# Graph of $u v$-paths in 2-connected graphs * 

Eduardo Rivera-Campo<br>Departamento de Matemáticas<br>Universidad Autónoma Metropolitana - Iztapalapa<br>erc@xanum.uam.mx

#### Abstract

For a 2-connected graph $G$ and vertices $u, v$ of $G$ we define an abstract graph $\mathcal{P}\left(G_{u v}\right)$ whose vertices are the paths joining $u$ and $v$ in $G$, where paths $S$ and $T$ are adjacent if $T$ is obtained from $S$ by replacing a subpath $S_{x y}$ of $S$ with an internally disjoint subpath $T_{x y}$ of $T$. We prove that $\mathcal{P}\left(G_{u v}\right)$ is always connected and give a necessary and a sufficient condition for connectedness in cases where the cycles formed by the replacing subpaths are restricted to a specific family of cycles of $G$.

## 1 Introduction

For any vertices $x, y$ of a path $L$, we denote by $L_{x y}$ the subpath of $L$ that joins $x$ and $y$. Let $G$ be a 2-connected graph and $u$ and $v$ be vertices of $G$. The $u v$ path graph of $G$ is the graph $\mathcal{P}\left(G_{u v}\right)$ whose vertices are the paths joining $u$ and $v$ in $G$, where two paths $S$ and $T$ are adjacent if $T$ is obtained from $S$ by replacing a subpath $S_{x y}$ of $S$ with an internally disjoint subpath $T_{x y}$ of $T$. The $u v$ path graph $\mathcal{P}\left(G_{u v}\right)$ is closely related to the graph $G(P, f)$ of $f$-monotone paths on a polytope $P$ (see C. A. Athanasiadis et al [1, 2]), whose vertices are the $f$-monotone paths on $P$ and where two paths $S$ and $T$ are adjacent if there is a 2-dimensional face $F$ of $P$ such that $T$ is obtained

[^0]from $S$ by replacing an $f$-monotone subpath of $S$ contained in $F$ with the complementary $f$-monotone subpath of $T$ contained in $F$.

In Section 2 we show that the graphs $\mathcal{P}\left(G_{u v}\right)$ are always connected as is the case for the graphs $G(P, f)$.

If $S$ and $T$ are adjacent paths in a $u v$-path graph $\mathcal{P}\left(G_{u v}\right)$, then $S \cup T$ is a subgraph of $G$ consisting of a unique cycle $\sigma$ joined to $u$ and $v$ by disjoint paths $P_{u}$ and $P_{v}$. See Figure 1.

Figure 1: $S \cup T$
Let $\mathcal{C}$ be a set of of cycles of $G$; the uv-path graph of $G$ defined by $\mathcal{C}$ is the spanning subgraph $\mathcal{P}_{\mathcal{C}}\left(G_{u v}\right)$ of $\mathcal{P}\left(G_{u v}\right)$ where two paths $S$ and $T$ are adjacent if and only if the unique cycle $\sigma$ which is contained in $S \cup T$ lies in $\mathcal{C}$. A graph $\mathcal{P}_{\mathcal{C}}\left(G_{u v}\right)$ may be disconnected.

The uv path graph $\mathcal{P}\left(G_{u v}\right)$ is also related to the well-known tree graph $\mathcal{T}(G)$ of a connected graph $G$, studied by R. L. Cummins [3], in which the vertices are the spanning trees of $G$ and the edges correspond to pairs of trees $S$ and $R$ which are obtained from each other by a single edge exchange. As in the $u v$ path graph, if two trees $S$ and $R$ are adjacent in $\mathcal{T}(G)$, then $S \cup R$ is a subgraph of $G$ containing a unique cycle. X. Li et al [5] define, in an analogous way, a subgraph $\mathcal{T}_{\mathcal{C}}(G)$ of $\mathcal{T}(G)$ for a set of cycles $\mathcal{C}$ of $G$ and give a necessary condition and a sufficient condition for $\mathcal{T}_{\mathcal{C}}(G)$ to be connected. In sections 3 and 4 we show that the same conditions apply to $u v$ path graphs $\mathcal{P}_{\mathcal{C}}\left(G_{u v}\right)$.

Similar results are obtained by A. P. Figueroa et al [4] with respect to the perfect matching graph $\mathcal{M}(G)$ of a graph $G$ where the vertices are the perfect matchings of $G$ and in which two matchings $L$ and $N$ are ajacent if their symmetric difference is a cycle of $G$. Again, if $L$ and $N$ are adjacent matchings in $\mathcal{M}(G)$, then $L \cup M$ contains a unique cycle of $G$.

