Topological parafermion corner states
in clock-symmetric non-Hermitian second-order topological insulator

Motohiko Ezawa
Department of Applied Physics, University of Tokyo, Hongo 7-3-1, 113-8656, Japan

Parafermions are a natural generalization of Majorana fermions. We consider a breathing Kagome lattice with complex hoppings by imposing $\mathbb{Z}_3$ clock symmetry in the complex energy plane. It is a non-Hermitian generalization of the second-order topological insulator characterized by the emergence of topological corner states. We demonstrate that the topological corner states are parafermions in the present $\mathbb{Z}_3$ clock-symmetric model. It is also shown that the model is realized in electric circuits properly designed, where the parafermion corner states are observed by impedance resonance. We also construct $\mathbb{Z}_4$ and $\mathbb{Z}_6$ parafermions on breathing square and honeycomb lattices, respectively.

I. INTRODUCTION

Topological quantum computation is a fault-tolerant quantum computation. Majorana fermions provide us with a most studied platform of topological quantum computation. The Majorana operator $\gamma$ satisfies $\gamma^2 = 1$. They are realized as topological boundary states of topological superconductors and Kitaev spin liquids. However, it is impossible to perform universal quantum computation only by the braiding of Majorana fermions since they can reproduce only a part of Clifford gates.

Parafermions are straightforward generalization of Majorana fermions. We consider a breathing Kagome lattice with complex hoppings by imposing $\mathbb{Z}_3$ clock symmetry in the complex energy plane. It is a non-Hermitian generalization of the second-order topological insulator characterized by the emergence of topological corner states. We demonstrate that the topological corner states are parafermions in the present $\mathbb{Z}_3$ clock-symmetric model. It is also shown that the model is realized in electric circuits properly designed, where the parafermion corner states are observed by impedance resonance. We also construct $\mathbb{Z}_4$ and $\mathbb{Z}_6$ parafermions on breathing square and honeycomb lattices, respectively.

II. MAJORANA FERMION AND PARAFERMION

Majorana fermion operators $\gamma_i$ satisfy the relations

$$ (\gamma_j)^2 = 1, \quad \gamma_j \gamma_k = -\gamma_k \gamma_j. \quad (1) $$

Majorana fermions are realized as zero-energy states of a topological superconductor, where particle-hole symmetry (PHS) preserves. It is understood as follows. The PHS operator $\Xi$ acts as $\Xi^{-1} H \Xi = -H$ with the eigen equation $H |\psi\rangle = E |\psi\rangle$. If a particle has an energy $E$, its antiparticle has the energy $-E$ in the presence of PHS. Namely, the wave functions always appear in a particle-hole pair with a pair of energies $(E, -E)$. If the states satisfy the relation $E = -E$, the particle is identical to its antiparticle, and a pair of Majorana fermions emerge. Hence, the zero-energy ($E = 0$) states respecting PHS are Majorana states.

Parafermions are a natural generalization of Majorana fermions. $\mathbb{Z}_d$ parafermions are defined through the relations

$$ (\gamma_j)^d = 1, \quad \gamma_j \gamma_k = \omega \gamma_k \gamma_j, \quad (2) $$

where $\omega = e^{2\pi i/d}$. The minimal model consists of two elements $\gamma_1$ and $\gamma_2$.

III. $\mathbb{Z}_3$ PARAFERMION

We start with a minimal model by setting $d = 3$ in Eq. (2). $\mathbb{Z}_3$ parafermions are represented by the shift operator

$$ \gamma_1 \equiv \tau = \begin{pmatrix} 0 & 0 & 1 \\ 1 & 0 & 0 \\ 0 & 1 & 0 \end{pmatrix}, \quad (3) $$

and the clock operator

$$ \gamma_2 \equiv \sigma = \text{diag.} \left( 1, \omega, \omega^2 \right), \quad (4) $$

where $\omega = e^{2\pi i/3}$. Here, $\tau$ and $\sigma$ satisfy the $\mathbb{Z}_3$ parafermion relations,

$$ \tau^3 = 1, \quad \sigma \tau = \omega \tau \sigma. \quad (5) $$
for (a1) topological phase. When \( t_b = 0 \) for zero-energy states. They are characterized by the properties

\[
\begin{align*}
\tau |\psi_0\rangle &= |\psi_1\rangle, & \tau |\psi_1\rangle &= |\psi_2\rangle, & \tau |\psi_2\rangle &= |\psi_0\rangle, \\
\sigma |\psi_0\rangle &= |\psi_0\rangle, & \sigma |\psi_1\rangle &= \omega |\psi_1\rangle, & \sigma |\psi_2\rangle &= \omega^2 |\psi_2\rangle,
\end{align*}
\]

from which the matrix representations follow.

