Abstract

In a graph G , the cardinality of the smallest ordered set of vertices that distinguishes every element of $V(G)$ (resp. $E(G)$) is called the vertex (resp. edge) metric dimension of G . In [16] it was shown that both vertex and edge metric dimension of a unicyclic graph G always take values from just two explicitly given consecutive integers that are derived from the structure of the graph. A natural problem that arises is to determine under what conditions these dimensions take each of the two possible values. In this paper for each of these two metric dimensions we characterize three graph configurations and prove that it takes the greater of the two possible values if and only if the graph contains at least one of these configurations. One of these configurations is the same for both dimensions, while the other two are specific for each of them. This enables us to establish the exact value of the metric dimensions for a unicyclic graph and also to characterize when each of these two dimensions is greater than the other one.

Keywords: vertex metric dimension; edge metric dimension; unicyclic graphs; cactus graphs.

AMS Subject Classification numbers: 05C12; 05C76

1 Introduction

In this paper we consider only simple and connected graphs unless explicitly stated otherwise. The distance between a pair of vertices u and v in a graph G is denoted by $d(u, v)$. We say that a vertex s from G *distinguishes* or *resolves* a pair of vertices u and v from G if $d(s, u) \neq d(s, v)$. A set of vertices $S \subseteq V(G)$ is called a *vertex metric generator*, if every pair of vertices in G is distinguished by at least one vertex from S . The cardinality of a smallest vertex generator in G is called the *vertex metric dimension* of G , and it is denoted by $\dim(G)$. For this variant of metric dimension the prefix "vertex" is sometimes omitted, so we say only metric generator and metric dimension.

The concept of metric generator was introduced in [19] under the name of locating set and the problem of uniquely identifying the location of an intruder in a network by its distances to the locating devices was considered. Independently, the same concept was studied in [5] under the name of resolving set. The complexity of approximating the metric dimension of a graph was studied in [11], applications of metric dimension in digital geometry in [14], the comparison of metric dimension of graphs and line graphs in [12], how the metric dimension can be affected by the addition of a single vertex in [1], vertices contained in all metric generators in [4], and the behaviour of metric dimension with respect to various graph operations in [2, 15].

Recently, the concept of metric dimension was extended from distinguishing vertices to distinguishing edges. Similarly as above, a vertex $s \in V(G)$ *distinguishes* two edges $e, f \in E(G)$ if $d(s, e) \neq d(s, f)$, where $d(e, s) = d(uv, s) = \min\{d(u, s), d(v, s)\}$. The authors of [10] noticed that there are graphs in which none of the smallest metric generators distinguishes all pairs of edges, so they were motivated to introduce a notion of an *edge metric generator* as any set $S \subseteq V(G)$ which distinguishes all pairs of edges, the *edge metric dimension* (denoted by $\text{edim}(G)$) as the cardinality of a smallest edge metric generator, and then study its relation with the vertex metric dimension. They presented families of graphs for which $\text{dim}(G) < \text{edim}(G)$, or $\text{dim}(G) = \text{edim}(G)$, or $\text{dim}(G) > \text{edim}(G)$, also they established that determining the edge metric dimension of a graph is NP-hard.

This new variant of metric dimension immediately attracted a lot of interest. The behaviour of edge metric dimension on several graph operations was studied in [22], the edge metric dimension of convex polytopes and its related graphs in [20], graphs with the maximum edge metric dimension in [21], pattern avoidance in graphs with bounded metric dimension or edge metric dimension in [3], an approximation algorithm for the edge metric dimension problem in [6], comparison of metric dimensions in [9, 13], bounds on vertex and edge metric dimension of graphs with edge disjoint cycles in [16].

Recently the mixed metric dimension was also introduced [8], where a mixed metric generator of a graph G is defined as any set S which distinguishes all pairs from $V(G) \cup E(G)$, the size of a smallest such set is the *mixed metric dimension* of G , and it is denoted by $\text{mdim}(G)$. The paper [8] contains lower and upper bounds for various graph classes. The mixed metric dimension was further studied in [18] for graphs with edge disjoint cycles, these results were further generalized to graphs with prescribed cyclomatic number in [17]. For a wider and systematic introduction of the topic of these three variants of metric dimension, we recommend the PhD thesis of Kelenc [7].

The focus of this paper is on the result from [16], where it was established that both $\text{dim}(G)$ and $\text{edim}(G)$ of a unicyclic graph G can take its value from only two consecutive integers which can be determined from the structure of the graph. In this paper, we go further and characterize when these two metric dimensions take each of the two possible values, a research direction which is proposed in [13]. This promptly resolves which of the following three situations $\text{dim}(G) < \text{edim}(G)$, or $\text{dim}(G) = \text{edim}(G)$, or $\text{dim}(G) > \text{edim}(G)$ holds for a unicyclic graph G .

2 Preliminaries

Throughout the paper we will use the following notation. The cycle in a unicyclic graph G is denoted by $C = v_0v_1 \cdots v_{g-1}$, where g is the length of C (i.e. $g = |V(C)|$). Additionally, each edge $v_i v_{i+1}$ of C is denoted by e_i . The connected component of $G - E(C)$ containing vertex v_i is denoted by T_{v_i} . A *thread* in a graph G is a path $u_1 u_2 \cdots u_k$ in which u_k is of degree 1, all other vertices of the thread are of degree 2 and the vertex u_1 is a neighbour of a vertex $v \in V(G)$ with $\deg(v) \geq 3$. For a vertex v from a unicyclic graph G we say that it is a *branching* vertex if $v \notin V(C)$ and $\deg(v) \geq 3$ or $v \in V(C)$ and $\deg(v) \geq 4$. We say that a vertex $v_i \in V(C)$ is *branch-active* if T_{v_i} contains a branching vertex. Let us denote by $b(C)$ the number of all branch-active vertices on C . As the cycle C is the only cycle in a unicyclic graph, we may use notation $b(G)$ instead of $b(C)$ as well.

Notice that every branching vertex v which belongs to T_{v_i} has at least two neighbours which are not distinguished by any vertex from outside of T_{v_i} , even more - it may not be distinguished by some vertices from T_{v_i} , see Figure 1.a) for illustration. Similarly holds for a pair of edges incident to branching vertices v and v_k . We say that a set $S \subseteq V(G)$ of a (unicyclic) graph G is *branch-resolving* if for every $v \in V(G)$ of degree at least 3, the set S contains a vertex from all threads hanging at v except possibly from one such thread, see Figure 1.b).

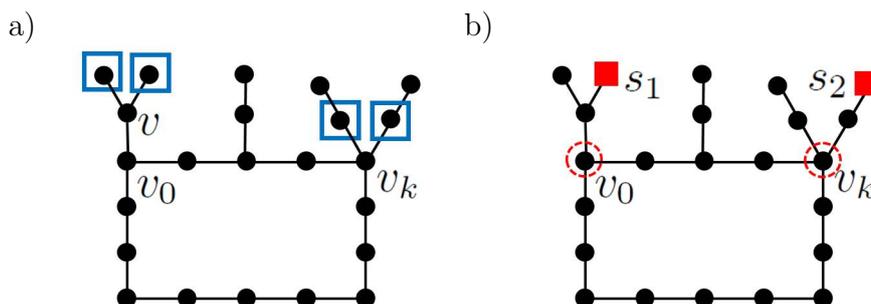

Figure 1: Both figures show the same graph for which: a) Two branching vertices are v and v_k , and each of them has a pair of neighbours which cannot be distinguished by a vertex outside of T_{v_0} and T_{v_k} respectively. b) $S = \{s_1, s_2\}$ is an example of a smallest branch-resolving and the set $\{v_0, v_k\}$ is both the set of S -active vertices, and the set of branch-active vertices.