For any subgraphs $F$ and $H$ of a graph $G$, we denote by $F \Delta H$ the subgraph of $G$ induced by the set of edges $(E(F) \backslash E(H)) \cup(E(H) \backslash E(F))$.

## 2 Preliminary results

In this section we prove that the $u v$ path graph is connected for any 2 connected graph $G$ and give an upper bound for the diameter of a graph $\mathcal{P}\left(G_{u v}\right)$.
Theorem 1. Let $G$ be a 2-connected graph. The uv-path graph $\mathcal{P}\left(G_{u v}\right)$ is connected for every pair of vertices $u, v$ of $G$.

Proof. For any different $u v$ paths $Q$ and $R$ in $G$ denote by $n(Q, R)$ the number of consecutive initial edges $Q$ and $R$ have in common. Assume the result is false and choose two $u v$ paths $S: u=x_{0}, x_{1}, \ldots, x_{s}=v$ and $T: u=$ $y_{0}, y_{1}, \ldots, y_{t}=v$ in different components of $\mathcal{P}\left(G_{u v}\right)$ for which $n^{*}=n(S, T)$ is maximum.

Since edges $x_{n^{*}} x_{n^{*}+1}$ and $y_{n^{*}} y_{n^{*}+1}$ are not equal, $x_{n^{*}+1} \neq y_{n^{*}+1}$. Let $j=\min \left\{i: x_{n^{*}+i} \in V(T)\right\}$ and $k=\min \left\{i: y_{n^{*}+i} \in V(S)\right\}$ and let $l$ and $m$ be integers such that $y_{l}=x_{n^{*}+j}, x_{m}=y_{n^{*}+k}$. Consider the path:

$$
S^{\prime}: u=x_{0}, x_{1}, \ldots, x_{n^{*}}, y_{n^{*}+1}, y_{n^{*}+2}, \ldots, y_{n^{*}+k}, x_{m+1}, x_{m+2}, \ldots, x_{s}=v
$$

Paths $S$ and $S^{\prime}$ are adjacent in $\mathcal{P}\left(G_{u v}\right)$ since $S^{\prime}$ is obtained from $S$ by replacing the subpath $x_{n^{*}}, x_{n^{*}+1}, \ldots, x_{m}$ of $S$ with the subpath $y_{n^{*}}, y_{n^{*}+1}, \ldots$, $y_{n^{*}+k}$ of $S^{\prime}$. Notice that $n\left(S^{\prime}, T\right) \geq n(S, T)+1$ since $x_{0} x_{1}, x_{1} x_{2}, \ldots, x_{n^{*}-1} x_{n^{*}}$, $x_{n^{*}} y_{n^{*}+1} \in E\left(S^{\prime}\right) \cap E(T)$. By the choice of $S$, and $T$, paths $S^{\prime}$ and $T$ are connected in $P\left(G_{u v}\right)$. This implies that $S$ and $T$ are also connected in $\mathcal{P}\left(G_{u v}\right)$ which is a contradiction.

For any two vertices $u$ and $v$ of a connected graph $G$ we denote by $d_{G}(u, v)$ the distance between $u$ and $v$ in $G$, that is the length of a shortest $u v$ path in $G$. The diameter of a connected graph $G$ is the maximum distance among pairs of vertices of $G$. For a path $P$, we denote by $l(P)$ the length of $P$.

Theorem 2. Let $u$ and $v$ be vertices of a 2-connected graph $G$. The diameter of the graph $\mathcal{P}\left(G_{u v}\right)$ is at most $2 d_{G}(u, v)$.

Proof. Let $S$ and $T$ be $u v$ paths in $G$ and let $P$ be a shortest $u v$ path in $G$. From the proof of Theorem 1 one can see that there are two paths $Q_{S}$ and $Q_{T}$ in $\mathcal{P}\left(G_{u v}\right)$, each with length at most $l(P)$, joining $S$ to $P$ and $T$ to $P$, respectively. Clearly $Q_{S} \cup Q_{T}$ contains a path joining $S$ and $T$ in $\mathcal{P}\left(G_{u v}\right)$ with length at most $2 l(P)=2 d_{G}(u, v)$.