Then, the \( \mathbb{Z}_3 \) parafermion relations are verified. Namely, it is necessary and sufficient to examine Eqs. (7) and (8) for a triplet set of zero-energy states in order to show that they are \( \mathbb{Z}_3 \) parafermions.

B. Breathing Kagome lattice

We propose a model possessing parafermions on the breathing Kagome lattice. The bulk Hamiltonian is given by

\[
H = \begin{pmatrix}
0 & h_{12} & \omega h_{13} \\
h_{12}^* & 0 & \omega^2 h_{23} \\
\omega h_{13}^* & \omega^2 h_{23}^* & 0
\end{pmatrix},
\]

with

\[
\begin{align*}
h_{12} &= t_a + t_b e^{i k_x}, \\
h_{23} &= t_a + t_b e^{-i (k_x/2 + \sqrt{3} k_y/2)}, \\
h_{13} &= t_a + t_b e^{-i (k_x/2 - \sqrt{3} k_y/2)},
\end{align*}
\]

where we have introduced two hopping parameters \( t_a \) and \( t_b \), corresponding to the magenta link and the cyan link along the horizontal axis in Fig. (a4). The hopping parameters along the other two triangle sides are given by \( \omega t_a \) and \( \omega^2 t_a \) for a magenta triangle, and \( \omega t_b \) and \( \omega^2 t_b \) for a cyan triangle. This model is non-Hermitian due to the presence of \( \omega \).

A comment is in order with respect to the breathing Kagome model. It is a typical model for the conventional second-order topological insulator, where the factor \( \omega \) is absent and it is Hermitian. The present generalization of the breathing Kagome lattice model provides us with a new type of non-Hermitian second-order topological insulators.

C. Clock symmetry

The Hamiltonian \( H \) has \( \mathbb{Z}_3 \) clock symmetry,

\[
\tau H (k) \tau^\dagger = \omega H (Rk),
\]

where \( R \) rotates the momentum by 120 degrees as

\[
R (k_x, 0) = \left( \frac{-k_x}{2}, \frac{\sqrt{3} k_y}{2} \right), \quad R \left( \frac{-k_x}{2}, \frac{\sqrt{3} k_y}{2} \right) = \left( \frac{-k_x}{2}, -\frac{\sqrt{3} k_y}{2} \right), \quad R \left( \frac{-k_x}{2}, -\frac{\sqrt{3} k_y}{2} \right) = (k_x, 0),
\]

satisfying \( \varepsilon_0 + \omega \varepsilon_n + \omega^2 \varepsilon_n = 0 \). The system is necessarily non-Hermitian because the eigen energies are complex except for zero-energy states.

A. Zero-energy parafermion states

It follows from Eq. (6) that only the zero-energy states form a set of degenerate states respecting \( \mathbb{Z}_3 \) clock symmetry. They are \( \mathbb{Z}_3 \) parafermion states. We denote them as \( |\psi_0\rangle, |\psi_1\rangle \) and

![FIG. 1: (a) Breathing Kagome lattice, (b) breathing square lattice and (c) breathing honeycomb lattice. The hopping parameters are \( t_a = 0 \) for (a1) ~ (c1), \( t_a, t_b \neq 0 \) for (a2) ~ (c2), and \( t_b = 0 \) for (a3) ~ (c3). There emerge three, four and six parafermion corner states in the topological phase. When \( t_a = 0 \), they are isolated as marked by blue disks in (a1), (b1) and (c1), respectively. The unit cells are given in (a4), (b4) and (c4) with the hopping parameters indicated.](image-url)
We show the bulk energy spectrum in Fig. 3(a) and Fig. 4(a), insulator non-Hermitian Hamiltonian in two ways. On is a point-gap insulator slightly deviates from the region geometry as indicated by the magenta flat-line segment in (d). The geometry as in (c), but zero-energy corner states emerge in triangle the topological phase, gapless edge states are absent in nanoribbon size effect.

making the energy spectrum have $Z_3$ symmetry in the complex plane as in Eq. (6). In addition, there is an anti-unitary symmetry

$$KH(k) = H^*(k), \quad (17)$$

where $K$ implies complex conjugate. It leads to reflection symmetry between $E$ and $E^*$. As a result, the energy spectrum has $C_3\sigma$ symmetry in the complex plane, which consists of the three-fold rotational symmetry and three reflection symmetries.

