(Dated: March 8, 2021)

We investigate the feasibility of performing quantum non-demolition (QND) measurements in relativistic quantum systems, using the one-dimensional Dirac oscillator as a specific example. We derive general expressions for its QND observables and find that they are intricate combinations of the position, momentum, and spin operators, which makes them challenging to realize experimentally in general. However, the situation is considerably simplified in both the weakly and strongly relativistic limits, where their experimental realization will be possible.

Introduction.— Under normal circumstances the uncertainty in a second measurement of an observable \( \hat{A} \) is limited by the Heisenberg Uncertainty Principle. It is the result of the back action of the initial measurement on the uncertainty of its conjugate variable, which results in increased uncertainty in the subsequent evolution of \( \hat{A} \). This difficulty is however circumvented for QND observables. These are observables such that if the measurements sequence starts with the system in an eigenvalue \( A_0 \) of \( \hat{A} \), its free evolution leaves it in an eigenstate of \( \hat{A} \) at each subsequent time in the measurement sequence. Continuous QND observables are observables that satisfy this condition at all times, as is the case if they are conserved,

\[
\frac{d\hat{A}}{dt} = -\frac{i}{\hbar}[\hat{A}, \hat{H}] + \frac{\partial \hat{A}}{\partial t} = 0 \quad (1)
\]

where \( \hat{H} \) is the system Hamiltonian.

For example, either of the two rotating quadrature operators of a simple harmonic oscillator of mass \( m \), frequency \( \omega \) and Hamiltonian \( \hat{H}_0 \),

\[
\begin{align*}
\hat{Y}_1 &= \hat{x} \cos \omega t - (\hat{p} / m \omega) \sin \omega t, \\
\hat{Y}_2 &= \hat{x} \sin \omega t + (\hat{p} / m \omega) \cos \omega t,
\end{align*}
\]

with \([\hat{Y}_1, \hat{Y}_2] = i\hbar / m \omega \), uncertainty relation \( \Delta \hat{Y}_1 \Delta \hat{Y}_2 \geq \hbar / 2m \omega \), and

\[
\frac{d\hat{Y}_\ell}{dt} = -\frac{i}{\hbar}[\hat{Y}_\ell, \hat{H}_0] + \frac{\partial \hat{Y}_\ell}{\partial t} = 0 \quad (\ell = 1, 2),
\]

can be chosen as QND observables (but of course not both simultaneously) [11]. They have been exploited in particular in optical and atomic interferometry [2], weak force and gravitational wave detection [3, 4], and the preparation of squeezed states [5].

The goal of this paper is to determine whether QND measurements can also be realized on the Dirac oscillator, an extension of the harmonic oscillator to relativistic quantum mechanics that is frequently used to investigate relativistic extensions of non-relativistic quantum effects. These include the generation of Dirac cat states [6], the study of a relativistically deformed uncertainty principle in (1+1) dimensions [7], and a relativistic quantum heat engine using a single Dirac particle trapped in an infinite one-dimensional potential as its working substance [8]. It has also found wide applications in nuclear physics, condensed matter physics and quantum optics, see e.g. the review [9]. Because of its non equidistant excitation spectrum and the presence of a spin-orbit coupling in its Hamiltonian, the dynamics of the Dirac oscillator differs significantly from that of the simple harmonic oscillator. For example, we showed in earlier work [10] that the interference between positive and negative energy states prevents the realization of quantum-mechanics free sub-systems that avoid quantum measurement backaction. But whether the more direct generation of QND observables is possible remains an open question.

The present paper derives the general form of a pair of QND observables of the (1+1) dimensional Dirac oscillator. We determine their dependence on the relativistic level of the oscillator, as characterized by the parameter \( \epsilon = \hbar \omega / mc^2 \) with \( \omega \) its frequency and \( m \) its rest mass. In both the weakly relativistic regime \( \epsilon \ll 1 \) and the extreme relativistic regime \( \epsilon \gg 1 \) they reduce to the quadrature operators \( \hat{Y}_{1,2} \) of the simple harmonic oscillator, albeit with spin-dependent frequencies, but in the intermediate regime they take the form of intricate spin-orbit coupling operators. We conclude with an estimate of experimental parameters achievable in QND measurements in implementations of the Dirac oscillator in either electrons or cold atoms.
In the (1+1) dimensional case the Hamiltonian of the Dirac oscillator reduces to the form
\[ H_D = c \sigma_x \hat{p} - mc \omega \sigma_y \hat{x} + mc^2 \sigma_z, \] (4)
where \( c \) is the velocity of light and \( \sigma_{x,y,z} \) are Pauli operators.

We proceed by introducing the bosonic annihilation and creation operators \( \hat{a} \) and \( \hat{a}^\dagger \) in the usual way, with \( \hat{x} = x_{\text{xp}}(\hat{a} + \hat{a}^\dagger) \) and \( \hat{p} = -i p_{\text{xp}}(\hat{a} - \hat{a}^\dagger) \), and the excitation number operator \( \hat{n} = \hat{a}^\dagger \hat{a} \), where \( x_{\text{xp}} = \sqrt{\hbar/2m\omega} \) and \( p_{\text{xp}} = \sqrt{\hbar \omega/2} \) are the zero-point position and momentum. The Hamiltonian (4) takes then the form of the anti-Jaynes-Cumming Hamiltonian
\[ \hat{H}_D = \eta \sigma_z \hat{a} + \eta^* \sigma_z \hat{a}^\dagger + mc^2 \sigma_z, \] (5)
where \( \eta = -i \sqrt{2mc^2} \). Its eigenstates are the dressed states
\[
|E_n^+\rangle = A_n |n, \uparrow\rangle - iB_n |n, \downarrow\rangle,
|E_n^-\rangle = B_{n+1} |n+1, \uparrow\rangle + iA_{n+1} |n, \downarrow\rangle,
\] (6)
with associated positive and negative eigenenergies
\[ E_n^+ = -E_{n+1}^- = -mc^2 \sqrt{1 + 2(n+1)\epsilon}. \] (7)
Here \( |\uparrow\rangle, |\downarrow\rangle \) are Pauli spinors, the states \( |n\rangle \) are eigenstates of the non-relativistic harmonic oscillator, and
\[ A_n = \sqrt{(E_n^+ + mc^2)/2E_n^+}; B_n = \sqrt{(E_n^+ - mc^2)/2E_n^+}. \] (8)

The asymmetry between the positive and negative energy branches and the property that the eigenstates are linear superpositions of motional states with opposite spins are direct consequences of the relativistic spin-orbit coupling component of the Hamiltonian (4).