In Figure 2 we show a 2-connected graph $G^{2}$ and paths $S$ and $T$ joining vertices $u$ and $v$ of $G^{2}$ such that $d_{G^{2}}(u, v)=2$ and $d_{\mathcal{P}\left(G_{u v}^{2}\right)}(S, T)=4$. For any positive integer $k>2$ the graph $G^{2}$ can be extended to a graph $G^{k}$ such that $d_{G^{k}}(u, v)=k$ and that the diameter of $\left.\mathcal{P}\left(G_{u v}^{k}\right)\right)$ is $2 k$. This shows that Theorem 2 is tight.

Figure 2: Graph $G^{2}$ and paths $S$ and $T$.

## 3 Necessary condition

Let $u$ and $v$ be vertices of a 2-connected graph $G$ and $S$ and $T$ be two $u v$ paths adjacent in $\mathcal{P}\left(G_{u v}\right)$. Since $T$ is obtained from $S$ by replacing a subpath $S_{x y}$ of $S$ with an internally disjoint subpath $T_{x y}$ of $T$, the graph $S \Delta T$ is the cycle $S_{x y} \cup T_{x y}$.

Theorem 3. Let $G$ be a 2-connected graph, $u$ and $v$ be vertices of $G$ and $\mathcal{C}$ be a set of cycles of $G$. If the graph $\mathcal{P}_{\mathcal{C}}\left(G_{u v}\right)$ is connected, then $\mathcal{C}$ spans the cycle space of $G$.

Proof. Let $\sigma$ be a cycle of $G$. Since $G$ is 2 -connected, there are two disjoint paths $P_{u}$ and $P_{v}$ joining, respectively, $u$ and $v$ to $\sigma$. Denote by $u^{\prime}$ and $v^{\prime}$ the unique vertices of $P_{u}$ and $P_{v}$, respectively, that lie in $\sigma$. Vertices $u^{\prime}$ and $v^{\prime}$ partition cycle $\sigma$ into two internally disjoint paths $Q$ and $R$. Let $S=P_{u} \cup Q \cup P_{v}$ and $T=P_{u} \cup R \cup P_{v}$. Clearly $S$ and $T$ are two different $u v$ paths in $G$ such that $S \Delta T=\sigma$.

Since $\mathcal{P}_{\mathcal{C}}\left(G_{u v}\right)$ is connected, there are $u v$ paths $S=W_{0}, W_{1}, \ldots, W_{k}=T$ such that for $i=1,2, \ldots k$, paths $W_{i-1}$ and $W_{i}$ are adjacent in $\mathcal{P}_{\mathcal{C}}\left(G_{u v}\right)$. For
$i=1,2, \ldots k$ let $\alpha_{i}=W_{i-1} \Delta W_{i}$. Then $\alpha_{1}, \alpha_{2}, \ldots, \alpha_{k}$ are cycles in $\mathcal{C}$ such that:
$\alpha_{1} \Delta \alpha_{2} \Delta \cdots \Delta \alpha_{k}=\left(W_{0} \Delta W_{1}\right) \Delta\left(W_{1} \Delta W_{2}\right) \Delta \cdots \Delta\left(W_{k-1} \Delta W_{k}\right)=W_{0} \Delta W_{k}=\sigma$
Therefore $\mathcal{C}$ spans $\sigma$.

Let $G$ be a complete graph with four vertices $u, x, y, v$ and let $\mathcal{C}=$ $\{\alpha, \beta, \delta\}$, where $\alpha=u x v, \beta=u y v$ and $\delta=u x y v$. Set $\mathcal{C}$ spans the cycle space of $G$ but the graph $\mathcal{P}_{\mathcal{C}}\left(G_{u v}\right)$ is not connected since the $u v$ path uyxv is an isolated vertex of $\mathcal{P}_{\mathcal{C}}\left(G_{u v}\right)$, see Fig 3. This shows that the condition in Theorem 3 is not sufficient for $P_{\mathcal{C}}\left(G_{u v}\right)$ to be connected.

Figure 3: Graph $G$, set $\mathcal{C}=\{\alpha, \beta, \delta\}$ and graph $\mathcal{P}_{C}\left(G_{u v}\right)$.

## 4 Sufficient condition

A unicycle of a connected graph $G$ is a spanning subgraph $\mathcal{U}$ of $G$ that contains a unique cycle. Let $u$ and $v$ be vertices of a 2-connected graph $G$. A uv-monocle of $G$ is a subgraph of $G$ that consists of a cycle $\sigma$ and two disjoint paths $P_{u}$ and $P_{v}$ that join, respectively $u$ and $v$ to $\sigma$, see Fig. 1. Clearly for each $u v$-monocle $\mathcal{M}$ of a 2 -connected graph $G$, there is a unicycle $\mathcal{U}$ of $G$ that contains $\mathcal{M}$.