The system also has a generalized chiral symmetry for a three-band model:  

$$\sigma H \sigma^{-1} = H_1, \quad \sigma H_1 \sigma^{-1} = H_2, \quad H + H_1 + H_2 = 0. \quad (18)$$

We show the bulk energy spectrum in Fig. 3(a) and Fig. 4(a), where $C_3\sigma$ symmetry is manifest for all parameters.

### D. Phase diagram

The notion of insulator and metal is generalized to the non-Hermitian Hamiltonian in two ways. On is a point-gap insulator where $|E|$ has a gap. The other is a line-gap insulator where $\text{Re}[E]$ or $\text{Im}[E]$ has a gap. In our model, we adopt the definition of the point-gap insulator due to $Z_3$ symmetry. We are able to determine the energy spectrum analytically at the $\Gamma = (0, 0)$ point as

$$E(0, 0) = (t_a + t_b), \quad \omega(t_a + t_b), \quad \omega^2(t_a + t_b), \quad (19)$$

and at the $K = (4\pi/3, 0)$ and $K' = (-4\pi/3, 0)$ points as

$$E^3(\pm 4\pi/3, 0) = (t_a + t_b) (t_a - 2t_b) (2t_a - t_b). \quad (20)$$

The point gap closes at the $K$ and $K'$ points for $t_a/t_b = 1/2$, $t_a/t_b = 2$, and at the $K$, $K'$ and $\Gamma$ points for $t_a/t_b = -1$, as in Fig. 2(b). This is also confirmed numerically by calculating the band spectrum as in Fig. 2(b).

### E. Topological number

The topological number is given by the Berry phase defined by

$$Q \equiv \frac{1}{2\pi i} \int_{0}^{2\pi} \langle \psi_0(k_x, 0) | \partial_{k_x} | \psi_0(k_x, 0) \rangle \, dk_x, \quad (21)$$

where $\psi_0$ is the eigen function of the Hamiltonian $(9)$ for the bulk, whose eigen energy is real along the $k_x$ axis (i.e., $k_y = 0$). We calculate it numerically, whose results are shown in Fig. 2(a). We find $Q = 1$ for $-1 < t_a/t_b < 1/2$, and $Q = 0$ for $t_a/t_b < -1$ and $t_a/t_b > 2$, while it continuously changes from 1 to 0 for $1/2 < t_a/t_b < 2$. In fact, $Q$ is quantized in the insulator phases.

### F. Edge states

We calculate the energy spectrum in a nanoribbon numerically. Edge states are observed in Fig. 3(a2)~(h2), where the complex energy spectrum is shown for various momentum $k$ specified by color. Three-fold symmetry is slightly broken in nanoribbon geometry. It is due to the finite size effect of a nanoribbon.
FIG. 4: Complex energy spectrum (a1)∼(h1) for the bulk, (a2)∼(h2) for a nanoribbon and (a3)∼(h3) for a triangle, where the hopping parameters are (a1)∼(a3) \( t_a = -1.5t_b \), (b1)∼(b3) \( t_a = -t_b \), (c1)∼(c3) \( t_a = -0.25t_b \), (d1)∼(d3) \( t_a = 0.25t_b \), (e1)∼(e3) \( t_a = 0.5t_b \), (f1)∼(f3) \( t_a = 1.25t_b \), (g1)∼(g3) \( t_a = 2t_b \) and (h1)∼(h3) \( t_a = 2.5t_b \). The horizontal axis is \( \text{Im}[E] \) and the vertical axis is \( \text{Re}[E] \).

The numerical value on the horizontal axis in (a1)∼(h1) is the energy in unit of \( t_b \). Color indicates the momentum of along the nanoribbon direction, where red color indicates \( k = \pi \) and blue color indicates \( k = 0 \) in a nanoribbon. We have used a nanoribbon with width 128 for (a2)∼(h2), and a triangle with size 16 for (a3)∼(h3). The magenta dots in (c3) and (d3) represent the topological corner states.

