# THE MULTIVARIATE FUNCTIONAL DE JONG CLT 

CHRISTIAN DÖBLER, MIKOŁAJ KASPRZAK AND GIOVANNI PECCATI

#### Abstract

We prove a multivariate functional version of de Jong's CLT (1990) yielding that, given a sequence of vectors of Hoeffding-degenerate U-statistics, the corresponding empirical processes on $[0,1]$ weakly converge in the Skorohod space as soon as their fourth cumulants in $t=1$ vanish asymptotically and a certain strengthening of the Lindeberg-type condition is verified. As an application, we lift to the functional level the 'universality of Wiener chaos' phenomenon first observed in Nourdin, Peccati and Reinert (2010).

Keywords: U-statistics, functional limit theorems, contractions, product formulae, Hoeffding decompositions, universality

## 1. Introduction and (SIMPLIFIED) STATEMENTS OF MAIN RESULTS

1.1. Motivation. Degenerate $U$-statistics (see Section 2 for definitions) are the fundamental components of Hoeffding decompositions for generic random variables of the type $f\left(X_{1}, \ldots, X_{n}\right)$, with $X_{1}, \ldots, X_{n}$ an independent sample, and are thus pivotal objects in stochastic analysis Hoe48, Ser80, KB94, ES81, LRR16. A special case of degenerate $U$-statistic is given by homogeneous sums [MOO10, NPR10a, Rot79, which are in turn the building blocks of Gaussian and Poisson Wiener chaoses [PT11,NP12], as well as the basis of the Fourier-Walsh expansion of mappings defined on discrete cubes ['D14,GS15. For future reference, we recall that a homogeneous sum of order $p \geq 1$ is a random variable $Q_{n}\left(f_{n}, \mathfrak{X}\right)$ with the form

$$
Q_{n}\left(f_{n}, \mathfrak{X}\right)=\sum_{i_{1}, \ldots, i_{p}=1}^{n} f_{n}\left(i_{1}, \ldots, i_{p}\right) \prod_{l=1}^{p} X_{i_{l}}
$$

where $\mathfrak{X}=\left(X_{i}\right)_{i \in \mathbb{N}}$ is a sequence of independent, mean zero and unit variance random variables and $f_{n}$ is a symmetric kernel (i.e. $f_{n}\left(i_{1}, \ldots, i_{n}\right)=f_{n}\left(i_{\pi(1)}, \ldots i_{\pi(n)}\right)$ for all permutations $\pi$ of $\{1, \ldots, n\}$ and all $\left.1 \leq i_{1}, \ldots, i_{n} \leq n\right)$ satisfying $f_{n}\left(i_{1}, \ldots, i_{p}\right)=0$, whenever there are $j \neq l$ such that $i_{l}=i_{j}$.

In the landmark paper dJ90, P. de Jong proved the following surprising result: If, for $n \in \mathbb{N}, W_{n}$ is a (non-symmetric) normalized degenerate $U$-statistic of a fixed order $p$, then $W_{n}$ converges in distribution to a standard normal random variable $Z$, provided $\lim _{n} \mathbb{E}\left[W_{n}^{4}\right]=\mathbb{E}\left[Z^{4}\right]=3$ and a further Lindeberg-Feller negligibility condition is satisfied.

De Jong's theorem is the ancestor of the class of 'fourth moment theorems' established in the last decade for elements of the Wiener chaos of Gaussian and Poisson random measures - see e.g. [NP12, Chapter 5], as well as DP18, DVZ18.

In DP17, the authors used Stein's method in order to establish quantitative uni- and multivariate counterparts to de Jong's theorem. The techniques introduced in DP17 put forward several combinatorial quantities that proved useful in further situations: for instance, as demonstrated by the references [DP19, DKP22, Döb20] the technical findings of [DP17] allow one to derive quantitative (functional) CLTs for symmetric $U$-statistics that are expressed in terms of purely analytical quantities, that is, norms of socalled of contraction kernels.

The aim of the present paper is to prove a multivariate functional version - in the sense of weak convergence in the Skorohod space of càdlàg mappings - of the main results of dJ90, DP17, under a

[^0]slightly stronger Lindeberg condition (see Condition 1.2 below). As a direct application, in Section 1.4 we derive a functional version of the universality of Wiener chaos phenomenon first detected in NPR10a.

Our main findings appear in Theorem 1.4 and Theorem 1.5 below. To the best of our expertise, these statements are the first examples of fourth moment theorems for random elements taking value in a metric space without a Hilbert space structure. See BC20 for related results in a Dirichlet/Hilbert setting.

Acknowledgments. This work is part of the first author's habilitation thesis at Heinrich Heine Universität Düsseldorf. The research leading to this paper was supported by the FNR grant FoRGES(R-AGR-3376-10) at Luxembourg University. This work is also part of project Stein-ML that has received funding from the European Union's Horizon 2020 research and innovation programme under the Marie Skłodowska-Curie grant agreement No 101024264. We thank an anonymous referee for several useful remarks. Data sharing not applicable to this article as no datasets were generated or analysed during the current study.
1.2. Setup and main theorems. We now introduce our objects of study, fix some notation and conditions, and state our main results. For the sake of generality, and at the cost of a slightly heavier notation than the one adopted in dJ90, dJ89, from now on we will work in the framework of triangular arrays.

Throughout this section, we fix positive integers $d$ and $1 \leq p_{1}<p_{2}<\ldots<p_{d}$, where $d$ always denotes dimension. For $m \in \mathbb{N}$, suppose that $X_{1}^{(m)}, \ldots, X_{n_{m}}^{(m)}$ are independent random elements, defined on a suitable probability space $\left(\Omega_{m}, \mathcal{F}_{m}, \mathbb{P}_{m}\right)$ and assuming values in the respective measurable spaces $\left(E_{1}^{(m)}, \mathcal{E}_{1}^{(m)}\right), \ldots,\left(E_{n_{m}}^{(m)}, \mathcal{E}_{n_{m}}^{(m)}\right)$. We will denote by $\mathbb{E}_{m}, \operatorname{Var}_{m}$ and $\operatorname{Cov}_{m}$ the expectation, variance and covariance with respect to $\mathbb{P}_{m}$, respectively. We will systematically assume that $\lim _{m \rightarrow \infty} n_{m}=+\infty$ and, to simplify the notation, we will sometimes suppress the dependence on $m$. For $k=1, \ldots, d$ and $m \in \mathbb{N}$ we assume that $W(k)=W^{(m)}(k)$ is a (completely) degenerate, non-symmetric $U$-statistic of order $p_{k}$ based on $X_{1}^{(m)}, \ldots, X_{n_{m}}^{(m)}$, with the form

$$
W(k)=W^{(m)}(k)=\sum_{J \in \mathcal{D}_{p_{k}}\left(n_{m}\right)} W_{J}^{(m)}(k)=\sum_{J \in \mathcal{D}_{p_{k}}\left(n_{m}\right)} W_{J}(k),
$$

where $W_{J}(k)$ is a degenerate kernel depending on $\left\{X_{n}: n \in J\right\}$ - see Section 2 below. Here and in what follows, for $p, n \in \mathbb{N}$, we write

$$
\mathcal{D}_{p}(n):=\{J \subseteq[n]:|J|=p\}
$$

for the collection of all $\binom{n}{p}$ distinct $p$-subsets of $[n]=\{1, \ldots, n\}$.
W.l.o.g. we will assume that $\operatorname{Var}_{m}\left(W^{(m)}(k)\right)=1$ for all $k=1, \ldots, d$ and all $m \in \mathbb{N}$. By $W=W^{(m)}$ we denote the vector $W=(W(1), \ldots, W(d))^{T}$ and, for $t \in[0,1]$ let $\mathbf{W}_{t}=\mathbf{W}_{t}^{(m)}=\left(\mathbf{W}_{t}^{(m)}(1), \ldots, \mathbf{W}_{t}^{(m)}(d)\right)^{T}$ be given by

$$
\begin{equation*}
\mathbf{W}_{t}^{(m)}(k):=\sum_{J \in \mathcal{D}_{p_{k}}\left(\left\lfloor n_{m} t\right\rfloor\right)} W_{J}^{(m)}(k)=\sum_{1 \leq i_{1}<\ldots<i_{p_{k}} \leq\left\lfloor n_{m} t\right\rfloor} W_{\left\{i_{1}, \ldots, i_{p_{k}}\right\}}^{(m)}(k), \quad k=1, \ldots, d, \tag{1}
\end{equation*}
$$

where $\lfloor x\rfloor$ denotes the integer part of the real number $x$. Then, for each $m \in \mathbb{N}$, the process

$$
\begin{equation*}
\mathbf{W}^{(m)}:=\left(\mathbf{W}^{(m)}(1), \ldots, \mathbf{W}^{(m)}(d)\right)^{T}:=\left(\mathbf{W}_{t}^{(m)}\right)_{0 \leq t \leq 1} \tag{2}
\end{equation*}
$$

is an element of the Skorohod space $D\left([0,1] ; \mathbb{R}^{d}\right)$ of càdlàg functions from $[0,1]$ to $\mathbb{R}^{d}$. As anticipated, in this paper we provide sufficient conditions for the sequence $\mathbf{W}^{(m)}, m \in \mathbb{N}$, to converge in distribution to a continuous Gaussian process $\mathbf{Z}=(\mathbf{Z}(1), \ldots, \mathbf{Z}(d))^{T}$ with respect to the Skorohod topology on $D\left([0,1] ; \mathbb{R}^{d}\right)$ (see e.g. Bil68, Sections 14-15] for details).

Note that, by degeneracy and since the $p_{k}$ 's are pairwise distinct, for $0 \leq s \leq t \leq 1$ and $1 \leq l, k \leq d$ we have

$$
\begin{aligned}
\operatorname{Cov}\left(\mathbf{W}_{t}^{(m)}(l), \mathbf{W}_{t}^{(m)}(k)\right) & =\mathbb{E}_{m}\left[\mathbf{W}_{t}^{(m)}(l) \mathbf{W}_{t}^{(m)}(k)\right]=\delta_{k, l} \sum_{J \in \mathcal{D}_{p_{k}}\left(\left\lfloor n_{m} s\right\rfloor\right)} \mathbb{E}_{m}\left[W_{J}^{(m)}(k)^{2}\right] \\
& =\delta_{k, l} \sigma_{m, k}^{2}\left(\left\lfloor n_{m} s\right\rfloor\right)
\end{aligned}
$$

where we set

$$
\sigma_{m, k}^{2}(j):=\sum_{J \in \mathcal{D}_{p_{k}}(j)} \mathbb{E}_{m}\left[W_{J}^{(m)}(k)^{2}\right], \quad k=1, \ldots, d, 0 \leq j \leq n_{m}
$$

In particular, we have $\sigma_{m, k}^{2}(0)=0$ and $\sigma_{m, k}^{2}\left(n_{m}\right)=\operatorname{Var}\left(W^{(m)}(k)\right)=1$.
We will now introduce and discuss the Conditions $1.1,1.2$ and 1.3 under which our main findings (Theorems 1.4 and 1.5 ) are stated.

CONDITION 1.1 (Convergence of time-changes). There are functions $v_{k}:[0,1] \rightarrow \mathbb{R}, 1 \leq k \leq d$, such that the pointwise limits

$$
\begin{equation*}
\lim _{m \rightarrow \infty} \sigma_{m, k}^{2}\left(\left\lfloor n_{m} s\right\rfloor\right)=v_{k}(s), \quad s \in[0,1] \tag{3}
\end{equation*}
$$

exist.
Note that the $v_{k}$ are necessarily non-decreasing on $[0,1]$ and satisfy $v_{k}(0)=0$ as well as $v_{k}(1)=1$. However, we need not assume any regularity of the functions $v_{k}$.

In order to concretely relate Condition 1.1 to functional results, we let $\mathbf{Z}=(\mathbf{Z}(1), \ldots, \mathbf{Z}(d))^{T}$ be a centered Gaussian process with independent components, defined on a suitable probability space $(\Omega, \mathcal{F}, \mathbb{P})$ and such that, for $1 \leq k \leq d$, the covariance function of $\mathbf{Z}(k)=\left(\mathbf{Z}_{t}(k)\right)_{t \in[0,1]}$ is given by

$$
\begin{equation*}
\operatorname{Cov}\left(\mathbf{Z}_{s}(k), \mathbf{Z}_{t}(k)\right)=\mathbb{E}\left[\mathbf{Z}_{s}(k) \mathbf{Z}_{t}(k)\right]=v_{k}(s \wedge t) \tag{4}
\end{equation*}
$$

implying that $\left(\mathbf{Z}_{1}(1), \ldots, \mathbf{Z}_{1}(d)\right)^{T}$ is a standard Gaussian vector in $\mathbb{R}^{d}$. It is easily verified that the $d$-dimensional process $\mathbf{Z}$ has the same distribution as

$$
\left(\mathbf{B}_{v_{1}(t)}(1), \ldots, \mathbf{B}_{v_{d}(t)}(d)\right)_{t \in[0,1]}
$$

where $(\mathbf{B}(1), \ldots, \mathbf{B}(d))$ is a standard Brownian motion (initialized at zero) in $\mathbb{R}^{d}$. This yields in particular that $\mathbf{Z}$ has a.s. $-\mathbb{P}$ continuous paths if and only if the functions $v_{k}$ 's are continuous.