Let us denote by $\ell(v)$ the number of all threads attached to a vertex v of degree ≥ 3 and let

$$L(G) = \sum (\ell(v) - 1),$$

where the sum runs over all vertices v of degree ≥ 3 of G with $\ell(v) > 1$. Note that for every branch-resolving set S we have $|S| \geq L(G)$ where equality holds if S is a branch-resolving sets of minimum cardinality.

For a set of vertices $S \subseteq V(G)$ we say that v_i from C is S -active if T_{v_i} contains a vertex from S . The number of S -active vertices on C is denoted by $a_S(C)$. Note that for a branch-resolving set S it holds that $a_S(C) \geq b(C)$ with equality holding for a smallest

branch-resolving set S in G . A smallest branch-resolving set usually is not unique, but all smallest branch-resolving sets have the same set of S -active vertices on the cycle which equals the set of branch-active vertices on the cycle (see again Figure 1.b)). Finally, we say that a thread hanging at a vertex v of degree ≥ 3 is S -free if it does not contain a vertex from S . Let us remark, as v is not a vertex of the thread, if $v \in S$, it does not prevent the thread to be S -free.

The following two properties of branch-resolving sets were shown in [16].

Lemma 1 *Let S be a metric generator or an edge metric generator of a unicyclic graph G . Then S is a branch-resolving set with $a_S(C) \geq 2$.*

Lemma 2 *Let G be a unicyclic graph and $S \subseteq V(G)$ a branch-resolving set with $a_S(C) \geq 2$. Then, any two vertices (also any two edges) from a same connected component of $G - E(C)$ are distinguished by S .*

We say that a set $S \subseteq V(G)$ is *biactive* if $a_S(C) \geq 2$. Thus, according to Lemma 1, if the set S is not branch-resolving or if it is not biactive, then S certainly is not a vertex nor an edge metric generator. The problem of non-distinguished pairs of vertices (resp. edges), if S is not branch-resolving, is already illustrated by Figure 1.a). Let us now consider when S is not biactive. If $a_S(C) = 0$ then $S = \phi$ and S cannot be a metric generator, on the other hand if $a_S(C) = 1$ then the pair of vertices (resp. edges) from C which are adjacent (resp. incident) to the only S -active vertex on C are not distinguished by S , see Figure 2.a) for illustration.

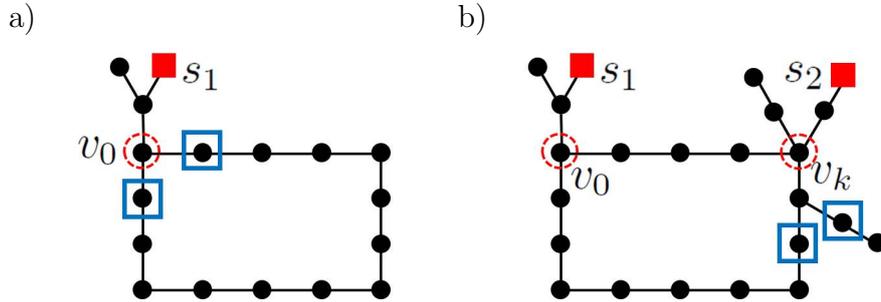

Figure 2: An example of a branch-resolving set S with: a) $a_S(C) = 1$, b) $a_S(C) = 2$, which is not a vertex metric generator. A pair of non-distinguished vertices is marked in the figure.

Yet, a biactive branch-resolving set S may or may not be a vertex (edge) metric generator, this depends also of the position of vertices on the cycle which have an S -free thread attached. For example, the set S from Figure 1.b) is a biactive branch-resolving set which is a vertex (edge) metric generator, and the set S from Figure 2.b) is also a biactive branch-resolving set but it is not a vertex (edge) metric generator. Notice that even if we add to S all vertices of T_{v_i} , for $0 \leq i \leq k$, the set S would still not be a vertex (edge) metric generator.

By the above, we need to introduce a configuration of S -active vertices on the cycle C which will suffice for a biactive branch-resolving set S to become a vertex (edge) metric generator. For this, let v_i, v_j , and v_k be three vertices of the cycle C . We say that v_i, v_j , and v_k form a *geodesic triple* of vertices on C , if

$$d(v_i, v_j) + d(v_j, v_k) + d(v_i, v_k) = |V(C)|.$$

Observe that for any two vertices of C , we can easily choose a third one such that they form a geodesic triple. It is also easy to observe that a geodesic triple of vertices distinguishes vertices from C . Moreover the following property of geodesic triples was shown in [16].

Lemma 3 *Let G be a unicyclic graph, and let S be a branch-resolving set of G with $a_S(C) \geq 3$ and with three S -active vertices on C forming a geodesic triple. Then, S is both a metric generator and an edge metric generator of G .*

By the all above, for a set of vertices $S \subseteq V(G)$ we can conclude the following:

- S1. If the set S is not a biactive branch-resolving set, then S cannot be a vertex (resp. edge) metric generator.
- S2. If the set S is a biactive branch-resolving set, then either:
 - (a) S is a vertex (resp. edge) metric generator by itself; or
 - (b) S is not a vertex (resp. edge) metric generator by itself, and it suffices to introduce precisely one more vertex to S in order to become a vertex (resp. edge) metric generator according to Lemma 3.

In this paper we will establish necessary and sufficient condition under which that one additional vertex must be introduced to a smallest biactive branch-resolving set S to become a vertex (resp. edge) metric generator. In order to do so, we will first consider unicyclic graphs with $b(G) \geq 2$ and identify three structural configurations \mathcal{A}, \mathcal{B} , and \mathcal{C} (resp. \mathcal{A}, \mathcal{D} , and \mathcal{E}) in such a graph which are the only obstacle for a smallest biactive branch-resolving set to be a vertex (resp. edge) metric generator. Since these configurations in graphs with $b(G) < 2$ depend on the set S , this approach is further extended by introducing a more general property of a graph which enables us to derive results which encapsulate also graphs with $b(G) < 2$, namely \mathcal{ABC} -positivity and \mathcal{ABC} -negativity (resp. \mathcal{ADE} -positivity and \mathcal{ADE} -negativity).

For characterization of the smallest biactive branch-resolving sets S that need to be introduced an additional vertex in order to become a metric generator, the position of S -active vertices on the cycle C matters. In order to be able to deal with them, we introduce the following labelling of the cycle.

Definition 4 *Let G be a unicyclic graph with the cycle C of length g and let S be a biactive branch-resolving set in G . We say that $C = v_0v_1 \cdots v_{g-1}$ is canonically labelled with respect to S if v_0 is S -active and $k = \max\{i : v_i \text{ is } S\text{-active}\}$ is as small as possible.*

Notice that when there is no geodesic triple of S -active vertices, the canonical labelling implies $k \leq g/2$. In particular, if $a_S(C) = 2$, then $k \leq g/2$. Throughout the paper we will assume that the cycle C is canonically labelled with respect to the given biactive branch-resolving set S , unless explicitly stated otherwise.

3 Vertex metric dimension

Regarding S2 we want to characterize when a smallest biactive branch-resolving set is a vertex metric generator by itself, and when an additional vertex must be added to such a set to become a vertex metric generator. For this, we introduce three structural configurations \mathcal{A} , \mathcal{B} , and \mathcal{C} of the graph G with respect to S which will be crucial for the characterization.

