{d,2,0}_{x,r,b}$ is solution to
\[
\begin{array}{l}
\{ 
z_{rr}(x, r; b) - A(x, \partial_x)z(x, r; b) = 0, \\
z(x, 0; b) = f(x, b), 
\end{array}
\]
then
\[
\bar{v}_f(x, r; b) = (1 - \ell)^{\frac{2\ell}{\tau}} \phi^\tau \phi(\tau + 1)^{\frac{2\ell}{\tau}} z_f \left( x, \phi(\tau) r, \phi(b + 1)^{1/(1-\ell)} \right)
\]
is solution to
\[
\begin{array}{l}
\{ 
\bar{v}_{rr}(x, r; b) - \bar{A}(x, \partial_x)\bar{v}(x, r; b) = 0, \\
\bar{v}(x, 0; b) = \bar{f}(x, b), 
\end{array}
\]
where $\bar{A}(x, \partial_x) = \phi^2(\varepsilon)A(x, \partial_x)$ and
\[
\bar{f}(x, \tau) = (1 - \ell)^{\frac{2\ell}{\tau}} \phi^\tau \phi(\tau + 1)^{\frac{2\ell}{\tau}} f(x, \varepsilon(\tau + 1)^{1/(1-\ell)}).
\]

Proof. Since
\[
\bar{f}(x, \tau) = \left( \frac{\phi(\varepsilon)}{\phi'(\varepsilon)} \right)^2 f(x, \varepsilon(\tau + 1)^{1/(1-\ell)}) = (1 - \ell)^{\frac{2\ell}{\tau}} \phi^\tau \phi(\tau + 1)^{\frac{2\ell}{\tau}} f(x, \varepsilon(\tau + 1)^{1/(1-\ell)})
\]
we obtain
\[
\bar{v}_f(x, r; b) = (1 - \ell)^{\frac{2\ell}{\tau}} \phi^\tau \phi(\tau + 1)^{\frac{2\ell}{\tau}} v_f(x, r; b),
\]
where the function $v = v_f(x, r; b)$ is defined by
\[
\begin{array}{l}
v_{rr}(x, r; b) - \bar{A}(x, \partial_x)v(x, r; b) = 0, \\
v(x, 0; b) = f(x, \varepsilon(b + 1)^{1/(1-\ell)}), \\
v_r(x, 0; b) = 0.
\end{array}
\]
Assume that the function $w = w(x, r; b) \in C^{d,2,0}_{x,r,b}$ solves
\[
\begin{array}{l}
w_{rr}(x, r; b) - \bar{A}(x, \partial_x)w(x, r; b) = 0, \\
w(x, 0; b) = f(x, b), \\
w_r(x, 0; b) = 0,
\end{array}
\]
then
\[
w(x, r; b) = z(x, \phi(\varepsilon)r; b).
\]
Lemma is proved. \(\square\)

Consider with $\tau = s - 1 = \frac{\phi(t)}{\phi(\varepsilon)} - 1 = \frac{\phi(t) - \phi(\varepsilon)}{\phi(\varepsilon)}$ the function
\[
u(x, t) = \int_0^r db \int_0^{\tau-b} \tilde{E}(r, r; b; \tilde{m})\bar{v}_f(x, r; b) dr
\]
\[
= \int_0^{\frac{\phi(t) - \phi(\varepsilon)}{\phi(\varepsilon)}} db \int_0^{\frac{\phi(t) - \phi(\varepsilon)}{\phi(\varepsilon)}} \tilde{E} \left( r, \frac{\phi(t) - \phi(\varepsilon)}{\phi(\varepsilon)}; b; \tilde{m} \right)
\]
\[
\times (1 - \ell)^{\frac{2\ell}{\tau}} \phi^\tau(\varepsilon) (b + 1)^{\frac{2\ell}{\tau}} z_f \left( x, \phi(\varepsilon)r; \varepsilon(b + 1)^{1/(1-\ell)} \right) dr.
\]
Using the substitution $y = \phi(\varepsilon)r$, we obtain
\[
u(x, t) = \frac{1}{\phi(\varepsilon)} \int_0^{\frac{\phi(t)}{\phi(\varepsilon)}} db \int_0^{\frac{\phi(t) - (b+1)\phi(\varepsilon)}{\phi(\varepsilon)}} \tilde{E} \left( \frac{y}{\phi(\varepsilon)} \phi(t) - \phi(\varepsilon); b; \tilde{m} \right)
\]
\[
\times (1 - \ell)^{\frac{2\ell}{\tau}} \phi^\tau(\varepsilon) (b + 1)^{\frac{2\ell}{\tau}} z_f \left( x, y; \varepsilon(b + 1)^{1/(1-\ell)} \right) dy.
\]
Introducing \( \eta = \varepsilon (b + 1)^{1/(1-\ell)} \) and using the following relations

\[
\begin{align*}
    b + 1 &= \frac{\phi(\eta)}{\phi(\varepsilon)}, \quad b = \frac{\phi(\eta) - \phi(\varepsilon)}{\phi(\varepsilon)}, \quad db = \frac{\phi'(\eta)}{\phi(\varepsilon)} d\eta, \\
    b = 0 \rightarrow \eta = \varepsilon, \quad b = \frac{\phi(t) - \phi(\varepsilon)}{\phi(\varepsilon)} \rightarrow \eta = t,
\end{align*}
\]
we obtain

\[
\begin{align*}
u(x, t) &= (\phi(\varepsilon))^{-1} (1 - \ell)^{2/\ell} \phi \left( \frac{t}{\varepsilon} \right) \int_{\varepsilon}^{t} d\eta \int_{0}^{\phi(t) - \phi(\eta)} \frac{\phi'(\eta)}{\phi(\varepsilon)} \left( \frac{\phi(\eta)}{\phi(\varepsilon)} \right)^{2/(1-\ell)} \\
    &\times \bar{E} \left( \frac{y}{\phi(\varepsilon)}; \frac{\phi(t) - \phi(\varepsilon)}{\phi(\varepsilon)}; \frac{\phi(\eta) - \phi(\varepsilon)}{\phi(\varepsilon)}; m \right) z_f (x, y; \eta) \ dy.
\end{align*}
\]
Now we use