Following dJ89, dJ90, DP17] we further introduce the quantities

$$
\begin{aligned}
\varrho_{m, k}^{2}:= & \max _{1 \leq i \leq n_{m}} \sum_{\substack{J \in \mathcal{D}_{p_{k}}\left(n_{m}\right): \\
i \in J}} \mathbb{E}_{m}\left[W_{J}^{(m)}(k)^{2}\right] \quad \text { and } \\
D_{m, k}:= & \sup _{\substack{J \in \mathcal{D}_{p_{k}}\left(n_{m}\right):}} \frac{\mathbb{E}_{m}\left[W_{J}^{(m)}(k)^{4}\right]}{\mathbb{E}_{m}\left[W_{J}^{(m)}(k)^{2}\right]^{2}}
\end{aligned}
$$

Note that, e.g. by Jensen's inequality, one necessarily has that $D_{m, k} \geq 1$.
CONDITION 1.2 (Reinforced Lindeberg condition). For all $1 \leq k \leq d, \lim _{m \rightarrow \infty} D_{m, k} \varrho_{m, k}^{2}=0$.
This condition roughly ensures that none of the individual random variables $X_{i}^{(m)}, 1 \leq i \leq n_{m}$, has an asymptotically dominant impact on the variance of $W^{(m)}(k), 1 \leq k \leq d$.

The following condition is inherent to all de Jong type CLTs such as e.g. those proved in dJ90, DP17.
CONDITION 1.3 (Fourth moment condition). For all $1 \leq k \leq d$ we have $\lim _{m \rightarrow \infty} \mathbb{E}_{m}\left[W^{(m)}(k)^{4}\right]=3$.
The forthcoming Theorems 1.4 and 1.5 are the main achievements of this work.
THEOREM 1.4. Let the above definitions and notation prevail and suppose that Conditions 1.1 - 1.3 hold. Then, the process $\mathbf{Z}$ has continuous paths and, as $m \rightarrow \infty$, the distributions of the sequence $\left(\mathbf{W}^{(m)}\right)_{m \in \mathbb{N}}$ weakly converge to the law of $\mathbf{Z}$, with respect to both the Skorohod and uniform topologies.

An assumption such as Condition 1.1 does not appear in the finite-dimensional settings of [DP17, dJ90]. It cannot be easily dispensed with without affecting the unicity of the limit in the previous statement. The following result shows that, if Condition 1.1 is removed, then the sequence $\left(\mathbf{W}^{(m)}\right)_{m \in \mathbb{N}}$ is still relatively compact, and each limit law is the law of a continuous Gaussian process.
Theorem 1.5. Suppose that the sequence $\left(\mathbf{W}^{(m)}\right)_{m \in \mathbb{N}}$ satisfies Conditions 1.2 and 1.3. Then, the collection of their laws is tight, hence relatively compact, in the class of distributions on the Skorohod space equipped with either the Skorohod or the uniform metric. Moreover, if the laws of a subsequence $\left(\mathbf{W}^{\left(m_{j}\right)}\right)_{j \in \mathbb{N}}$ converge weakly, then the limit is the law of a continuous, d-dimensional centered Gaussian process with independent components.

The detailed proofs of Theorems 1.4 and 1.5 are deferred to Section 3 We observe that the proof of Theorem 1.5 implicitly shows that, if $\left(\mathbf{W}^{(m)}\right)_{m \in \mathbb{N}}$ satisfies Conditions 1.2 and 1.3 , then from every subsequence $\left(\mathbf{W}^{\left(m_{j}\right)}\right)_{j \in \mathbb{N}}$ one can extract a sub-subsequence $\left(\mathbf{W}^{\left(m_{j}^{\prime}\right)}\right)_{j \in \mathbb{N}}$ verifying Condition 1.1 for some continuous functions $v_{k}$, whose definition depends on the choice of the subsequence.

Some representative examples of kernels directly verifying the assumptions of Theorem 1.4 are described in Example 1.12, yielding in particular that, for all $p \geq 3$ and all integers $a \in\{2, \ldots, p-1\}$, there exists a sequence of homogeneous sums whose associated empirical processes converge in distribution to a multiple of $B\left(t^{p / a}\right)$, where $B$ is a standard Brownian motion issued from zero. It is important to notice that such a limit behaviour is in principle not achievable in the framework of symmetric and degenerate $U$-statistics. Indeed, in [DKP22, Corollary 3.7] it is proved that, given a sequence of symmetric and degenerate $U$ statistics of order $p \geq 2$ verifying asymptotic relations that are roughly equivalent to Conditon [1.3, the corresponding sequence of normalized empirical processes always converges in distribution to a multiple of $B\left(t^{p}\right)$.
Remark 1.6. (a) Theorem 1.4 provides a strong functional extension of the finite-dimensional de Jong type theorems from dJ90, DP17 under very mild additional assumptions. As already observed, Condition 1.1 and Condition 1.3 are indeed natural in this context dJ90, DP17, so that only Condition 1.2 might appear non-optimal, since - whenever there is a $k$ such that $D_{k, m}$ is unbounded in $m$ it is strictly stronger than the usual negligibility condition demanding that $\lim _{m \rightarrow \infty} \varrho_{m, k}^{2}=0$ for all $1 \leq k \leq d$, see again dJ90, DP17. To address this issue, we observe first that, in many instances, the $D_{k, m}$ are in fact bounded in $m$ for all $1 \leq k \leq d$ and in this case, the two conditions are in fact equivalent. This happens in the case of homogeneous sums such that the underlying sequence $\mathfrak{X}$ has a uniformly bounded fourth moment (see Section 1.4 below). Moreover, it is not clear whether the convergence of finite dimensional distributions of $\mathbf{W}$ to those of $\mathbf{Z}$ would still hold, if one replaced Condition 1.2 with the weaker variant (see Subsection 3.1.1 for details). Some preliminary computations have indeed shown that, if one only assumed that $\lim _{m \rightarrow \infty} \varrho_{m, k}^{2}=0$ for all $1 \leq k \leq d$, one might have to replace Condition 1.3 with the assumption that $\lim _{m \rightarrow \infty} \mathbb{E}\left[\mathbf{W}_{t}(k)^{4}\right]=3 v_{k}(t)^{2}$ for all $t \in[0,1]$ and all $1 \leq k \leq d$, which would be much more complicated to verify than Condition [1.3.
(b) Note that Conditions 1.1 1.3, implying the joint convergence of the random processes $\mathbf{W}^{(m)}(k)$, $1 \leq k \leq d$, are just the aggregation of the conditions for the componentwise convergence of these processes.
(c) We find it remarkable that one uniquely has to take into account the behaviour of the fourth moments of the components of $\mathbf{W}^{(m)}$ at time 1 and not at other times $t<1$.
(d) We compare our Theorem 1.4to a few existing functional CLTs (FCLTs) for degenerate (symmetric and non-symmetric) $U$-statistics in the scarce literature on this topic. In accordance with the univariate case (see e.g. DM83, Gre77,Ser80), in order to satisfy a FCLT, a symmetric degenerate $U$-statistic of order $p>1$ must have a variable kernel, i.e. one that depends on the sequential parameter $m$. In the recent work DKP22] we have proved FCLTs for this situation with sufficient conditions for convergence that are expressed in norms of contraction kernels and, hence, are completely analytical in nature. A more general class of statistics is given by the so-called weighted, degenerate $U$-statistics of order $p$. These have the form $U_{n}=\sum_{1 \leq i_{1}<\ldots<i_{p} \leq n} a\left(i_{1}, \ldots, i_{p}\right) \psi_{n}\left(X_{i_{1}}, \ldots, X_{i_{p}}\right)$, where $X_{1}, \ldots, X_{n}$ are i.i.d.
elements of some space $E, a\left(i_{1}, \ldots, i_{p}\right), 1 \leq i_{1}, \ldots, i_{p} \leq n$ is a symmetric array of real numbers that vanishes on diagonals (i.e. $a\left(i_{1}, \ldots, i_{p}\right)=0$ if $i_{l}=i_{k}$ for some $l \neq k$ ) and $\psi_{n}$ is a symmetric, canonical kernel, i.e. $\mathbb{E}\left[\psi_{n}\left(X_{1}, \ldots, X_{p}\right) \mid X_{1}, \ldots, X_{p-1}\right]=0$ a.s. In particular, they constitute a strict subclass of the non-symmetric $U$-statistics investigated in the present paper. In the case $p=2$, Mik93] derives functional limit theorems for weighted degenerate $U$-statistics by using methods that heavily depend on the peculiarities of the case $p=2$. In the very recent paper DK21 the first and the second author have introduced a functional version of Stein's method of exchangeable pairs and applied it to prove quantitative, multidimensional FCLTs for degenerate weighted $U$-statistics. As explained in detail in DK21, Subsection 1.5], the limit theorems that build on the bounds of [DK21] rather involve third absolute moments and absolute values of the coefficient arrays and, hence, are complementary to the present ones involving fourth moment conditions. As to FCLTs for homogeneous sums, apart from our paper [DK21] we only mention the two references Mik91] and Bas94, where, again, Mik91] only considers the case $p=2$ of quadratic forms. The paper Bas94 instead, considers homogeneous sums of arbitrary order $p$ but the results of this paper are in question. Indeed, we have found that the argument leading to Bas94, Theorem 1.1] is flawed, as carefully explained in part 2 of DK21, Remark 5.6].
1.3. About our approach. Our method of proof turns out to be a combination of a quantitative, multivariate CLT for vectors of degenerate $U$-statistics to obtain convergence of finite-dimensional distributions (see Lemma 3.1 below), and a martingale representation, which we exploit via Doob's $L^{4}$-inequality, in order to derive tightness. In order to conclude from Condition 1.3 that the fourth cumulant of $\mathbf{W}_{t}^{(m)}(k)$, $1 \leq k \leq d$, also converges to zero for all fixed $t \in[0,1)$ as $m \rightarrow \infty$, we elaborate on a result from the monograph dJ90 (see Lemma 3.2 below). Moreover, for the application of Lemma 3.1 we prove and make use of several new results about degenerate $U$-statistics and their Hoeffding decompositions in Section 2, which are of independent interest.

Since in his original proof of the one-dimensional CLT dJ89, de Jong made use of a classical martingale CLT due to Heyde and Brown HB70, it is a natural question whether one could similarly apply a FCLT for martingales, like for instance MPU19, Theorem 2.34], in order to derive Theorem[1.4. Indeed, adapting the computations beginning on page 286 of (dJ89) and using our Lemma 3.2 one could verify that (an adaptation to deterministic time changes of) the "square bracket condition" (2.48) in MPU19 holds for all fixed $t \in[0,1]$. Since the uniform negligibility condition (2.46) in MPU19 is satisfied for any sequence of normalized $L^{2}$-martingales, MPU19, Theorem 2.34] could be applied to yield another proof of the one-dimensional version of Theorem 1.4. In order to derive the full multidimensional result, one could try to similarly adapt a multivariate FCLT for martingales to our setting, like for example Whi07, Theorem 2.1]. However, the mixed square bracket condition (3) in Whi07 seems to be less amenable to analysis in the present setting than its univariate counterpart, i.e. condition (2.48) in MPU19. Hence, adapting the techniques used in [dJ90] so as to obtain our multivariate result appears considerably more difficult. One of the main reasons for this fact is that de Jong's arguments rely on a large collection of exact combinatorial identities, that one uses in order to verify the square bracket condition evoked above. In contrast, our direct arguments merely use probabilistic inequalities, which makes the structure of the proof significantly simpler and probably also more robust. Finally, we mention that our arguments are in principle quantitative in nature and that, via an elaboration of Stein's method for diffusion approximation Bar90, Kas20b, Kas20a, DK21, one would be able to prove a quantitative version of Theorem 1.4 Since, at the time of writing, we are only in the position to do this with respect to the stronger $L^{1}$-topology on $D\left([0,1] ; \mathbb{R}^{d}\right)$, we decide to leave this point open for further investigation.
1.4. Application: universal FCLTS for homogeneous sums. We will now apply our main results to the setting of homogeneous sums: as a consequence, in Theorem 1.10 we will establish functional versions of the main findings of NPR10a, where the authors proved the universality of Gaussian Wiener chaos with respect to the normal approximation of homogeneous sums. Such a result roughly states that, if a sequence of homogeneous sums with Gaussian arguments verifies a CLT, then so does the sequence obtained by replacing the Gaussian input with an arbitrary collection of independent random variables (see
e.g. NPR10a, Theorem 1.2] for a precise statement). The findings from NPR10a have found applications e.g. in the analysis of disordered systems [CSZ17,CSZ20], mathematical statistics [Koi19], random matrix theory and free probability PN10, NPPS16.