Definition 5 *Let G be a unicyclic graph, and let S be a biactive branch-resolving set in G . We say that the graph G with respect to S contains configurations:*

- A. If $a_S(C) = 2$, g is even, and $k = g/2$;*
- B. If $k \leq \lfloor g/2 \rfloor - 1$ and there is an S -free thread hanging at a vertex v_i for some $i \in [k, \lfloor g/2 \rfloor - 1] \cup [\lfloor g/2 \rfloor + k + 1, g - 1] \cup \{0\}$;*
- C. If $a_S(C) = 2$, g is even, $k \leq g/2$ and there is an S -free thread of the length $\geq g/2 - k$ hanging at a vertex v_i for some $i \in [0, k]$.*

Notice that configuration \mathcal{C} with $k = g/2$ is also configuration \mathcal{A} , and configuration \mathcal{C} with $i \in \{0, k\}$ and $k \leq g/2 - 1$ is also configuration \mathcal{B} .

The above configurations are illustrated by Figure 3. In every graph from Figure 3, a pair of vertices is marked which is not distinguished by S . In the next theorem we will show that this holds in general, i.e. that every set S for which the cycle C has one of these configurations is not a vertex metric generator, and otherwise S is a vertex metric generator.

Lemma 6 *Let G be a unicyclic graph and let S be a biactive branch-resolving set in G . If G contains configuration \mathcal{A} , \mathcal{B} , or \mathcal{C} with respect to S , then S is not a vertex metric generator in G .*

Proof. Let us assume that G contains configuration \mathcal{A} , \mathcal{B} , or \mathcal{C} with respect to S and it is sufficient to find a pair of vertices $x, x' \in V(G)$ which are not distinguished by S .

If G contains configuration \mathcal{A} then $x = v_1$ and $x' = v_{g-1}$ are not distinguished by S .

Next, if G contains configuration \mathcal{B} , let v_i be a vertex from C with an S -free thread hanging at it, where $i \in [k, \lfloor g/2 \rfloor - 1] \cup [\lfloor g/2 \rfloor + k + 1, g] \cup \{0\}$. Let w be the neighbour of v_i which belongs to the thread hanging at v_i . If $i \in [k, \lfloor g/2 \rfloor - 1]$ then $x = w$ and $x' = v_{i+1}$ are not distinguished by S . And if $i \in [\lfloor g/2 \rfloor + k + 1, g - 1] \cup \{0\}$, then $x = w$ and $x' = v_{i-1}$ are not distinguished by S .

Finally, suppose that G contains configuration \mathcal{C} . Let v_i with $i \in [0, k]$ be a vertex on the cycle C with an S -free thread of the length $\geq g/2 - k$ hanging at it. Let x be the vertex on that thread such that $d(x, v_i) = g/2 - k$, let $j = 2k - i + d(x, v_i) = g/2 + k - i$ and let $x' = v_j$. We argue that x and x' are not distinguished by S . Note that $i \in [0, k]$ implies $j \in [g/2, g/2 + k]$, therefore $d(v_j, v_k) = j - k$ and $d(v_j, v_0) = g - j$. Now a simple calculation yields that x and x' are not distinguished by $\{v_0, v_k\}$, and therefore they are not distinguished by S . ■

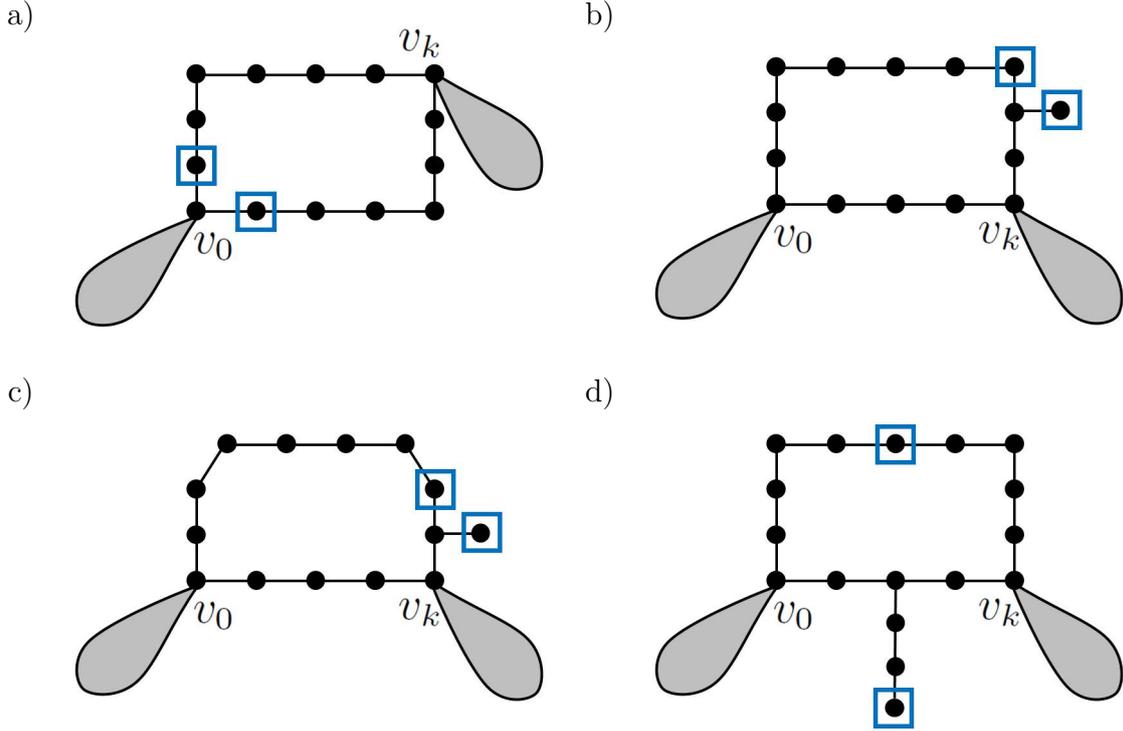

Figure 3: In all examples we consider a branch-resolving set S , where v_0 and v_k are the only two S -active vertices on C . Configuration \mathcal{A} with respect to S is illustrated by a). Configuration \mathcal{B} is shown: b) for even cycle, c) for odd cycle. Finally, configuration \mathcal{C} is illustrated by d). In every graph a pair of vertices is marked which is not distinguished by S .

In the above lemma we have shown that configurations \mathcal{A} , \mathcal{B} , and \mathcal{C} are the obstacles for S to be a vertex metric generator in G . Let us now prove that these configurations are the only such.

Lemma 7 *Let G be a unicyclic graph and let S be a biactive branch-resolving set in G . If G does not contain any of the configurations \mathcal{A} , \mathcal{B} , and \mathcal{C} with respect to S , then the set S is a vertex metric generator in G .*

Proof. Let us assume that G does not contain any of the configurations \mathcal{A} , \mathcal{B} , and \mathcal{C} with respect to S and let us suppose the contrary to the claim, i.e. S is not a vertex metric generator. By Lemma 3, there is no geodesic triple of S -active vertices on C , and hence the canonical labelling of G implies $k \leq g/2$.

Suppose first that $k = g/2$, which implies that g is even. If $a_S(C) \geq 3$, then $k = g/2$ implies that the third S -active vertex on C together with v_0 and v_k forms a geodesic triple of S -active vertices on C , which is a contradiction. On the other hand, if $a_S(C) = 2$, then $k = g/2$ implies that the graph G contains the configuration \mathcal{A} which is again a contradiction.