Limiting cases—In the weakly relativistic limit \( \epsilon \ll 1 \) we have \( E_n^+ \approx mc^2 + n\hbar \omega \approx A_n \approx 1 \) and \( B_n \approx 0 \), so that the superpositions of opposite spin states disappear, the eigenstates reducing to \( |n, \uparrow\rangle \) and \( i |n, \downarrow\rangle \), respectively. Hence the effective Hamiltonian can be approximated as that of a harmonic oscillator with a spin-dependent oscillating frequency—positive frequency for spin up and negative frequency for spin down,
\[ \hat{H}_\text{nr} = mc^2 \sigma_z + \hbar \omega \sigma_z (\hat{n} + \frac{1}{2}) - \frac{\hbar \omega}{2}. \] (9)

In this limit \( \sigma_z \) is a constant of motion and hence a QND observable. In addition, it also follows that the system possesses a pair of QND observables \( \hat{X}_\ell \hat{Y}_\ell \), \( \ell = (1, 2) \), of precisely the same form as the quadrature operators \( \hat{Y}_\ell \) of Eqs. (2) but with the important difference that the frequency becomes now a spin-dependent frequency operator
\[ \omega \rightarrow \hat{\omega}_\text{nr} = \omega \sigma_z, \] (10)
so that
\[
\hat{X}_{1,\text{nr}} = x_{\text{xp}}^\prime (\hat{a} e^{i\hat{\omega}_\text{nr} t} + \text{h.c.}),
\hat{X}_{2,\text{nr}} = ix_{\text{xp}}^\prime (e^{-i\hat{\omega}_\text{nr} t} \hat{a}^\dagger - \text{h.c.}).
\] (11)
Since \( \{\hat{a}, \hat{\omega}_\text{nr}\} = 0 \) they obey the same commutation relation as \( \hat{Y}_{1,2} \).

In the other extreme limit, \( \epsilon \gg 1 \), the spin-orbit coupling term \( \eta \sigma_z \hat{a} + \eta^* \sigma_z \hat{a}^\dagger \) dominates the Hamiltonian so that \( E_n^+ \approx mc^2 \sqrt{2\hbar \omega} \) and \( A_n \approx B_n \approx 1/\sqrt{2} \). Moreover, the energy difference between neighboring motional states \( |n\rangle \) and \( |n-1\rangle \) scales as \( 1/\sqrt{n} \) and approaches for large excitations \( n \gg 1 \). The eigenstates of \( H_D \) can then be approximated by the factorized motional and spin states \( |E_n^\pm\rangle \approx |n\rangle (|\uparrow\rangle \mp i|\downarrow\rangle)/\sqrt{2} \), corresponding to the effective Hamiltonian
\[ \hat{H}_t = -\sigma_y \sqrt{2mc^2 \hbar \omega n}. \] (12)

In contrast to \( \hat{H}_\text{nr} \) the eigenenergy spectrum of \( \hat{H}_t \) is not equidistant, and \( \sigma_y \) rather than \( \sigma_z \) is now a constant of motion, and hence a QND observable. Like in the weakly relativistic case \( \hat{H}_t \) also possesses a pair of QND observables \( \hat{X}_t, \hat{Y}_t \) that are formally identical with the quadrature operators (11), but now with the replacement of \( \omega \) by a frequency operator \( \hat{\omega}_t \) with both a motional and spin dependence,
\[ \omega \rightarrow \hat{\omega}_t = \omega \sqrt{2/\epsilon (\sqrt{n} - 1 - \sqrt{n})} \sigma_y. \] (13)

With the equality \( \hat{a} f(n) = f(n+1) \hat{a} \) one can readily show that the dynamical evolution and uncertainty relation of \( \hat{X}_t, \hat{Y}_t \) are the same as those of the quadrature operators \( \hat{Y}_t \). (Note that since \( \{\hat{a}, \hat{\omega}_t\} \neq 0 \) the operator ordering in \( \hat{X}_t, \hat{Y}_t \) cannot be arbitrarily changed.)

General case.—It is easily verified that the formal similarity between the QND observables \( \hat{X}_t \) of the Dirac oscillator in the limits \( \epsilon \ll 1 \) and \( \epsilon \gg 1 \) and the quadratures \( \hat{Y}_t \) of the simple harmonic oscillator follows from the fact that in both limits \( \hat{n} \) is a conserved quantity (approximately so for \( \epsilon \gg 1 \)), in which case QND observables in that general form can always be found, with an appropriately selected frequency operator \( \omega \). However, in the intermediate regime of the Dirac oscillator \( \hat{n} \) is no longer a conserved quantity, a consequence of the spin-orbit induced exchange of energy between the motional and spin degrees of freedom.