FIG. 5: (a1)∼(h1) Bulk band structure, where the horizontal axis is \( k_x \). Color in the spectrum indicates \( k_y \), where red color indicates \( k_y = 0 \) while cyan color indicates \( k_y = 2\pi/\sqrt{3} \). (a2)∼(h2) Band structure of a nanoribbon, where the horizontal axis is \( k \). The vertical axis is \( |E| \). The values of \( t_a \) and \( t_b \) are the same as in Fig.4. It is notable that there are no gapless edge states in the topological phase.

We present the band structure of a nanoribbon in Fig.5(a2)∼(h2), where we observe the absence of gapless edge states in the topological phase.

G. Corner states

We calculate the energy spectrum in triangle geometry numerically. \( C_3 \) symmetry is manifest as shown in Fig.3(a) and in Fig.4(a3)∼(h3). It is because the triangle respects \( Z_3 \) clock symmetry. We find zero-energy states in the region \(-1 < t_a/t_b < 1/2\), as indicated by a magenta line in Fig.2(d). We also show the energy spectrum as a function of \( t_a/t_b \) in Fig.3(b), where the emergence of the zero-energy states is manifest in the topological phase.

Consequently, the present model is a second-order topological insulator in the region \(-1 < t_a/t_b < 1/2\), being characterized by the emergence of topological corner states.

It is possible to obtain explicitly the wave functions of the three corner states by numerical calculation. We have numerically confirmed that they satisfy the relations (7) and (8). Therefore, they are \( Z_3 \) parafermions.

H. Electric-circuit implementation

Electric circuits are governed by the Kirchhoff current law. By making the Fourier transformation with respect to time, the Kirchhoff current law is expressed as

\[
I_a(\omega) = \sum_b J_{ab}(\omega)V_b(\omega),
\]

where \( I_a \) is the current between node \( a \) and the ground, while \( V_b \) is the voltage at node \( b \). The matrix \( J_{ab}(\omega) \) is called the circuit Laplacian. Once the circuit Laplacian is given, we can uniquely setup the corresponding electric circuit. By equating it with the Hamiltonian \( H \),

\[
J_{ab}(\omega) = i\omega H_{ab}(\omega),
\]

it is possible to simulate various topological phases of the Hamiltonian by electric circuit. The relations be-
the capacitance whose value is $X_1 i\omega C$, evaluate the positive and negative hoppings in the Hamiltonian, circuit are determined by this formula. The parameters in the Hamiltonian and in the electric circuit are tuned by this formula. The circuit Laplacian is constructed as follows. To simulate the positive and negative hoppings in the Hamiltonian, we replace them with the capacitance $i\omega C$ and the inductance $1/i\omega L$, respectively. We note that $\sin k = (e^{ik} - e^{-ik})/2i$ represents an imaginary hopping in the tight-bind model. The imaginary hopping is realized by an operational amplifier [26].

We thus make the following replacements with respect to hoppings in the Hamiltonian to derive the circuit Laplacian: (i) $+X \rightarrow i\omega C_X$ for $X = t_a$ and $t_b$, where $C_X$ represents the capacitance whose value is $X$ [pF]. (ii) $-X \rightarrow 1/i\omega L_X$ for $X = t_a/2$ and $t_b/2$, where $L_X$ represents the inductance whose value is $X$ [H].

We explicitly study the breathing Kagome lattice described by (9), where the electric circuit is given by Fig.6(a). The Hamiltonian (9) is decomposed into

$$H = H_1 + H_2,$$

with

$$H_1 = \begin{pmatrix} 0 & h_{12}^* & -\frac{1}{2} h_{13} \\ h_{12} & 0 & \omega^2 h_{23} \\ -\frac{1}{2} h_{13}^* & \omega^2 h_{23}^* & 0 \end{pmatrix}$$

and

$$H_2 = \frac{\sqrt{3}}{2} \begin{pmatrix} 0 & 0 & i h_{13} \\ 0 & 0 & -i h_{23} \\ i h_{13}^* & -i h_{23}^* & 0 \end{pmatrix},$$

where $H_1$ is Hermitian ($H_1^\dagger = H_1$), and $H_2$ is anti-Hermitian ($H_2^\dagger = -H_2$). It is necessary to construct imaginary hopping Hamiltonians

$$\frac{\sqrt{3}}{2} t_a \begin{pmatrix} 0 & 0 & i \\ 0 & 0 & 0 \\ i & 0 & 0 \end{pmatrix},$$

and

$$\frac{\sqrt{3}}{2} t_a \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & -i \\ 0 & -i & 0 \end{pmatrix}$$

for the magenta lines in Fig.6(a). They are constructed by using operational amplifiers and resistors.