Suppose now that $k < g/2$. As we assumed that S is not a vertex metric generator, there must exist a pair of vertices x and x' in G which is not distinguished by S . Let us

assume that $x \in V(T_{v_i})$ and $x' \in V(T_{v_j})$. If $i = j$, then x and x' would be distinguished by S according to Lemma 2. Therefore, without loss of generality, we may assume $i < j$. Now, we consider the following five cases regarding i and j in order to conclude the proof.

Case 1: $i, j \in [0, k]$. If x and x' are not distinguished by $S \cap V(T_{v_0})$, then $i < j$ implies $d(x, v_i) > d(x', v_j)$ which further implies $d(x, s) > d(x', s)$ for every $s \in S \cap V(T_{v_k})$. Therefore, S distinguishes x and x' which is a contradiction.

Case 2: $i, j \in [k + 1, g - 1]$. Since we do not have a configuration \mathcal{B} , it must be $\lfloor g/2 \rfloor \leq i < j \leq \lceil g/2 \rceil + k$. But then notice the following. If $d(v_j, x') < d(v_i, x)$ then v_0 distinguishes these two vertices as x' is closer to v_0 than x . And, similarly if $d(v_j, x') > d(v_i, x)$ then v_k distinguishes these two vertices as x is closer. So we infer $d(v_j, x') = d(v_i, x)$. Then v_0 does not distinguish x and x' only if g is odd and v_i and v_j are the antipodals of v_0 . But then v_i and v_j cannot be antipodals of v_k , and so v_k distinguishes them.

Case 3: $i \in [1, k - 1]$ and $j \in [k + 1, g - 1]$. If $j \leq \lfloor g/2 \rfloor$, then the fact that $S \cap V(T_{v_k})$ does not distinguish x and x' implies $d(x, v_i) < d(x', v_i)$, so x and x' are distinguished by $S \cap V(T_{v_0})$. The similar argument holds if $j \geq \lceil g/2 \rceil + k$. Therefore, we may assume that $j \in [\lfloor g/2 \rfloor + 1, \lceil g/2 \rceil + k - 1]$, which implies that $d(v_j, v_0) + d(v_j, v_k) = g - k$. Now, the facts that $S \cap V(T_{v_0})$ and $S \cap V(T_{v_k})$ do not distinguish x and x' imply

$$\begin{aligned} d(x, v_i) + d(v_i, v_0) &= d(x', v_j) + d(v_j, v_0) \\ d(x, v_i) + d(v_i, v_k) &= d(x', v_j) + d(v_j, v_k), \end{aligned}$$

respectively. Summing these two equalities further implies $d(x, v_i) - d(x', v_j) = g/2 - k$. The fact $k < g/2$ implies $g/2 - k > 0$, so plugging this expression in the above equalities we obtain $d(v_j, v_0) > d(v_i, v_0)$ and $d(v_j, v_k) > d(v_i, v_k)$. Now, in the case when $a_S(C) \geq 3$, there is $l \in (0, k)$ such that v_l is S -active, but then for $l \in (0, i]$ the fact that $S \cap V(T_{v_0})$ does not distinguish x and x' implies $S \cap V(T_{v_l})$ distinguishes them which is a contradiction, and for $l \in [i, k)$ when $S \cap V(T_{v_k})$ instead of $S \cap V(T_{v_0})$ a similar argument holds. So, we may assume that $a_S(C) = 2$. But in this case the fact $d(x, v_i) - d(x', v_j) = g/2 - k > 0$ implies $g/2 - k$ is an integer so g must be even and also it implies that there is a sufficiently long S -free thread hanging at v_i for G to contain configuration \mathcal{C} which is a contradiction.

Case 4: $i = k$ and $j > k$. The fact that $S \cap V(T_{v_k})$ does not distinguish x and x' implies $d(x, v_k) > d(x', v_j)$, which further implies $x \neq v_k$. Notice that x does not belong to an S -free thread hanging at v_k as that would mean G contains configuration \mathcal{B} in all cases except when g is odd and $k = \lfloor g/2 \rfloor$, but in that case $d(x, v_k) > d(x', v_j)$ implies $d(x, v_0) > d(x', v_0)$, so x and x' are distinguished by $S \cap V(T_{v_0})$, which is a contradiction. Since x does not belong to an S -free thread, we conclude there must exist a vertex $s \in S \cap V(T_{v_k})$ distinct from v_k such that the shortest path P from x to s does not contain v_k .

Let v be the vertex on the path P which is closest to v_k . Since x and x' are not distinguished by $S \cap V(T_{v_k})$, by definition we have $d(x, s) = d(x', s)$, which implies

$$d(x, v) = d(x', v_k) + d(v_k, v) \tag{1}$$

and hence

$$d(x, v_k) = d(x', v_k) + 2d(v_k, v). \tag{2}$$

The equality (2) implies $d(x, v_k) > d(x', v_k)$. If $j \leq \lfloor g/2 \rfloor$, then the shortest path from both x and x' to v_0 leads through v_k , so $d(x, v_k) > d(x', v_k)$ would imply that x and x' are distinguished by $S \cap V(T_{v_0})$, a contradiction.

Suppose therefore that $j > \lfloor g/2 \rfloor$. In this case a shortest path from x' to v_0 does not lead through v_k , so we have $d(x', v_0) = d(x', v_j) + g - j$. Also, equality (1) implies

$$\begin{aligned} d(x, v_0) &= d(x, v) + d(v, v_k) + k \\ &= d(x', v_k) + 2d(v, v_k) + k \\ &= d(x', v_j) + j + 2d(v, v_k). \end{aligned}$$

Subtracting these expressions for $d(x, v_0)$ and $d(x', v_0)$ we obtain

$$d(x', v_0) - d(x, v_0) = g - 2j - 2d(v, v_k),$$

where the fact that $d(v_k, v) \neq 0$ further implies $d(x', v_0) - d(x, v_0) \leq g - 2j - 2$. Note that $j > \lfloor g/2 \rfloor$ implies $g - 2j - 2 < 0$, so we conclude that $S \cap V(T_{v_0})$ distinguishes x and x' which is a contradiction.

Case 5: $i = 0$ and $j > k$. This case is analogous to Case 4.

By the above analysis, we have shown that any pair of vertices from G is distinguished by S , so S is a vertex metric generator, which concludes the proof. \blacksquare

The last two lemmas give us the necessary and sufficient condition for a biactive branch-resolving set of vertices S to be a vertex metric generator. In order to establish the exact value of the vertex metric dimension for a unicyclic graph G we have to find a smallest set S which meets the condition from Lemmas 6 and 7.

Notice that a branch-resolving set S activates all branch-active vertices in G , so if $b(G) \geq 2$ then every branch-resolving set is biactive. Therefore, for a smallest branch-resolving set S in a unicyclic graph with $b(G) \geq 2$, the set of S -active vertices is fixed by the structure of G and coincides with the set of branch-active vertices. Since the presence of configurations \mathcal{A} , \mathcal{B} , and \mathcal{C} by definition depends on the position of S -active vertices, we can observe the following.

Observation 8 *If a unicyclic graph G contains at least two branch-active vertices on \mathcal{C} , i.e. $b(G) \geq 2$, then the graph G contains configuration \mathcal{A} , \mathcal{B} , or \mathcal{C} either with respect to all smallest biactive branch-resolving sets or to none of them.*

The above observation allows us to omit the set S in the definition of containment of configurations \mathcal{A} , \mathcal{B} , and \mathcal{C} in a unicyclic graph G . We can simply say " G contains a configuration" instead of " G contains a configuration with respect to S ". Now, for unicyclic graphs with at least two branch-active vertices we can state and prove the following theorem which gives the exact value of the vertex metric dimension.