The effects of this coupling are formally eliminated in the Foldy-Wouthuysen (FW) representation (11), as we now show. For the one-dimensional Dirac oscillator, the FW and the original Dirac representation are related by the unitary transformation (12),
\[ \hat{U} = \begin{pmatrix} \hat{A}_n & i\hat{B}_n / \sqrt{n} \\ -i\hat{B}_n / \sqrt{n} & \hat{A}_{n+1} \end{pmatrix}, \] (14)
where the operators \( \hat{A}_n \) and \( \hat{B}_n \) are obtained by replacing \( n \) by \( \hat{n} \) in the expressions for \( A_n \) and \( B_n \) of Eqs. (3). The
transformed Hamiltonian takes the \( \hat{n} \)-conserving form
\[
\hat{H}_F(\hat{n}) = \hat{U} \hat{H}_0 \hat{U}^\dagger = \sigma_z mc^2 \sqrt{1 + (2\hat{n} - \sigma_z + 1)\epsilon},
\]
with eigenstates \(|n, \uparrow\rangle\) and \(|n, \downarrow\rangle\) and associated positive and negative eigenenergies \(E^+_n\) and \(E^-_n\), respectively. Importantly, the FW eigenstates do not involve superpositions of the two spin states, that is, the positive and negative energy eigenstates are uniquely associated with spin up and spin down, respectively, as was the case in the weakly relativistic limit \(\epsilon \ll 1\). Following a similar approach we can therefore again construct a pair of QND observables
\[
\hat{X}_{1,F} = x_{\text{opt}}(\hat{a} e^{i\omega t} + \text{h.c.}), \\
\hat{X}_{2,F} = i x_{\text{opt}}(e^{-i\omega t} \hat{a}^\dagger - \text{h.c.}),
\]
where the frequency operator is now
\[
\hat{\omega} \equiv \left[ \hat{H}_F(\hat{n}) - \hat{H}_F(\hat{n} - 1) \right] /\hbar,
\]
and accounts for the unequally-spaced energy spectrum. As in the previous cases these quadratures obey the commutation relation \([\hat{X}_{1,F}, \hat{X}_{2,F}] = i\hbar /m\omega\).

From Eq. (17), the eigenvalues \(\omega_n^\pm\) of \(\hat{\omega}\), given by \(\hat{\omega}_+|n, \uparrow\rangle = \omega_n^+|n, \uparrow\rangle\) \((n \geq 1)\) and \(\hat{\omega}_-|n, \downarrow\rangle = \omega_n^-|n, \downarrow\rangle\) \((n \geq 0)\), are simply the differences in frequency of neighboring eigenstates of the FW-transformed Dirac oscillator. In the weakly relativistic limit \(\epsilon \ll 1\) they approach the constant value \(\omega\) characteristic of a harmonic oscillator, while for a system deep in the relativistic regime we have \(\omega_n^\pm /\omega \to 0\) for large \(n\), a signature of the increasing anharmonicity of the system.

Ignoring for now the important point that \(\hat{X}_{1,F}\) needs to be transformed back to the Dirac representation to assess possible practical measurement schemes, it could formally be monitored e.g. by continuous QND measurements described by the total Hamiltonian
\[
\hat{H}_\text{tot} = \hat{H}_F + \hbar \omega_b \hat{b}^\dagger \hat{b} + g \hat{X}_{1,F} \hat{b}^\dagger \hat{b}, \tag{18}
\]
where \(\hat{b}\) represents the annihilation operator of an optical mode of frequency \(\omega_b\), a form reminiscent of the optomechanical Hamiltonian of quantum optics. The associated Heisenberg equations of motion \(d\hat{X}_{1,F}/dt = 0\), \(d\hat{X}_{2,F}/dt = -g\hat{b}^\dagger \hat{b} /m\omega\) and \(d\hat{b}/dt = -i(\omega_b + g \hat{X}_{1,F} /\hbar)\hat{b}\) show that the QND variable \(\hat{X}_{1,F}\) is imprinted on the phase of the optical mode \(\hat{b}\), while \(\hat{X}_{2,F}\) is subject to the time measurement backaction from the radiation pressure force \(g\hat{b}^\dagger \hat{b}\). For example, for a Dirac oscillator initially in the state \(|\phi\rangle_F = |\alpha\rangle \otimes (c_1 |\uparrow\rangle + c_2 |\downarrow\rangle)\), with \(|\alpha\rangle\) a coherent state and \(c_1\) and \(c_2\) arbitrary probability amplitudes, we have that \(\Delta \hat{X}_{2,F}^2(0) = \Delta \hat{X}_{1,F}^2(0) = \hbar /2m\omega\). In that case, as shown in Fig. 1(a), the mean value and the uncertainty of the measured observable \(\hat{X}_{1,F}\) remain constant in time, as characteristic of QND measurements, while the mean value and variance of \(\hat{X}_{2,F}\) become
\[
\langle \hat{X}_{2,F}(t) \rangle = \langle \hat{X}_{2,F}(0) \rangle - (gt/m\omega)(\hat{n}_b) \text{ and } \Delta \hat{X}_{2,F}^2(t) = \hbar /2m\omega + (gt/m\omega)^2 \Delta \hat{n}_b^2.
\]

**Implementation.**—Unfortunately, when expressed in the Dirac representation the observables \(\hat{X}_\epsilon = \hat{U}^\dagger \hat{X}_{1,F} \hat{U}\) become in general intricate combinations of \(\hat{x}\), \(\hat{p}\), and spin operators. As shown in Fig. 1(b) in addition to slow oscillations at a frequency of order \(\omega\), these observables are characterized by high-frequency Zitterbewegung oscillations induced by the interference between the positive and negative energy states \([10]\). As expected, they also experience significant relativistic measurement backaction.

Because of the intricate form of \(\hat{X}_{1,\text{nr}}\), QND measurements of the Dirac oscillator for arbitrary \(\epsilon\), while possible in principle, are likely to remain unrealistic in practice. When QND observables are linear combinations of several easily accessible physical quantities such as \(\hat{x}\) and \(\hat{p}\) their measurement can sometimes be realized by time-dependent combinations of them. This is for instance so in the case of the simple harmonic oscillator when using balanced homodyne quadrature measurements of the quadrature \(\hat{Y}_1\) simultaneously access position and momentum. In the present situation, however, the explicit expressions of \(\hat{X}_{1,2}\) in the Dirac representation in-
not commute with $\hat{c}$ of the composite observables in $\hat{c}$, we have

$$\hat{c}_r \neq \hat{c} \hat{r} + \text{h.c.}$$

As we have seen, the relativistic induced anharmonicity results in an excitation frequency that is no longer constant, but rather a quantum observable $\tilde{\omega}_r$ that does not commute with $\hat{x}$ and $\hat{p}$. In that case the measurement of the composite observables in $\hat{c}_r$ requires a coupling between the probe and $\hat{x}$ and $\hat{p}$ that is sensitive to the excitation frequency. However, the time evolution of $\tilde{\omega}_r$ is far slower than the other observables, so that this coupling can be realized by introducing an additional probe to $\tilde{\omega}_r$ and then combining with a probe of the motional observables [15].

