# A CENTRAL LIMIT THEOREM FOR THE AVERAGE TARGET HITTING TIME FOR A RANDOM WALK ON A RANDOM GRAPH 

MATTHIAS LÖWE AND SARA TERVEER

#### Abstract

Consider a simple random walk on a realization of an Erdős-Rényi graph. Assuming that it is asymptotically almost surely (a.a.s.) connected, we prove a Central Limit Theorem (CLT) for the average target hitting time. The latter is the expected time it takes the random walk on average to first hit a fixed vertex $j$. The average is taken over all possible starting vertices, with respect to $\pi$, the invariant measure of the random walk.

## 1. Introduction

Let $G_{n}=\left(V_{n}, E_{n}\right)$ be a realization of an Erdős-Rényi random graph $\mathcal{G}(n, p)$, i.e. we set $V_{n}:=\{1, \ldots, n\}$ and we connect any two vertices $i \neq j \in V_{n}$ by an undirected edge $\{i, j\}$ with probability $p$, independently of all other edges. We collect the resulting edges in $E_{n}$. We will choose the probability $p=p_{n}$ such that it may and typically will depend on $n$ and such that $n p_{n}$ diverges to infinity. More precisely, we will require that for some fixed $\xi>1$,

$$
\begin{equation*}
\frac{(\log n)^{6 \xi}}{n p_{n}} \rightarrow 0 \tag{1.1}
\end{equation*}
$$

as $n \rightarrow \infty$ to ensure that the random graph is asymptotically almost surely connected and our results always tacitly assume connectivity of the graph. The parameter $\xi$ is immaterial for most of the proof and arises solely as an artifact of a spectral property of (a close relative of) the adjacency matrix of $G_{n}$ to be discussed later (see Lemma 4.1 below).
We will additionally require

$$
\begin{equation*}
p \leq \bar{p}<1 \tag{1.2}
\end{equation*}
$$

for some fixed $\bar{p} \in(0,1)$. In the following we omit the index $n$ whenever suitable. Unless otherwise remarked, the calculations are made on $G=G_{n}=\left(V_{n}, E_{n}\right)=$ $(V, E)$.
For fixed $n$ consider the simple random walk in discrete time $\left(X_{t}\right)$ on $G$ : If $X_{t}$ is in the vertex $i \in V$ at time $t, X_{t+1}$ will be in the vertex $j$ with probability $\frac{1}{d_{i}}$, where

[^0]$d_{i}$ denotes the degree of $i$, if $\{i, j\} \in E$, and with probability 0 , otherwise. The invariant distribution of this walk is given by
$$
\pi_{i}:=\frac{d_{i}}{\sum_{j \in V} d_{j}}=\frac{d_{i}}{2|E|} .
$$

Let $H_{i j}$ be the expected time it takes the walk to reach vertex $j \in V$ when starting from vertex $i \in V$. Of course, $H_{i j}$ will generally, among others, depend on the graph distance of $i$ and $j$. To compensate for this one introduces

$$
\begin{equation*}
H_{j}:=\sum_{i \in V} \pi_{i} H_{i j} \quad \text { and } \quad H^{i}:=\sum_{j \in V} \pi_{j} H_{i j} \tag{1.3}
\end{equation*}
$$

These quantities are called the mean target hitting time and the mean starting hitting time, respectively. Note that $H_{j}$ and $H^{i}$ are expectation values in the random walk measure, but with respect to the realization of the random graph, they are random variables. In [LT14], the asymptotic behaviour of $H_{j}$ and $H^{i}$ was analyzed on the level of a Law of Large Numbers. It was shown that

$$
H_{j}=n(1+o(1)) \quad \text { as well as } \quad H^{i}=n(1+o(1))
$$

asymptotically almost surely proving a conjecture from [SRBA04]. In [HL19] this result was extended to random hypergraphs. Such results can be considered Laws of Large Numbers for the average target or starting hitting times, respectively. After having proved them, a natural question is the one about fluctuations around such a Law of Large Numbers. In [LT20b] we proved a Central Limit Theorem (CLT) for the mean starting hitting time $H^{i}$ based on a CLT for incomplete U-statistics over a triangular array of random variables proved in [LT20a]. However, this technique cannot be used to also prove a CLT for the mean target hitting time.
The goal of this note is to also prove a CLT for $H_{j}$. Our main result will be
Theorem 1.1. Let $H_{j}$ be defined as in (1.3) and assume $p$ satisfies (1.1) and (1.2). Then

$$
\sqrt{\frac{p}{n(1-p)}}\left(H_{j}-n\right) \stackrel{n \rightarrow \infty}{\Longrightarrow} \mathcal{N}(0,1)
$$

where $\Rightarrow$ denotes convergence in distribution and $\mathcal{N}(0,1)$ is a standard normally distributed random variable.

To prove this theorem, we will proceed as follows: In Section 2, we will start by recalling a classic spectral decomposition of the hitting times by Lov96]. The resulting term (see (2.1) below) will be considered in two parts: The first one can be treated using an application of (a refined version of) the Delta method in Section 3. It will turn out that this term is responsible for the Gaussian fluctuations. The second part is a sum over inverse eigenvalues multiplied with components of the eigenvectors of a transformed adjacency matrix of the realization of the random graph. We will show that it is negligible on the scale of the CLT in Theorem 1.1.

Finally, in Section [5, we prove the main theorem by merging the aforementioned results and, yet again, applying the Delta method. Some auxiliary results are given in the Appendix.
Throughout this note, we will use the notation $a_{n} \approx b_{n}$ for $a_{n}=b_{n}(1+o(1))$ and $a_{n} \lesssim b_{n}$, if $a_{n} \leq b_{n}(1+o(1))$.