Theorem 9 *Let G be a unicyclic graph with at least two branch-active vertices, i.e. $b(G) \geq 2$. Then*

$$\dim(G) = L(G) + \Delta,$$

where $\Delta = 0$ if the graph G does not contain any of the configurations \mathcal{A} , \mathcal{B} , \mathcal{C} , and $\Delta = 1$ otherwise.

Proof. Let S be a smallest branch-resolving set in G . Since G has at least two branch-active vertices on C , i.e. $b(G) \geq 2$, it follows that S is biactive, and so $a_S(C) = b(G)$. If the graph G does not contain any of the configurations \mathcal{A} , \mathcal{B} , and \mathcal{C} , then Lemma 7 implies that S is a vertex metric generator. Therefore, $\dim(G) = |S| = L(G)$.

On the other hand, if G contains any of the configurations \mathcal{A} , \mathcal{B} , or \mathcal{C} , then S is not a vertex metric generator according to Lemma 6. Let v be a vertex from C which forms a geodesic triple with two branch-active vertices on C , and let $S' = S \cup \{v\}$. Notice that according to Lemma 3, the set S' is a vertex metric generator, therefore $\dim(G) = |S'| = L(G) + 1$. \blacksquare

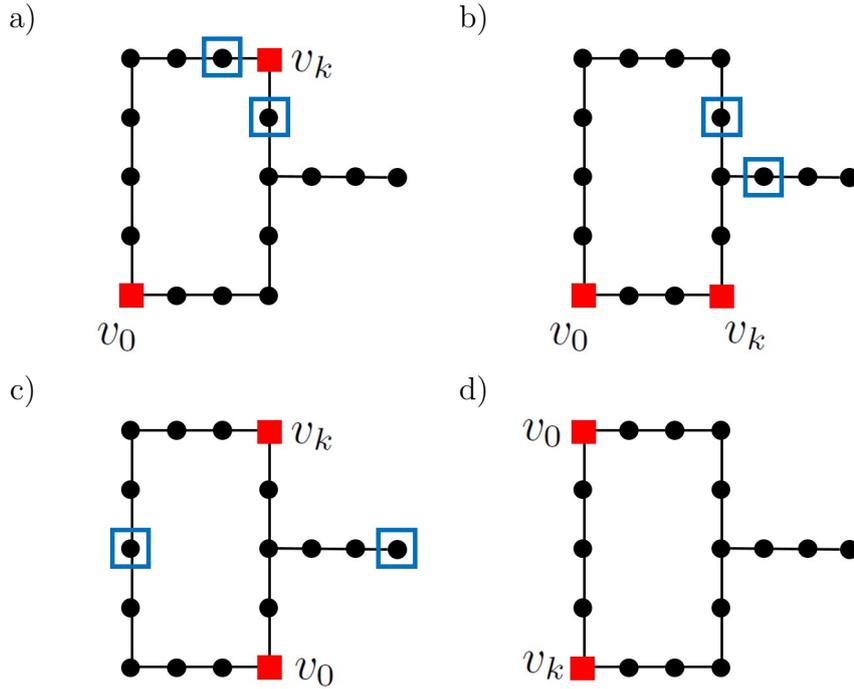

Figure 4: In all four examples we consider the same graph G without branch-active vertices on C and four different smallest biactive branch-resolving sets $S = \{v_0, v_k\}$ chosen so that the graph G with respect to S contains: a) configuration \mathcal{A} , b) configuration \mathcal{B} , c) configuration \mathcal{C} , d) none of the configurations \mathcal{A} , \mathcal{B} , and \mathcal{C} . In the first three examples the set S is not a vertex metric generator, so a pair of vertices non-distinguished by S is marked in G .

So far we have determined the exact value of unicyclic graphs G with $b(G) \geq 2$ and our characterization depends on the presence of configurations \mathcal{A} , \mathcal{B} , and \mathcal{C} in the graph G . Now we want to deal with unicyclic graphs G with $b(G) < 2$. The problem with such graphs is that different biactive sets S impose different S -active vertices on C , and we derive presence of different configurations (see Figure 4).

We conclude that we cannot speak of presence/absence of a particular configuration in a graph, unless we have a biactive branch-resolving set S . So, we introduce the following

definition to unify both cases $b(G) \geq 2$ and $b(G) < 2$.

Definition 10 *Let G be a unicyclic graph. We say that G is \mathcal{ABC} -negative, if there exists a smallest biactive branch-resolving set S such that G does not contain any of the configurations \mathcal{A} , \mathcal{B} , and \mathcal{C} with respect to S . Otherwise we say that G is \mathcal{ABC} -positive.*

Notice that the above definition extends the case when G contains two or more branch-active vertices, i.e. $b(G) \geq 2$, in which case G will be \mathcal{ABC} -negative if it does not contain any of the configurations \mathcal{A} , \mathcal{B} , \mathcal{C} , and G is \mathcal{ABC} -positive if it contains at least one of the configurations \mathcal{A} , \mathcal{B} , \mathcal{C} .

As an example of \mathcal{ABC} -negative and \mathcal{ABC} -positive graphs G with $b(G) < 2$, we can consider corona product graphs $C_n \odot K_1$ which are obtained from the cycle C_n by appending a leaf to every vertex in C_n . We leave to the reader to verify that if n is odd, then corona product $C_n \odot K_1$ is \mathcal{ABC} -negative, and for even $n \geq 6$ it is \mathcal{ABC} -positive (see Figure 5). Corona product graphs $C_n \odot K_1$ are examples of unicyclic graphs with $b(G) = 0$, but if we replace one leaf in $C_n \odot K_1$ by any acyclic structure, we obtain a graph with $b(G) = 1$ and the same reasoning holds.

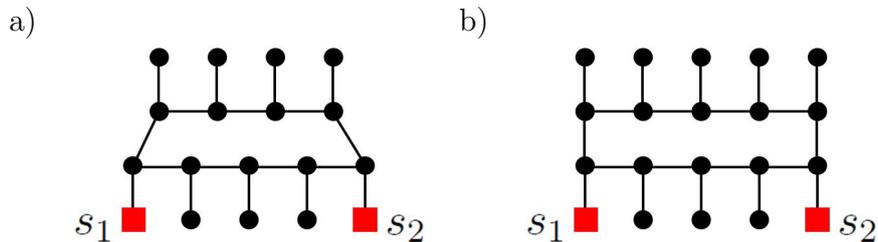

Figure 5: Figure shows corona product graphs: a) $C_9 \odot K_1$ which is \mathcal{ABC} -negative and $S = \{s_1, s_2\}$ is a vertex metric generator, b) $C_{10} \odot K_1$ which is \mathcal{ABC} -positive with $S = \{s_1, s_2\}$ being such that it avoids configurations \mathcal{A} and \mathcal{B} , but does not avoid configuration \mathcal{C} .

Now, we can state a more general version of Theorem 9 which encapsulates unicyclic graphs with less than two branch-active vertices.

Theorem 11 *Let G be a unicyclic graph. Then*

$$\dim(G) = L(G) + \max\{0, 2 - b(G)\} + \Delta,$$

where $\Delta = 0$ if the graph G is \mathcal{ABC} -negative, and $\Delta = 1$ if G is \mathcal{ABC} -positive.

Proof. Assume first that G is \mathcal{ABC} -negative. This implies that there is a smallest biactive branch-resolving set S such that G does not contain any of the configurations \mathcal{A} , \mathcal{B} , and \mathcal{C} with respect to S . Then, Lemma 7 implies that S is a vertex metric generator, so $\dim(G) = |S| = L(G) + \max\{0, 2 - b(G)\}$.