Let $\mathcal{C}$ be a set of cycles of $G$. A cycle $\sigma$ of $G$ has Property $\Delta^{*}$ with respect to $\mathcal{C}$ if for every unicycle $\mathcal{U}$ containing $\sigma$ there is an edge $e$ of $G$, not in $\mathcal{U}$ and two cycles $\alpha, \beta \in \mathcal{C}$, contained in $\mathcal{U}+e$, such that $\sigma=\alpha \Delta \beta$.

Lemma 1. Let $G$ be a 2-connected graph and $u$ and $v$ be vertices of $G$. Also let $\mathcal{C}$ be a set of cycles of $G$ and $\sigma$ be a cycle having Property $\Delta^{*}$ with respect to $\mathcal{C}$. The graph $\mathcal{P}_{\mathcal{C} \cup\{\sigma\}}\left(G_{u v}\right)$ is connected if and only if $\mathcal{P}_{\mathcal{C}}\left(G_{u v}\right)$ is connected. Proof. If $\mathcal{P}_{\mathcal{C}}\left(G_{u v}\right)$ is connected, then $\mathcal{P}_{\mathcal{C} \cup\{\sigma\}}\left(G_{u v}\right)$ is connected since the former is a subgraph of the latter.

Assume now $\mathcal{P}_{\mathcal{C} \cup\{\sigma\}}\left(G_{u v}\right)$ is connected and let $S$ and $T$ be $u v$ paths in $G$ which are adjacent in $\mathcal{P}_{\mathcal{C} \cup\{\sigma\}}\left(G_{u v}\right)$. We show next that $S$ and $T$ are connected in $\mathcal{P}_{\mathcal{C}}\left(G_{u v}\right)$ by a path of length at most 2.

If $\omega=S \Delta T \in \mathcal{C}$, then $S$ and $T$ are adjacent in $\mathcal{P}_{\mathcal{C}}\left(G_{u v}\right)$. For the case $\omega=\sigma$ denote by $\mathcal{M}$ the $u v$-monocle given by $S \cup T$.

Let $\mathcal{U}$ be a unicycle of $G$ containing $\mathcal{M}$. Since $\sigma$ has Property $\Delta^{*}$ with respect to $\mathcal{C}$, there exists an edge $e=x y$ of $G$, not in $\mathcal{U}$, and two cycles $\alpha, \beta \in \mathcal{C}$ contained in $\mathcal{U}+e$ such that $\sigma=\alpha \Delta \beta$.

Let $x^{\prime}$ and $y^{\prime}$ denote the vertices in $\mathcal{M}$ which are closest in $\mathcal{U}$ to $x$ and $y$, respectively. Then there exists a path $R_{x^{\prime} y^{\prime}}$ in $G$, with edges in $E(\mathcal{U}+$ $e) \backslash E(\mathcal{M})$ joining $x^{\prime}$ and $y^{\prime}$ and such that cycles $\alpha$ and $\beta$ are contained in $\mathcal{M} \cup R_{x^{\prime} y^{\prime}}$. We analyze several cases according to the location of $x^{\prime}$ and $y^{\prime}$ in $\mathcal{M}$.

Denote by $P_{u}$ and $P_{v}$ the unique paths, contained in $\mathcal{M}$, that join $u$ and $v$ to $\sigma$ and by $u^{\prime}$ and $v^{\prime}$ the vertices where $P_{u}$ and $P_{v}$, respectively, meet $\sigma$.

Case 1.- $x^{\prime} \in V\left(P_{u}\right), y^{\prime} \in V\left(P_{v}\right)$. Without loss of generality we assume $\alpha=S_{x^{\prime} y^{\prime}} \cup R_{y^{\prime} x^{\prime}}$ and $\beta=T_{x^{\prime} y^{\prime}} \cup R_{y^{\prime} x^{\prime}}$, see Fig. 4.

Figure 4: Left: $\mathcal{M} \cup R_{y^{\prime} x^{\prime}}$. Right: Cycles $\alpha$ and $\beta$.
Let $Q$ be the $u v$-path obtained from $S$ by replacing $S_{x^{\prime} y^{\prime}}$ with $R_{x^{\prime} y^{\prime}}$. Notice that $Q$ can also be obtained from $T$ by replacing $T_{x^{\prime} y^{\prime}}$ with $R_{x^{\prime} y^{\prime}}$.