## 2. Spectral decomposition of the hitting times

We start as in [LT14], the spectral decomposition of the hitting times, taken from [Lov96], Section 3. To introduce it, let $A$ be the adjacency matrix of $G$, i.e. $A=\left(a_{i j}\right)$, with $a_{i j}=\mathbb{1}_{\{i, j\} \in E}$ as above. Let $D$ be the diagonal matrix $D=\left(\operatorname{diag}\left(d_{i}\right)\right)_{i=1}^{n}$. With $A$ we associate the matrix $B$ defined as $B:=D^{-\frac{1}{2}} A D^{-\frac{1}{2}}$. The matrix $B$ is intrinsically related to the symmetrically normalized Laplacian matrix $L$ of $G$ defined as $L:=\operatorname{Id}-B$. Note that $B=\left(b_{i j}\right)$ with

$$
b_{i j}=\frac{a_{i j}}{\sqrt{d_{i} d_{j}}}
$$

Therefore, $B$ is symmetric and hence has real eigenvalues. $\lambda_{1}=1$ is an eigenvalue of $B$, since $w:=\left(\sqrt{d_{1}}, \cdots, \sqrt{d_{n}}\right)$ satisfies $B w=w$ and by the Perron-Frobenius theorem $\lambda_{1}$ is the largest eigenvalue. We order the eigenvalues $\lambda_{k}$ of $B$ such that

$$
\lambda_{1} \geq \lambda_{2} \geq \cdots \geq \lambda_{n}
$$

and we normalize the eigenvectors $v_{k}$ to the eigenvalues $\lambda_{k}$ to have length one. Thus, in particular,

$$
v_{1}:=\frac{w}{\sqrt{2|E|}}=\left(\sqrt{\frac{d_{j}}{2|E|}}\right)_{j=1}^{n}=\left(\sqrt{\pi_{j}}\right)_{j=1}^{n} .
$$

Also recall that the matrix of the eigenvectors is orthogonal and the scalar product of two eigenvectors $v_{i}$ and $v_{j}$ satisfies $\left\langle v_{i}, v_{j}\right\rangle=\delta_{i j}$. With this, one has the following representation of $H_{j}$ :
Proposition 2.1 (cf. Lov96], Theorem 3.1 and Formula (3.3)). For all $i \neq j \in V$ we have $H_{i j}=2|E| \sum_{k=2}^{n} \frac{1}{1-\lambda_{k}}\left(\frac{v_{k, j}^{2}}{d_{j}}-\frac{v_{k, i} v_{k, j}}{\sqrt{d_{i} d_{j}}}\right)$. Thus,

$$
\begin{equation*}
H_{j}=\frac{2|E|}{d_{j}} \sum_{k=2}^{n} \frac{1}{1-\lambda_{k}} v_{k j}^{2} . \tag{2.1}
\end{equation*}
$$

Notice that the terms in the sum cannot be easily controlled because a priori we know little about the eigenvectors of $B$. This is in contrast to the situation where one considers the eigenvectors of $A$. For them, in [EKYY13] the authors showed complete delocalization (with the exception of the Perron-Frobenius eigenvector, of course).
We will subsequently decompose the expression in (2.1) into the term in front of the sum and the sum itself and analyze both separately.

## 3. The Delta Method

We begin with the factor in front of the sum in (2.1): If we denote by $N_{j}$ those edges that link vertex $j$ to another vertex, we have that $\left|N_{j}\right|=d_{j}$ and thus

$$
\frac{2|E|}{d_{j}}=\frac{2\left|E \backslash N_{j}\right|}{d_{j}}+2,
$$

where $E \backslash N_{j}$ denotes the set of edges excluding those that link $j$ to other vertices. In a first step, we will prove that $\log \frac{\left|E \backslash N_{j}\right|}{d_{j}}$ is asymptotically normally distributed.
Proposition 3.1. Under the assumptions of Theorem 1.1,

$$
\begin{equation*}
\sqrt{\frac{n p}{1-p}}\left(\log \left(2 \frac{\left|E \backslash N_{j}\right|}{d_{j}}+2\right)-\log n\right) \stackrel{n \rightarrow \infty}{\Longrightarrow} \mathcal{N}(0,1) . \tag{3.1}
\end{equation*}
$$

We will prepare the proof of Proposition 3.1 by a lemma. To this end, let us fix a vertex $j$ and have a closer look at $E \backslash N_{j}$. Notice that

$$
\left|E \backslash N_{j}\right|=\sum_{\substack{i<k \\ i, k \neq j}} a_{i k} .
$$

We can immediately prove a result on convergence in distribution for this last term:
Lemma 3.2. By the Lindeberg-Feller CLT for triangular arrays of random variables, we have

$$
\sqrt{\frac{\binom{n-1}{2}}{p(1-p)}}\left(\frac{\left|E \backslash N_{j}\right|}{\binom{n-1}{2}}-p\right) \stackrel{n \rightarrow \infty}{\Longrightarrow} \mathcal{N}(0,1) .
$$

Proof. For $i=2, \ldots, n, i \neq j$ let $S_{n, i}:=\sum_{\substack{k=1 \\ k \neq j}}^{i-1} a_{i k}$ and set

$$
Y_{n, i}:=\frac{1}{\sqrt{\binom{n-1}{2} p(1-p)}}\left(S_{n, i}-\mathbb{E} S_{n, i}\right) .
$$