Assume now that G is \mathcal{ABC} -positive and let S be a smallest biactive branch-resolving set in G . Definition of \mathcal{ABC} -positivity implies that G contains at least one of the configurations \mathcal{A} , \mathcal{B} , or \mathcal{C} with respect to S , so S is not a vertex metric generator according to

Lemma 13. But then, let v be a vertex from C which forms a geodesic triple with two S -active vertices on C , and let $S' = S \cup \{v\}$. Now, Lemma 3 implies that S' is a metric generator, so $\dim(G) = |S'| = L(G) + \max\{0, 2 - b(G)\} + 1$. ■

4 Edge metric dimension

Now we want to apply a similar study for the edge metric dimension of unicyclic graphs. Similarly as for the vertex metric dimension, Lemma 1 implies that a set $S \subseteq V(G)$ which is not a branch-resolving set or for which $a_S(C) < 2$ cannot be an edge metric generator, and Lemma 3 implies that a branch-resolving set S with a geodesic triple of S -active vertices on the cycle C certainly is an edge metric generator. Therefore, it remains to consider branch-resolving sets S with $a_S(C) \geq 2$, but without a geodesic triple of S -active vertices. Such a set may or may not be an edge metric generator, and we want to establish necessary and sufficient conditions for it to be an edge metric generator.

Let us consider the graphs from Figure 3. Notice that in the graph G from a), which contains configuration \mathcal{A} , there is a pair of edges incident to v_0 which is not distinguished by S . Similarly holds for graphs in b) and c) which contain configuration \mathcal{B} . Moreover, in the example c) where the cycle is odd there will be a pair of undistinguished edges even if the S -free thread is hanging at v_i for $i = \lceil g/2 \rceil - 1$ or $i = \lfloor g/2 \rfloor + k + 1$. So, in the case of edge metric dimension configuration \mathcal{B} will have to be extended to a new configuration \mathcal{D} . Finally, in the graph G from d) there is no pair of undistinguished edges, so configuration \mathcal{C} is not an obstacle for S to be an edge metric generator, but there is a counterpart configuration for the edge metric dimension which will be configuration \mathcal{E} .

Definition 12 *Let G be a unicyclic graph and let S be a biactive branch-resolving set S in G . We say that the graph G with respect to S contains configuration:*

- \mathcal{D} . *If $k \leq \lceil g/2 \rceil - 1$ and there is an S -free thread hanging at a vertex v_i for some $i \in [k, \lceil g/2 \rceil - 1] \cup [\lfloor g/2 \rfloor + k + 1, g - 1] \cup \{0\}$;*
- \mathcal{E} . *If $a_S(C) = 2$ and there is an S -free thread of the length $\geq \lfloor g/2 \rfloor - k + 1$ hanging at a vertex v_i with $i \in [0, k]$. Moreover, if g is even, an S -free thread must be hanging at the vertex v_j with $j = g/2 + k - i$.*

Notice that if G contains configuration \mathcal{B} , then it certainly contains configuration \mathcal{D} , but the oposite does not hold. As for configuration \mathcal{E} , notice that for odd g we encounter configuration \mathcal{E} just with a thread hanging at v_i (as j is not integer anyway). Configuration \mathcal{E} is illustrated by Figure 6, where a pair of undistinguished edges is marked and we will show that the same holds generally, i.e. that configuration \mathcal{E} is an obstacle for set S to be an edge metric generator.

Lemma 13 *Let G be a unicyclic graph and let S be a biactive branch-resolving set in G . If the graph G contains configuration \mathcal{A} , \mathcal{D} , or \mathcal{E} with respect to S , then the set S is not an edge metric generator in G .*

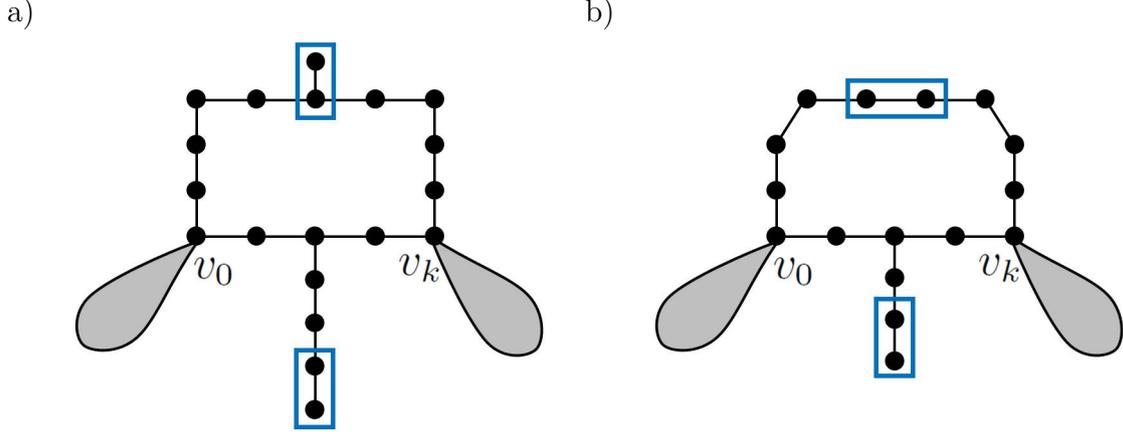

Figure 6: In both examples we consider a branch-resolving set S , where v_0 and v_k are the only two S -active vertices on C . Configuration \mathcal{E} with respect to S is shown: a) for an even cycle, b) for an odd cycle. In both graphs a pair of edges is marked which is not distinguished by S .

Proof. Let us assume that G contains configuration \mathcal{A} , \mathcal{D} , or \mathcal{E} with respect to S , and it is sufficient to find a pair of edges $x, x' \in E(G)$ which are not distinguished by S .

If G contains configuration \mathcal{A} , then edges v_0v_1 and v_0v_{g-1} are not distinguished by S .

Next, if G contains configuration \mathcal{D} , let v_i be the "problematic" vertex on C with an S -free thread hanging at it and let w be the neighbour of v_i on that thread. Then either pair of edges wv_i and v_iv_{i+1} or the pair wv_i and v_iv_{i-1} are not distinguished by S .

Finally, assume that G contains configuration \mathcal{E} . By definition this implies that $a_S(C) = 2$ and there is an S -free thread hanging at v_i for $i \in [0, k]$ of the length $\geq \lfloor g/2 \rfloor - k + 1$ and also an S -free thread hanging at v_j for $j = g/2 + k - i$ (if g is even). Let e be an edge in T_{v_i} such that $d(e, v_i) = \lfloor g/2 \rfloor - k$, note that such an edge must exist due to the fact that the thread attached to v_i is of length $\geq \lfloor g/2 \rfloor - k + 1$. If g is even, then v_j has an S -free thread attached, so let e' be the first edge on that thread (i.e. e' is incident to v_j). Then e and e' are not distinguished by S . If g is odd, let $e' = v_{\lfloor j \rfloor}v_{\lfloor j \rfloor + 1}$. Then again e and e' are not distinguished by S . ■

So far we have shown that configurations \mathcal{A} , \mathcal{D} , and \mathcal{E} are indeed the obstacle for S to be an edge metric generator. Next, we show that these are the only obstacles.