\[
\phi(\eta) = \frac{1}{1 - \ell} \eta^{1-\ell}, \quad \phi'(\eta) = \eta^{-\ell}, \quad \eta = [(1 - \ell) \phi(\eta)]^{1-\ell}, \quad \phi'(\eta) = (1 - \ell) \frac{1}{1-\ell} \phi(\eta)^{1-\ell},
\]
and derive

\[
u(x, t) = (\phi(\varepsilon))^{-2} (1 - \ell)^{2/\ell} \phi \left( \frac{t}{\varepsilon} \right) \int_{\varepsilon}^{t} d\eta \int_{0}^{\phi(t) - \phi(\eta)} \frac{\phi(\eta)}{\phi(\varepsilon)} \left( \frac{\phi(\eta)}{\phi(\varepsilon)} \right)^{2/(1-\ell)} \\
    \times \bar{E} \left( \frac{y}{\phi(\varepsilon)}; \frac{\phi(t) - \phi(\varepsilon)}{\phi(\varepsilon)}; \frac{\phi(\eta) - \phi(\varepsilon)}{\phi(\varepsilon)}; m \right) z_f (x, y; \eta) \ dy \\
    = (1 - \ell) \frac{1}{1-\ell} \int_{\varepsilon}^{t} \phi(\eta) \frac{1}{\phi(\varepsilon)} d\eta \int_{0}^{\phi(t) - \phi(\eta)} \frac{\phi(\eta)}{\phi(\varepsilon)} \left( \frac{\phi(\eta)}{\phi(\varepsilon)} \right)^{2/(1-\ell)} \\
    \times \bar{E} \left( \frac{y}{\phi(\varepsilon)}; \frac{\phi(t) - \phi(\varepsilon)}{\phi(\varepsilon)}; \frac{\phi(\eta) - \phi(\varepsilon)}{\phi(\varepsilon)}; m \right) z_f (x, y; \eta) \ dy.
\]
On the other hand, since

\[
\bar{E}(r, \tau; b; m) = 2^{2i\bar{m}} (1 + b) 2^{i\bar{m}} \left( (\tau + b + 2)^2 - r^2 \right)^{-i\bar{m}} F \left( i\bar{m}, i\bar{m}; 1; \frac{(\tau - b)^2 - r^2}{(\tau + b + 2)^2 - r^2} \right),
\]
we obtain

\[
\begin{align*}
\bar{E} \left( \frac{y}{\phi(\varepsilon)}; \frac{\phi(t) - \phi(\varepsilon)}{\phi(\varepsilon)}; \frac{\phi(\eta) - \phi(\varepsilon)}{\phi(\varepsilon)}; m \right) \\
= 2^{2i\bar{m}} (\phi(\eta))^{2i\bar{m}} \left( (\phi(t) + \phi(\eta))^2 - y^2 \right)^{-i\bar{m}} F \left( i\bar{m}, i\bar{m}; 1; \frac{(\phi(t) - \phi(\eta))^2 - y^2}{(\phi(t) + \phi(\eta))^2 - y^2} \right)
\end{align*}
\]
and

\[
\begin{align*}
u(x, t) &= 2^{2i\bar{m}} (1 - \ell)^{\frac{1}{1-\ell}} \int_{\varepsilon}^{t} \phi(\eta) \frac{1}{\phi(\varepsilon)} d\eta \int_{0}^{\phi(t) - \phi(\eta)} \left( (\phi(t) + \phi(\eta))^2 - y^2 \right)^{-i\bar{m}} \\
    &\times F \left( i\bar{m}, i\bar{m}; 1; \frac{(\phi(t) - \phi(\eta))^2 - y^2}{(\phi(t) + \phi(\eta))^2 - y^2} \right) z_f (x, y; \eta) \ dy.
\end{align*}
\]
Hence, if we define

\[
\begin{align*}
E(y, t; \eta; m) &= 2^{2i\bar{m}} (1 - \ell)^{\frac{1}{1-\ell}} \phi(\eta) \frac{1}{\phi(\varepsilon)} \left( (\phi(t) + \phi(\eta))^2 - y^2 \right)^{-i\bar{m}} \\
    &\times F \left( i\bar{m}, i\bar{m}; 1; \frac{(\phi(t) - \phi(\eta))^2 - y^2}{(\phi(t) + \phi(\eta))^2 - y^2} \right),
\end{align*}
\]

16
Thus, we have proved the case of

\[ u(x, t) = 2\int_{\epsilon}^{t} d\eta \int_{0}^{\phi(t) - \phi(\eta)} E(y, t; \eta; m) z_f(x, y; \eta) \, dy, \]

solves equation (22) in accordance to the integral transform approach of [30, 31]. Thus, we have proved the case of \( \varphi_0 = \varphi_1 = 0 \) of Theorem 4.1.

### 4.4 Proof of Theorem 4.1 with \( \varphi_1 \). Case of \( f = 0 \), \( \varphi_0 = 0 \)

According to Theorem 5.3, the function

\[ \bar{u}(x, \tau) = \int_{0}^{\tau} K_1(r, \tau; m) v_{\varphi_1}(x, r) \, dr \]

solves the Cauchy problem

\[ \begin{cases} \bar{u}_{\tau}(x, \tau) - \bar{A}(x, \partial_x) \bar{u}(x, \tau) + \frac{2im}{\tau + 1} \bar{u}(x, \tau) = 0, \\
\bar{u}(x, 0) = 0, \quad \bar{u}_r(x, 0) = \varphi_1(x). \end{cases} \]

Consider the function

\[ u(x, t) = \int_{0}^{\tau} K_1(r, \tau; m) v_{\varphi_1}(x, r) \, dr \]

\[ = \phi(\varepsilon) \int_{0}^{\phi(t) - \phi(\varepsilon)} K_1 \left( \phi(\varepsilon) y, \phi(t) - \phi(\varepsilon); m \right) v_{\varphi_1}(x, \phi(\varepsilon) y) \, dy \]

\[ = 2^{2im} \phi(\varepsilon) \int_{0}^{\phi(t) - \phi(\varepsilon)} \left( \frac{\phi(t) - \phi(\varepsilon)}{\phi(\varepsilon)} + 2 \right)^{2 - (\phi(\varepsilon) y)^2} v_{\varphi_1}(x, \phi(\varepsilon) y) \, dy, \quad t \geq \varepsilon > 0 \]

with \( \tau = s - 1 = \frac{\phi(t)}{\phi(\varepsilon)} - 1 = \frac{\phi(t) - \phi(\varepsilon)}{\phi(\varepsilon)} \). Finally

\[ u(x, t) = 2^{2im} \phi^{1 + im} \int_{0}^{\phi(t) - \phi(\varepsilon)} \left( \frac{\phi(t) + \phi(\varepsilon)}{\phi(\varepsilon)} + 2 \right)^{2 - (\phi(\varepsilon) y)^2} v_{\varphi_1}(x, \phi(\varepsilon) y) \, dy, \quad t \geq \varepsilon > 0. \]

Thus, we have proved the case of \( \varphi_0(x) = 0 \) and \( f(x, t) = 0 \) of Theorem 4.1.