Obviously, the $S_{n, i}$ and therefore the $Y_{n, i}$ are independent in $i$ for fixed $n$ by construction. Furthermore, $\mathbb{E} Y_{n, i}=0$. Denoting by $X \sim \operatorname{Bin}(N, q)$ the binomial distribution with parameters $N$ and $q$ of a random variable, from $S_{n, i} \sim \operatorname{Bin}(i-1, p)$ for $i<j$ and $S_{n, i} \sim \operatorname{Bin}(i-2, p)$ for $i>j$ we obtain:

$$
\begin{aligned}
\sum_{\substack{i=1 \\
i \neq j}}^{n} \mathbb{E} Y_{n, i}^{2} & =\sum_{\substack{i=1 \\
i \neq j}}^{n} \frac{\mathbb{V} S_{n, i}}{\binom{n-1}{2} p(1-p)}=\frac{1}{\binom{n-1}{2} p(1-p)}\left(\sum_{i=1}^{j-1}(i-1) p(1-p)+\sum_{i=j+1}^{n}(i-2) p(1-p)\right) \\
& =\frac{1}{\binom{n-1}{2}}\left(\sum_{i=1}^{n}(i-1)-(j-1)-\sum_{i=j+1}^{n} 1\right)=\frac{1}{\binom{n-1}{2}}\left(\binom{n}{2}-(n-1)\right)=1 .
\end{aligned}
$$

Furthermore, using that the fourth central moment of a $B(N, q)$ distributed random variable $Z$ is given by $\mathbb{E}\left[(Z-\mathbb{E} Z)^{4}\right]=N q(1-q)(1+3(N-2) q(1-q))$ we find that

$$
\begin{aligned}
E Y_{n, i}^{4} & =\frac{1}{\binom{n-1}{2}^{2} p^{2}(1-p)^{2}} \mathbb{E}\left[\left(S_{n, i}-\mathbb{E} S_{n, i}\right)^{4}\right] \\
& \leq \frac{1}{\binom{n-1}{2}^{2} p^{2}(1-p)^{2}} i p(1-p)(1+3(i-2) p(1-p)) \\
& \lesssim \frac{n p(1-p) 3(n-2) p(1-p)}{\binom{n-1}{2}^{2} p^{2}(1-p)^{2}}=\frac{3 n(n-2)}{\binom{n-1}{2}^{2}} \approx \frac{12}{n^{2}}
\end{aligned}
$$

Thus, by the Cauchy-Schwarz inequality and Markov's inequality we estimate that $\sum_{\substack{i=1 \\ i \neq j}}^{n} \mathbb{E}\left[Y_{n, i}^{2} \mathbb{1}_{\left\{\left|Y_{n, i}\right|>\delta\right\}}\right] \leq \sum_{\substack{i=1 \\ i \neq j^{1}}}^{n} \sqrt{\mathbb{E}\left[Y_{n, i}^{4}\right] \mathbb{P}\left(\left|Y_{n, i}\right|>\delta\right)} \leq \sum_{\substack{i=1 \\ i \neq j}}^{n} \sqrt{\frac{\mathbb{E}\left[Y_{n, i}^{4}\right]^{2}}{\delta^{4}}} \lesssim n \frac{12}{n^{2}} \frac{1}{\delta^{2}} \xrightarrow{n \rightarrow \infty} 0$.
Therefore, the Lindeberg-condition holds and we can apply the Lindeberg-Feller CLT for triangular arrays to $\left(\left(Y_{n, i}\right)_{i}\right)_{n}$. This immediately yields

$$
\sum_{i=1}^{n} Y_{n i} \stackrel{n \rightarrow \infty}{\longrightarrow} \mathcal{N}(0,1)
$$

From $\sum_{\substack{i=1 \\ i \neq j}}^{n} S_{n, i}=\left|E \backslash N_{j}\right|$ and thus $\sum_{\substack{i=1 \\ i \neq j}}^{n} \mathbb{E} S_{n, i}=\binom{n-1}{2} p$ we arrive at

$$
\frac{1}{\sqrt{\binom{n-1}{2} p(1-p)}}\left(\left|E \backslash N_{j}\right|-\binom{n-1}{2} p\right)=\sum_{\substack{i=1 \\ i \neq j}} Y_{n, i} \stackrel{n \rightarrow \infty}{\longrightarrow} \mathcal{N}(0,1) .
$$

This is our claim.
We would like to apply this lemma by applying the Delta method in the form of Theorem A. 2 in the appendix. To do so, we need to define uniform continuity of a function over a sequence:

Definition 3.3. Consider an open set $D \subset \mathbb{R}^{k}, k \in \mathbb{N}$ and a sequence of vectors $\left(x_{n}\right)_{n \in \mathbb{N}} \subset D$. For $l \in \mathbb{N}$, let $f: D \rightarrow \mathbb{R}^{l}$ be a continuous function (on $D$ ). We call $f$ uniformly continuous with respect to the sequence $\left(x_{n}\right)$ if for any $\varepsilon>0$ there is a $\delta>0$ and an $N \in \mathbb{N}$, so that for all $z \in \mathbb{R}^{k}$ with $\|z\|<\delta$ and $n \geq \mathbb{N}$

$$
\left\|f\left(x_{n}+z\right)-f\left(x_{n}\right)\right\|<\varepsilon .
$$

Here, by $\|\cdot\|$, we denote the Euclidean norm.
With this definition and the Delta method as stated in the appendix in mind, we can prove the proposition:

Proof of Proposition 3.1. Note that by Levy's CLT, we also know that

$$
\frac{1}{\sqrt{(n-1) p(1-p)}}\left(d_{j}-(n-1) p\right) \stackrel{n \rightarrow \infty}{\longrightarrow} \mathcal{N}(0,1) .
$$

Thus by independence of $d_{j}$ and $E \backslash N_{j}$ and Lemma 3.2:

$$
\left(\frac{\left|E \backslash N_{j}\right|}{\sqrt{\binom{n-1}{2} p(1-p)}}, \frac{d_{j}}{\sqrt{(n-1) p(1-p)}}\right)-\left(\frac{\binom{n-1}{2} p}{\sqrt{\binom{n-1}{2} p(1-p)}}, \frac{(n-1) p}{\sqrt{(n-1) p(1-p)}}\right) \stackrel{n \rightarrow \infty}{\Longrightarrow} \mathcal{N}(0, I)
$$

where $I$ is the $2 \times 2$ identity matrix. Consequently

$$
r_{n} \cdot\left(T_{n}-\theta_{n}\right) \stackrel{n \rightarrow \infty}{\Longrightarrow} \mathcal{N}(0, I)=T
$$

with

$$
\begin{equation*}
r_{n}:=\sqrt{\frac{(n-1) p}{1-p}}, T_{n}:=\left(\frac{\left|E \backslash N_{j}\right|}{\sqrt{\binom{n-1}{2}(n-1) p^{2}}}, \frac{d_{j}}{(n-1) p}\right)^{t}, \text { and } \theta_{n}=\left(\sqrt{\frac{n-2}{2}}, 1\right)^{t} \tag{3.2}
\end{equation*}
$$

Now consider the situation of Definition 3.3 with $k=2$ and $D=(0, \infty)^{2}$. Then $\theta_{n} \in D$ for $n \geq 3$. Moreover, consider the continuous differentiable function

$$
\phi: D \rightarrow \mathbb{R}, \quad(x, y) \mapsto \log \frac{x}{y}
$$

Note that $\nabla \phi(x, y)=\left(\frac{1}{x},-\frac{1}{y}\right)$ is uniformly continuous on $D^{\prime}=\left(\frac{1}{2}, \infty\right)^{2}$, and since $\theta_{n} \in D^{\prime}$ for all $n \geq 3, \nabla \phi(x, y)$ is uniformly continuous with respect to $\theta_{n}$. Furthermore, $\lim _{n \rightarrow \infty} \nabla \phi\left(\theta_{n}\right)=(0,-1)^{t}$. Thus, we can apply Theorem A. 2

$$
r_{n}\left(\phi\left(T_{n}\right)-\phi\left(\theta_{n}\right)\right) \xrightarrow{n \rightarrow \infty}\left(\lim _{n \rightarrow \infty} \nabla \phi\left(\theta_{n}\right)\right)^{t} \cdot T .
$$

Since $T$ is a two-dimensional normal distribution with expectation vector 0 and identity covariance matrix, multiplication by $(0,-1)^{t}$ gives a one-dimensional standard normal distribution $\mathcal{N}(0,1)$. Hence

$$
\sqrt{\frac{(n-1) p}{1-p}}\left[\log \left(\sqrt{\frac{2}{n-2}} \cdot \frac{\left|E \backslash N_{j}\right|}{d_{j}}\right)-\log \left(\sqrt{\frac{n-2}{2}}\right)\right] \stackrel{n \rightarrow \infty}{\Longrightarrow} \mathcal{N}(0,1)
$$

which leads to

$$
\sqrt{\frac{(n-1) p}{1-p}}\left(\log \left(2 \frac{\left|E \backslash N_{j}\right|}{d_{j}}\right)-\log (n-2)\right) \stackrel{n \rightarrow \infty}{\Longrightarrow} \mathcal{N}(0,1) .
$$

For another application of the Delta method, let $k=1$,
$D=(0, \infty), r_{n}=\sqrt{\frac{(n-1) p}{1-p}}, T_{n}=\log \left(2 \frac{\left|E \backslash N_{j}\right|}{d_{j}}\right), \theta_{n}=\log (n-2)$, and $\phi(x)=\log \left(e^{x}+2\right)$.
Note that again $\phi$ is continuously differentiable on $D$ with $\nabla \phi(x)=\frac{1}{1+\frac{2}{\exp (x)}}$ and $\lim _{n \rightarrow \infty} \nabla \phi\left(\theta_{n}\right)=1$. Furthermore, $\nabla \phi$ is uniformly continuous with respect to $\theta_{n}$. By Theorem A.2, we obtain $\sqrt{\frac{(n-1) p}{1-p}}\left(\log \left(2 \frac{\left|E \backslash N_{j}\right|}{d_{j}}+2\right)-\log n\right) \stackrel{n \rightarrow \infty}{\longrightarrow} \mathcal{N}(0,1)$ which was our claim (equivalently, one could apply Slutzky's theorem).