Case 2.- $x^{\prime} \in V\left(P_{u}\right), y^{\prime} \in S \cap \sigma$. Without loss of generality we assume $\alpha=S_{x^{\prime} y^{\prime}} \cup R_{y^{\prime} x^{\prime}}$ and $\beta=T_{x^{\prime} v^{\prime}} \cup S_{v^{\prime} y^{\prime}} \cup R_{y^{\prime} x^{\prime}}$, see Fig. 5.

Figure 5: Left: $\mathcal{M} \cup R_{y^{\prime} x^{\prime}}$. Right: Cycles $\alpha$ and $\beta$.
Again let $Q$ be the $u v$-path obtained from $S$ by replacing $S_{x^{\prime} y^{\prime}}$ with $R_{x^{\prime} y^{\prime}}$. In this case, $Q$ can also be obtained from $T$ by replacing $T_{x^{\prime} v^{\prime}}$ with $R_{x^{\prime} y^{\prime}} \cup S_{y^{\prime} v^{\prime}}$.

Case 3.- $x^{\prime}, y^{\prime} \in S \cap \sigma$. Without loss of generality we assume $\alpha=S_{x^{\prime} y^{\prime}} \cup R_{y^{\prime} x^{\prime}}$ and $\beta=S_{u^{\prime} x^{\prime}} \cup R_{x^{\prime} y^{\prime}} \cup S_{y^{\prime} v^{\prime}} \cup T_{v^{\prime} u^{\prime}}$, see Fig. 6.

Figure 6: Left: $\mathcal{M} \cup R_{y^{\prime} x^{\prime}}$. Right: Cycles $\alpha$ and $\beta$.
Let $Q$ be the $u v$-path obtained from $S$ by replacing $S_{x^{\prime} y^{\prime}}$ with $R_{x^{\prime} y^{\prime}}$. Path $Q$ is also obtained from $T$ by replacing $T_{u^{\prime} v^{\prime}}$ with $S_{u^{\prime} x^{\prime}} \cup R_{x^{\prime} y^{\prime}} \cup S_{y^{\prime} v^{\prime}}$.

Case 4.- $x^{\prime} \in S \cap \sigma$ and $y^{\prime} \in T \cap \sigma$. Without loss of generality we assume $\alpha=S_{u^{\prime} x^{\prime}} \cup R_{x^{\prime} y^{\prime}} \cup T_{y^{\prime} u^{\prime}}$ and $\beta=T_{y^{\prime} v^{\prime}} \cup S_{v^{\prime} x^{\prime}} \cup R_{x^{\prime} y^{\prime}}$, see Fig. 7.

Let $Q$ be the $u v$-path obtained from $S$ by replacing $S_{u^{\prime} x^{\prime}}$ with $T_{u^{\prime} y^{\prime}} \cup R_{y^{\prime} x^{\prime}}$. Now $Q$ can also be obtained from $T$ by replacing $T_{y^{\prime} v^{\prime}}$ with $R_{y^{\prime}, x^{\prime}} \cup S_{x^{\prime} v^{\prime}}$

Figure 7: Left: $\mathcal{M} \cup R_{y^{\prime} x^{\prime}}$. Right: Cycles $\alpha$ and $\beta$.
In each case $S \Delta Q=\alpha$ and $Q \Delta T=\beta$. Since $\alpha, \beta \in \mathcal{C}$, path $S$ is adjacent to $Q$ and path $Q$ is adjacent to $T$ in $P_{\mathcal{C}}\left(G_{u v}\right)$. Therefore $S$ and $T$ are connected in $\mathcal{P}_{\mathcal{C}}\left(G_{u v}\right)$ by a path with length at most 2 .