### 4.5 Proof of Theorem 4.1 with \( \varphi_0 \). Case of \( f = 0 \), \( \varphi_1 = 0 \)

According to Theorem 5.3, if the function \( v = v_{\varphi_0}(x, r) \in C_{x, r}^{2,2} \) solves the Cauchy problem

\[ \begin{cases} v_{rr}(x, r) - A(x, \partial_x) v(x, r) = 0, \\
v(x, 0) = \varphi_0(x), \quad \partial_r v(x, 0) = 0, \end{cases} \]

then the function

\[ \bar{u}(x, \tau) = (1 + \tau)^{-3im} v_{\varphi_0}(x, \tau) + \int_{0}^{\tau} \left[ K_0(r, \tau; m) + 2im K_1(r, \tau; m) \right] v_{\varphi_0}(x, r) \, dr \]
Here $\Omega$ is a domain in $\mathbb{R}$ in the following generalized Euler-Poisson-Darboux equation
\begin{equation}
\bar{u}_{rr}(x, \tau) - \bar{A}(x, \partial_x)\bar{u}(x, \tau) + \frac{2im}{\tau + 1}\bar{u}_r(x, \tau) = 0,
\end{equation}
with $\Omega^m$.

Set $\tau = s - 1 = \frac{\phi(t)}{\phi(t)} - 1 = \frac{\phi(t) - \phi(t)}{\phi(t)}$, then the function
\begin{equation}
\begin{aligned}
u(x, t) &= (1 + \tau)^{-im}v_{\varphi_0}(x, \tau) + \int_0^\tau \left[ K_0(r, \tau; m) + 2imK_1(r, \tau; m) \right]v_{\varphi_0}(x, r) \ dr \\
&= \left( \frac{\phi(t)}{\phi(\tau)} \right)^{-im}v_{\varphi_0}(x, \tau) + \frac{\phi(t) - \phi(\tau)}{\phi(\tau)} - \int_0^{\frac{\phi(t) - \phi(\tau)}{\phi(\tau)}} \left[ K_0 \left( r, \frac{\phi(t) - \phi(\tau)}{\phi(\tau)} ; m \right) + 2imK_1 \left( r, \frac{\phi(t) - \phi(\tau)}{\phi(\tau)} ; m \right) \right]v_{\varphi_0}(x, r) \ dr.
\end{aligned}
\end{equation}

solves the problem
\begin{equation}
\begin{cases}
u_{tt} - t^{-2\ell}A(x, \partial_x)\nu + t^{-1}(t + 2im)\nu_t = 0, \\
u(x, \tau) = \varphi_0(x), \quad \nu_t(x, \tau) = 0.
\end{cases}
\end{equation}

Thus, we have proved the case of $\varphi_1(x) = 0$ and $f(x, t) = 0$ of Theorem 4.1.

5 Integral transform approach to generalized Euler-Poisson-Darboux equation

After change to $s = \tau + 1$ with $\phi(t) = \frac{1}{1 + \tau}t^\ell - t^\ell, \ m = \frac{m}{\ell}e, \ m \in \mathbb{C}$, and (24),(25),(26),(27) we arrive at the equation
\begin{equation}
\partial_t^2\bar{u} - \bar{A}(x, \partial_x)\bar{u} + \frac{2im}{\tau + 1}\partial_r\bar{u} = \tilde{f}
\end{equation}

with the Cauchy data on the hyperplane $\tau = 0$.

From now on in this section we will omit “tilde” in the notations. The rest of this section is devoted to the following generalized Euler-Poisson-Darboux equation
\begin{equation}
\partial_t^2u - A(x, \partial_x)u + \frac{2im}{\tau + 1}\partial_r u = f,
\end{equation}

where $m \in \mathbb{C}$ and $A(x, \partial_x)$ is a pseudo-differential operator with the symbol $A(x, \xi)$ defined for $(x, \xi) \in \Omega \times \mathbb{R}^n$. Here $\Omega$ is a domain in $\mathbb{R}^n$. For the sake of the previous sections it is enough to set $\Omega = \mathbb{R}^n$. For the cases with $\Omega \neq \mathbb{R}^n$ one can consult [31].

There is a very extensive literature on Euler-Poisson-Darboux equation, that equation (29) with $A(x, \partial_x) = \Delta$ (see, e.g., [4, 8, 9, 10, 22, 26, 28, 29, 31] and bibliography therein). In particular, Wirth [29] used Bessel functions to represent the solution of Euler-Poisson-Darboux equation. In [21] the version of integral transform approach [30, 32] was employed by Palmieri for the derivation of the integral representation formulas for the solution of a linear equation with the coefficients, which are scale-invariant and independent of $x$ variable. Then Palmieri and coauthors [14] applied these formulas to examine the blowup phenomena for the wave equations with different types of nonlinearities in spacetime with power type expansion.

By the integral transform approach suggested in [30, 31, 32, 35] several results presented in the literature can be extended to the generalized Euler-Poisson-Darboux equation (29). Here we present one of such generalization.
5.1 Kernels for Generalized Euler-Poisson-Darboux equation.