Lemma 14 *Let G be a unicyclic graph, and let S be a biactive branch-resolving set in G . If the graph G does not contain any of the configurations \mathcal{A} , \mathcal{D} , and \mathcal{E} with respect to S , then the set S is an edge metric generator in G .*

Proof. Suppose that the graph G does not contain any of the configurations \mathcal{A} , \mathcal{D} , and \mathcal{E} with respect to S . Let us suppose the contrary to the claim, i.e. that S is not an edge metric generator. Let $e = xy$ and $e' = x'y'$ be two edges in G which are not distinguished by S . If e (resp. e') is not an edge of C , then assume that x (resp. x') is closer to C than y (resp. y'). Also, let $G_1 = G/\{e, e'\}$ and let the vertex of G_1 obtained by contracting e

(resp. e') be denoted by x (resp. x'). Denote by $d_1(u, v)$ the distance of vertices u and v in G_1 . The length of the cycle in G_1 will be denoted by g_1 . Now we consider the following three cases.

Case 1: $e, e' \in E(C)$. Edges e and e' are not distinguished by S only if g is even and $a_S(C) = 2$, where the only two S -active vertices are an antipodal pair, which implies $k = g/2$. Hence, we infer that G contains configuration \mathcal{A} which is a contradiction.

Case 2: $e, e' \notin E(C)$. Let $e \in E(T_{v_i})$ and $e' \in E(T_{v_j})$. Lemma 2 then implies $i \neq j$, where without loss of generality we may assume $i < j$. Let $G_y, G_{y'}$ and G_x be the connected components of $G - \{e, e'\}$ that contains vertices y, y' and x respectively. If there is a vertex $s \in S \cap V(G_y \cup G_{y'})$, then obviously s distinguishes e and e' . So, let us assume $S \subseteq V(G_x)$ which implies $d(s, e) = d(s, x) = d_1(s, x)$ and $d(s, e') = d(s, x') = d_1(s, x')$. Hence, e and e' are distinguished by S in G if and only if x and x' are distinguished by S in G_1 .

As we assumed that e and e' are not distinguished by S in G , Lemma 7 implies that G_1 contains configurations \mathcal{A}, \mathcal{B} or \mathcal{C} . If G_1 contains configuration \mathcal{A} (resp. \mathcal{B}), then G obviously contains configuration \mathcal{A} (resp. \mathcal{D}), which is contradiction. On the other hand, if x and x' are not distinguished by S in G_1 due to configuration \mathcal{C} , then $g = g_1$ is even and $a_S(C) = 2$. Also, from $i < j$ we infer that x belongs to an S -free thread hanging at a vertex v_i for some $i \in [0, k]$ and $d(x, v_i) \geq g/2 - k$. Moreover, since x and x' are not distinguished by S , then x' must belong to T_{v_j} for $j = g/2 + k - i$. Given the fact that in G there is an edge e and e' attached to vertices x and x' respectively, this implies that G contains configuration \mathcal{E} , a contradiction.

Case 3: $e \in E(C)$ and $e' \notin E(C)$. Suppose $e = e_i = v_i v_{i+1}$ and $e' \in E(T_{v_j})$. Let $G_{x'}$ and $G_{y'}$ be the connected components of $G - e'$ containing vertices x' and y' respectively. If there is a vertex $s \in S \cap V(G_{y'})$, then e and e' would be distinguished by s . Therefore assume $S \subseteq V(G_{x'})$. If there is a vertex $s \in S$ such that the shortest path connecting vertices x' and s contains e , then e and e' would obviously be distinguished by S . Therefore, assume that no path from x' to vertices from S contains the edge e .

If e and e' are incident, say $x' = v_i$, then e and e' are not distinguished by S only if $i \in [k, \lceil g/2 \rceil - 1]$. Since $e' \notin E(C)$, this implies that G contains configuration \mathcal{D} . So, let us assume that e and e' are not incident which implies $x \neq x'$ in G_1 . Since no path from x' to vertices from S contains the edge e , we conclude that $d(e, s) = d_1(x, s)$ and $d(e', s) = d_1(x', s)$ for every $s \in S$. As we assumed that e and e' are not distinguished by S in G , it follows that x and x' are not distinguished by S in G_1 , so according to Lemma 7 the graph G_1 contains configuration \mathcal{A}, \mathcal{B} , or \mathcal{C} . Notice that in this case $g_1 = g - 1$.

Similarly as in the previous case, if G_1 contains configuration \mathcal{B} , then G contains configuration \mathcal{D} , which is contradiction. If G_1 contains configuration \mathcal{A} , then g_1 is even, so g is odd and $k = \lfloor g/2 \rfloor$. Also, as $e \in E(C)$ and $e' \notin E(C)$, it must hold $i \in [k, g - 1]$ and $j \in [0, k]$. Since $x' \in T_{v_j}$ has an edge $e' \notin E(C)$ attached to it, this implies there is an S -free thread hanging at v_j of the length $\geq 1 = \lfloor g/2 \rfloor - k + 1$. Therefore, G contains configuration \mathcal{E} on odd cycle, a contradiction.

Finally, let us assume x and x' are not distinguished by S in G_1 due to configuration \mathcal{C} . This implies g_1 is even and x' belongs to an S -free thread hanging at v_j for $j \in [0, k]$ and $d(x', v_j) \geq g/2 - k$. Since there is an edge e' hanging at x' in G , this implies G contains

configuration \mathcal{E} on odd cycle.

Altogether, we conclude that any two distinct edges are distinguished by S , which implies that S is an edge metric generator. \blacksquare

In the previous two lemmas we have established the necessary and sufficient condition for a set of vertices to be an edge metric generator, so now we can proceed with determining the exact value of the edge metric dimension of a unicyclic graph G . Notice that configuration \mathcal{D} and \mathcal{E} , similarly as configurations \mathcal{A} , \mathcal{B} , and \mathcal{C} , depend only on the position of S -active vertices on C . Therefore, Observation 8 holds also for configurations \mathcal{D} and \mathcal{E} and we can say that unicyclic graphs with $b(G) \geq 2$ contain configuration \mathcal{D} or \mathcal{E} without explicitly stating the set S . So, for unicyclic graphs with $b(G) \geq 2$ we can state the theorem which gives the edge metric dimension as follows.

Theorem 15 *Let G be a unicyclic graph with at least two branch-active vertices. Then*

$$\dim(G) = L(G) + \Delta_e,$$

where $\Delta_e = 0$ if the graph G does not contain any of the configurations \mathcal{A} , \mathcal{D} , or \mathcal{E} , and $\Delta_e = 1$ otherwise.

Proof. The proof is analogous to the proof of Theorem 9, using configurations \mathcal{D} and \mathcal{E} instead of configurations \mathcal{B} and \mathcal{C} respectively. Also, Lemmas 13 and 14 need to be applied instead of Lemmas 6 and 7, respectively. \blacksquare

Finally, if a unicyclic graph G contains less than two branch-active vertices on C , then a smallest branch-resolving set S is not biactive and needs to be introduced $2 - b(G)$ vertices to become biactive, the consequence of which is that different smallest *biactive* branch-resolving sets S may have different set of S -active vertices on C . Since the presence of configurations \mathcal{D} and \mathcal{E} depends on the position of S -active vertices on C , this implies that a unicyclic graph G with $b(G) < 2$ does contain configuration \mathcal{D} or \mathcal{E} with respect to one smallest biactive branch-resolving set, but not with respect to another. Since we need a smallest biactive branch-resolving set such that G does not contain any of the configurations \mathcal{A} , \mathcal{D} , and \mathcal{E} with respect to S , we introduce the following definition.