In this subsection, we let $(\Omega, \mathcal{F}, \mathbb{P})$ denote a suitable probability space on which all random quantities subsequently dealt with are defined. We will consider the following sequences of real random variables:

- $\mathfrak{X}=\left(X_{i}\right)_{i \in \mathbb{N}}$ denotes a (generic) sequence of independent, mean zero and unit variance random variables in $L^{4}(\mathbb{P})$;
- $\mathfrak{G}=\left(G_{i}\right)_{i \in \mathbb{N}}$ is a sequence of independent standard normal random variables; and
- $\mathfrak{P}=\left(P_{i}\right)_{i \in \mathbb{N}}$ is a sequence of independent, normalized Poisson random variables, i.e. there are $\lambda_{i} \in$ $(0, \infty)$ and independent Poisson random variables $N_{i}$ with mean $\lambda_{i}$ such that $P_{i}=N_{i} / \sqrt{\lambda_{i}}-\sqrt{\lambda_{i}}$, $i \in \mathbb{N}$.
On the sequence $\mathfrak{X}$, we will further impose the integrability condition that

$$
\begin{equation*}
\beta:=\sup _{i \in \mathbb{N}} \mathbb{E}\left|X_{i}\right|^{4}<\infty . \tag{5}
\end{equation*}
$$

This is in particular satisfied if the random variables $X_{i}, i \in \mathbb{N}$, are i.i.d, since we have assumed that they are in $L^{4}(\mathbb{P})$. We observe that, in the case of the Poisson sequence $\mathfrak{P}$, condition (5) can be equivalently re-expressed in terms of the coefficients $\lambda_{i}$. In fact, since $\mathbb{E}\left[P_{i}^{4}\right]=3+\lambda_{i}^{-1}$, the sequence $\mathfrak{P}$ satisfies (5) if and only if $\inf _{i \in \mathbb{N}} \lambda_{i}>0$.

In what follows, we let $n_{m}=m$ and, for given arrays $a_{J}^{(m)}(k), J \in \mathcal{D}_{p_{k}}(m), 1 \leq k \leq d$, of real numbers we suppose that $W_{J}^{(m)}(k)=a_{J}^{(m)}(k) \prod_{i \in J} X_{i}$ is given as

$$
W_{J}^{(m)}(k)=a_{J}^{(m)}(k) \prod_{i \in J} X_{i}=: a_{J}^{(m)}(k) X_{J}
$$

Thus, for $k=1, \ldots, d$,

$$
\begin{equation*}
W^{(m)}(k)=\sum_{J \in \mathcal{D}_{p_{k}}(m)} a_{J}^{(m)}(k) \prod_{i \in J} X_{i} \tag{6}
\end{equation*}
$$

is a homogeneous sum or homogeneous multilinear form of order $p_{k}$ and, in particular, it is a non-symmetric, degenerate $U$-statistic. As before, we will systematically assume that

$$
\operatorname{Var}\left(W^{(m)}(k)\right)=\sum_{J \in \mathcal{D}_{p_{k}}(m)} a_{J}^{(m)}(k)^{2}=1, \quad \text { for } k=1, \ldots, d
$$

Then, as in (11) and (2), we use these $d$ homogeneous sums to define the random element $\mathbf{W}^{(m)}=$ $\left(\mathbf{W}^{(m)}(1), \ldots, \mathbf{W}^{(m)}(d)\right)^{T}$ with values in $D\left([0,1] ; \mathbb{R}^{d}\right)$.

Note that from (5), for $1 \leq k \leq d$ and all $J \in \mathcal{D}_{p_{k}}(m)$ such that $a_{J}^{(m)}(k) \neq 0$, we have that

$$
\frac{\mathbb{E}\left[W_{J}^{(m)}(k)^{4}\right]}{\left(\mathbb{E}\left[W_{J}^{(m)}(k)^{2}\right]\right)^{2}}=\frac{a_{J}^{(m)}(k)^{4} \mathbb{E}\left[\prod_{i \in J} X_{i}^{4}\right]}{a_{J}^{(m)}(k)^{4}\left(\mathbb{E}\left[\prod_{i \in J} X_{i}^{2}\right]\right)^{2}}=\prod_{i \in J} \mathbb{E}\left[X_{i}^{4}\right] \leq \beta^{p_{k}} .
$$

Hence, also

$$
\sup _{m \in \mathbb{N}} D_{m, k} \leq \beta^{p_{k}}<\infty
$$

In this context, one would typically like to replace the fourth moment condition, Condition 1.3, by a condition, which is rather expressed in terms of the coefficient arrays. To this end, let us first define the symmetric functions $f_{k}^{(m)}:[m]^{p_{k}} \rightarrow \mathbb{R}$ by

$$
f_{k}^{(m)}\left(i_{1}, \ldots, i_{p_{k}}\right):= \begin{cases}\frac{1}{p_{k}!} a_{\left\{i_{1}, \ldots, i_{p_{k}}\right\}}^{(m)}(k), & \text { if }\left|\left\{i_{1}, \ldots, i_{p_{k}}\right\}\right|=p_{k}, \\ 0, & \text { otherwise }\end{cases}
$$

Observe that the function $f_{k}^{(m)}$ vanishes on diagonals, that is, $f_{k}^{(m)}\left(i_{1}, \ldots, i_{p_{k}}\right)=0$ if two coordinates of $\left(i_{1}, \ldots, i_{p_{k}}\right)$ coincide. Then, we have

$$
\begin{aligned}
W^{(m)}(k) & =Q_{p_{k}}\left(m, f_{k}^{(m)}, \mathfrak{X}\right):=\sum_{i_{1}, \ldots, i_{p_{k}}=1}^{m} f_{k}^{(m)}\left(i_{1}, \ldots, i_{p_{k}}\right) X_{i_{1}} \cdot \ldots \cdot X_{i_{p_{k}}} \\
& =p_{k}!\sum_{1 \leq i_{1}<\ldots<i_{p_{k}} \leq m} f_{k}^{(m)}\left(i_{1}, \ldots, i_{p_{k}}\right) X_{i_{1}} \cdot \ldots \cdot X_{i_{p_{k}}}
\end{aligned}
$$

as well as

$$
\varrho_{m, k}^{2}=\max _{1 \leq i \leq m} \sum_{\substack{1 \leq j_{2}<\ldots<j_{p_{k}} \leq m: \\ j_{2}, \ldots, j_{p_{k}} \neq i}} a_{\left\{i, j_{2}, \ldots, j_{p_{k}}\right\}}^{(m)}(k)^{2}=\left(p_{k}!\right)^{2} \operatorname{Inf}_{i}\left(f_{k}^{(m)}\right)
$$

where

$$
\operatorname{Inf}_{i}\left(f_{k}^{(m)}\right)=\frac{1}{\left(p_{k}-1\right)!} \sum_{j_{2}, \ldots, j_{p_{k}}=1}^{m} f_{k}^{(m)}\left(i, j_{2}, \ldots, j_{p_{k}}\right)^{2}=\sum_{1 \leq j_{2}<\ldots<j_{p_{k}} \leq m} f_{k}^{(m)}\left(i, j_{2}, \ldots, j_{p_{k}}\right)^{2}
$$

denotes the influence of the random variable $X_{i}$ on the variance of $W^{(m)}(k)$ (see MOO10, GS15). Thus, we have shown that, under (5), Condition 1.2 is equivalent to

$$
\begin{equation*}
\lim _{m \rightarrow \infty} \max _{1 \leq i \leq m} \operatorname{Inf}_{i}\left(f_{k}^{(m)}\right)=0 \quad \text { for } \quad 1 \leq k \leq d \tag{7}
\end{equation*}
$$

For $1 \leq k \leq d$ and $1 \leq r \leq p_{k}-1$, we define the contraction kernel $f_{k}^{(m)} \star_{r} f_{k}^{(m)}:[m]^{2 p_{k}-2 r} \rightarrow \mathbb{R}$ by

$$
\begin{aligned}
& f_{k}^{(m)} \star_{r} f_{k}^{(m)}\left(i_{1}, \ldots, i_{p_{k}-r}, j_{1}, \ldots, j_{p_{k}-r}\right) \\
& :=\sum_{l_{1}, \ldots, l_{r}=1}^{m} f_{k}^{(m)}\left(i_{1}, \ldots, i_{p_{k}-r}, l_{1}, \ldots, l_{r}\right) f_{k}^{(m)}\left(j_{1}, \ldots, j_{p_{k}-r}, l_{1}, \ldots, l_{r}\right)
\end{aligned}
$$

Consider the following condition.
CONDITION 1.7. For all $1 \leq k \leq d$ and all $1 \leq r \leq p_{k}-1$ it holds that $\lim _{m \rightarrow \infty}\left\|f_{k}^{(m)} \star_{r} f_{k}^{(m)}\right\|_{2}=0$.
Here, $\left\|f_{k}^{(m)} \star_{r} f_{k}^{(m)}\right\|_{2}$ denotes the $L^{2}$-norm of the contraction kernel $f_{k}^{(m)} \star_{r} f_{k}^{(m)}$ with respect to the $\left(2 p_{k}-2 r\right)$-fold product of the counting measure on $[m$ ], i.e. with respect to the counting measure on $[m]^{2 p_{k}-2 r}$.

Proposition 1.8. Suppose that (5) and Condition 1.7 hold and that $p_{k} \geq 2$ for all $1, \ldots, d$. Then, Conditions 1.2 and 1.3 are satisfied as well.

Proof. We have already shown that Condition 1.2 holds if and only if (7) holds. Relation (7) however holds true by virtue of Condition 1.7 and display (1.9) in [NPR10a. That Condition 1.3 holds under Condition 1.7 as well, follows from a combination of [NPR10a, Proposition 1.6] and the estimate (1.13) in NPR10a.

Note further that the functions $\sigma_{m, k}^{2}\left(\left\lfloor n_{m} s\right\rfloor\right)$ from Condition 1.1 are in this situation more explicitly given by

$$
\begin{equation*}
\sigma_{m, k}^{2}\left(\left\lfloor n_{m} s\right\rfloor\right)=\sum_{J \in \mathcal{D}_{p_{k}}\left(\left\lfloor n_{m} s\right\rfloor\right)} a_{J}^{(m)}(k)^{2}=p_{k}!\sum_{i_{1}, \ldots, i_{p_{k}}=1}^{\left\lfloor n_{m} s\right\rfloor} f_{k}^{(m)}\left(i_{1}, \ldots, i_{p_{k}}\right)^{2}=: S f_{k}^{(m)}(s) \tag{8}
\end{equation*}
$$

THEOREM 1.9. Suppose that the sequence $\mathfrak{X}$ of independent, mean zero and unit variance random variables satisfies (5). Moreover, assume that the sequences $\left(S f_{k}^{(m)}\right)_{m \in \mathbb{N}}, 1 \leq k \leq d$, defined in (8), satisfy Condition 1.1, that Condition 1.7 holds and that $p_{k} \geq 2$ for all $k=1, \ldots, d$. Then, the sequence $\left(\mathbf{W}^{(m)}\right)_{m \in \mathbb{N}}$ of processes, defined through (2) and (6), converges in distribution with respect to the Skorohod topology to
the continuous, centered Gaussian process $\mathbf{Z}=(\mathbf{Z}(1), \ldots, \mathbf{Z}(d))^{T}$ with independent components, which is defined via (3).

Proof. This follows from Theorem 1.4 and Proposition 1.8
The proof of Theorem 1.9 (via the implicit use of Proposition (1.8) strongly relies on the techniques developed in NPR10a. As anticipated, we will now prove a functional version of the universality results from [NPR10a. For completeness, we will also include the discussion of universality of Poisson homogeneous sums, as provided by [PZ14, DVZ18].