To solve the Cauchy problem for (29) with \( m \in \mathbb{C} \) and data on \( \tau = 0 \) we use the following kernel functions

\[
E(r, \tau; b; m) = 2^{2im}(1 + b)^{2im} \left( (\tau + b + 2)^2 - r^2 \right)^{-im} F \left( im, im; 1; \frac{(\tau - b)^2 - r^2}{(\tau + b + 2)^2 - r^2} \right),
\]

\[
K_1(r, \tau; m) = \lim_{b \to 0} E(r, \tau; b; m) = 2^{2im} \left( (\tau + 2)^2 - r^2 \right)^{-im} F \left( im, im; 1; \frac{\tau^2 - r^2}{(\tau + 2)^2 - r^2} \right),
\]

\[
K_0(r, \tau; m) = \lim_{b \to 0} \left( -\frac{\partial}{\partial b} E(r, \tau; b; m) \right) = -2^{2im} m \left( (\tau + 2)^2 - r^2 \right)^{-im}
\]

\[
\times \left( \frac{2i (r^2 - \tau(\tau + 1))}{\tau^2 - r^2} \right) F \left( im, im; 1; \frac{\tau^2 - r^2}{(\tau + 2)^2 - r^2} \right)
\]

\[
- \frac{4i(\tau + 1)(\tau(\tau + 2) - r^2)}{(\tau^2 - r^2)((\tau + 2)^2 - r^2)} F \left( im + 1, im; 1; \frac{\tau^2 - r^2}{(\tau + 2)^2 - r^2} \right).
\]

The statements of the next theorem are consequences of Theorem 2.12 [35], Propositions 2.14, 2.15 [35].

**Theorem 5.1** The functions \( E, K_0, \) and \( K_1 \), solve the Euler-Poisson-Darboux equation, that is,

\[
E_{\tau\tau}(r, \tau; b; m) - E_{r\tau}(r, \tau; b; m) + \frac{2im}{\tau + 1} E_{\tau}(r, \tau; b; m) = 0,
\]

(30)

\[
K_{0\tau\tau}(r, \tau; m) - K_{0r\tau}(r, \tau; m) + \frac{2im}{\tau + 1} K_{0\tau}(r, \tau; m) = 0,
\]

(31)

\[
K_{1\tau\tau}(r, \tau; m) - K_{1r\tau}(r, \tau; m) + \frac{2im}{\tau + 1} K_{1\tau}(r, \tau; m) = 0,
\]

(32)

respectively.

**Proof.** We prove the statement for the function \( E \) only, since for two remaining functions the statements follow from the first one. According to Theorem 2.12 [35], the function

\[
W\left(r, \tau; b; M\right) := 4^{-M(b)} b^{-M} \left( (b + \tau)^2 - r^2 \right)^{M - \frac{3}{2}} F \left( \frac{1}{2} - M, \frac{1}{2} - M; 1; \frac{(b - \tau)^2 - r^2}{(b + \tau)^2 - r^2} \right)
\]

solves the following linear partial differential equation with parameters \( b \) and \( M \):

\[
W_{r\tau} - W_{\tau r} + \frac{1}{\tau} W_{\tau} - \frac{1}{\tau^2} M^2 W = 0.
\]

Furthermore, for the function \( W = \tau^{-M} V \) we obtain

\[
V_{r\tau} - V_{\tau r} + \frac{1 - 2M}{\tau} V_{\tau} = 0.
\]

Hence with \( 1 - 2M = 2im \)

\[
\tau^{-im + \frac{3}{2}} W \left( r, \tau; b; im - \frac{1}{2} \right) = V \left( r, \tau; b; im - \frac{1}{2} \right)
\]

and the function

\[
V \left( r, \tau; b; im - \frac{1}{2} \right) = 2^{2im - 1} (b)^{-(\frac{3}{2} - im)} \left( (b + \tau)^2 - r^2 \right)^{-im} F \left( im, im; 1; \frac{(b - \tau)^2 - r^2}{(b + \tau)^2 - r^2} \right)
\]

\[
\Rightarrow
\]
Proposition 5.1

The next proposition is an analog of Propositions 2.9, 2.13, 2.15 [35].

\[ v \text{ solves the Cauchy problem} \]

Then the function

\[ E(r, \tau; b; m) = 2^{2im} (1 + b)^{2im} ((\tau + b + 2)^2 - r^2)^{-im} F \left( \frac{im}{\tau + 1}; \frac{(\tau - b)^2 - r^2}{(\tau + b + 2)^2 - r^2} \right) \]

solves equation (30). Theorem is proved. □

Lemma 5.2 We have

\[
\lim_{\tau \to 0} K_1(\tau, \tau; m) = 1, \\
\lim_{\tau \to 0} (K_0(\tau, \tau; m) + 2imK_1(\tau, \tau; m)) = im.
\]

The next proposition is an analog of Propositions 2.9, 2.13, 2.15 [35].

Proposition 5.1 The following hold for the kernel functions

\[ E(0, \tau; \tau; m) = 1, \]

\[ E_r(\tau - b, \tau; b; m) + E_r(\tau - b, \tau; b; m) + \frac{im}{\tau + 1} E(\tau - b, \tau; b; m) = 0, \]

\[ K_1(\tau, \tau; m) + K_1(\tau, \tau; m) + \frac{im}{\tau + 1} K_1(\tau, \tau; m) = 0, \]

\[ 2K_0(\tau, \tau; m) + 2K_0(\tau, \tau; m) + \frac{2im}{\tau + 1} K_0(\tau, \tau; m) = -m(m + i)(\tau + 1)^{-2-im}. \]

5.2 Solution with \( f, \varphi_1, \varphi_0 \) for equation in the proper time

Theorem 5.3 Let the function \( v = v_f(x, r; b) \in C^{d,2,0}_{x,r,b} \) be a solution to the Cauchy problem

\[
\begin{cases}
    v_{rr}(x, r; b) - A(x, \partial_x) v(x, r; b) = 0, \\
    v(x, 0; b) = f(x, b), \quad v_r(x, 0; b) = 0,
\end{cases}
\]

while \( v = v_\varphi(x, r) \in C^{d,2}_{x,r} \) is a solution to the problem

\[
\begin{cases}
    v_{rr}(x, r) - A(x, \partial_x) v(x, r) = 0, \\
    v(x, 0; b) = \varphi(x), \quad v_r(x, 0) = 0.
\end{cases}
\]

Then the function

\[
u(x, \tau) = \int_0^\tau db \int_0^{\tau-b} E(r, \tau; b; m) v_f(x, r; b) dr + \int_0^\tau K_1(r, \tau; m) v_{\varphi_1}(x, r) dr \\
+ (1 + \tau)^{-im} v_{\varphi_0}(x, \tau) + \int_0^\tau \left[ K_0(r, \tau; m) + 2imK_1(r, \tau; m) \right] v_{\varphi_0}(x, r) dr
\]

solves the Cauchy problem

\[
\begin{cases}
    \partial_r^2 u(x, \tau) - A(x, \partial_x) u(x, \tau) + \frac{2im}{\tau + 1} u_r(x, \tau) = f(\tau, x), \\
    u(x, 0) = \varphi_0(x), \quad u_r(x, 0) = \varphi_1(x).
\end{cases}
\]

We stress here that the operator \( A(x, \partial_x) \) is a pseudo-differential operator without any restriction on its order \( d \) or type. Thus, there is no any assumption on the type of equation (29). Furthermore, the source term and initial data may be chosen from the Sobolev spaces as well.