Definition 16 *We say that a unicyclic graph G is \mathcal{ADE} -negative, if there is a smallest biactive branch-resolving set S such that G does not contain any of the configurations \mathcal{A} , \mathcal{D} , and \mathcal{E} with respect to S . Otherwise, we say that G is \mathcal{ADE} -positive.*

Again, a unicyclic graph G with $b(G) \geq 2$ is \mathcal{ADE} -negative if it does not contain any of the configurations \mathcal{A} , \mathcal{D} , and \mathcal{E} , otherwise it is \mathcal{ADE} -positive. In case of unicyclic graphs with $b(G) < 2$, we can again consider corona product graphs $C_n \odot K_1$ as an example (see Figure 5). Notice that in this case it is opposite to the situation with vertex metric dimension, now a corona graph $C_n \odot K_1$ with odd $n \geq 7$ is \mathcal{ADE} -positive as the set $S = \{s_1, s_2\}$ shown in Figure 5.a) does not avoid configuration \mathcal{E} . On the other hand, a graph $C_n \odot K_1$ with even n is \mathcal{ADE} -negative (the set $S = \{s_1, s_2\}$ shown in Figure 5.b) avoids all three configurations and is therefore an edge metric generator).

Theorem 17 *Let G be a unicyclic graph. Then*

$$\text{edim}(G) = L(G) + \max\{0, 2 - b(G)\} + \Delta_e$$

where $\Delta_e = 0$ if the graph G is \mathcal{ADE} -negative, and $\Delta_e = 1$ if G is \mathcal{ADE} -positive.

Proof. Analogous to the proof of Theorem 11. ■

5 Difference between metric dimensions

Now, we can use the results proven in the previous two sections, and so we answer a proposal from [16]. Namely, in [16] it was shown that for a unicyclic graph G it holds that $|\dim(G) - \text{edim}(G)| \leq 1$ and the problem of determining whether the difference $\dim(G) - \text{edim}(G)$ is -1 , 0 and 1 was posed as a natural question. This can be easily answered for unicyclic graphs G with $b(G) \geq 2$ using Theorems 9 and 15.

Theorem 18 *Let G be a unicyclic graph with $b(G) \geq 2$. It holds that*

$$\dim(G) - \text{edim}(G) = \begin{cases} 1 & \text{if } G \text{ contains configuration } \mathcal{C}, \text{ but none of } \mathcal{A}, \mathcal{D}, \text{ and } \mathcal{E}, \\ -1 & \text{if } G \text{ contains configuration } \mathcal{D} \text{ or } \mathcal{E}, \text{ but none of } \mathcal{A}, \mathcal{B}, \text{ and } \mathcal{C}, \\ 0 & \text{otherwise.} \end{cases}$$

Proof. According to Theorems 11 and 17 both $\dim(G)$ and $\text{edim}(G)$ take their value from

$$L(G) + \max\{2 - b(G), 0\} \quad \text{and} \quad L(G) + \max\{2 - b(G), 0\} + 1.$$

Moreover, $\dim(G)$ (resp. $\text{edim}(G)$) will take the greater value of the two, if G contains configuration \mathcal{A} , \mathcal{B} , or \mathcal{C} (resp. configuration \mathcal{A} , \mathcal{D} , or \mathcal{E}). The observation that G cannot contain configuration \mathcal{B} without containing configuration \mathcal{D} concludes the proof. ■

A more general version of Theorem 18, which encapsulates also unicyclic graphs G with $b(G) < 2$, can be established using Theorems 11 and 17.

Theorem 19 *Let G be a unicyclic graph. It holds that*

$$\dim(G) - \text{edim}(G) = \begin{cases} 1 & \text{if } G \text{ is } \mathcal{ABC}\text{-positive and } \mathcal{ADE}\text{-negative}, \\ -1 & \text{if } G \text{ is } \mathcal{ABC}\text{-negative and } \mathcal{ADE}\text{-positive}, \\ 0 & \text{otherwise.} \end{cases}$$

Proof. It goes similarly as the proof of Theorem 18. ■

An example of graphs G with $b(G) < 2$ which are at the same time \mathcal{ABC} -positive and \mathcal{ADE} -negative, is the family of corona graphs $C_n \odot K_1$ with $n \geq 6$ even (see Figure 5). Therefore, for such graphs we have $\dim(C_n \odot K_1) - \text{edim}(C_n \odot K_1) = 3 - 2 = 1$. On the other hand, if $n \geq 7$ is odd, then the corona graphs $C_n \odot K_1$ can serve as an example of unicyclic graphs G with $b(G) < 2$ which are \mathcal{ABC} -negative and \mathcal{ADE} -positive. For them we derive $\dim(C_n \odot K_1) - \text{edim}(C_n \odot K_1) = 2 - 3 = -1$.

It is of interest to determine the classes of graphs for which $\dim(G)$ is smaller, equal or bigger from $\text{edim}(G)$. Several such families of graphs were presented in [10]. We can now make the same distinction in the class of unicyclic graphs.

Corollary 20 *Let G be a unicyclic graph with its cycle C . If C is odd then $\dim(G) \leq \text{edim}(G)$ and the inequality is strict if G is \mathcal{ABC} -negative and \mathcal{ADE} -positive. If C is even then $\dim(G) \geq \text{edim}(G)$ and the inequality is strict if G is \mathcal{ABC} -positive and \mathcal{ADE} -negative.*

Proof. Let C be the cycle in G and assume first that C is of odd length. According to Theorem 19, the inequality $\dim(G) \leq \text{edim}(G)$ will hold if every G which is \mathcal{ABC} -positive is also \mathcal{ADE} -positive. But that is the obvious consequence of the fact that configuration \mathcal{B} is also configuration \mathcal{D} , i.e. graph G which contains configuration \mathcal{B} certainly contains configuration \mathcal{D} with respect to the same set S , and the fact that graph on odd cycle cannot contain configuration \mathcal{C} .

Assume now that C is of even length. Again, Theorem 19 implies that the inequality $\dim(G) \geq \text{edim}(G)$ holds if every G which is \mathcal{ABC} -negative is also \mathcal{ADE} -negative. Since configuration \mathcal{B} is also \mathcal{D} and on even cycle every graph which contains \mathcal{E} also contains \mathcal{C} , the claim follows.

The claim on strictness is the direct consequence of Theorem 19. ■

Regarding Corollary 20, let us mention that in [9], it was shown that for bipartite graphs $\dim(G) \geq \text{edim}(G)$. Our result extends to all unicyclic graphs and characterizes when the equality holds.

6 Concluding remarks

By our previous work, both the vertex and the edge metric dimensions of a unicyclic graph G takes their value in

$$L(G) + \max\{2 - b(G), 0\} \quad \text{and} \quad L(G) + \max\{2 - b(G), 0\} + 1.$$

In this paper, we first characterize for unicyclic graphs G with $b(G) \geq 2$ when the above two values are encountered depending on the presence of configurations \mathcal{A} , \mathcal{B} , \mathcal{C} , \mathcal{D} , and \mathcal{E} . Afterwards, the approach was extended to unicyclic graphs G with $b(G) < 2$ by extending the concept of containment of configuration to \mathcal{X} -positivity and \mathcal{X} -negativity for $\mathcal{X} \in \{\mathcal{ABC}, \mathcal{ADE}\}$.

One may try to characterize unicyclic graphs G with $b(G) < 2$ and that are \mathcal{X} -positive and \mathcal{Y} -negative for distinct $\mathcal{X}, \mathcal{Y} \in \{\mathcal{ABC}, \mathcal{ADE}\}$, as this may need different approaches and this paper is already lengthy, we decided not to conduct this direction of research here. Here we state it explicitly as a problem.

Problem 21 *Characterize which unicyclic graphs G with $b(G) < 2$ are \mathcal{X} -positive and \mathcal{Y} -negative for distinct $\mathcal{X}, \mathcal{Y} \in \{\mathcal{ABC}, \mathcal{ADE}\}$.*