The fact that in the weakly and extreme relativistic limits $\epsilon \ll 1$ and $\epsilon \gg 1$ QND variables $\hat{X}_{1,\text{nr}}$ and $\hat{X}_{1,\text{r}}$ are amenable to direct detection suggests exploiting departures from their QND character during continuous measurements as probes of relativistic effects.

This is illustrated for the example of $\hat{X}_{1,\text{nr}}$ in Fig. 2, which shows both its evolution and the evolution of its conjugate variable $\hat{X}_{2,\text{nr}}$ for three values of $\epsilon$. In the weakly relativistic regime $\epsilon = 10^{-3}$ of Figs. 2(a) and 2(d), $\hat{X}_{1,\text{nr}}$ behaves as expected as a QND observable, but it starts departing from this behavior as $\epsilon$ increases. This is apparent also from the temporal increase in its variance, as well as by the onset of Zitterbewegung superposed to damped oscillations at frequency $2\omega$ for large enough $\epsilon$. Fig. 2(g) shows the dependence on $\epsilon$ of $\hat{X}_{1,\text{nr}}$ and $\hat{X}_{2,\text{nr}}$ at a fixed time $t = 4\pi/\omega$, for the same parameters, illustrating the sensitivity of both $\langle \hat{X}_{1,\text{nr}} \rangle$ and its variance on $\epsilon$.

More quantitatively, on the weakly relativistic side, and keeping terms up to the first order of $\epsilon$ in $\hat{H}_D$, the Heisenberg equations for $\hat{X}_{1,\text{nr}}$ become

$$\frac{d\hat{X}_{1,\text{nr}}}{dt} \approx -\frac{\omega_{nr}}{2} [i\hat{X}_{1,\text{nr}} + (2\hat{n} - \hat{\sigma}_z + 1)\hat{X}_{2,\text{nr}}],$$

$$\frac{d\hat{X}_{2,\text{nr}}}{dt} \approx -\frac{\omega_{nr}}{2} [i\hat{X}_{2,\text{nr}} - (2\hat{n} - \hat{\sigma}_z + 1)\hat{X}_{1,\text{nr}}] + \frac{g\hat{b}^\dagger \hat{b}}{m\omega},$$

which illustrates the $\epsilon$-dependence of measurement-induced backaction on $\hat{X}_{1,\text{nr}}$. (The results of Fig. 2 were obtained numerically, keeping $\epsilon$ to all orders.)

Similarly, slightly departing from the extreme relativistic limit the Heisenberg equations for $\hat{X}_{1,\text{r}}$ are

$$\frac{d\hat{X}_{1,\text{r}}}{dt} \approx \frac{1}{8\epsilon} (i[\hat{X}_{1,\text{r}} - \hat{X}_{2,\text{r}}] \frac{\omega_r}{\hbar} + \text{h.c.}),$$

$$\frac{d\hat{X}_{2,\text{r}}}{dt} \approx \frac{1}{8\epsilon} (i[\hat{X}_{1,\text{r}} + \hat{X}_{2,\text{r}}] \frac{\omega_r}{\hbar} + \text{h.c.}) - \frac{g\hat{b}^\dagger \hat{b}}{m\omega}.$$
limit condition, the oscillating frequency \( \omega \sim 10^6 \text{Hz} \) and \( \Delta \chi_1 \sim 10^{-7} \text{m} \). The energy level decreases to a manageable \( 10^{-9} \text{eV} \).

Conclusion and outlook.—We have established that despite the existence of anharmonicity and spin-orbit coupling resulting from relativistic effects one can identify a pair of conjugate QND observables of the one-dimensional Dirac oscillator. They can be monitored relatively simply in the weakly and strongly relativistic limits of the oscillator, and may be used for instance as probes of departures from the weakly or strongly relativistic regimes. We suggest that such QND measurements on Dirac oscillator also provide a simple and universal model to investigate aspects of relativistic quantum measurements \[10\] and the generalized relativistic uncertainty principle \[17–19\]. The existence of these observables may also find applications in the development of new relativistic quantum technologies for gravimeters, clocks and sensors. A laboratory implementation should be possible in artificial Dirac systems.

SUPPLEMENTARY MATERIAL

Transforms between the Dirac representation and the Foldy-Wouthuysen representation

In the Dirac representation the Hamiltonian of a (1+1) dimensional Dirac oscillator can be written in the of form the anti-Jaynes-Cummings model

\[
\hat{H}_D = \eta \hat{a} \hat{a}^+ + \eta^* \hat{a}^+ \hat{a} + mc^2 \hat{\sigma}_z,
\]

(23)

where the coupling strength \( \eta = -i\sqrt{2\epsilon}mc^2 \) with the parameter \( \epsilon = \hbar \omega/mc^2 \) measuring the relativistic level of the oscillator. The matrix forms of the Pauli operators are

\[
\hat{\sigma}_z = \begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix}, \quad \hat{\sigma}_+ = \begin{bmatrix} 0 & 1 \\ 0 & 0 \end{bmatrix}, \quad \hat{\sigma}_- = \begin{bmatrix} 0 & 0 \\ 1 & 0 \end{bmatrix}.
\]

(24)