If we assume that \( A(x, \partial_x) \) is an elliptic operator of the second order, then equation (29) is strictly hyperbolic. Therefore, from the last theorem and from the well-posedness of the Cauchy problem for the hyperbolic operator in the domain \( t > 0 \) follow the next statements about the fundamental solutions.
Theorem 5.4 Let $E_A$ be a fundamental solution solution of the Cauchy problem

$$
\begin{align*}
\left\{ \begin{array}{l}
\partial^2_\tau E_A(x, r; x_0) - A(x, \partial_x) E_A(x, r; x_0) = 0, \\
E_A(x, 0; x_0) = \delta(x - x_0), \quad \partial_r E_A(x, 0; x_0) = 0,
\end{array} \right.
\end{align*}
$$

then the distribution with the support in $\mathbb{R}^{n+1}_+(x_0, \tau_0)$ that is defined by

$$
E_+(x, \tau; x_0, \tau_0) = \int_0^{\tau-\tau_0} E(r, \tau; \tau_0; m)E_A(x, r; x_0) dr \quad \text{if} \quad \tau > \tau_0 > 0,
$$
solves the equation

$$
\partial^2_\tau E_+(x, \tau; x_0, \tau_0) - A(x, \partial_x) E_+(x, \tau; x_0, \tau_0) + \frac{2im}{\tau + 1} \partial_r E_+(x, \tau; x_0, \tau_0) = \delta(x - x_0) \delta(\tau - \tau_0).
$$

Theorem 5.5 Let $E_A$ be a fundamental solution solution of the Cauchy problem, that is

$$
\begin{align*}
\left\{ \begin{array}{l}
\partial^2_\tau E_A(x, r; x_0) - A(x, \partial_x) E_A(x, r; x_0) = 0, \\
E_A(x, 0; x_0) = \delta(x - x_0), \quad \partial_r E_A(x, 0; x_0) = 0,
\end{array} \right.
\end{align*}
$$

then the distributions

$$
\begin{align*}
E_0(x, \tau; x_0) &= (1 + \tau)^{-im} E_A(x, \tau; x_0) + \int_0^\tau \left[ K_0(r, \tau; m) + 2im K_1(r, \tau; m) \right] E_A(x, r; x_0) dr, \\
E_1(x, \tau; x_0) &= \int_0^\tau K_1(r, \tau; m) E_A(x, r; x_0) dr
\end{align*}
$$
solve the Cauchy problem

$$
\begin{align*}
\left\{ \begin{array}{l}
\partial^2_\tau E_i(x, \tau; x_0) - A(x, \partial_x) E_i(x, \tau; x_0) + \frac{2im}{\tau + 1} \partial_r E_i(x, \tau; x_0) = 0, \\
E_i(x, 0; x_0) = \delta_0(x - x_0), \quad \partial_r E_i(x, 0; x_0) = \delta_1 \delta(x - x_0), \quad i = 0, 1.
\end{array} \right.
\end{align*}
$$

5.3 Proof of Theorem 5.3 for problem with $\varphi_0$. Case of $f = 0$, $\varphi_1 = 0$

Next, we will suppress subindex $\varphi_0$ of $v_{\varphi_0}(x, \tau)$. It is convenient to split the solution $u(x, \tau)$ into two parts $u(x, \tau) = \tilde{u}(x, \tau) + \widetilde{u}(x, \tau)$, where

$$
\begin{align*}
\tilde{u}(x, \tau) &= (1 + \tau)^{-im} v(x, \tau) + \int_0^\tau K_0(r, \tau; m) v(x, r) dr, \\
\widetilde{u}(x, \tau) &= 2im \int_0^\tau K_1(r, \tau; m) v(x, r) dr.
\end{align*}
$$

It is easy to see that $u(x, 0) = \varphi_0(x)$ and

$$
\begin{align*}
u_\tau(x, \tau) &= \partial_\tau ((1 + \tau)^{-im} v(x, \tau)) + \partial_\tau \int_0^\tau [K_0(r, \tau; m) + 2im K_1(r, \tau; m)] v(x, r) dr \\
&= -im(1 + \tau)^{-im-1} v(x, \tau) + (1 + \tau)^{-im} \partial_\tau v(x, \tau) \\
&\quad + [K_0(\tau, \tau; m) + 2im K_1(\tau, \tau; m)] v(x, \tau) \\
&\quad + \int_0^\tau [\partial_r K_0(r, \tau; m) + 2im \partial_r K_1(r, \tau; m)] v(x, r) dr.
\end{align*}
$$

It follows from Lemma 5.2 that

$$
\lim_{\tau \to 0} u_\tau(x, \tau) = - \lim_{\tau \to 0} imv(x, 0) + \lim_{\tau \to 0} [K_0(\tau, \tau; m) + 2im K_1(\tau, \tau; m)] v(x, 0) = 0.
$$
According to Theorem 5.3 the function $\tilde{u}(x, \tau)$ (34) solves the equation, therefore it remains to verify that the function $\tilde{u}(x, \tau)$ (33) solves the equation. For the first order derivative we obtain

$$\tilde{u}_r(x, \tau) = \partial_\tau ((1+\tau)^{-im}v(x, \tau)) + \partial_\tau \int_0^\tau K_0(r, \tau; m) v(x, r) \, dr$$

$$= -im(1+\tau)^{-im-1}v(x, \tau) + (1+\tau)^{-im}\partial_\tau v(x, \tau)$$

$$+ K_0(\tau, \tau; m) v(x, \tau) + \int_0^\tau K_0(\tau, \tau; m) v(x, r) \, dr.$$ 