Theorem 1.10 (Functional universality of homogeneous sums). With the above notation and definitions, consider the following assumptions:
$\left(A_{1}\right)$ There are functions $v_{k}:[0,1] \rightarrow \mathbb{R}$ such that $\lim _{m \rightarrow \infty}\left(S f_{k}^{(m)}\right)=v_{k}$ pointwise, $1 \leq k \leq d$.
$\left(A_{2, \mathfrak{X}}\right)$ As $m \rightarrow \infty,\left(Q_{p_{1}}\left(m, f_{1}^{(m)}, \mathfrak{X}\right), \ldots, Q_{p_{d}}\left(m, f_{d}^{(m)}, \mathfrak{X}\right)\right)^{T}$ converges in distribution to a d-dimensional standard normal vector.
$\left(A_{3, \mathfrak{X}}\right)$ The sequences $Q_{p_{k}}\left(m, f_{k}^{(m)}, \mathfrak{X}\right)_{m \in \mathbb{N}}, 1 \leq k \leq d$, satisfy Condition 1.3 .
$\left(A_{4, \mathfrak{X}}\right)$ The above defined sequence $\left(\mathbf{W}^{(m)}(1), \ldots, \mathbf{W}^{(m)}(d)\right)^{T}, m \in \mathbb{N}$, of processes based on $\mathfrak{X}$, converges in distribution with respect to the Skorohod topology to a continuous centered Gaussian process $\mathbf{Z}=(\mathbf{Z}(1), \ldots, \mathbf{Z}(d))^{T}$ with independent components, whose covariance function is given by (3).
$\left(A_{5}\right)$ Condition 1.7 is satisfied.
( $A_{6}$ ) One has $\inf _{i \in \mathbb{N}} \lambda_{i}>0$.
Assume that Assumption $\left(A_{1}\right)$ holds and $p_{k} \geq 2$ for all $k=1, \ldots, d$. Then, the following implications are in order:

$$
\begin{align*}
\left(A_{3, \mathfrak{P}}\right) & \Rightarrow\left(A_{2, \mathfrak{H})} \Leftrightarrow\left(A_{3, \mathfrak{H}}\right) \Leftrightarrow\left(A_{4, \mathfrak{H}}\right) \Leftrightarrow\left(A_{5}\right)\right.  \tag{9}\\
& \Rightarrow \forall \mathfrak{X} \text { satisfying (5) }:\left(\left(A_{2, \mathfrak{X}}\right) \wedge\left(A_{3, \mathfrak{X}}\right) \wedge\left(A_{4, \mathfrak{X}}\right)\right) .
\end{align*}
$$

If, additionally to $\left(A_{1}\right)$, also $\left(A_{6}\right)$ holds and $p_{k} \geq 2$ for all $k=1, \ldots, d$, then we have in fact that

$$
\begin{align*}
\left(A_{3, \mathfrak{P}}\right) & \Leftrightarrow\left(A_{2, \mathfrak{H}}\right) \Leftrightarrow\left(A_{3, \mathfrak{H}}\right) \Leftrightarrow\left(A_{4, \mathfrak{H}}\right) \Leftrightarrow\left(A_{5}\right)  \tag{10}\\
& \Rightarrow \forall \mathfrak{X} \text { satisfying (5) }:\left(\left(A_{2, \mathfrak{X}}\right) \wedge\left(A_{3, \mathfrak{x}}\right) \wedge\left(A_{4, \mathfrak{X}}\right)\right) .
\end{align*}
$$

Proof. Suppose first that $\left(A_{1}\right)$ holds. That $\left(A_{2, \mathfrak{G}}\right),\left(A_{3, \mathfrak{C}}\right)$ and $\left(A_{5}\right)$ are all equivalent is a consequence of [NPR10a, Proposition 1.6] (even without assuming $\left.\left(A_{1}\right)\right)$. Of course, $\left(A_{4, \mathfrak{G}}\right)$ implies $\left(A_{2, \mathfrak{G}}\right)$. By Theorem 1.9 applied to $\mathfrak{G}$, under $\left(A_{1}\right)$ we have that $\left(A_{5}\right)$ implies $\left(A_{4, \mathfrak{G}}\right)$, since $\mathfrak{G}$ obviously satisfies (5). Moreover, again by Theorem 1.9 and by Proposition 1.8, if the sequence $\mathfrak{X}$ satisfies (5) and if $\left(A_{5}\right)$ holds, then (since we have assumed $\left(A_{1}\right)$ ), we can conclude that $\left(A_{3, \mathfrak{X}}\right)$ and ( $A_{4, \mathfrak{x}}$ ) hold, immediately implying $\left(A_{2, \mathfrak{x}}\right)$ as well. Finally, [DVZ18, Theorem 1.11] ensures that $\left(A_{3, \mathfrak{P}}\right)$ implies $\left(A_{2, \mathfrak{E}}\right)$.

Suppose now that both $\left(A_{1}\right)$ and $\left(A_{6}\right)$ hold. Then, DVZ18, Theorem 1.11] guarantees that $\left(A_{2, \mathfrak{E}}\right)$ also implies $\left(A_{3, \mathfrak{P}}\right)$.

Remark 1.11 (Removing condition $\left(A_{1}\right)$ ). If Condition $\left(A_{1}\right)$ is removed, then the conclusions of Theorem 1.10 continue to hold, provided condition $\left(A_{4, \mathfrak{x}}\right)$ is replaced by
$\left(A_{4, \mathfrak{X}}^{\prime}\right)$ The collection of distributions of the above defined sequence $\left(\mathbf{W}^{(m)}(1), \ldots, \mathbf{W}^{(m)}(d)\right)^{T}, m \in \mathbb{N}$, of processes based on $\mathfrak{X}$, is relatively compact with respect to the Skorohod topology, and every converging subsequence admits as a limit a continuous centered Gaussian process with independent components.
The proof of this fact follows the same lines as the proof of Theorem 1.5 (see Section 3.3); the details are left to the reader.

EXAMPLE 1.12 (Fractional products). For every integer $p \geq 3$ we will now demonstrate the existence of a sequence of symmetric kernels $f^{(m)}:\{1, \ldots, m\}^{p} \rightarrow \mathbb{R}$, vanishing on diagonals and such that Conditions 1.7 and $\left(A_{1}\right)$ in Theorem 1.10 (for $d=1$ ) are satisfied, with $v_{1}(s)=v(s)=s^{p / a}$, for some integer $2 \leq a \leq p-1$.

The definition of $f^{(m)}$ is based on a slight variation of the construction of fractional cartesian products, as described in Ble01, Chapter XIII], as well as in BJ04, NPR10b. Fix $a, p$ as above, and consider an injective mapping $\varphi: \mathbb{N}^{a} \mapsto \mathbb{N}$ with the properties that, for all $k \geq 1$, (a) $\varphi\left([k]^{a}\right) \subset\left[k^{a}\right]$, and (b) $\varphi\left([k+1]^{a}\right) \backslash \varphi\left([k]^{a}\right) \subset\left[(k+1)^{a}\right] \backslash\left[k^{a}\right]$. Such a mapping is easily defined by recursion on $k$. Observe in particular that Property (a) implies that, for all $N \geq 1$, the image of the restriction of $\varphi$ to $\left[\left\lfloor N^{1 / a}\right\rfloor\right]^{a}$ is contained in $[N]$. Consider in addition a collection $\left\{S_{1}, \ldots, S_{p}\right\}$ of non-empty distinct subsets of [p], satisfying the properties that (i) $\left|S_{i}\right|=a$, and (ii) each index $i \in[p]$ appears in exactly $a$ of the sets $S_{i}$ (yielding in particular $\left.[p]=\cup_{i} S_{i}\right)$. For every $i$ and every vector $\mathbf{t}=\left(t_{1}, \ldots, t_{p}\right)$, we set $\pi_{S_{i}} \mathbf{t}=\left(t_{k}: k \in S_{i}\right)$, where the indices belonging to $S_{i}$ are implicitly listed in increasing order. Our aim is to use the mapping $\varphi$ and the sets $S_{i}$ in order to define a sparse subset $F_{m}$ of $[m]^{p}$ for every integer $m>p^{a}$ (this last relation is required in order to ensure that $\left[\left\lfloor m^{1 / a}\right\rfloor\right]$ contains at least $p$ elements): the nature of the sparsity of $F_{m}$ will be encoded by the ratio $p / a$, corresponding to its fractional dimension Ble01,BJ04. For every $m \geq 1$ we start by setting

$$
F_{m}^{0}:=\left\{\mathbf{k}=\left(k_{1}, \ldots, k_{p}\right): \mathbf{k}=\left(\varphi\left(\pi_{S_{1}} \mathbf{t}\right), \ldots, \varphi\left(\pi_{S_{p}} \mathbf{t}\right)\right), \text { for some } \mathbf{t} \in \Delta_{\left\lfloor m^{1 / a}\right\rfloor}^{p}\right\} \subset[m]^{p}
$$

where, the symbol $\Delta_{N}^{p}$ indicates the class of all vectors $\left(t_{1}, \ldots, t_{p}\right)$ such that $1 \leq t_{1}<\cdots<t_{p} \leq N$; when $m \leq p^{a}, F_{m}^{0}$ can be empty. The injectivity of $\varphi$ readily implies that, when $m>p^{a}$, the entries of any $\mathbf{k}=\left(k_{1}, \ldots, k_{p}\right) \in F_{m}^{0}$ are pairwise distinct, and also that, if $\mathbf{k} \neq \mathbf{k}^{\prime}$ belong to $F_{0}^{m}$, then $\mathbf{k}$ cannot be obtained from $\mathbf{k}^{\prime}$ via a permutation of its entries. We eventually set

$$
F_{m}:=\operatorname{sym}\left(F_{m}^{0}\right) \subset[m]^{p}, \quad m \geq 1,
$$

that is, $F_{m}$ is the class of those $\left(k_{1}, \ldots, k_{p}\right)$ such that $\left(k_{\sigma(1)}, \ldots, k_{\sigma(p)}\right) \in F_{m}^{0}$ for some permutation $\sigma$. Immediate combinatorial considerations imply that there exists a finite constant $b>0$ such that, as $N \rightarrow \infty,\left|F_{N}\right| \sim b \cdot N^{p / a}$. For $m>p^{a}$, we define

$$
f^{(m)}\left(i_{1}, \ldots, i_{p}\right):=\frac{1}{\left(p!\left|F_{m}\right|\right)^{1 / 2}} \mathbf{1}_{F_{m}}\left(i_{1}, \ldots, i_{p}\right), \quad\left(i_{1}, \ldots i_{p}\right) \in[m]^{p}
$$

The computations in NPR10b, Section 6.2 and Section 6.3] readily imply that $f^{(m)}$ verifies Condition 1.7 Moreover, since

$$
\begin{equation*}
\left|F_{m} \cap[\lfloor t m\rfloor]^{p}\right| \sim\left|F_{\lfloor t m\rfloor}\right| \sim b \cdot t^{p / a} m^{p / a}, \tag{11}
\end{equation*}
$$

we deduce that Assumption $\left(A_{1}\right)$ in Theorem 1.10 is satisfied with $v(t)=t^{p / a}$. Using the chain of implications (9), we infer that, given a sequence $\mathfrak{X}$ of centred unit variance random variables verifying (5), the corresponding empirical process $W^{(m)}$, defined via (11), converges in distribution to $\left\{B_{t^{p} / a}: t \in[0,1]\right\}$, where $B$ is a standard Brownian motion. Selecting pairwise distinct integers $p_{1}, \ldots, p_{d}$ yields examples of $d$-dimensional sequences verifying Conditions 1.7 and $\left(A_{1}\right)$ in Theorem 1.10. For the sake of completeness, a proof of (11) is sketched in Section 3.4,
REmARK 1.13. In the finite-dimensional setting considered in NPR10a (see, in particular Theorem 1.2 therein), universality of Gaussian homogeneous sums is established under the weaker condition that $\sup _{i \in \mathbb{N}} \mathbb{E}\left|X_{i}\right|^{3}<\infty$ (of course without implying ( $A_{3, \mathfrak{x}}$ ), in this case). This is not possible following our method of proof in the functional situation, since it is based on Theorem 1.4, which is a genuine fourth moment theorem. On the contrary, the proofs in NPR10a rely on a combination of Malliavin calculus on Gaussian spaces and an invariance principle for multilinear forms, proved in MOO10 via an elaboration of the Lindeberg swapping trick. Since this invariance principle only requires finite third moments, it is possible to dispense with fourth moment conditions on $\mathfrak{X}$ in that framework. See also [CSZ17, Theorem 4.2].

Remark 1.14. Proposition 1.8 and Theorems 1.9 and 1.10 all require that $p_{k} \geq 2$ for all $k=1, \ldots, d$. This is because display (1.9) in NPR10a used in their proofs relies on this assumption. Relation (7), however, still implies Condition [1.2, even if $p_{1}=1$. In this case, writing $a_{i}^{(m)}(1)$ for $a_{\{i\}}^{(m)}(1)$, we have
$\operatorname{Inf}_{i}\left(f_{1}^{(m)}\right)=a_{i}^{(m)}(1)^{2}$. Moreover, a straightforward computation shows that, for $p_{1}=1$, item a) below implies Condition (1.3. Therefore, by part b) of Remark 1.6) if $p_{1}=1$ and (5) and all of the following hold:
a) $\lim _{m \rightarrow \infty} \max _{\leq i \leq m} a_{i}^{(m)}(1)^{2}=0$;
b) $\lim _{m \rightarrow \infty} \sum_{i=1}^{\left\lfloor n_{m} s\right\rfloor} a_{i}^{(m)}(1)^{2}=v_{1}(s)$ for some $v_{1}:[0,1] \rightarrow \mathbb{R}$;
c) the assumptions of Theorem 1.9 are satisfied for the $(d-1)$-dimensional sequence of processes $\left(Q_{p_{2}}\left(m, f_{2}^{(m)}, \mathfrak{X}\right), \ldots, C\right.$ substituted in place of $\left(W^{m}\right)_{m \in \mathbb{N}}$,
then the whole $d$-dimensional sequence $\left(Q_{p_{1}}\left(m, f_{1}^{(m)}, \mathfrak{X}\right), \ldots, Q_{p_{d}}\left(m, f_{d}^{(m)}, \mathfrak{X}\right)\right)_{m \in \mathbb{N}}$ converges in distribution with respect to the Skorohod topology to the continuous, centered Gaussian process $\mathbf{Z}=(\mathbf{Z}(1), \ldots, \mathbf{Z}(d))^{T}$ with independent components, which is defined via (3)).