Then its eigenstates are in the form of dressed states,

\[
|E_n^+\rangle = A_n|n, \uparrow\rangle - iB_n|n-1, \downarrow\rangle,
|E_n^-\rangle = B_{n+1}|n+1, \uparrow\rangle + iA_{n+1}|n, \downarrow\rangle,
\]

(25)

with \( |n\rangle \) the eigenstates of the harmonic oscillator, the Pauli spinors,

\[
|\uparrow\rangle = \begin{bmatrix} 1 \\ 0 \end{bmatrix}, \quad |\downarrow\rangle = \begin{bmatrix} 0 \\ 1 \end{bmatrix},
\]

(26)

and the coefficients,

\[
A_n = \sqrt{(E_n^+ + mc^2)/2E_n^+},
B_n = \sqrt{(E_n^- - mc^2)/2E_n^-},
\]

(27)

associated with the corresponding positive eigenenergies

\[
E_n^+ = mc^2\sqrt{1 + 2\epsilon},
\]

(28)
and the negative eigenenergies
\[ E_n^- = -E_{n+1}^+. \]  
(29)

In the Foldy-Wouthuysen (FW) representation, the complications associated with the spin-orbit coupling can be formally eliminated, which gives the eigenstates \(|n, \uparrow\rangle\) and \(|n, \downarrow\rangle\) corresponding to the positive eigenenergies \(E_n^+\) and the negative eigenenergies \(E_n^-\), respectively.

The eigenstates \(|n, \uparrow\rangle\) and the eigenstates in the Dirac representation \(|E_{n}^{\pm}\rangle\) are related by the unitary transformation

\[ |n, \uparrow\rangle = \hat{U}|E_n^+\rangle, \]
\[ |n, \downarrow\rangle = \hat{U}|E_n^-\rangle, \]  
(30)

where the unitary transformation operators \(\hat{U}\) has the form

\[ \hat{U} = \begin{bmatrix} \hat{A}_n & \frac{i\hat{B}_n}{\sqrt{n}} \hat{a}^\dagger \\ \frac{\hat{B}_n}{\sqrt{n}} & -i\hat{A}_{n+1} \end{bmatrix}, \]  
(31)

where the operators \(\hat{A}_n\) and \(\hat{B}_n\) are given by replacing \(n\) by operator \(\hat{n}\) in the expressions of \(A_n\) and \(B_n\).

The Hamiltonian \(\hat{H}_D\) becomes into a diagonal 2 \(\times\) 2 matrix in the FW representation,

\[ \hat{H}_F(\hat{n}) = \hat{U} \hat{H}_D \hat{U}^\dagger \]
\[ = m\epsilon^2 \begin{bmatrix} \sqrt{1 + 2\hat{n}\epsilon} & 0 \\ 0 & -\sqrt{1 + 2(\hat{n} + 1)\epsilon} \end{bmatrix}. \]  
(32)

and the transformed frequency operator \(\hat{\omega}_e\) is no longer diagonal in the spin states

\[ \frac{\hat{U}^\dagger \hat{\omega}_e \hat{U}}{\omega} = \begin{bmatrix} \chi_e(\hat{n}) & i\sqrt{2}\chi_e(\hat{n})\hat{a}^\dagger \\ -i\sqrt{2}\chi_e(\hat{n}) & -\chi_e(\hat{n} + 1) \end{bmatrix}, \]  
(38)

where

\[ \chi_e(\hat{n}) = \frac{1}{\epsilon}\left(1 - \sqrt{1 - \frac{2\epsilon}{1 + 2\epsilon\hat{n}}} \right). \]  
(39)

The minimum uncertainty state in the Dirac representation is

\[ |\phi\rangle_D = \hat{U}^\dagger|\phi\rangle_F = e^{-\frac{1}{2}|\alpha|^2} \sum_{n=0}^{\infty} \frac{\alpha^n}{\sqrt{n!}} (c_1|E_n^+\rangle + c_2|E_n^-\rangle). \]  
(40)

Note that in the calculation of the transformation we used the equality \(\hat{a}f(\hat{n}) = f(\hat{n} + 1)\hat{a}\).

Then the QND observables for a (1+1) dimensional Dirac oscillator is simply expressed in the FW representation,

\[ \hat{X}_{1,F} = \sqrt{\frac{\hbar}{2m\omega}}(\hat{a}e^{i\hat{\omega}_e t} + e^{-i\hat{\omega}_e t}\hat{a}^\dagger), \]
\[ \hat{X}_{2,F} = i\sqrt{\frac{\hbar}{2m\omega}}(e^{-i\hat{\omega}_e t}\hat{a}^\dagger - \hat{a}e^{i\hat{\omega}_e t}), \]  
(33)

where we defined a frequency operator

\[ \hbar\hat{\omega}_e = \hat{H}_F(\hat{n}) - \hat{H}_F(\hat{n} - 1). \]  
(34)

The corresponding minimum uncertainty state

\[ |\phi\rangle_F = |\alpha\rangle \otimes (c_1|\uparrow\rangle + c_2|\downarrow\rangle). \]  
(35)

If we go back to the Dirac representation, the QND observables become

\[ \hat{X}_{\ell,D} = \hat{U}^\dagger \hat{X}_{\ell,F} \hat{U}, \quad \ell = 1, 2, \]  
(36)

where the operator \(\hat{a}\) and \(\hat{a}^\dagger\) are transformed into the forms with spin-orbit coupling,

\[ \hat{U}^\dagger \hat{a} \hat{U} = \begin{bmatrix} (\hat{A}_n\hat{A}_{n+1} + \frac{\sqrt{n}}{\sqrt{n+1}} \hat{B}_n\hat{B}_{n+1})\hat{a} & i\left(\frac{\hat{A}_n\hat{B}_{n+1}}{\sqrt{n+1}} - \frac{\hat{A}_{n+1}\hat{B}_n}{\sqrt{n}}\right)\hat{a}^\dagger \\ i\hat{a}\left(\frac{\hat{B}_n}{\sqrt{n+1}} - \frac{\hat{B}_{n+1}}{\sqrt{n}}\right) & (\hat{A}_{n+1}\hat{A}_{n+2} + \frac{\sqrt{n+2}}{\sqrt{n+1}} \hat{B}_{n+1}\hat{B}_{n+2})\hat{a} \end{bmatrix}, \]  
(37)