For the second order derivative we have

$$\tilde{u}_{rr}(x, \tau) = -im(-im-1)(1+\tau)^{-im-2}v(x, \tau) - 2im(1+\tau)^{-im-1}v_r(x, \tau) + (1+\tau)^{-im}v_{rr}(x, \tau)$$

$$+ \partial_\tau \left\{ K_0(\tau, \tau; m) v(x, \tau) + \int_0^\tau K_0(\tau, \tau; m) v(x, r) \, dr \right\}.$$ 

Thus,

$$\tilde{u}_{rr}(x, \tau) = -im(-im-1)(1+\tau)^{-im-2}v(x, \tau) - 2im(1+\tau)^{-im-1}v_r(x, \tau) + (1+\tau)^{-im}v_{rr}(x, \tau)$$

$$+ \left[ K_0(r, \tau; m) v(x, \tau) + 2K_0(\tau, \tau; m) v(x, \tau) + K_0(\tau, \tau; m) v_r(x, \tau)$$

$$+ \int_0^\tau K_0(\tau, \tau; m) v(x, r) \, dr \right].$$ 

Next we consider an application of the operator $A(x, \partial_x)$ to the function (33):

$$A(x, \partial_x)\tilde{u}(x, \tau) = A(x, \partial_x)(1+\tau)^{-im}v(x, \tau) + \int_0^\tau K_0(r, \tau; m) A(x, \partial_x) v(x, r) \, dr$$

$$= (1+\tau)^{-im} A(x, \partial_x) v(x, \tau) + B(x, \tau),$$

where we have denoted

$$B(x, \tau) := \int_0^\tau K_0(r, \tau; m) v_{rr}(x, r) \, dr.$$ 

Integrating by parts and using $K_0(0, \tau; m) = 0$, we obtain

$$B(x, \tau) = K_0(\tau, \tau; m) v_r(x, \tau) - \int_0^\tau K_0(\tau, \tau; m) v_r(x, r) \, dr$$

$$= K_0(\tau, \tau; m) v_r(x, \tau) - K_0(\tau, \tau; m) v(x, \tau) + K_0(\tau, 0; m) v(x, 0)$$

$$+ \int_0^\tau K_0(\tau, \tau; m) v(x, r) \, dr.$$ 

Since $K_0(0, \tau; m) = 0$, it follows

$$A(x, \partial_x)\tilde{u}(x, \tau) = (1+\tau)^{-im} A(x, \partial_x) v(x, \tau) + \left[ K_0(\tau, \tau; m) v_r(x, \tau) - K_0(\tau, \tau; m) v(x, \tau)$$

$$+ K_0(0, \tau; m) v(x, 0) + \int_0^\tau K_0(\tau, \tau; m) v(x, r) \, dr \right].$$

Thus,

$$\tilde{u}_{rr}(x, \tau) - A(x, \partial_x)\tilde{u}(x, \tau) + \frac{2im}{r+1} \tilde{u}_r(x, \tau)$$

$$= 0.$$
where we have used

\[
- \text{im}(-\text{im} - 1)(1 + \tau)^{-\text{im} - 2}v(x, \tau) - 2\text{im}(1 + \tau)^{-\text{im} - 1}v_{\tau}(x, \tau) + (1 + \tau)^{-\text{im}}v_{\tau\tau}(x, \tau)
\]

In particular,

\[
\left[ K_0(r, \tau; m)v(x, \tau) + 2K_0(r, \tau; m)\right]v(x, \tau) + K_0(r, \tau; m)v_{\tau}(x, \tau)
\]

\[
+ \int_0^r K_0(r, \tau; m)v(x, r) dr \right]\}
\]

By application of (31) and the definition of the function \( v = v(x, \tau) \) we obtain

\[
\begin{align*}
\bar{u}_{\tau\tau}(x, \tau) - A(x, \partial_x)\bar{u}(x, \tau) + \frac{2i\text{m}}{\tau + 1}\bar{u}_{\tau}(x, \tau) \\
= \left[ - \text{im}(-\text{im} - 1)(1 + \tau)^{-\text{im} - 2} + 2K_0(r, \tau; m) + 2K_0(r, \tau; m) \\
+ \frac{2i\text{m}}{\tau + 1}\left\{ - \text{im}(1 + \tau)^{-\text{im} - 1} + K_0(r, \tau; m) \right\} \right]v(x, \tau) \\
= m(m + i\text{m})(1 + \tau)^{-\text{im} - 2}v(x, \tau) \\
+ \left[ 2K_0(r, \tau; m)v(x, \tau) + 2K_0(r, \tau; m) + \frac{2i\text{m}}{\tau + 1}K_0(r, \tau; m) \right]v(x, \tau).
\end{align*}
\]

Then we apply the last equation of Proposition 5.1 and obtain

\[
m(m + i\text{m})(1 + \tau)^{-\text{im} - 2} + \left[ 2K_0(r, \tau; m) + 2K_0(r, \tau; m) + \frac{2i\text{m}}{\tau + 1}K_0(r, \tau; m) \right] = 0.
\]

Thus, this case of Theorem 5.3 is proved. \( \square \)

### 5.4 Proof of Theorem 5.3 for problem with \( \varphi_1 \). Case of \( f = 0, \varphi_0 = 0 \)

Next, we will suppress subindex \( \varphi_1 \) of \( v_{\varphi_1}(x, \tau) \). It is evident that \( u(x, 0) = 0 \). For the derivative \( \partial_{\tau}u(x, \tau) \) we have

\[
\partial_{\tau}u(x, \tau) = \partial_{\tau} \int_0^r K_1(r, \tau; m)v(x, r) dr = K_1(\tau, \tau; m)v(x, \tau) + \int_0^r K_1(\tau, \tau; m)v(x, r) dr. \quad (35)
\]

In particular,

\[
\lim_{\tau \to 0} \partial_{\tau}u(x, \tau) = \lim_{\tau \to 0} K_1(\tau, \tau; m)v(x, \tau) = \varphi_1(x),
\]

where we have used

\[
K_1(\tau, \tau; m) = 2^{\text{i}\text{m}}((\tau + 2)^2 - \tau^2)^{-\text{i}\text{m}}.
\]