We review a negative impedance converter with current inversion based on an operational amplifier with resistors [26]. The voltage-current relation for the operational amplifier circuit is given by

$$\begin{pmatrix} I_1 \\ I_2 \end{pmatrix} = \frac{1}{R} \begin{pmatrix} -\nu & \nu \\ -1 & 1 \end{pmatrix} \begin{pmatrix} V_1 \\ V_2 \end{pmatrix},$$

with $\nu = R_b/R_a$, where $R$, $R_a$ and $R_b$ are the resistances in an operational amplifier: See Fig.6(d). We note that the resistors in the operational amplifier circuit are tuned to be $\nu = 1$ in the literature [26] so that the system becomes Hermitian, where the corresponding Hamiltonian represents a spin-orbit interaction.

In this paper, we use two negative impedance converters parallely connected with the opposite direction as in Fig.6(c). The circuit Laplacian due to these two converters is given by

$$\frac{1}{R} \left[ \begin{pmatrix} -\nu & \nu \\ -1 & 1 \end{pmatrix} + \begin{pmatrix} 1 & -1 \\ \nu & -\nu \end{pmatrix} \right] = \frac{1}{R} \begin{pmatrix} 1 & -\nu & -1 \\ \nu & -1 & -\nu \end{pmatrix}.$$

It corresponds to the Hamiltonian

$$H = \frac{1}{i\omega R} \begin{pmatrix} 1 & -\nu & -1 \\ -\nu & 1 & -\nu \end{pmatrix},$$

It is embedded in the $3 \times 3$ matrix as

$$H = \frac{1}{i\omega R} \begin{pmatrix} 0 & 0 & 0 \\ 1 -\nu & 0 & 0 \\ 0 & \nu -1 & 0 \end{pmatrix},$$

where we have set

$$\frac{\sqrt{3}}{2} t_a = \frac{1}{\omega R} -\nu$$

with $\nu < 1$, and

$$H = \frac{1}{i\omega R} \begin{pmatrix} 0 & 0 & 0 \\ 0 & 1 -\nu & 0 \\ 0 & 0 & \nu -1 \end{pmatrix},$$

where we have set

$$\frac{\sqrt{3}}{2} t_a = \frac{\nu -1}{\omega R}$$
with \( \nu > 1 \). These matrices are different from Eqs.\((27)\) and \((28)\) by the diagonal terms. They are cancelled by adding a resistor (for \( \nu > 1 \)) or an operational amplifier (for \( \nu < 1 \)) with the amount of

\[
\frac{1 - \nu}{i \omega R}
\]

between a lattice site and the ground.

\section{Impedance resonance}

The zero-energy parafermion corner states are well observed by impedance resonance, which is defined\(^{25}\) by

\[
Z_{ab} = V_a / I_b = G_{ab}
\]

where \( G = J^{-1} \) is the Green function. It diverges at the frequency where the admittance is zero \( (J = 0) \). Taking the nodes \( a \) and \( b \) at two corners, we show the impedance in topological, metallic and trivial phases in Figs.\(7(a)\)~\(7(c)\), respectively. A strong impedance peak is observed at the critical frequency where the admittance is zero \( (G = 0) \), which is defined by impedance resonance, which is defined\(^{25}\) by

\[
Z_{IV} \equiv \frac{C}{R} = \frac{C}{i \omega R}
\]

where \( C \) is the same as in \((b)\).

\section{Z\(_4\) PARAFERMION}

We proceed to a model with \( d = 4 \). \( Z_4 \) parafermions are represented by the shift operators\(^{23,32,35}\)

\[
\gamma_1 \equiv \tau = \begin{pmatrix} 0 & 0 & 0 & 1 \\ 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \end{pmatrix},
\]

and the clock operator\(^{23,32,35}\)

\[
\gamma_2 \equiv \sigma = \text{diag.}(1, i, -1, -i).
\]

Here, \( \tau \) and \( \sigma \) satisfy the \( Z_4 \) parafermion relations,

\[
\tau^4 = \sigma^4 = 1, \quad \tau \sigma = \omega \sigma \tau.
\]

In the \( Z_4 \) clock-symmetric model, the energy spectrum is composed of quartets \( E_n^{(0,1,2,3)} \), \( n = 0, 1, 2, \cdots \),

\[
E_n^{(0,1,2,3)} = \epsilon_n, \quad i \epsilon_n, \quad -\epsilon_n, \quad -i \epsilon_n.
\]

The system is necessarily non-Hermitian because the eigen energies are complex except for zero-energy states.