## 4. Negligibility of the remaining term

The remaining term is a composition of non-Perron eigenvalues of $B$ and entries of their corresponding eigenvectors. We begin by stating the following result on the spectral gap:

Lemma 4.1. Under the assumptions of Theorem 1.1, with probability converging to 1 we have for all $k=2, \ldots, n$

$$
\left|\lambda_{k}\right| \lesssim \frac{2}{\sqrt{n p}}
$$

Proof. Let $X$ have a $\operatorname{Bin}(n-2, p)$-distribution and define

$$
\mu:=\mathbb{E}\left[\frac{1}{X+1}\right] \quad \text { and } \quad \tau:=\mathbb{E}\left[\frac{1}{\sqrt{X+1}}\right] .
$$

Recall that by a result from [Ž09] for a random variable $X$ with $X \sim \operatorname{Bin}(n, p)$ we have

$$
\mathbb{E}\left[\left(\frac{1}{X+1}\right)^{r}\right] \approx \frac{1}{(n p)^{r}}
$$

for all $r>0$. Now let

$$
B^{\prime}=\frac{1}{\rho} B
$$

with

$$
\rho^{2}=(n-1)\left(p \mu^{2}-p^{2} \tau^{4}\right) \leq n p \mu^{2} \approx \frac{1}{n p} .
$$

Denote by $\mu_{1} \geq \ldots \geq \mu_{n}, k=1, \ldots, n$ the eigenvalues of $B^{\prime}$. Since $B^{\prime}$ satisfies Definition 2.2 in [EKYY13], by Corollary 6.6 in the same paper,

$$
\begin{equation*}
\left|\mu_{k}\right| \lesssim 2+o(1) \tag{4.1}
\end{equation*}
$$

for all $k=2, \ldots, n$ with probability converging to 1 (note, however, the different indexing: we sorted eigenvalues in descending order, [EKYY13] sort them increasingly. Furthermore, notice the difference in nomenclature: in EKYY13] $\lambda_{k}, k=1, \ldots, n$ denotes the eigenvalues of $H$, unlike here, where they denote the eigenvalues of $B$ ). We obtain that $\lambda_{k}=\rho \mu_{k}$ for the eigenvalues $\lambda_{k}, k=1, \ldots, n$ of $B$. Thus, for $k=2, \ldots, n$ by (4.1)

$$
\lambda_{k}=\rho \mu_{k} \lesssim \frac{2}{\sqrt{n p}}
$$

with probability converging to 1 and the claim holds.
We will now prove that the sum in (2.1) is asymptotically negligible on the appropriate scale:

Proposition 4.2. Under the assumptions of Theorem 1.1,

$$
\sqrt{\frac{n p}{1-p}} \log \left(\sum_{k=2}^{n} \frac{1}{1-\lambda_{k}} v_{k j}^{2}\right) \xrightarrow[n \rightarrow \infty]{\mathbb{P}} 0
$$

as $n \rightarrow \infty$ for every $j \in\{1, \ldots, n\}$.

Proof. To prove the proposition, let us rewrite the term in the logarithm. By expanding the geometric series (note that $\left|\lambda_{k}\right|<1$ ),
$Z_{n}:=\sum_{k=2}^{n} \frac{1}{1-\lambda_{k}} v_{k j}^{2}=\sum_{k=2}^{n} \sum_{m=0}^{\infty} \lambda_{k}^{m} v_{k j}^{2}=\sum_{k=2}^{n}\left(1+\lambda_{k}+\lambda_{k}^{2} \sum_{m=0}^{\infty} \lambda_{k}^{m}\right) v_{k j}^{2}=\sum_{k=2}^{n}\left(1+\lambda_{k}+\frac{\lambda_{k}^{2}}{1-\lambda_{k}}\right) v_{k j}^{2}$
As seen earlier in Section 2 we have that $v_{1 j}^{2}=\pi_{j}, \sum_{k=1}^{n} v_{k j}^{2}=1$ and moreover,

$$
\sum_{k=1}^{n} \lambda_{k} v_{k j}^{2}=\sum_{k=1}^{n} \sum_{i=1}^{n} b_{j i} v_{k i} v_{k j}=\sum_{i=1}^{n} b_{j i} \cdot\left\langle v_{i}, v_{j}\right\rangle=b_{j j}=0
$$

Thus we arrive at

$$
Z_{n}=\sum_{k=2}^{n} v_{k j}^{2}+\sum_{k=2}^{n} \lambda_{k} v_{k j}^{2}+\sum_{k=2}^{n} \frac{1}{1-\lambda_{k}} \lambda_{k}^{2} v_{k j}^{2}=1-2 \pi_{j}+\sum_{k=2}^{n} \frac{\lambda_{k}^{2}}{1-\lambda_{k}} v_{k j}^{2} .
$$

Finally, making use of Lemma 4.1

$$
0 \leq \sum_{k=2}^{n} \frac{\lambda_{k}^{2}}{1-\lambda_{k}} v_{k j}^{2}=O\left(\frac{1}{n p}\right) \cdot \sum_{k=2}^{n} \frac{1}{1-\lambda_{k}} v_{k j}^{2}=O\left(\frac{1}{n p}\right) \cdot Z_{n},
$$

with probability converging to 1 and hence

$$
1-2 \pi_{j} \leq Z_{n} \quad \text { as well as } Z_{n} \leq 1-2 \pi_{j}+Z_{n} \cdot O\left(\frac{1}{n p}\right)
$$

which is equivalent to saying that

$$
\begin{equation*}
-2 \pi_{j} \leq Z_{n}-1 \leq-2 \pi_{j} \cdot(1+o(1))+O\left(\frac{1}{n p}\right) \tag{4.2}
\end{equation*}
$$

with probability converging to 1 .
As $\pi_{j}=\frac{d_{j}}{2|E|}$ for all $j=1, \ldots, n$ it is immediate to see that the $\pi_{j}$ are identically distributed for $j=1, \ldots, n$. Furthermore, $\sum_{j=1}^{n} d_{j}=2|E|$. Thus obviously, we have

$$
n \mathbb{E}\left[\pi_{j}\right]=\sum_{j=1}^{n} \mathbb{E}\left[\pi_{j}\right]=\frac{1}{2|E|} \mathbb{E}\left[\sum_{j=1}^{n} d_{j}\right]=1 .
$$