## 2. Degenerate $U$-statistics and Hoeffding decompositions

In this section we prove and collect useful auxiliary results about degenerate $U$-statistics based on an independent sample. For reasons of simplicity, we abandon the setup of triangular arrays in this section. Thus, we let $(\Omega, \mathcal{F}, \mathbb{P})$ be a generic probability space, on which independent random elements $X_{1}, X_{2} \ldots$ are defined that have values in the respective measurable spaces $\left(E_{1}, \mathcal{E}_{1}\right),\left(E_{2}, \mathcal{E}_{2}\right), \ldots$ Moreover, for $n \in \mathbb{N}$ fixed we let $[n]:=\{1, \ldots, n\}$ and, for $J \subseteq[n]$, we define $\mathcal{F}_{J}:=\sigma\left(X_{i}, i \in J\right)$. Note that, whenever

$$
f: \prod_{j=1}^{n} E_{j} \rightarrow \mathbb{R} \quad \text { is } \quad \bigotimes_{j=1}^{n} \mathcal{E}_{j}-\mathcal{B}(\mathbb{R}) \text { - measurable }
$$

such that

$$
Y:=f\left(X_{1}, \ldots, X_{n}\right) \in L^{1}(\mathbb{P}),
$$

then there is a $\mathbb{P}$-a.s. unique representation of the form

$$
\begin{equation*}
Y=\sum_{M \subseteq[n]} Y_{M}=\sum_{s=0}^{n}\left(\sum_{\substack{M \subseteq[n]: \\|M|=s}} Y_{M}\right) \tag{12}
\end{equation*}
$$

where, for each $M \subseteq[n]$, the summand $Y_{M}$ is measurable with respect to $\mathcal{F}_{M}$ and, furthermore,

$$
\mathbb{E}\left[Y_{M} \mid \mathcal{F}_{J}\right]=0 \quad \text { holds, whenever } M \nsubseteq J .
$$

Note that, in particular, there are measurable functions

$$
f_{M}: \prod_{j \in M} E_{j} \rightarrow \mathbb{R}, \quad M \subseteq[n],
$$

such that $Y_{M}=f_{M}\left(X_{j}, j \in M\right)$. The representation (12) is the celebrated Hoeffding decomposition of $Y$. The following well-known explicit formula for the Hoeffding components $Y_{M}, M \subseteq[n]$, is easily deduced from the exclusion-inclusion principle:

$$
\begin{equation*}
Y_{M}=\sum_{J \subseteq M}(-1)^{|M|-|J|} \mathbb{E}\left[Y \mid \mathcal{F}_{J}\right], \tag{13}
\end{equation*}
$$

yielding in particular that $Y_{\emptyset}=\mathbb{E}[Y]$ a.s.- $\mathbb{P}$. Equation (13) directly implies the linearity of the Hoeffding decomposition. It should also be noted that, whenever $Y \in L^{p}(\mathbb{P})$ for some $p \in[1, \infty]$, then automatically $Y_{M} \in L^{p}(\mathbb{P})$ for all $M \subseteq[n]$. Moreover, if $Y \in L^{2}(\mathbb{P})$, then its Hoeffding components are mutually orthogonal in $L^{2}(\mathbb{P})$.

For $p \in[n]$, we call $Y$ a (completely) degenerate $U$-statistic of order $p$, based on $X_{1}, \ldots, X_{n}$, if its Hoeffding decomposition (12) is of the form

$$
\begin{equation*}
Y=\sum_{J \in \mathcal{D}_{p}(n)} Y_{J}, \tag{14}
\end{equation*}
$$

i.e. if $Y_{M}=0 \mathbb{P}$-a.s. whenever $|M| \neq p$. Here and in what follows we write

$$
\mathcal{D}_{p}(n):=\{J \subseteq[n]:|J|=p\}
$$

for the collection of all $\binom{n}{p}$ different $p$-subsets of $[n]$.
Now suppose that we are given two positive integers $m$ and $n$, as well as $p \in[n]$ and $q \in[m]$ and consider two degenerate $U$-statistics $V$ based on $X_{1}, \ldots, X_{m}$ and $W$ based on $X_{1}, \ldots, X_{n}$ of respective orders $q$ and $p$. Hence, we have the respective Hoeffding decompositions

$$
V=\sum_{J \in \mathcal{D}_{q}(m)} V_{J} \quad \text { and } \quad W=\sum_{J \in \mathcal{D}_{p}(n)} W_{J}
$$

We further assume that $\mathbb{E}|W|^{4}, \mathbb{E}|V|^{4}<\infty$. Moreover, for $l \in[m]$ and $k \in[n]$ let us define

$$
\varrho_{l, V}^{2}:=\max _{1 \leq j \leq l} \sum_{\substack{J \in \mathcal{D}_{q}(l): \\ j \in J}} \mathbb{E}\left[V_{J}^{2}\right] \quad \text { and } \quad \varrho_{k, W}^{2}:=\max _{1 \leq j \leq k} \sum_{\substack{J \in \mathcal{D}_{p}(k): \\ j \in J}} \mathbb{E}\left[W_{J}^{2}\right]
$$

as well as

$$
\sigma_{l, V}^{2}:=\sum_{J \in \mathcal{D}_{q}(l)} \mathbb{E}\left[V_{J}^{2}\right] \quad \text { and } \quad \sigma_{k, W}^{2}:=\sum_{J \in \mathcal{D}_{p}(k)} \mathbb{E}\left[W_{J}^{2}\right]
$$

In particular, we have $\sigma_{m, V}^{2}=\mathbb{E}\left[V^{2}\right]$ and $\sigma_{n, W}^{2}=\mathbb{E}\left[W^{2}\right]$ as well as the inequalities

$$
\begin{equation*}
\sigma_{k, W}^{2} \leq \sigma_{n, W}^{2} \quad \text { and } \quad \varrho_{k, W}^{2} \leq \varrho_{n, W}^{2} \tag{15}
\end{equation*}
$$

and analogous ones for $V$ in place of $W$. Note that $V W$ is an integrable function of $X_{1}, \ldots, X_{n \vee m}$. Hence, it follows from (13) and the assumptions on $V$ and $W$ that it has a Hoeffding decomposition of the form

$$
V W=\sum_{\substack{M \subseteq[n \vee m]: \\|M| \leq p+q}} U_{M}(V, W)
$$

For simplicity, we write $U_{M}(W)$ for $U_{M}(W, W)$ and $U_{M}(V)$ for $U_{M}(V, V)$ so that

$$
V^{2}=\sum_{\substack{M \subseteq[m]: \\|M| \leq 2 q}} U_{M}(V) \quad \text { and } \quad W^{2}=\sum_{\substack{N \subseteq[n]: \\|N| \leq 2 p}} U_{N}(W)
$$

are the Hoeffding decompositions of $V^{2}$ and $W^{2}$, respectively. We will use the conventions $U_{M}(V)=0$ and $U_{N}(W)=0$ implicitly, whenever $M \nsubseteq[m]$ and $N \nsubseteq[n]$, respectively. Let us define the collection $\mathcal{S}_{0}:=\mathcal{S}_{0}(m, n, q, p)$ of all quadruples $(I, J, K, L) \in \mathcal{D}_{q}(m)^{2} \times \mathcal{D}_{p}(n)^{2}$ such that
(i) $I \cap K=J \cap L=\emptyset$,
(ii) $\emptyset \neq I \cap J=I \backslash(I \cap L) \neq I$,
(iii) $\emptyset \neq J \cap I=J \backslash(J \cap K) \neq J$,
(iv) $\emptyset \neq K \cap J=K \backslash(L \cap K) \neq K$ and
(v) $\emptyset \neq L \cap I=L \backslash(L \cap K) \neq L$.

Similarly, we denote by $\mathcal{S}_{1}:=\mathcal{S}_{1}(m, n, p)$ the collection of all quadruples $(I, J, K, L) \in \mathcal{D}_{p}(m \wedge n)^{4}$ such that
(i) $I \cap J=K \cap L=\emptyset$,
(ii) $\emptyset \neq I \cap K=I \backslash(I \cap L) \neq I$,
(iii) $\emptyset \neq J \cap K=J \backslash(J \cap L) \neq J$,
(iv) $\emptyset \neq K \cap J=K \backslash(I \cap K) \neq K$ and
(v) $\emptyset \neq L \cap I=L \backslash(L \cap J) \neq L$.

Moreover, we define the quantities

$$
S_{0}(V, W)=\sum_{(I, J, K, L) \in \mathcal{S}_{0}} \mathbb{E}\left[V_{I} V_{J} W_{K} W_{L}\right] \quad \text { and, if } p=q
$$

$$
S_{1}(V, W)=\sum_{(I, J, K, L) \in \mathcal{S}_{1}} \mathbb{E}\left[V_{I} V_{J} W_{K} W_{L}\right] .
$$

In particular, we have $S_{0}(W, W)=S_{1}(W, W)$. More generally, if $p=q, m \leq n$ and $V_{J}=W_{J}$ for all $J \in \mathcal{D}_{p}(m)$, then $S_{1}(V, W)=S_{0}(V, V)$.

Remark 2.1. The quadruples $(I, J, K, L) \in \mathcal{S}_{0}$ play a crucial role in all proofs of de Jong type CLTs via the quantities $S_{0}(V, W)$ (see dJ90, DP17). Note that these quadruples are all bifold, meaning that each element $i \in I \cup J \cup K \cup L$ lies in exactly two of the sets $I, J, K, L$. In particular, there can be no free index, which is an element that appears in only one of the sets $I, J, K, L$. Moreover, no two of the sets $I, J, K, L$ can be the same and each of these sets is disjoint to precisely one other among these sets. An analogous remark applies to the quadruples $(I, J, K, L) \in \mathcal{S}_{1}$. Note further that the existence of a free index for a quadruple $(I, J, K, L)$ necessarily implies $\mathbb{E}\left[V_{I} V_{J} W_{K} W_{L}\right]=0$ by degeneracy. This rule will be tacitly applied in what follows.

Lemma 2.2. There exists a finite constant $C_{p, q}$, only depending on $p$ and $q$, such that

$$
S_{0}(V, W) \geq-C_{p, q} \max \left(\sigma_{m, V}^{2} \varrho_{n, W}^{2}, \sigma_{n, W}^{2} \varrho_{m, V}^{2}\right) .
$$

Proof. This follows from a straightforward generalization of Propositions 3.5 and 3.6 of DP17 to the situation of possibly different $m$ and $n$ and possibly non-unit variances. We omit the details here.

Lemma 2.3. We have that

$$
S_{0}(W, W) \leq \mathbb{E}\left[W^{4}\right]-3 \sigma_{n, W}^{4}+2 p \sigma_{n, W}^{2} \varrho_{n, W}^{2}
$$

Proof. This follows from the first inequality in equation (2.13) of DP17] by noticing that the left hand side of this inequality is nonnegative and by taking into account that $\operatorname{Var}(W)=\sigma_{n, W}^{2}$ is not necessarily equal to 1 , here.

The next two lemmas will be of vital importance for proving convergence of finite dimensional distributions. Lemma 2.5 is an extension of results and techniques provided in [DP17, Section 3], whereas Lemma 2.4 is taken directly from there.