Then we use (35) to find the second order derivative

\[
\partial_{\tau}^2u(x, \tau) = K_1(\tau, \tau; m)v(x, \tau) + 2K_1(\tau, \tau; m)v(x, \tau) + K_1(\tau, \tau; m)v_{\tau}(x, \tau) + \int_0^r K_1(\tau, \tau; m)v(x, r) dr.
\]
Using the definition of the function \( v(x, r) \) and the integration by parts twice, we derive

\[
A(x, \partial_x)u(x, \tau) = \int_0^\tau K_1(r, \tau; m)A(x, \partial_x)v(x, r) \, dr \\
= \int_0^\tau K_1(r, \tau; m)v_{rr}(x, r) \, dr \\
= K_1(r, \tau; m)v_r(x, \tau) - \left\{ K_1(r, \tau; m)v(x, \tau) - K_1(r, 0, \tau; m)v(x, 0) \right\} \\
- \int_0^\tau K_1rr(r, \tau; m)v(x, r) \, dr .
\]

Since \( K_1(r, 0, \tau; m) = 0 \), we obtain

\[
A(x, \partial_x)u(x, \tau) = K_1(r, \tau; m)v_r(x, \tau) - K_1(r, \tau; m)v(x, \tau) + \int_0^\tau K_1rr(r, \tau; m)v(x, r) \, dr .
\]

Consequently, according to (32) of Theorem 5.1 and Proposition 5.1 since \( v_r(x, \tau) = v_\tau(x, \tau) \), we obtain

\[
u_{rr}(x, \tau) - A(x, \partial_x)u(x, \tau) + \frac{2im}{\tau + 1}u_\tau(x, \tau)
= \left\{ K_1(r, \tau; m)v(x, \tau) + K_1(r, \tau; m)v_r(x, \tau) + 2K_1(r, \tau; m)v(x, \tau) + \int_0^\tau K_1rr(r, \tau; m)v(x, r) \, dr \right\}
- \left\{ K_1(r, \tau; m)v_r(x, \tau) - K_1(r, \tau; m)v(x, \tau) + \int_0^\tau K_1rr(r, \tau; m)v(x, r) \, dr \right\}
+ \frac{2im}{\tau + 1} \left\{ K_1(r, \tau; m)v(x, \tau) + \int_0^\tau K_1rr(r, \tau; m)v(x, r) \, dr \right\}
= \left\{ 2K_1(r, \tau; m) + 2K_1(r, \tau; m) + \frac{2im}{\tau + 1}K_1(r, \tau; m) \right\} v(x, \tau) = 0 .
\]

Thus, this case of Theorem 5.3 is proved. \( \square \)

### 5.5 Proof of Theorem 5.3 for problem with \( f \).

#### Case of \( \varphi_0 = \varphi_1 = 0 \)

Next, we will suppress subindex \( f \) of \( v_f(x, r; b) \). We write \( v(x, r; b) \) for \( v_f(x, r; b) \) and calculate the derivative

\[
\partial_\tau u(x, \tau) = \int_0^\tau db \partial_\tau \int_0^{\tau-b} E(r, \tau; b; m)v(x, \tau - b; b) \, dr \\
= \int_0^\tau E(\tau - b, \tau; b; m)v(x, \tau - b; b) \, db + \int_0^\tau db \int_0^{\tau-b} E_\tau(\tau; b; m)v(x, \tau; b) \, dr .
\]

It follows that the function takes required initial data as well as

\[
\partial_\tau^2 u(x, \tau) = E(0, \tau; m)f(x, \tau) + \int_0^\tau E_\tau(\tau - b, \tau; b; m)v(x, \tau - b; b) \, db \\
+ \int_0^\tau E(\tau - b, \tau; b; m)v_r(x, \tau - b; b) \, db + 2 \int_0^\tau E_\tau(\tau - b, \tau; b; m)v(x, \tau - b; b) \, db \\
+ \int_0^\tau db \int_0^{\tau-b} \partial_\tau^2 E(r, \tau; b; m)v(x, \tau; b) \, dr .
\]
Thus, using the definition of the function $v = v(x, r)$ and the integration by parts twice, we derive

$$A(x, \partial_x)u(x, \tau) = \int_0^\tau db \int_0^{\tau-b} E(r, \tau; b; m)A(x, \partial_x)\nu(x, r; b) dr$$

$$= \int_0^\tau db \int_0^{\tau-b} E(r, \tau; b; m)\partial_r^2 v(x, r; b) dr$$

$$= \int_0^\tau db \left[ E(\tau - b, \tau; b; m)v_r(x, \tau - b) - E(0, \tau; b; m)v_r(x, 0; b) \right.$$

$$- \int_0^{\tau-b} \partial_r E(r, \tau; b; m)v_r(x, r; b) dr \biggr]$$

$$= \int_0^\tau db \left[ E(\tau - b, \tau; b; m)v_r(x, \tau - b) - \int_0^{\tau-b} \partial_r E(r, \tau; b; m)v_r(x, r; b) dr \right].$$

Hence

$$u_{\tau\tau}(x, \tau) - A(x, \partial_x)u(x, \tau) + \frac{2im}{\tau + 1} u_r(x, \tau)$$

$$= \left[ E(0, \tau; \tau; m) f(x, \tau) + \int_0^\tau E_r(\tau - b, \tau; b; m)v(x, \tau - b; b) db \right.$$  

$$+ \int_0^\tau E(\tau - b, \tau; b; m)v_r(x, \tau - b; b) db + 2 \int_0^\tau E_r(\tau - b, \tau; b; m)v(x, \tau - b; b) db$$

$$+ \int_0^\tau db \int_0^{\tau-b} \partial_r^2 E(r, \tau; b; m)v(x, r; b) dr$$

$$- \left[ \int_0^\tau db \left\{ E(\tau - b, \tau; b; m)v_r(x, \tau - b; b) - \int_0^{\tau-b} \partial_r E(r, \tau; b; m)v_r(x, r; b) dr \right\} \right]$$

$$+ \frac{2im}{\tau + 1} \left[ \int_0^\tau E(\tau - b, \tau; b; m)v(x, \tau - b; b) db + \int_0^\tau db \int_0^{\tau-b} E_r(r, \tau; b; m)v(x, r; b) dr \right].$$