Therefore,

$$
\mathbb{E}\left[\sqrt{\frac{n p}{1-p}} \pi_{j}\right]=\sqrt{\frac{p}{n(1-p)}} \xrightarrow{n \rightarrow \infty} 0
$$

and by non-negativity of $\sqrt{\frac{n p}{1-p}} \pi_{j}$ and Markov's inequality,

$$
\begin{equation*}
\sqrt{\frac{n p}{1-p}} \pi_{j} \xrightarrow[n \rightarrow \infty]{\mathbb{P}} 0 \tag{4.3}
\end{equation*}
$$

and therefore together with (4.2), $\sqrt{\frac{n p}{1-p}}\left(Z_{n}-1\right) \xrightarrow[n \rightarrow \infty]{\mathbb{P}} 0$, using that $n p(1-p) \rightarrow \infty$ as $n \rightarrow \infty$. By Lemma A.1, we therefore obtain

$$
\sqrt{\frac{n p}{1-p}} \log Z_{n} \xrightarrow[n \rightarrow \infty]{\mathbb{P}} 0,
$$

proving the claim.

## 5. Proof of Theorem 1.1

We proceed by completing the proof, using the decomposition (2.1)

$$
\begin{gathered}
\sqrt{\frac{n p}{1-p}}\left(\log \left(H_{j}\right)-\log n\right)=\sqrt{\frac{n p}{1-p}}\left[\log \left(2 \frac{\left|E \backslash N_{j}\right|}{d_{j}}+2\right)+\log \left(\sum_{k=2}^{n} \frac{1}{1-\lambda_{k}} v_{k j}^{2}\right)-\log n\right] \\
=\sqrt{\frac{n p}{1-p}}\left[\log \left(2 \frac{\left|E \backslash N_{j}\right|}{d_{j}}+2\right)-\log n\right]+\sqrt{\frac{n p}{1-p}} \log \left(\sum_{k=2}^{n} \frac{1}{1-\lambda_{k}} v_{k j}^{2}\right) .
\end{gathered}
$$

The first term converges to a standard Gaussian random variable in distribution by Proposition 3.1. The second part converges to 0 in probability by Proposition 4.2, By Slutzky's theorem we obtain

$$
\begin{equation*}
\sqrt{\frac{n p}{1-p}}\left(\log H_{j}-\log n\right) \stackrel{n \rightarrow \infty}{\longrightarrow} \mathcal{N}(0,1) \tag{5.1}
\end{equation*}
$$

We apply one more instance of the Delta method: Choose $k=2$,

$$
D=\left(\mathbb{R}^{+}\right)^{2}, r_{n}=\sqrt{\frac{n p}{1-p}}, T_{n}=\left(\log H_{j}, n\right)^{t}, \theta_{n}=(\log n, n)^{t}, \text { and } \phi(x, y)=\frac{1}{y} \exp (x) .
$$

Notice that $\phi$ is continuously differentiable with

$$
\nabla \phi(x, y)=\left(\frac{1}{y} \exp (x),-\frac{1}{y^{2}} \exp (x)\right)^{t}
$$

and that $\lim _{n \rightarrow \infty} \nabla \phi\left(\theta_{n}\right)=(1,0)^{t}$.
Furthermore, $\nabla \phi$ is uniformly continuous with respect to $\theta_{n}$ : Let $\varepsilon>0$ arbitrary, but fixed, and choose $\delta=\log \left(\frac{\varepsilon}{2}+1\right)$ and $z=\left(z_{1}, z_{2}\right)$ with $0<\|z\|<\delta$. Without loss of generality, let $z_{1}, z_{2}>0$ (for negative $z_{1}$ or $z_{2}$, the procedure is analogous).

$$
\begin{aligned}
\nabla \phi\left(\theta_{n}+z\right)-\nabla \phi\left(\theta_{n}\right) & =\left(\frac{1}{n+z_{2}} \exp \left(\log n+z_{1}\right),-\frac{1}{\left(n+z_{2}\right)^{2}} \exp \left(\log \left(n+z_{1}\right)\right)\right)^{t}-\left(1,-\frac{1}{n}\right)^{t} \\
& =\left(\frac{1}{n+z_{2}} n e^{z_{1}}-1,-\frac{1}{\left(n+z_{2}\right)^{2}} n e^{z_{1}}-\frac{1}{n}\right)^{t}
\end{aligned}
$$

The second component is of order $O\left(\frac{1}{n}\right)$. Thus,

$$
\begin{aligned}
\left\|\nabla \phi\left(\theta_{n}+z\right)-\nabla \phi\left(\theta_{n}\right)\right\| & =\sqrt{\left(\frac{1}{n+z_{2}} n e^{z_{1}}-1\right)^{2}+O\left(\frac{1}{n}\right)^{2}} \\
& \leq\left|\frac{n\left(e^{z_{1}}-1\right)-z_{2}}{n+z_{2}}\right|+O\left(\frac{1}{n}\right) \leq\left|e^{z_{1}}-1\right|+\frac{z_{2}}{n}+O\left(\frac{1}{n}\right)=e^{z_{1}}-1+O\left(\frac{1}{n}\right),
\end{aligned}
$$

since $z_{1}>0$. Now by $z_{1}<\|z\|<\delta, e^{z_{1}}<e^{\delta}=\frac{\varepsilon}{2}+1$. Additionally, there is some $N \in \mathbb{N}$ so that for all $n \geq N$, the $O\left(\frac{1}{n}\right)$-term is bounded by $\frac{\varepsilon}{2}$. Thus, for all $n \geq N$ and all $z \in D$ with $\|z\|<\delta$,

$$
\left\|\nabla \phi\left(\theta_{n}+z\right)-\nabla \phi\left(\theta_{n}\right)\right\|<\varepsilon
$$

which proves uniform continuity with respect to $\theta_{n}$. By Theorem A.2.

$$
\sqrt{\frac{n p}{1-p}}\left(\frac{H_{j}}{n}-1\right)=\sqrt{\frac{n p}{1-p}} \frac{H_{j}-n}{n}=\sqrt{\frac{p}{n(1-p)}}\left(H_{j}-n\right) \stackrel{n \rightarrow \infty}{\Longrightarrow} \mathcal{N}(0,1) .
$$

This completes the proof of theorem 1.1.