Lemma 2.4 (Lemma 2.10 of DP17). There is a finite constant $\kappa_{p}$ only depending on $p$ such that

$$
\sum_{\substack{M \subseteq[n]: \\ 1 \leq|M| \leq 2 p-1}} \operatorname{Var}\left(U_{M}(W)\right) \leq \mathbb{E}\left[W^{4}\right]-3 \sigma_{n, W}^{4}+\kappa_{p} \sigma_{n, W}^{2} \varrho_{n, W}^{2}
$$

Lemma 2.5. (i) If $p=q$, then

$$
\begin{aligned}
& \sum_{\substack{M \subseteq[n \vee m]: \\
|M| \leq 2 p-1}} \operatorname{Var}\left(U_{M}(V, W)\right) \leq p \min \left(\varrho_{n, W}^{2} \sigma_{m, V}^{2}, \varrho_{m, V}^{2} \sigma_{n, W}^{2}\right)+p \varrho_{m \wedge n, V} \varrho_{m \wedge n, W} \sigma_{m \wedge n, V} \sigma_{m \wedge n, W} \\
&+\left(\sum_{\substack{M \subseteq[m \wedge n]: \\
1 \leq|M| \leq 2 p-1}} \operatorname{Var}\left(U_{M}(V)\right)\right)^{1 / 2} \cdot\left(\sum_{\substack{M \subseteq[m \wedge n]: \\
1 \leq|M| \leq 2 p-1}} \operatorname{Var}\left(U_{M}(W)\right)\right)^{1 / 2}+S_{1}(V, W)-S_{0}(V, W) .
\end{aligned}
$$

(ii) If $p \neq q$, then

$$
\begin{aligned}
& \sum_{\substack{M \subseteq[n \vee m]: \\
|M| \leq p+q-1}} \operatorname{Var}\left(U_{M}(V, W)\right) \leq \min \left(q \varrho_{n, W}^{2} \sigma_{m, V}^{2}, p \varrho_{m, V}^{2} \sigma_{n, W}^{2}\right)-S_{0}(V, W) \\
& \\
& +\left(\sum_{\substack{M \subseteq[m \wedge n]: \\
1 \leq|M| \leq 2(p \vee q)-1}} \operatorname{Var}\left(U_{M}(V)\right)\right)^{1 / 2} \cdot\left(\sum_{\substack{M \subseteq[m \wedge n]: \\
1 \leq|M| \leq 2(p \vee q)-1}} \operatorname{Var}\left(U_{M}(W)\right)\right)^{1 / 2} .
\end{aligned}
$$

Proof. We begin with some computations that are valid in all different cases.

$$
\begin{aligned}
& \sum_{\substack{M \subseteq[n \vee m]: \\
|M| \leq p+q-1}} \operatorname{Var}\left(U_{M}(V, W)\right)=\operatorname{Var}(V W)-\sum_{\substack{M \subseteq[n \vee m]: \\
|M|=p+q}} \operatorname{Var}\left(U_{M}(V, W)\right) \\
& =\operatorname{Var}(V W)-\sum_{\substack{M \subseteq[n \vee m]: \\
|M|=p+q}} \operatorname{Var}\left(\sum_{\substack{J \in \mathcal{D}_{q}(m), K \in \mathcal{D}_{p}(n): \\
J \cup K=M}} V_{J} W_{K}\right) \\
& =\operatorname{Var}(V W)-\sum_{\substack{M \subseteq[n \vee m]: \\
|M|=p+q}} \sum_{\substack{ \\
\mid, J \in \mathcal{D}_{q}(m), K, L \in \mathcal{D}_{p}(n):}} \mathbb{E}\left[V_{I} V_{J} W_{K} W_{L}\right] \\
& |M|=p+q \quad K, L \in \mathcal{D}_{p}(n): \\
& \begin{array}{l}
I \cap K=J \cap L=\emptyset, \\
I \cup K=M=J \cup L
\end{array} \\
& =\operatorname{Var}(V W)-\sum_{\substack{I, J \in \mathcal{D}_{q}(m), K, L \in \mathcal{D},(n),}} \mathbb{E}\left[V_{I} V_{J} W_{K} W_{L}\right] \\
& K, L \in \mathcal{D}_{p}(n): \\
& =\operatorname{Var}(V W)-\sum_{\substack{I \in \mathcal{D}_{q}(m), K \in \mathcal{D}_{p}(n): \\
I \cap K=\emptyset}} \mathbb{E}\left[V_{I}^{2}\right] \mathbb{E}\left[W_{K}^{2}\right]-\sum_{\substack{I, J \in \mathcal{D}_{q}(m), K, L \in \mathcal{D}_{p}(n) ; \\
I N K=\emptyset, \emptyset \neq I \cap J=I \backslash \backslash(I \cap L) \neq I, \emptyset \neq J \cap I=J(J \cap K) \neq J}} \mathbb{E}\left[V_{I} V_{J} W_{K} W_{L}\right] \\
& -\delta_{p, q} \sum_{\substack{I, K \in \mathcal{D}_{q}(m \wedge n): \\
I \cap K=\emptyset}} \mathbb{E}\left[V_{I} W_{I}\right] \mathbb{E}\left[V_{K} W_{K}\right]
\end{aligned}
$$

Noting that

$$
\operatorname{Var}(V W)=\operatorname{Cov}\left(V^{2}, W^{2}\right)+\mathbb{E}\left[V^{2}\right] \mathbb{E}\left[W^{2}\right]-\mathbb{E}[V W]^{2}
$$

and also, for reasons of degeneracy, that

$$
\sum_{\substack{\left.I, J \in \mathcal{D}_{q}(m), K, L \in \mathcal{D}_{p}(n) ; \\ I \cap K=\emptyset, \emptyset \neq I \cap J=I \backslash L \backslash I \cap L\right) \neq I, \emptyset \neq J \cap I=J \backslash(J \cap K) \neq J}} \mathbb{E}\left[V_{I} V_{J} W_{K} W_{L}\right]=S_{0}(V, W)
$$

we hence obtain that

$$
\begin{align*}
& \sum_{\substack{M \subseteq[n \vee m]: \\
|M| \leq p+q-1}} \operatorname{Var}\left(U_{M}(V, W)\right)=\operatorname{Cov}\left(V^{2}, W^{2}\right)+\mathbb{E}\left[V^{2}\right] \mathbb{E}\left[W^{2}\right]-\mathbb{E}[V W]^{2} \\
&-\sum_{\substack{I \in \mathcal{D}_{q}(m), K \in \mathcal{D}_{p}(n): \\
I \cap K=\emptyset}} \mathbb{E}\left[V_{I}^{2}\right] \mathbb{E}\left[W_{K}^{2}\right]-S_{0}(V, W)-\delta_{p, q} \sum_{\substack{I \in \mathcal{D}_{q}(m), K \in \mathcal{D}_{p}(n): \\
I \cap K=\emptyset}} \mathbb{E}\left[V_{I} W_{I}\right] \mathbb{E}\left[V_{K} W_{K}\right] . \tag{16}
\end{align*}
$$

We now deal with the individual terms appearing on the right hand side of (16).

$$
\begin{aligned}
& \sum_{\substack{I \in \mathcal{D}_{q}(m), K \in \mathcal{D}_{p}(n): \\
I \cap K=\emptyset}} \mathbb{E}\left[V_{I}^{2}\right] \mathbb{E}\left[W_{K}^{2}\right]=\sum_{\substack{I \in \mathcal{D}_{q}(m), K \in \mathcal{D}_{p}(n)}} \mathbb{E}\left[V_{I}^{2}\right] \mathbb{E}\left[W_{K}^{2}\right]-\sum_{\substack{I \in \mathcal{D}_{q}(m), K \in \mathcal{D}_{p}(n) ; \\
I \cap K \neq \emptyset}} \mathbb{E}\left[V_{I}^{2}\right] \mathbb{E}\left[W_{K}^{2}\right] \\
& \\
& =\mathbb{E}\left[V^{2}\right] \mathbb{E}\left[W^{2}\right]-\sum_{\substack{I \in \mathcal{D}_{q}(m), K \in \mathcal{D}_{p}(n): \\
I K K \neq \emptyset}} \mathbb{E}\left[V_{I}^{2}\right] \mathbb{E}\left[W_{K}^{2}\right] .
\end{aligned}
$$

Hence,

$$
\begin{aligned}
& \sum_{\substack{M \subseteq[n \vee m]: \\
|M| \leq p+q-1}} \operatorname{Var}\left(U_{M}(V, W)\right)=\operatorname{Cov}\left(V^{2}, W^{2}\right)-\mathbb{E}[V W]^{2} \\
&+\sum_{\substack{I \in \mathcal{D}_{q}(m), K \in \mathcal{D}_{p}(n): \\
I \cap K \neq \emptyset}} \mathbb{E}\left[V_{I}^{2}\right] \mathbb{E}\left[W_{K}^{2}\right]-S_{0}(V, W)-\delta_{p, q} \sum_{\substack{I, K \in \mathcal{D}_{q}(m \wedge n): \\
I \cap K=\emptyset}} \mathbb{E}\left[V_{I} W_{I}\right] \mathbb{E}\left[V_{K} W_{K}\right] .
\end{aligned}
$$

Moreover, if $p=q$ then

$$
\begin{aligned}
& \sum_{\substack{I, K \in \mathcal{D}_{p}(m \wedge n): \\
I \cap K=\emptyset}} \mathbb{E}\left[V_{I} W_{I}\right] \mathbb{E}\left[V_{K} W_{K}\right] \\
= & \left(\sum_{\substack{I \in \mathcal{D}_{p}(m \wedge n)}} \mathbb{E}\left[V_{I} W_{I}\right]\right)^{2}-\sum_{\substack{I, K \in \mathcal{D}_{p}(m \wedge n): \\
I \cap K \neq \emptyset}} \mathbb{E}\left[V_{I} W_{I}\right] \mathbb{E}\left[V_{K} W_{K}\right] \\
= & \mathbb{E}[V W]^{2}-\sum_{\substack{I, K \in \mathcal{D}_{p}(m \wedge n): \\
I \cap K \neq \emptyset}} \mathbb{E}\left[V_{I} W_{I}\right] \mathbb{E}\left[V_{K} W_{K}\right] .
\end{aligned}
$$

Hence, using that $\mathbb{E}[V W]=0$ if $p \neq q$, we obtain that

$$
\begin{align*}
& \sum_{\substack{M \subseteq[n \vee m]: \\
|M| \leq p+q-1}} \operatorname{Var}\left(U_{M}(V, W)\right)=\operatorname{Cov}\left(V^{2}, W^{2}\right)-2 \delta_{p, q} \mathbb{E}[V W]^{2} \\
& \quad+\sum_{\substack{I \in \mathcal{D}_{q}(m), K \in \mathcal{D}_{p}(n): \\
I \cap K \neq \emptyset}} \mathbb{E}\left[V_{I}^{2}\right] \mathbb{E}\left[W_{K}^{2}\right]-S_{0}(V, W)+\delta_{p, q} \sum_{\substack{I, K \in \mathcal{D}_{p}(m \wedge n): \\
I \cap K \neq \emptyset}} \mathbb{E}\left[V_{I} W_{I}\right] \mathbb{E}\left[V_{K} W_{K}\right] . \tag{17}
\end{align*}
$$

In particular, if $p \neq q$, then

$$
\begin{equation*}
\sum_{\substack{M \subseteq[n \vee m]: \\|M| \leq p+q-1}} \operatorname{Var}\left(U_{M}(V, W)\right)=\operatorname{Cov}\left(V^{2}, W^{2}\right)+\sum_{\substack{I \in \mathcal{D}_{q}(m), K \in \mathcal{D}_{p}(n): \\ I \cap K \neq \emptyset}} \mathbb{E}\left[V_{I}^{2}\right] \mathbb{E}\left[W_{K}^{2}\right]-S_{0}(V, W) \tag{18}
\end{equation*}
$$

Now,

$$
\begin{aligned}
\sum_{\substack{I \in \mathcal{D}_{q}(m), K \in \mathcal{D}_{p}(n): \\
I \cap K \neq \emptyset}} \mathbb{E}\left[V_{I}^{2}\right] \mathbb{E}\left[W_{K}^{2}\right] & =\sum_{I \in \mathcal{D}_{q}(m)} \mathbb{E}\left[V_{I}^{2}\right] \sum_{i \in I} \sum_{\substack{K \in \mathcal{D}_{p}(n): \\
\max (K \cap I)=i}} \mathbb{E}\left[W_{K}^{2}\right] \\
& \leq q \varrho_{n, W}^{2} \sum_{I \in \mathcal{D}_{q}(m)} \mathbb{E}\left[V_{I}^{2}\right]=q \varrho_{n, W}^{2} \mathbb{E}[V]^{2}=q \varrho_{n, W}^{2} \sigma_{m, V}^{2},
\end{aligned}
$$

and, analogously,

$$
\sum_{\substack{I \in \mathcal{D}_{q}(m), \\ \text { S亻二 } \\ I \cap K \neq \emptyset \\ I \cap K}} \mathbb{E}\left[V_{I}^{2}\right] \mathbb{E}\left[W_{K}^{2}\right] \leq p \varrho_{m, V}^{2} \mathbb{E}[W]^{2}=p \varrho_{m, V}^{2} \sigma_{n, W}^{2} .
$$

Hence,

$$
\begin{equation*}
\sum_{\substack{I \in \mathcal{D}_{q}(m), K \in \mathcal{D}_{p}(n): \\ I \cap K \neq \emptyset}} \mathbb{E}\left[V_{I}^{2}\right] \mathbb{E}\left[W_{K}^{2}\right] \leq \min \left(q \varrho_{n, W}^{2} \sigma_{m, V}^{2}, p \varrho_{m, V}^{2} \sigma_{n, W}^{2}\right) \tag{19}
\end{equation*}
$$