QND observables in the weakly relativistic limit

In the weakly relativistic limit \(\epsilon \sim 0\), we have

\[ \hat{A}_n \approx 1 - \hat{n}\epsilon/4, \quad \hat{B}_n \approx \sqrt{n\epsilon}/\sqrt{2}. \]  
(41)

To the first order of \(\epsilon\), the transforms \(\hat{U}\) of the operators \(\hat{a}\) and \(\hat{a}^\dagger\) are approximated as

\[ \hat{U}^\dagger \hat{a} \hat{U} \approx \hat{a} - \frac{\epsilon}{4}\hat{\sigma}_2 \hat{a} + i\sqrt{\frac{\epsilon}{2}} \hat{\gamma}_+ \]  
(42)

and because

\[ \chi_e(\hat{n}) \approx 1 + \left(\frac{1}{2} - 2\hat{n}\right)\epsilon, \]  
(43)
the transformed frequency operator is approximated as
\[ \frac{\hat{U}^\dagger \hat{\omega} \hat{U}}{\omega} \approx \hat{\sigma}_z + \epsilon - (2\hat{n} + 1)i\hat{\sigma}_z + i\sqrt{2\epsilon}(\hat{a}^\dagger \hat{\sigma}_+ - \hat{\sigma}_-), \] (44)

So in the Dirac representation for a vanishing \( \epsilon \), retaining the leading order terms the QND observables are still in the form of quadrature operators
\[ \hat{X}_1 \approx \hat{X}_{1,\text{nr}} = \sqrt{\frac{\hbar}{2m\omega}}(\hat{a}e^{i\omega z t} + \hat{a}^\dagger e^{-i\omega z t}), \]
\[ = \hat{x} \cos \omega t - \frac{\hat{p}_x}{m\omega} \sin \omega t, \]
\[ \hat{X}_2 \approx \hat{X}_{2,\text{nr}} = -i\sqrt{\frac{\hbar}{2m\omega}}(\hat{a}e^{i\omega z t} - \hat{a}^\dagger e^{-i\omega z t}), \]
\[ = \hat{x} \sin \omega t + \frac{\hat{p}_x}{m\omega} \cos \omega t, \] (45)
associated with a weakly relativistic minimum uncertainty state (40).

|\phi\rangle_D \approx |\alpha\rangle \otimes (|c_1\rangle \uparrow + i|c_2\rangle \downarrow). \] (46)

The quadrature observables can be measured by the combination of the measurements of \( \hat{x}, \hat{p} \), and \( \hat{\sigma}_z \). The measurement scheme is conceptually described by the total Hamiltonian
\[ \hat{H}_{\text{tot}} = \hat{H}_D + \hbar \omega \hat{b}^\dagger \hat{b} + \hat{g} \hat{X}_{1,\text{nr}} \hat{b}^\dagger \hat{b}, \] (47)
where \( \hat{H}_D \) and \( \hbar \omega \hat{b}^\dagger \hat{b} \) are the Hamiltonian of the Dirac oscillator and the optical probe mode, respectively. In the weakly relativistic limit,
\[ \hat{H}_D \approx H_{\text{nr}} = [mc^2 + \hbar \omega (\hat{n} + \frac{1}{2})] \hat{\sigma}_z - \frac{\hbar \omega}{2}, \] (48)
resulting in the Heisenberg equations of motion,
\[ \frac{d\hat{X}_{1,\text{nr}}}{dt} = 0, \quad \frac{d\hat{X}_{2,\text{nr}}}{dt} = -\frac{\hat{p}_x}{m\omega} \hat{b}, \]
\[ \frac{db}{dt} = -i(\omega b + \frac{\hat{g} \hat{X}_{1,\text{nr}}}{\hbar})b, \] (49)
which certifies that \( \hat{X}_{1,\text{nr}} \) is a QND observable and all the measurement backactions are undertaken by \( \hat{X}_{2,\text{nr}} \).

When the Dirac oscillator departs from the weakly relativistic limit, its Hamiltonian, retaining the small terms of next order, becomes
\[ \hat{H}_D \approx H_{\text{nr}} - \frac{\hbar \omega}{8} \hat{\sigma}_z (2\hat{n} - \hat{\sigma}_z + 1)^2 \epsilon. \] (50)

If \( \hat{X}_{1,\text{nr}} \) is still the observable to be measured, it is no longer a QND observable because the Heisenberg equations of motion become
\[ \frac{d\hat{X}_{1,\text{nr}}}{dt} = -\frac{\epsilon \omega \hat{\sigma}_z}{2}(\hat{X}_{1,\text{nr}} + (2\hat{n} - \hat{\sigma}_z + 1)\hat{X}_{2,\text{nr}}), \]
\[ \frac{d\hat{X}_{2,\text{nr}}}{dt} = -\frac{\epsilon \omega \hat{\sigma}_z}{2}(i\hat{X}_{2,\text{nr}} - (2\hat{n} - \hat{\sigma}_z + 1)\hat{X}_{1,\text{nr}}) - \frac{\hat{g} \hat{b}^\dagger \hat{b}}{m\omega}, \]
\[ \frac{db}{dt} = -i(\omega b + \frac{\hat{g} \hat{X}_{1,\text{nr}}}{\hbar})b, \] (51)
which show the measurement backactions affect the evolution of \( \hat{X}_{1,\text{nr}} \) through the coupling between \( \hat{X}_{1,\text{nr}} \) and \( \hat{X}_{2,\text{nr}} \).