All remaining cases are analogous to either Case 2 or to Case 3 .
Consider a 2-connected graph $G$ with two specified vertices $u$ and $v$ and let $\mathcal{C}$ be a set of cycles of $G$. Construct a sequence of sets of cycles $\mathcal{C}=$ $\mathcal{C}_{0}, \mathcal{C}_{1}, \ldots, \mathcal{C}_{k}$ as follows: If there is a cycle $\sigma_{1}$ not in $\mathcal{C}_{0}$ that has Property $\Delta^{*}$ with respect to $\mathcal{C}_{0}$ add $\sigma_{1}$ to $\mathcal{C}_{0}$ to obtain $\mathcal{C}_{1}$. At step $t$ add to $\mathcal{C}_{t}$ a new cycle $\sigma_{t+1}$ (if it exists) that has Property $\Delta^{*}$ with respect to $\mathcal{C}_{t}$ to obtain $\mathcal{C}_{t+1}$. Stop at a step $k$ where there are no cycles, not in $\mathcal{C}_{k}$, having Property $\Delta^{*}$ with respect to $\mathcal{C}_{k}$. We denote by $\mathrm{Cl}(\mathcal{C})$ the final set obtained with this process. Li et al [5] proved that the final set of cycles obtained is independent of which cycle $\sigma_{t}$ is added at each step in the case of multiple possibilities.

A set of cycles of $G$ is $\Delta^{*}$-dense if $C l(\mathcal{C})$ is the whole set of cycles of $G$.
Theorem 4. If $\mathcal{C}$ is $\Delta^{*}$-dense, then $\mathcal{P}_{\mathcal{C}}\left(G_{u v}\right)$ is connected.
Proof. Since $\mathcal{C}$ is $\Delta^{*}$-dense, $\operatorname{Cl}(\mathcal{C})$ is the set of cycles of $G$ and therefore $\mathcal{P}_{C l(\mathcal{C})}\left(G_{u v}\right)=\mathcal{P}\left(G_{u v}\right)$ which is connected by Theorem 1 .

Let $\mathcal{C}=\mathcal{C}_{0}, \mathcal{C}_{1}, \ldots, \mathcal{C}_{k}=C l(\mathcal{C})$ be a sequence of sets of cycles obtained from $\mathcal{C}$ as above. By Lemma1, all graphs $\mathcal{P}_{C l(\mathcal{C})}\left(G_{u v}\right)=\mathcal{P}_{\mathcal{C}_{k}}\left(G_{u v}\right), \mathcal{P}_{\mathcal{C}_{k-1}}\left(G_{u v}\right)$, $\ldots, \mathcal{P}_{\mathcal{C}_{0}}\left(G_{u v}\right)=\mathcal{P}_{\mathcal{C}}\left(G_{u v}\right)$ are connected.

Li et al [5] proved the following:

Theorem 5. If $G$ is a plane 2-connected graph and $\mathcal{C}$ is the set of internal faces of $G$, then $\mathcal{C}$ is $\Delta^{*}$-dense.

Theorem 6. If $G$ is a 2-connected graph and $\mathcal{C}$ is the set of cycles that contain a given edge e of $G$, then $\mathcal{C}$ is $\Delta^{*}$-dense.

We end this section with the following immediate corollaries.
Collorary 1. Let $u$ and $v$ be vertices of a 2 -connected plane graph $G$. If $\mathcal{C}$ is the set of internal faces of $G$, then $\mathcal{P}_{\mathcal{C}}\left(G_{u v}\right)$ is connected.

Proof. By Theorem 5, $\mathcal{C}$ is $\Delta^{*}$-dense and by Theorem $4, \mathcal{P}_{\mathcal{C}}\left(G_{u v}\right)$ is connected.

Collorary 2. Let $u$ and $v$ be vertices of a 2 -connected graph $G$. If $\mathcal{C}$ is the set of cycles of $G$ that contain a given edge e, then $\mathcal{P}_{\mathcal{C}}\left(G_{u v}\right)$ is connected.

Proof. By Theorem 6, $\mathcal{C}$ is $\Delta^{*}$-dense and by Theorem $4, \mathcal{P}_{\mathcal{C}}\left(G_{u v}\right)$ is connected.

Collorary 3. Let $u$ and $v$ be vertices of a 2-connected graph $G$. If $\mathcal{C}_{u}$ is the set of cycles of $G$ that contain vertex $u$, then $\mathcal{P}_{\mathcal{C}_{u}}\left(G_{u v}\right)$ is connected.

Proof. Let $e$ be an edge of $G$ incident with vertex $u$. Clearly the set $\mathcal{C}(e)$ of cycles that contain edge $e$ is a subset of the set $\mathcal{C}_{u}$. Therefore $\mathcal{P}_{\mathcal{C}(e)}\left(G_{u v}\right)$ is a subgraph of $\mathcal{P}_{\mathcal{C}_{u}}\left(G_{u v}\right)$. By Corollary 2 , the graph $\mathcal{P}_{\mathcal{C}(e)}\left(G_{u v}\right)$ is connected.