We have

$$
\begin{aligned}
& \left|\sum_{\substack{I, K \in \mathcal{D}_{p}(m \wedge n): \\
I \cap K \neq \emptyset}} \mathbb{E}\left[V_{I} W_{I}\right] \mathbb{E}\left[V_{K} W_{K}\right]\right| \leq \sum_{I \in \mathcal{D}_{p}(m \wedge n)}\left|\mathbb{E}\left[V_{I} W_{I}\right]\right| \sum_{\substack{K \in \mathcal{D}_{p}(m \wedge n): \\
I \cap K \neq \emptyset}}\left|\mathbb{E}\left[V_{K} W_{K}\right]\right| \\
& =\sum_{\substack{I \in \mathcal{D}_{p}(m \wedge n)}}\left|\mathbb{E}\left[V_{I} W_{I}\right]\right| \sum_{i \in I} \sum_{\substack{K \in \mathcal{D}_{p}(m \wedge n): \\
\max (I \cap K)=i}}\left|\mathbb{E}\left[V_{K} W_{K}\right]\right| \\
& \leq \sum_{\substack{I \in \mathcal{D}_{p}(m \wedge n)}}\left|\mathbb{E}\left[V_{I} W_{I}\right]\right| \sum_{i \in I}\left(\sum_{\substack{K \in \mathcal{D}_{p}(m \wedge n): \\
\max (I \cap K)=i}} \mathbb{E}\left[V_{K}^{2}\right]\right)^{1 / 2} \cdot\left(\sum_{\substack{K \in \mathcal{D}_{p}(m \wedge n): \\
\max (I \cap K)=i}} \mathbb{E}\left[W_{K}^{2}\right]\right)^{1 / 2} \\
& \leq p \varrho_{m \wedge n, V} \varrho_{m \wedge n, W} \sum_{I \in \mathcal{D}_{p}(m \wedge n)}\left|\mathbb{E}\left[V_{I} W_{I}\right]\right| \\
& \leq p \varrho_{m \wedge n, V} \varrho_{m \wedge n, W}\left(\sum_{I \in \mathcal{D}_{p}(m \wedge n)} \mathbb{E}\left[V_{I}^{2}\right]\right)^{1 / 2} \cdot\left(\sum_{I \in \mathcal{D}_{p}(m \wedge n)} \mathbb{E}\left[W_{I}^{2}\right]\right)^{1 / 2} \\
& =p \varrho_{m \wedge n, V} \varrho_{m \wedge n, W} \sigma_{m \wedge n, V} \sigma_{m \wedge n, W} .
\end{aligned}
$$

Hence, we obtain the inequalities

$$
\begin{align*}
&-p \varrho_{m \wedge n, V} \varrho_{m \wedge n, W} \sigma_{m \wedge n, V} \sigma_{m \wedge n, W} \leq \sum_{\substack{I \in \mathcal{D}_{p}(m), K \in \mathcal{D}_{p}(n): \\
I \cap K \neq \emptyset}} \mathbb{E}\left[V_{I} W_{I}\right] \mathbb{E}\left[V_{K} W_{K}\right] \\
& \leq p \varrho_{m \wedge n, V} \varrho_{m \wedge n, W} \sigma_{m \wedge n, V} \sigma_{m \wedge n, W} \tag{20}
\end{align*}
$$

We estimate the term $\operatorname{Cov}\left(V^{2}, W^{2}\right)$ seperately according to whether $p=q$ or not. First assume that $p=q$. Then, due to the orthogonality of Hoeffding components we have

$$
\begin{aligned}
& \operatorname{Cov}\left(V^{2}, W^{2}\right)= \sum_{\substack{M \subseteq[m], N \subseteq[n]: \\
1 \leq|M|,|N| \leq 2 p}} \mathbb{E}\left[U_{M}(V) U_{N}(W)\right]=\sum_{\substack{M \subseteq[m \wedge n]: \\
1 \leq|M| \leq 2 p}} \mathbb{E}\left[U_{M}(V) U_{M}(W)\right] \\
&=\sum_{\substack{M \subseteq[m \wedge n]: \\
1 \leq|M| \leq 2 p-1}} \mathbb{E}\left[U_{M}(V) U_{M}(W)\right]+\sum_{\substack{M \subseteq[m \wedge n]: \\
|M|=2 p}} \mathbb{E}\left[U_{M}(V) U_{M}(W)\right] \\
&=: T_{1}+T_{2} .
\end{aligned}
$$

Using the Cauchy-Schwarz inequality twice we can estimate

$$
\begin{aligned}
\left|T_{1}\right| & \leq \sum_{\substack{M \subseteq[m \wedge n]: \\
1 \leq|M| \leq 2 p-1}} \sqrt{\operatorname{Var}\left(U_{M}(V)\right)} \sqrt{\operatorname{Var}\left(U_{M}(W)\right)} \\
& \leq\left(\sum_{\substack{M \subseteq[m \wedge n]: \\
1 \leq|M| \leq 2 p-1}} \operatorname{Var}\left(U_{M}(V)\right)\right)^{1 / 2} \cdot\left(\sum_{\substack{M \subseteq[m \wedge n]: \\
1 \leq|M| \leq 2 p-1}} \operatorname{Var}\left(U_{M}(W)\right)\right)^{1 / 2} .
\end{aligned}
$$

On the other hand, we have

$$
T_{2}=\sum_{\substack{M \subseteq[m \wedge n]:}} \sum_{\substack{I, J \in \mathcal{D}_{p}(m),\left|M, L \in \mathcal{D}_{p}(n): \\|M|=2 p\right.}} \mathbb{E}\left[V_{I} V_{J} W_{K} W_{L}\right]=\sum_{\substack{I, J \in \mathcal{D}_{p}(m), I \cup J, L \in \mathcal{D}_{p}(n) \\ I \cap J=K \cap L=\emptyset, I \cup J=K \cup M \cup L}} \mathbb{E}\left[V_{I} V_{J} W_{K} W_{L}\right]
$$

$$
\begin{aligned}
& =\sum_{\substack{I, J \in \mathcal{D}_{p}(m), K, L \in \mathcal{D}_{p}(n): \\
I \cap J=K \cap L=\emptyset}} \mathbb{E}\left[V_{I} V_{J} W_{K} W_{L}\right] \\
& =2 \sum_{\substack{I, J \in \mathcal{D}_{p}(m \wedge n): \\
I \cap J=\emptyset}} \mathbb{E}\left[V_{I} W_{I}\right] \mathbb{E}\left[V_{J} W_{J}\right]+\sum_{\substack{I, J \in \mathcal{D}_{p}(m), K, L \in \mathcal{D}_{p}(n): \\
I \cap J=K \cap L=\emptyset, \emptyset \neq I \cap K=I \backslash(I \cap L) \neq I}} \mathbb{E}\left[V_{I} V_{J} W_{K} W_{L}\right] \\
& =2 \sum_{\substack{I, J \in \mathcal{D}_{p}(m \wedge n):}} \mathbb{E}\left[V_{I} W_{I}\right] \mathbb{E}\left[V_{J} W_{J}\right]+S_{1}(V, W) \\
& =2 \mathbb{E}[V]^{2}-2 \sum_{\substack{ \\
I, J \in \mathcal{D}_{p}(m \wedge n): \\
I \cap J \neq \emptyset}} \mathbb{E}\left[V_{I} W_{I}\right] \mathbb{E}\left[V_{J} W_{J}\right]+S_{1}(V, W),
\end{aligned}
$$

where we have used that, due to degeneracy,

$$
\sum_{\substack{I, J \in \mathcal{D}_{p}(m), K, L \in \mathcal{D}_{p}(n): \\ I \cap J=K \cap L=\emptyset, \emptyset \neq I \cap K=I \backslash(I \cap L) \neq I}} \mathbb{E}\left[V_{I} V_{J} W_{K} W_{L}\right]=\sum_{\substack{I, J, K, L \in \mathcal{D}_{p}(m \wedge n): \\ I \cap J=K \cap L=\emptyset, I \neq I \cap K=I \cap K, L \in \mathcal{D}_{p}(m \wedge n):}} \mathbb{E}\left[V_{I} V_{J} W_{K} W_{L}\right]
$$

Hence, if $p=q$ then we obtain that

$$
\begin{align*}
\operatorname{Cov}\left(V^{2}, W^{2}\right) \leq & \left.\sum_{\substack{M \subseteq[m \wedge n]: \\
1 \leq|M| \leq 2 p-1}} \operatorname{Var}\left(U_{M}(V)\right)\right)^{1 / 2} \cdot\left(\sum_{\substack{M \subseteq[m \wedge n]: \\
1 \leq|M| \leq 2 p-1}} \operatorname{Var}\left(U_{M}(W)\right)\right)^{1 / 2} \\
& +2 \mathbb{E}[V W]^{2}-2 \sum_{\substack{ \\
I, K \in \mathcal{D}_{p}(m \wedge n): \\
I \cap K \neq \emptyset}} \mathbb{E}\left[V_{I} W_{I}\right] \mathbb{E}\left[V_{K} W_{K}\right]+S_{1}(V, W) . \tag{21}
\end{align*}
$$

Altogether, in the case $p=q$, we obtain from (17)-(21) that

$$
\begin{aligned}
& \sum_{\substack{M \subseteq[n \vee m]: \\
|M| \leq p+q-1}} \operatorname{Var}\left(U_{M}(V, W)\right) \leq p \min \left(\varrho_{n, W}^{2} \sigma_{m, V}^{2}, \varrho_{m, V}^{2} \sigma_{n, W}^{2}\right) \\
+ & p \varrho_{m \wedge n, V} \varrho_{m \wedge n, W} \sigma_{m \wedge n, V} \sigma_{m \wedge n, W}+S_{1}(V, W)-S_{0}(V, W) \\
+ & \left(\sum_{\substack{M \subseteq[m \wedge n]: \\
1 \leq|M| \leq 2 p-1}} \operatorname{Var}\left(U_{M}(V)\right)\right)^{1 / 2} \cdot\left(\sum_{\substack{M \subseteq[m \wedge n]: \\
1 \leq|M| \leq 2 p-1}} \operatorname{Var}\left(U_{M}(W)\right)\right)^{1 / 2}
\end{aligned}
$$

proving part (i). Let us now assume that $p \neq q$. Let $r:=p \wedge q<p \vee q=$ : $s$. In this case, clearly, $\mathbb{E}[V W]=0$. Moreover, similarly as before, we have

$$
\operatorname{Cov}\left(V^{2}, W^{2}\right)=\sum_{\substack{M \subseteq[m], N \subseteq[n]: \\ 1 \leq|M| \leq 2 q, 1 \leq|N| \leq 2 p}} \mathbb{E}\left[U_{M}(V) U_{N}(W)\right]=\sum_{\substack{M \subseteq[m \wedge n]: \\ 1 \leq|M| \leq 2 r}} \mathbb{E}\left[U_{M}(V) U_{M}(W)\right]
$$

$$
\begin{aligned}
& =\sum_{\substack{M \subseteq[m \wedge n]: \\
1 \leq|M| \leq 2 s-1}} \mathbb{E}\left[U_{M}(V) U_{M}(W)\right] \\
& \leq \sum_{\substack{M \subseteq[m \wedge n]: \\
1 \leq|M| \leq 2 s-1}} \sqrt{\operatorname{Var}\left(U_{M}(V)\right)} \sqrt{\operatorname{Var}\left(U_{M}(W)\right)} \\
& \leq\left(\sum_{\substack{M \subseteq[m \wedge n]: \\
1 \leq|M| \leq 2 s-1}} \operatorname{Var}\left(U_{M}(V)\right)\right)^{1 / 2} \cdot\left(\sum_{\substack{M \subseteq[m \wedge n]: \\
1 \leq|M| \leq 2 s-1}} \operatorname{Var}\left(U_{M}(W)\right)\right)^{1 / 2}
\end{aligned}
$$

This finishes the proof of (ii).
Corollary 2.6. In the situation of Lemma 2.5 (i) assume that, additionally, $m \leq n$ and $V_{J}=W_{J}$ hold for all $J \in \mathcal{D}_{p}(m)$. Then, we have

$$
\begin{aligned}
& \sum_{\substack{M \subseteq[n \vee m]: \\
|M| \leq 2 p-1}} \operatorname{Var}\left(U_{M}(V, W)\right) \leq \mathbb{E}\left[V^{4}\right]-3 \sigma_{m, V}^{4}+2 p \sigma_{m, V}^{2} \varrho_{m, V}^{2}+\left(C_{p, q}+2 p\right) \varrho_{n, W}^{2} \sigma_{n, W}^{2} \\
& +\left(\mathbb{E}\left[V^{4}\right]-3 \sigma_{m, V}^{4}+\kappa_{p} \sigma_{m, V}^{2} \varrho_{m, V}^{2}\right)^{1 / 2} \cdot\left(\mathbb{E}\left[W^{4}\right]-3 \sigma_{n, W}^{4}+\kappa_{p} \sigma_{n, W}^{2} \varrho_{n, W}^{2}\right)^{1 / 2}
\end{aligned}
$$

where $\kappa_{p}$ is a finite constant depending only on $p$.
Proof. Since $S_{1}(V, W)=S_{0}(V, V)$ in this case, the result follows immediately from Lemmas 2.5 (i), 2.4, 2.2, 2.3 and (15).