To the present relativistic level, the QND observables should also include the small terms of next order,
\[ \hat{X}_1 \approx \sqrt{\frac{\hbar}{2m\omega}}(\hat{a}e^{i\omega z t} + i\frac{\epsilon}{2} \hat{\sigma}_+ e^{i\omega z t} + h.c) + \sqrt{\frac{\hbar}{2m\omega}}\sqrt{2\epsilon}((\hat{a}^\dagger \hat{\sigma}_- - \hat{\sigma}_-)\hat{a}^\dagger + h.c) \sin(\omega t), \]
\[ \hat{X}_2 \approx -i\sqrt{\frac{\hbar}{2m\omega}}(\hat{a}e^{i\omega z t} + i\frac{\epsilon}{2} \hat{\sigma}_+ e^{i\omega z t} - h.c) - \sqrt{\frac{\hbar}{2m\omega}}\sqrt{2\epsilon}((\hat{a}^\dagger \hat{\sigma}_+ - \hat{\sigma}_-)\hat{a}^\dagger + h.c) \sin(\omega t), \] (52)
in which except the terms in Eq. (45) there are additional components involving spin and spin-orbit coupling terms. When the Dirac oscillator slides into more relativistic regime, the QND observables have increasingly complex forms, which means their measurements are challenging.

**QND observables in the extreme relativistic limit**

In the extreme relativistic limit \( \epsilon \gg 1 \), we have
\[ \hat{A}_n \approx \hat{B}_n \approx 1/\sqrt{2}, \] (53)
and then the transforms on \( \hat{a} \) is approximately as
\[ \hat{a}_r = \hat{U}^\dagger \hat{a} \hat{U} \]
\[ \approx \frac{1}{2}(1 + \sqrt{n})\hat{a} + (\frac{\sqrt{n} + 2 - \sqrt{n}}{\sqrt{n} + 1})\frac{1}{4}\hat{\sigma}_- \hat{a} \]
\[ + \frac{i}{2}(\frac{1}{\sqrt{n} + 1} - \frac{1}{n})\hat{a}^\dagger \hat{\sigma}_+ + \hat{\sigma}_- \hat{a}(\frac{1}{\sqrt{n} + 1} - \frac{1}{n})\hat{a}^\dagger \] (54)
and the operator \( \chi_\epsilon(\hat{n}) \) is approximated as
\[ \chi_\epsilon(\hat{n}) \approx \frac{1}{\epsilon}(1 - \sqrt{1 - \frac{1}{n}}), \] (55)
such that the transformed frequency operator \( \hat{\omega}_c \) becomes
\[ \frac{\hat{U}^\dagger \hat{\omega}_c \hat{U}}{\omega} \approx \sqrt{\frac{2}{\epsilon}} \begin{bmatrix} 0 & i(1 - \sqrt{1 - \frac{1}{n}})\hat{a}^\dagger \\
-i\hat{a}(1 - \sqrt{1 - \frac{1}{n}}) & 0 \end{bmatrix}. \] (56)

Then the QND observables are in the forms
\[ \hat{X}_{1,r} \approx \sqrt{\frac{\hbar}{2m\omega}}(\hat{a}_r e^{i\omega z t} + e^{-i\omega z t}\hat{a}_r^\dagger), \]
\[ \hat{X}_{2,r} \approx -i\sqrt{\frac{\hbar}{2m\omega}}(\hat{a}_r e^{i\omega z t} - e^{-i\omega z t}\hat{a}_r^\dagger), \] (57)
In the high excited level $n \gg 1$, the operators $\hat{a}_r$ and $\hat{a}^\dagger_r$ can be approximated as $\hat{a}$ and $\hat{a}^\dagger$, respectively, and then

$$
\dot{X}_{1,r} \approx \frac{1}{2} (\hat{x} + \frac{i\hat{p}}{m\omega}) e^{i\omega_{sr}t} + h.c.,
$$

$$
\dot{X}_{2,r} \approx -\frac{i}{2} ((\hat{x} + \frac{i\hat{p}}{m\omega}) e^{i\omega_{sr}t} - h.c.),
$$

where

$$
\omega_r \approx \omega \sqrt{2/\varepsilon (\sqrt{n} - 1 - \sqrt{n})} \sigma_y,
$$

associated with the approximated minimum uncertainty state

$$
|\phi\rangle_D \approx |\alpha\rangle \otimes \frac{(c_1 + c_2)|\uparrow \rangle - i(c_1 - c_2)|\downarrow \rangle}{\sqrt{2}}.
$$

Similarly, as the case of weakly relativistic side, the measurement scheme is described by $H_{\text{tot}}$ [47]. In the extreme relativistic limit, to the leading-order approximation of $\epsilon$,

$$
\dot{H}_D \approx \dot{H}_t = -\sigma_y mc^2 \sqrt{2\varepsilon n},
$$

based on which the QND measurement of $\hat{X}_{1,r}$ is certified.

When departing from the extreme relativistic limit, the Hamiltonian, retaining the small terms of next order, becomes

$$
\dot{H}_D \approx \dot{H}_t - \sigma_y mc^2 \frac{2}{\sqrt{2\varepsilon n}},
$$

based on which the Heisenberg equations of motion display the breakage of the QND measurement and the influence of the measurement backactions,

$$
\frac{d\hat{X}_{1,r}}{dt} = \frac{1}{8\epsilon} [(i\hat{X}_{1,r} - \hat{X}_{2,r}) \frac{\omega_r}{n} - h.c.],
$$

$$
\frac{d\hat{X}_{2,r}}{dt} = \frac{1}{8\epsilon} [(i\hat{X}_{2,r} + \hat{X}_{1,r}) \frac{\omega_r}{n} + h.c.] - \frac{\hat{b}^\dagger \hat{b}}{m\omega},
$$

$$
\frac{d\hat{b}}{dt} = -\frac{i}{\hbar} (\omega_b + \frac{g}{\hbar} \hat{X}_{1,r}) \hat{b},
$$