\subsection{Zero-energy parafermion states}

It follows from Eq.\((41)\) that only the zero-energy states form a set of degenerate states respecting \( Z_4 \) clock symmetry. They are \( Z_4 \) parafermion states. We denote them as \( |\psi_0\rangle, |\psi_1\rangle, |\psi_2\rangle \) and \( |\psi_3\rangle \). They are characterized by the properties

\[
\tau |\psi_0\rangle = |\psi_1\rangle, \quad \tau |\psi_1\rangle = |\psi_2\rangle, \quad \tau |\psi_2\rangle = |\psi_3\rangle, \quad \tau |\psi_3\rangle = |\psi_0\rangle,
\]

\[
|\psi_0\rangle = |\psi_0\rangle, \quad |\psi_1\rangle = i |\psi_1\rangle, \quad |\psi_2\rangle = -i |\psi_2\rangle, \quad |\psi_3\rangle = -i |\psi_3\rangle,
\]

from which the matrix representations \((3)\) and \((4)\) follow. Then, the \( Z_4 \) parafermion relations \((5)\) are verified. Namely, it is necessary and sufficient to examine Eqs.\((7)\) and \((8)\) for a triplet set of zero-energy states in order to show that they are \( Z_4 \) parafermions.

\subsection{Breathing square lattice}

The quadrupole insulator has been proposed on the breathing square lattice\(^{24}\). We propose a model possessing \( Z_4 \) parafermions on the breathing square lattice. The bulk Hamiltonian is given by

\[
H = \begin{pmatrix} 0 & f_x^* & 0 & i f_y^* \\ -f_x & 0 & i f_y & 0 \\ 0 & -i f_y & 0 & -f_x \\ -i f_y & 0 & f_x^* & 0 \end{pmatrix},
\]

with

\[
f_x = t_a + t_b e^{i k_x}, \quad f_y = t_a + t_b e^{i k_y},
\]

where we have introduced two hopping parameters \( t_a \) and \( t_b \), which are shown in Fig.\(7(b4)\).

The Hamiltonian \((46)\) has \( Z_4 \) clock symmetry\(^{24}\)

\[
\tau H (k) \tau^\dagger = -i H (Rk),
\]

where \( R \) rotates the momentum by 90 degrees as

\[
R(k_x, 0) = (0, -k_y), \quad R(0, k_y) = (k_x, 0),
\]

making the energy spectrum have \( Z_4 \) symmetry in the complex plane as in Eq.\((41)\).
by a combination of operational amplifier and capacitors. Therefore, they are the four corner states. We have confirmed that they satisfy the emergence of topological corner states.

\[ C_{4v} \] symmetry is manifest in the topological phase. It is possible to obtain numerically the wave functions of the four corner states. We have confirmed that they satisfy the relations (7) and (8). Therefore, they are \( Z_4 \) parafermions.

![Fig. 9](image)

**Fig. 9:** (a) Electric circuit implementation of the breathing square model shown in Fig.1(b), where the hopping parameters correspond to those in Fig.1(b). (b) Configuration of negative impedance converter with current inversion realizing imaginary hopping, and (c) the one realizing nonreciprocal hopping, corresponding to those in (a).

### C. Edge and corner states

The topological number is defined by (21), where \( \psi_0 \) is the eigen function of the Hamiltonian (46) for the bulk. We find the topological insulator phase for \(|t_a/t_b| < 1\), where \( Q = 1 \) and the trivial insulator phase for \(|t_a/t_b| > 1\), where \( Q = 0 \).

We calculate the energy spectrum in square geometry numerically. \( C_{4v} \) symmetry is manifest as shown in Fig.8(a). It is because the square lattice respects \( Z_4 \) clock symmetry. We also show the energy spectrum as a function of \( t_a/t_b \) in Fig.8(b), where the emergence of the zero-energy states is manifest in the topological phase.

Consequently, the present model is a second-order topological insulator in the region \(|t_a/t_b| < 1\), being characterized by the emergence of topological corner states.