## Appendix A. Auxiliary Results

The following lemma shows the convergence in probability of logarithmic terms:
Lemma A.1. Let $a_{n}$ be a sequence of non-negative numbers and $X_{n}$ a sequence of random variables, so that, as $n \rightarrow \infty, a_{n} \rightarrow \infty$ and $a_{n} X_{n} \rightarrow 0$ in probability. Then $a_{n} \log \left(1+X_{n}\right)$ converges to 0 in probability.

Proof. Let $\varepsilon>0$ and choose $\zeta>0$ such that $\zeta+\frac{\zeta^{2}}{2}=\varepsilon$. Since $a_{n} X_{n} \rightarrow 0$ in probability, $\mathbb{P}\left(\left|a_{n} X_{n}\right| \leq \zeta\right) \rightarrow 1$, so for every $\delta>0$ there is a $N(\delta) \in \mathbb{N}$ such that for all $n \geq N(\delta), \mathbb{P}\left(\left|a_{n} X_{n}\right| \leq \zeta\right) \geq 1-\delta$ and $a_{n} \geq 1$ (since $a_{n} \rightarrow \infty$ ). Using a Taylor series, there is an $\alpha \geq 0$ such that $\log (1+x)=x-\frac{1}{2(1+\alpha)} x^{2}$, therefore for $\omega \in \Omega_{n, \zeta}:=\left\{\left|a_{n} X_{n}(\omega)\right| \leq \zeta\right\}$,
$\left|a_{n} \log \left(1+X_{n}(\omega)\right)\right|=\left|a_{n} X_{n}(\omega)-\frac{a_{n}}{2(1+\alpha)} X_{n}^{2}(\omega)\right| \leq\left|a_{n} X_{n}(\omega)\right|+\left|\frac{a_{n}}{2} X_{n}^{2}(\omega)\right| \leq \zeta+\frac{\zeta^{2}}{2}=\varepsilon$.
Thus, for every $\delta>0$, there is a $N(\delta) \in \mathbb{N}$ such that for all $n \geq N(\delta)$,

$$
\mathbb{P}\left(\left|a_{n} \log \left(1+X_{n}(\omega)\right)\right| \leq \varepsilon\right) \geq \mathbb{P}\left(\left|a_{n} X_{n}\right| \leq \zeta\right) \geq 1-\delta,
$$

i.e. $\mathbb{P}\left(\left|a_{n} \log \left(1+X_{n}(\omega)\right)\right| \leq \varepsilon\right) \rightarrow 1$. Since $\varepsilon>0$ was chosen arbitrarily, $a_{n} \log (1+$ $\left.X_{n}(\omega)\right) \rightarrow 0$ in probability.
The uniform Delta method, c.f. Theorem 3.8. in vdV98], is a crucial point in our analysis. We extend the result by van der Vaart to include the setting where one or multiple components of $\theta_{n}$ tend to infinity as $n$ increases:

Theorem A. 2 (Delta-Method). Consider an open set $D \subset \mathbb{R}^{k}$ and random vectors $T_{n}$ with values in $D$ and satisfying $r_{n}\left(T_{n}-\theta_{n}\right) \xrightarrow{n \rightarrow \infty} T$ for vectors $\theta_{n} \in D$, scalars $r_{n} \rightarrow \infty$ and a random vector $T \in \mathbb{R}^{k}$. Consider a continuously differentiable function $\phi: D \rightarrow \mathbb{R}$. Furthermore, assume that $\nabla \phi$ is uniformly continuous with respect to $\theta_{n}$ and that $\lim _{n \rightarrow \infty} \nabla \phi\left(\theta_{n}\right)$ exists. Then

$$
r_{n}\left(\phi\left(T_{n}\right)-\phi\left(\theta_{n}\right)\right) \xrightarrow{n \rightarrow \infty}\left(\lim _{n \rightarrow \infty} \nabla \phi\left(\theta_{n}\right)\right)^{t} \cdot T .
$$

By $\nabla \phi$ we denote the gradient of $\phi$.
Proof. For fixed $h \in \mathbb{R}^{k}$ and $s \in[0,1]$, define $g_{n}(s)=\phi\left(\theta_{n}+s h\right)$. Because $\phi$ is continuously differentiable, $g_{n}:[0,1] \rightarrow \mathbb{R}$ is also continuously differentiable with derivative $g_{n}^{\prime}(s)=\left(\nabla \phi\left(\theta_{n}+s h\right)\right)^{t} \cdot h$. By the mean-value theorem, $g_{n}(1)-g_{n}(0)=$ $g_{n}^{\prime}(\xi)$ for some $\xi \in[0,1]$. Thus,