$$
\frac{d\hat{\Sigma}_x}{dt} = -2\omega_x \hat{\Sigma}_y - ig \sqrt{\frac{2}{m\hbar\omega}} (\hat{a}(\hat{\Sigma}_x - i\hat{\Sigma}_y) - h.c.)(\hat{b}^\dagger + \hat{b}),
$$

$$
\frac{d\hat{\Sigma}_y}{dt} = -\omega_x \hat{\Sigma}_z + 2\omega_y \hat{\Sigma}_x + g \sqrt{\frac{2}{m\hbar\omega}} (\hat{a}\hat{\Sigma}_x + h.c.)(\hat{b}^\dagger + \hat{b}),
$$

$$
\frac{d\hat{\Sigma}_z}{dt} = \omega_x \hat{\Sigma}_y + ig \sqrt{\frac{2}{m\hbar\omega}} (\hat{a}\hat{\Sigma}_x - h.c.)(\hat{b}^\dagger + \hat{b}),
$$

$$
\frac{d\omega_r}{dt} = \frac{i\sigma_y}{\hbar} g (2\sqrt{n} - \sqrt{n + 1} - \sqrt{n - 1}) \hat{a}(\hat{\Sigma}_x - i\hat{\Sigma}_y)(\hat{b}^\dagger + \hat{b}) + h.c.,
$$

$$
\frac{d\hat{a}}{dt} = -i\hat{a}\omega_r - \frac{i\sigma_y}{\hbar} g \sqrt{\frac{2m\hbar\omega}{2}} (2\sqrt{n} - \sqrt{n + 1} - \sqrt{n - 1}) \hat{a}\hat{\Sigma}_x - \frac{ig}{\sqrt{2m\hbar\omega}} (\hat{\Sigma}_z + i\hat{\Sigma}_y)(\hat{b}^\dagger + \hat{b}),
$$

where $\hat{x}$ and $\hat{p}$ are represented as $\hat{a} = \sqrt{m\omega/2\hbar}(\hat{x} + i\hat{p}/m\omega)$ and $\hat{a}^\dagger = \sqrt{m\omega/2\hbar}(\hat{x} - i\hat{p}/m\omega)$.

**QND measurements scheme in the extreme relativistic limit**

In the extreme relativistic limit the QND observable $\hat{X}_{1,r}$ in Eq. (58) is a composite observable including the excitation frequency $\omega_r$, the position operator $\hat{x}$, and the momentum operator $\hat{p}$. So its measurement requires several correlated probes or one probe with several correlated degree of freedoms.

As an example, we consider a probe with its internal degree of freedoms described by the spin operators $\hat{\Sigma}_{x,y,z}$ and its external degree of freedom by the bosonic operators $\hat{b}$ and $\hat{b}^\dagger$. The measurement scheme is described by the total Hamiltonian

$$
\hat{H}_{\text{tot}} = \hat{H}_t + \hat{H}_p + \hat{H}_m,
$$

where $\hat{H}_t$ is the Hamiltonian [61] for the Dirac oscillator in the extreme relativistic limit, $\hat{H}_p$ is the Hamiltonian for the probe,

$$
\hat{H}_p = \hbar \omega_b \hat{b}^\dagger \hat{b} + \hbar \omega_x \hat{\Sigma}_z,
$$

and $\hat{H}_m$ describes the measurement interaction,

$$
\hat{H}_m = \frac{\hbar \omega_r}{2} \hat{\Sigma}_x + \frac{g}{\sqrt{2}} [(\hat{x} + \frac{i\hat{p}}{m\omega})(\hat{\Sigma}_y - i\hat{\Sigma}_x) + h.c.](\hat{b}^\dagger + \hat{b})
$$

where the spin flip of the probe is dependent on the excitation frequency $\omega_r$ of the Dirac oscillator, and specially the coupling strength of the Jaynes-Cumming-like interaction between the internal degree of freedoms $\hat{\Sigma}_{y,z}$ and the external degree of freedom $\hat{b}$ and $\hat{b}^\dagger$ of the probe is dependent on the momentum and the position of the Dirac oscillator.

The Heisenberg equations of motion are
In the extreme relativistic limit, the excitation frequency of the Dirac oscillator, the internal frequency of the probe, and the measurement strength have the size relationship \( \langle \hat{\omega}_r \rangle \gg \omega_s \gg g/\sqrt{m\hbar \omega} \), so the Heisenberg equations of \( \hat{\Sigma}_{x,y,z} \) can be approximated as

\[
\frac{d\hat{\Sigma}_x}{dt} \approx 0, \quad \frac{d\hat{\Sigma}_y}{dt} = -\hat{\omega}_r \hat{\Sigma}_z, \quad \frac{d\hat{\Sigma}_z}{dt} \approx \hat{\omega}_r \hat{\Sigma}_y, \quad (68)
\]

which gives

\[
\hat{\Sigma}_x(t) \approx \hat{\Sigma}_x(0), \quad \hat{\Sigma}_y(t) \approx \hat{\Sigma}_y(0) \cos \hat{\omega}_r t - \hat{\Sigma}_z(0) \sin \hat{\omega}_r t, \quad \hat{\Sigma}_z(t) \approx \hat{\Sigma}_y(0) \sin \hat{\omega}_r t + \hat{\Sigma}_z(0) \cos \hat{\omega}_r t. \quad (69)
\]

Substituting them into \( \hat{H}_m \) and if the initial internal state of the probe is \( |\uparrow\rangle_s \), resulting in \( \langle \hat{\Sigma}_{x,y}(0) \rangle = 0 \) and \( \langle \hat{\Sigma}_z(0) \rangle = 1 \), the effective form of the measurement interaction becomes into the requested one of QND measurement,

\[
\hat{H}_m \approx \frac{g}{2} [(\hat{x} + \frac{i\hat{p}}{m\omega})e^{i\hat{\omega}_r t} + h.c.](\hat{b}^\dagger + \hat{b}) = g\hat{X}_{1,r}(\hat{b}^\dagger + \hat{b}). \quad (70)
\]