On the other hand, the integration by parts leads to

$$\int_0^\tau db \int_0^{\tau-b} E_r(r, \tau; b; m)v_r(x, r; b) dr$$

$$= \int_0^\tau \left\{ E_r(\tau - b, \tau; b; m)v(x, \tau - b; b) - E_r(0, \tau; b; m)v(x, 0; b) - \int_0^{\tau-b} E_{\tau\tau}(r, \tau; b; m)v(x, r; b) dr \right\} db.$$

Then we use $E_r(0, \tau; b; m) = 0$. Consequently,

$$\int_0^\tau db \int_0^{\tau-b} \partial_r E(r, \tau; b; m)v_r(x, r; b) dr$$

$$= \int_0^\tau \left\{ \partial_r E(\tau - b, \tau; b; m)v(x, \tau - b; b) - \partial_r E(0, \tau; b; m)f(x, b) - \int_0^{\tau-b} \partial_{rr} E(r, \tau; b; m)v(x, r; b) dr \right\} db$$

$$= \int_0^\tau E_r(\tau - b, \tau; b; m)v(x, \tau - b; b) db - \int_0^\tau db \int_0^{\tau-b} E_{\tau\tau}(r, \tau; b; m)v(x, r; b) dr.$$

Thus,

$$u_{\tau\tau}(x, \tau) - A(x, \partial_x)u(x, \tau) + \frac{2im}{\tau + 1} u_r(x, \tau)$$

25
= \left[ E(0; \tau; \tau; m)f(x, \tau) + \int_0^\tau E_r(\tau - b, \tau; b; m)v(x, \tau - b; b) \, db \
+ \int_0^\tau E(\tau - b, \tau; b; m)v_r(x, \tau - b; b) \, db + 2 \int_0^\tau E_r(\tau - b, \tau; b; m)v(x, \tau - b; b) \, db \
+ \int_0^\tau db \int_0^{\tau - b} \partial_r^2 E_r(r, \tau; b; m)v(x, r; b) \, dr \right] - \int_0^\tau E(r - b, \tau; b; m)v_r(x, \tau - b; b) \, db \
+ \left\{ \int_0^\tau E_r(\tau - b, \tau; b; m)v(x, \tau - b; b) \, db - \int_0^\tau db \int_0^{\tau - b} E_r(\tau - b, \tau; b; m)v(x, r; b) \, dr \right\} \
+ \frac{2im}{\tau + 1} \int_0^\tau E(\tau - b, \tau; b; m)v(x, \tau - b; b) \, db + \int_0^\tau db \int_0^{\tau - b} E_r(\tau, \tau; b; m)v(x, r; b) \, dr \right].

The double integrals of the last equation can be unified as follows

\[
\int_0^\tau db \int_0^{\tau - b} \partial_r^2 E_r(r, \tau; b; m)v(x, r; b) \, dr - \int_0^\tau db \int_0^{\tau - b} E_r(r, \tau; b; m)v(x, r; b) \, dr \
+ \frac{2im}{\tau + 1} \int_0^\tau E(r - b, \tau; b; m)v_r(x, \tau - b; b) \, db
\]

\[
= \int_0^\tau db \int_0^{\tau - b} \left\{ E_{rr}(r, \tau; b; m) - E_{rr}(r, \tau; b; m) + \frac{2im}{\tau + 1} E_r(\tau, \tau; b; m) \right\} v(x, r; b) \, dr = 0.
\]

Hence, according to (30) we derive

\[
u_{rr}(x, \tau) - A(x, \partial_x)u(x, \tau) + \frac{2im}{\tau + 1} u_r(x, \tau)
\]

\[
= E(0; \tau; \tau; m)f(x, \tau) + \int_0^\tau E_r(\tau - b, \tau; b; m)v(x, \tau - b; b) \, db \
+ \int_0^\tau E(\tau - b, \tau; b; m)v_r(x, \tau - b; b) \, db + 2 \int_0^\tau E_r(\tau - b, \tau; b; m)v(x, \tau - b; b) \, db \
- \int_0^\tau E(r - b, \tau; b; m)v_r(x, \tau - b; b) \, db + \int_0^\tau E(r - b, \tau; b; m)v(x, \tau - b; b) \, db \
+ \frac{2im}{\tau + 1} \int_0^\tau E(\tau - b, \tau; b; m)v(x, \tau - b; b) \, db.
\]

Next we use \( v_r(x, \tau - b; b) = v_r(x, \tau - b; b) \) in

\[
\int_0^\tau E(\tau - b, \tau; b; m)v_r(x, \tau - b; b) \, db - \int_0^\tau E(\tau - b, \tau; b; m)v_r(x, \tau - b; b) \, db = 0.
\]

Hence

\[
u_{rr}(x, \tau) - A(x, \partial_x)u(x, \tau) + \frac{2im}{\tau + 1} u_r(x, \tau)
\]

\[
= E(0; \tau; \tau; m)f(x, \tau) \
+ \int_0^\tau E_r(\tau - b, \tau; b; m)v(x, \tau - b; b) \, db + 2 \int_0^\tau E_r(\tau - b, \tau; b; m)v(x, \tau - b; b) \, db \
+ \int_0^\tau E_r(\tau - b, \tau; b; m)v(x, \tau - b; b) \, db + \frac{2im}{\tau + 1} \int_0^\tau E(\tau - b, \tau; b; m)v(x, \tau - b; b) \, db
\]

\[
= E(0; \tau; \tau; m)f(x, \tau) \
+ \int_0^\tau \left[ 2E_r(\tau - b, \tau; b; m) + 2E_r(\tau - b, \tau; b; m) + \frac{2im}{\tau + 1} E(\tau - b, \tau; b; m) \right] v(x, \tau - b; b) \, db.
\]

26
Then we apply Proposition 5.1 and obtain
\[ u_{\tau\tau}(x, \tau) - A(x, \partial_x)u(x, \tau) + \frac{2im}{\tau + 1}u_{\tau}(x, \tau) = f(x, \tau). \]

This case of Theorem 5.3 is proved. Theorem 5.3 is proved. \(\square\)