$$
\begin{align*}
R_{n}(h) & :=\phi\left(\theta_{n}+h\right)-\phi\left(\theta_{n}\right)-\left(\lim _{n \rightarrow \infty} \nabla \phi\left(\theta_{n}\right)\right)^{t} \cdot h  \tag{A.1}\\
& =g_{n}(1)-g_{n}(0)-\left(\lim _{n \rightarrow \infty} \nabla \phi\left(\theta_{n}\right)\right)^{t} \cdot h
\end{align*}
$$

$$
\begin{align*}
& =g_{n}^{\prime}(\xi)-\left(\lim _{n \rightarrow \infty} \nabla \phi\left(\theta_{n}\right)\right)^{t} \cdot h \\
& =\left(\nabla \phi\left(\theta_{n}+\xi h\right)\right)^{t} \cdot h-\left(\lim _{n \rightarrow \infty} \nabla \phi\left(\theta_{n}\right)\right)^{t} \cdot h \\
& =\left[\left(\nabla \phi\left(\theta_{n}+\xi h\right)\right)-\left(\lim _{n \rightarrow \infty} \nabla \phi\left(\theta_{n}\right)\right)\right]^{t} \cdot h . \tag{A.2}
\end{align*}
$$

Now denote by $\|\cdot\|$ the Euclidean norm. By the triangle inequality,

$$
\begin{aligned}
\|\left(\nabla \phi\left(\theta_{n}+\xi h\right)\right)^{t}- & \left(\lim _{n \rightarrow \infty} \nabla \phi\left(\theta_{n}\right)\right)^{t} \| \\
& \leq\left\|\left(\nabla \phi\left(\theta_{n}+\xi h\right)\right)^{t}-\left(\nabla \phi\left(\theta_{n}\right)\right)^{t}\right\|+\left\|\left(\nabla \phi\left(\theta_{n}\right)\right)^{t}-\left(\lim _{n \rightarrow \infty} \nabla \phi\left(\theta_{n}\right)\right)^{t}\right\| .
\end{aligned}
$$

For any $\varepsilon>0$, the second term on the right hand side is bounded by $\varepsilon / 2$ for sufficiently large $n$ by definition of the limit. Furthermore, by uniform continuity of $\nabla \phi$ with respect to $\theta_{n}$, there is some $\delta>0$ so that the first term on the right hand side is also bounded by $\varepsilon / 2$ as long as $\|\xi h\|<\delta$. Thus, if $\|h\|<\delta$ and therefore by $0 \leq \xi \leq 1$ also $\|\xi h\|<\delta$, we find by eq. (A.2)

$$
\begin{align*}
\left|R_{n}(h)\right| & =\left|\left\langle\nabla \phi\left(\theta_{n}+\xi h\right)-\lim _{n \rightarrow \infty} \nabla \phi\left(\theta_{n}\right), h\right\rangle\right| \\
& \leq\left\|\nabla \phi\left(\theta_{n}+\xi h\right)-\lim _{n \rightarrow \infty} \nabla \phi\left(\theta_{n}\right)\right\| \cdot\|h\|<\varepsilon\|h\|<\varepsilon \delta \tag{A.3}
\end{align*}
$$

for sufficiently large $n$. For any $\eta>0$, denote $A_{n}=\left\{\left\|R_{n}\left(T_{n}-\theta_{n}\right)\right\| \geq \frac{\eta}{r_{n}}\right\}$ and $B_{n}=\left\{\left\|T_{n}-\theta_{n}\right\| \geq \delta\right\}$. Then, by eq. (A.3), $A_{n} \cap B_{n}^{c} \subseteq\left\{\varepsilon \delta \geq \frac{\eta}{r_{n}}\right\}$. Since $r_{n} \rightarrow \infty$, this set is asymptotically empty, therefore $\mathbb{P}\left(A_{n} \cap B_{n}^{c}\right) \xrightarrow{n \rightarrow \infty} 0$. On the other hand,

$$
\mathbb{P}\left(A_{n} \cap B_{n}\right) \leq \mathbb{P}\left(B_{n}\right) \xrightarrow{n \rightarrow \infty} 0,
$$

because from $r_{n}\left(T_{n}-\theta_{n}\right) \xrightarrow{n \rightarrow \infty} T$ we conclude that $\left\|T_{n}-\theta_{n}\right\| \xrightarrow[n \rightarrow \infty]{\mathbb{P}} 0$. Altogether, $\mathbb{P}\left(A_{n}\right) \xrightarrow{n \rightarrow \infty} 0$, i.e. $r_{n} \cdot R_{n}\left(T_{n}-\theta_{n}\right)$ converges to 0 in probability. Thus, by eq. (A.1)

$$
r_{n}\left(\phi\left(T_{n}\right)-\phi\left(\theta_{n}\right)\right)-\left(\lim _{n \rightarrow \infty} \nabla \phi\left(\theta_{n}\right)\right)^{t} \cdot r_{n}\left(T_{n}-\theta_{n}\right) \xrightarrow[n \rightarrow \infty]{\mathbb{P}} 0 .
$$

Since $\left(\lim _{n \rightarrow \infty} \nabla \phi\left(\theta_{n}\right)\right)^{t} \cdot r_{n}\left(T_{n}-\theta_{n}\right)$ converges to $\left(\lim _{n \rightarrow \infty} \nabla \phi\left(\theta_{n}\right)\right)^{t} \cdot T$ in distribution,

$$
r_{n}\left(\phi\left(T_{n}\right)-\phi\left(\theta_{n}\right)\right) \stackrel{n \rightarrow \infty}{\longrightarrow}\left(\lim _{n \rightarrow \infty} \nabla \phi\left(\theta_{n}\right)\right)^{t} \cdot T
$$

which completes the proof.