It is possible to obtain numerically the wave functions of the four corner states. We have confirmed that they satisfy the relations (7) and (8). Therefore, they are \( Z_4 \) parafermions.

### D. Electric-circuit implementation

In the Hamiltonian (46), there are nonreciprocal hopping terms along the \( x \) axis. Nonreciprocal hopping is constructed by a combination of operational amplifier and capacitors, \( \gamma_1 \equiv \tau \equiv \begin{pmatrix} 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \end{pmatrix} \), with the clock operator \( \gamma_2 \equiv \sigma = \begin{pmatrix} 1, \omega, \omega^2, \omega^3, \omega^4, \omega^5 \end{pmatrix} \).

It corresponds to the Hamiltonian

\[ H = C \begin{pmatrix} \begin{pmatrix} -1 & 1 \\ -1 & 1 \end{pmatrix} \end{pmatrix} \begin{pmatrix} V_1 \\ V_2 \end{pmatrix} \]  

(51)

We add an inductor or a capacitor in order to cancel the diagonal term.

We construct an electric circuit as shown in Fig.9(a), where the \( x \) axis is constructed by Fig.9(c) and the \( y \) axis is constructed by Fig.9(b).

![Fig. 10](image)

**Fig. 10:** Energy spectrum of a hexagon shown in Fig.1(c2). (a) the vertical axis is \( \text{Re}[E] \) and the horizontal axis is \( \text{Im}[E] \), while (b) the vertical axis is \( |E| \) and the horizontal axis is \( t_a/t_b \). Color indicates the value of \( t_a/t_b \) in (a). \( C_{6v} \) symmetry in the complex energy plane is manifest in (a). The emergence of zero-energy corner states is clear in (b). The green curves are calculated from the bulk Hamiltonian, while red curves are calculated based on the hexagon. The cyan curve is the energy at the \( \Gamma \) point, while the blue curve is the energy at the \( K \) point calculated based on the bulk Hamiltonian.

### V. \( Z_6 \) PARAFERMION

Finally, we construct a \( Z_6 \) parafermion model. The parafermion operators are represented by the shift operator

\[ \gamma_3 \equiv \sigma = \begin{pmatrix} 1, \omega, \omega^2, \omega^3, \omega^4, \omega^5 \end{pmatrix} \]  

(54)

and the clock operator

\[ \gamma_6 \equiv \tau = \begin{pmatrix} 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \end{pmatrix} \]  

(53)

Here, \( \tau \) and \( \sigma \) satisfy the \( Z_6 \) parafermion relations,

\[ \tau^6 = \sigma^6 = 1, \quad \tau \sigma = \omega \sigma \tau. \]  

(55)

In the \( Z_6 \) clock-symmetric model, the energy spectrum is composed of sextets \( E_n^{(0,1,2,3,4,5)}, n = 0, 1, 2, \ldots \),

\[ E_n^{(0,1,2,3,4,5)} = \varepsilon_n, \quad \omega \varepsilon_n, \quad \omega^2 \varepsilon_n, \quad \omega^3 \varepsilon_n, \quad \omega^4 \varepsilon_n, \quad \omega^5 \varepsilon_n. \]  

(56)

The system is necessarily non-Hermitian because the eigen energies are complex except for zero-energy states.

A Hermitian second-order topological insulator has been proposed on the breathing honeycomb lattice. We generalize it to a non-Hermitian model with \( Z_6 \) clock symmetry by introducing complex hoppings. The bulk Hamiltonian is defined on the breathing honeycomb lattice and given by
We diagonalize this Hamiltonian for a hexagon shown in Fig1(c2). $C_{6v}$ symmetry is manifest in the complex energy plane as in Fig1(a). Furthermore, we find six zero-energy topological corner states for $|t_a/t_b| < 1$, as shown in Fig1(b). We also find the trivial insulator phase for $t_a/t_b < -2$ and $t_a/t_b > 1$. Additionally, there is metallic phase for $-2 < t_a/t_b < -1$.

VI. CONCLUSION

We have constructed a $\mathbb{Z}_4$ parafermion model on the breathing Kagome lattice, a $\mathbb{Z}_4$ parafermion model on the breathing honeycomb lattice. These model exhaust all the possible realization of $\mathbb{Z}_d$ parafermions since there are only three-fold, four-fold and six-fold rotational symmetries that are compatible with the periodic lattices. We note that two-fold symmetry corresponds to Majorana fermions.