Corollary 2.7. If, in the situation of Lemma 2.5 (ii), we additionally have $p<q$, then

$$
\begin{aligned}
& \sum_{\substack{M \subseteq[n \vee m]: \\
|M| \leq p+q-1}} \operatorname{Var}\left(U_{M}(V, W)\right) \leq\left(C_{p, q}+q\right) \max \left(\sigma_{m, V}^{2} \varrho_{n, W}^{2}, \sigma_{n, W}^{2} \varrho_{m, V}^{2}\right) \\
& +\left(\mathbb{E}\left[V^{4}\right]-3 \sigma_{m, V}^{4}+\kappa_{q} \sigma_{m, V}^{2} \varrho_{m, V}^{2}\right)^{1 / 2} \cdot\left(\mathbb{E}\left[W^{4}\right]-\sigma_{n, W}^{4}\right)^{1 / 2}
\end{aligned}
$$

where $\kappa_{q}$ is a finite constant depending only on $q$.
Proof. This follows from Lemma 2.5 (ii), Lemma 2.4 (applied to $V$ ) and from the obvious facts that

$$
\sum_{\substack{M \subseteq[m \wedge n]: \\ 1 \leq|M| \leq 2(p \vee q)-1}} \operatorname{Var}\left(U_{M}(V)\right) \leq \sum_{\substack{M \subseteq[m]: \\ M \subseteq[m \wedge n]: \\ 1 \leq|M| \leq 2(p \vee q)-1}} \operatorname{Var}\left(U_{M}(W)\right) \leq \sum_{\substack{M \subseteq[n]: \\ 1 \leq|M| \leq 2 q-1}} \operatorname{Var}\left(U_{M}(V)\right)
$$

## 3. PROOFS

In this Section we provide detailed proofs of Theorem 1.4. Theorem 1.5 and relation (11).
3.1. Proof of Theorem 1.4. The proof of Theorem 1.4 will follow the classical two-step procedure (see [Bil68, Section15]) of establishing convergence of finite dimensional distributions and checking tightness.
3.1.1. Convergence of finite dimensional distributions. We fix time points $0 \leq t_{1}<t_{2}<\ldots<t_{l} \leq 1$ and, with $r:=l d$, consider the random vector $V=V^{(m)}=\left(V_{1}, \ldots, V_{r}\right)^{T} \in \mathbb{R}^{r}$ of degenerate $U$-statistics, defined as follows. Given an integer $1 \leq i \leq r$, write $i=a l+b$ with integers $0 \leq a \leq d-1$ and $1 \leq b \leq l$ and define

$$
V_{i}:=\mathbf{W}_{t_{b}}^{(m)}(a+1)
$$

In other words, we have

$$
V=\left(\mathbf{W}_{t_{1}}^{(m)}(1), \ldots, \mathbf{W}_{t_{l}}^{(m)}(1), \mathbf{W}_{t_{1}}^{(m)}(2), \ldots, \mathbf{W}_{t_{l}}^{(m)}(2), \ldots, \mathbf{W}_{t_{1}}^{(m)}(d), \ldots, \mathbf{W}_{t_{l}}^{(m)}(d)\right)^{T} .
$$

Moreover, for the same $i$ we write $n_{m}(i):=\left\lfloor n_{m} t_{b}\right\rfloor, \sigma_{m}(i)^{2}:=\operatorname{Var}\left(V_{i}\right), q_{i}:=p_{a+1}$ and

$$
\varphi_{m}(i)^{2}:=\max _{1 \leq j \leq n_{m}} \sum_{\substack{J \in \mathcal{D}_{p_{a+1}}\left(n_{m}(i)\right): \\ j \in J}} \mathbb{E}\left[W_{J}^{(m)}(a+1)^{2}\right] .
$$

Then, we have the straightforward inequalities

$$
\begin{equation*}
\sigma_{m}(i)^{2} \leq 1 \quad \text { and } \quad \varphi_{m}(i)^{2} \leq \varrho_{m, a+1}^{2} \leq \max _{1 \leq k \leq d} \varrho_{m, k}^{2} \tag{23}
\end{equation*}
$$

Let $\Sigma_{m}=\left(s_{i, k}^{(m)}\right)_{1 \leq i, k \leq r} \in \mathbb{R}^{r \times r}$ denote the covariance matrix of $V$. Then, for $1 \leq i \leq k \leq r$, such that

$$
\begin{equation*}
i=a l+b, \quad k=a^{\prime} l+b^{\prime}, \quad \text { where } \quad 0 \leq a \leq a^{\prime} \leq d-1 \quad \text { and } \quad 1 \leq b, b^{\prime} \leq l \tag{24}
\end{equation*}
$$

we have

$$
s_{i, k}^{(m)}=\mathbb{E}_{m}\left[\mathbf{W}_{t_{b}}^{(m)}(a+1) \mathbf{W}_{t_{b^{\prime}}}^{(m)}\left(a^{\prime}+1\right)\right]=\delta_{a, a^{\prime}} \mathbb{E}_{m}\left[\mathbf{W}_{t_{b}}^{(m)}(a+1)^{2}\right]=\delta_{a, a^{\prime}} \sigma_{m}^{2}(i) .
$$

In particular, the diagonal elements of $\Sigma_{m}$ are given by $s_{i, i}^{(m)}=\sigma_{m}^{2}(i), 1 \leq i \leq r$. Thus, thanks to Condition 1.1 we have that $\Sigma_{m}$ converges to the covariance matrix $\Sigma=\left(s_{i, k}\right)_{1 \leq i, k \leq r}$, whose elements are given by

$$
\begin{equation*}
s_{i, k}=\delta_{a, a^{\prime}} \lim _{m \rightarrow \infty} \sigma_{m}^{2}(i)=\delta_{a, a^{\prime}} v_{a+1}\left(t_{b}\right), \tag{25}
\end{equation*}
$$

if again $i$ and $k$ are as in (24). Finally, we denote by $N^{(m)}=\left(N_{1}^{(m)}, \ldots, N_{r}^{(m)}\right)^{T}$ and $N=\left(N_{1}, \ldots, N_{r}\right)^{T}$ centered Gaussian vectors on $(\Omega, \mathcal{F}, \mathbb{P})$ with covariance matrices $\Sigma_{m}$ and $\Sigma$, respectively.

Next we make use of the well-known fact that the collection $\mathcal{H}_{3}$ of all functions $h \in C^{3}\left(\mathbb{R}^{r}\right)$, each of whose partial derivative of order $\leq 3$ is uniformly bounded, is convergence determining for weak convergence on $\mathbb{R}^{3}$. Then, by the triangle inequality we have

$$
\begin{equation*}
\left|\mathbb{E}_{m}[h(V)]-\mathbb{E}[h(N)]\right| \leq\left|\mathbb{E}_{m}[h(V)]-\mathbb{E}\left[h\left(N^{(m)}\right)\right]\right|+\left|\mathbb{E}\left[h\left(N^{(m)}\right)\right]-\mathbb{E}[h(N)]\right| . \tag{26}
\end{equation*}
$$

Note that the second term on the right hand side of (26) converges to zero as $m \rightarrow \infty$, since $\lim _{m \rightarrow \infty} \Sigma_{m}=$ $\Sigma$.

In order to deal with the first term as well, we apply the following central lemma, which is a slightly modified version of DP19, Lemma 4.1 (a)], adapted to the present notation. The main difference is that in the statement of the result in DP19, the term $\varphi_{m}(i)^{2}$ has already been replaced with the more concrete term $q_{i} / n_{m}(i)$, which is its value in the particular case of symmetric $U$-statistics. The proof given in [DP19, however, works in the more general present situation as well.

In what follows, for $1 \leq i, k \leq r$, we let

$$
V_{i} V_{k}=\sum_{\substack{M \subseteq\left[n_{m}(i) \vee n_{m}(k)\right]: \\|M| \leq q_{i}+q_{k}}} U_{M}(i, k)
$$

denote the Hoeffding decomposition of $V_{i} V_{k}$.
Lemma 3.1. Under the above assumptions, there are constants $\kappa_{q_{i}} \in(0, \infty)$, only depending on $q_{i}, 1 \leq$ $i \leq r$, such that the following holds: For any $h \in \mathcal{H}_{3}$, there are constants $C_{1}(h), C_{2}(h) \in[0, \infty)$ such that

$$
\left|\mathbb{E}_{m}[h(V)]-\mathbb{E}\left[h\left(N^{(m)}\right)\right]\right| \leq \frac{C_{1}(h)}{4 q_{1}} \sum_{i, k=1}^{r}\left(q_{i}+q_{k}\right)\left(\sum_{\substack{M \subseteq\left[n_{m}(i) \vee n_{m}(k)\right]: \\|M| \leq q_{i}+q_{k}-1}} \operatorname{Var}_{m}\left(U_{M}(i, k)\right)\right)^{1 / 2}
$$

$$
\begin{aligned}
& +\frac{2 C_{2}(h) \sqrt{r}}{9 q_{1}} \sum_{i=1}^{r} q_{i} \sigma_{m}(i)\left(\sum_{\substack{M \subseteq\left[n_{m}(i)\right]: \\
|M| \leq 2 q_{i}-1}} \operatorname{Var}_{m}\left(U_{M}(i, i)\right)\right)^{1 / 2} \\
& +\frac{\sqrt{2 r} C_{2}(h)}{9 q_{1}} \sum_{i=1}^{r} q_{i} \sqrt{\kappa_{q_{i}}} \sigma_{m}(i)^{3} \varphi_{m}(i) .
\end{aligned}
$$

We will also rely on the following crucial lemma, which essentially goes back to de Jong's monograph dJ89.
Lemma 3.2. Under Conditions 1.2 and 1.3 and with the notation of this subsection, we have that

$$
\lim _{m \rightarrow \infty} \mathbb{E}\left[V_{i}^{4}\right]-3 \sigma_{m}^{4}(i)=0
$$

for all $1 \leq i \leq r$.
Proof. Fix $1 \leq i \leq r$ given as in (24). Then, we have

$$
V_{i}=\sum_{J \in \mathcal{D}_{p_{a+1}}\left(n_{m}(i)\right)} W_{J}^{(m)}(a+1)=\sum_{J \in \mathcal{D}_{p_{a+1}}\left(n_{m}\right)} b_{J} W_{J}^{(m)}(a+1)
$$

where, for $J \in \mathcal{D}_{p_{a+1}}\left(n_{m}\right)$, we let

$$
b_{J}=\prod_{j \in J} \mathbb{1}_{\left\{1 \leq j \leq n_{m}(i)\right\}}
$$

This ensures that the coefficient sequence $\left(b_{J}\right)_{J \in \mathcal{D}_{p_{a+1}}\left(n_{m}\right)}$ is of rank one in de Jong's terminology (see dJ89, Subsection 4.1] and Remark 3.3 (b), below) and we obviously have $0 \leq \mathbb{1}_{\left\{1 \leq j \leq n_{m}(i)\right\}} \leq 1$ for all $1 \leq j \leq n_{m}$. Hence, by dJ89, Proposition 4.1.2.] we have $\lim _{m \rightarrow \infty} \mathbb{E}\left[V_{i}^{4}\right]-3 \sigma_{m}^{4}(i)=0$.

Remark 3.3. (a) We mention that the statement of đJ89, Proposition 4.1.2.] actually only implies the statement $\lim _{m \rightarrow \infty} \mathbb{E}\left[V_{i}^{4}\right]-3 \sigma_{m}^{4}(i)=0$ of Lemma 3.2 under the stronger condition that $D_{k, m}$ is bounded in $m$ for each $1 \leq k \leq d$. However, as can be seen from the proof of dJ89, Proposition 4.1.2.], the result remains true under the more relaxed Condition 1.2, since the quantities $\tau^{\prime}$ and $\left(\tau^{\prime}\right)^{*}$ appearing there still converge to zero, thanks to the inequality

$$
\left(\tau^{\prime}\right)^{*} \leq D_{m} \tau^{\prime} \lesssim D_{m} \varrho_{m}^{2},
$$

the second part of which holds true by virtue of [DP17, Proposition 2.9]. The first (and easy) part of it is proved in dJ89.
(b) In dJ89 the following definition of a rank one coefficient sequence $\left(a_{J}\right)_{J \in \mathcal{D}_{p}\left(n_{m}\right)}$ is given: One has $\left|a_{J}\right| \leq 1$ for all $J \in \mathcal{D}_{p}\left(n_{m}\right)$ and there is a sequence $\left(c_{j}\right)_{1 \leq j \leq n_{m}}$ such that $a_{J}=\prod_{j \in J} c_{j}$ for all $J \in \mathcal{D}_{p}\left(n_{m}\right)$.

In order to prove that the first term on the right hand side of (26) converges to zero, we will make sure that the right hand side of (27) goes to zero as $m \rightarrow \infty$. By (23) and the assumption of Theorem 1.4 for the last term we have

$$
\begin{equation*}
\lim _{m \rightarrow \infty} \frac{\sqrt{2 r} C_{2}(h)}{9 q_{1}} \sum_{i=1}^{r} q_{i} \sqrt{\kappa_{q_{i}}} \sigma_{m}(i)^{3} \varphi_{m}(i)=0 \tag{28}
\end{equation*}
$$

In order to deal with the first two terms, we invoke Corollaries 2.6 and 2.7. Thus, suppose again that $1 \leq i \leq k \leq r$ are given by (24).

Case 1: $a<a^{\prime}$ : In this case, we have $q_{i}=p_{a+1}<p_{a^{\prime}+1}=q_{k}$ and, hence, we are in the situation of Corollary [2.7. Thus, we have that

$$
\sum_{\substack{M \subseteq\left[n_{m}(i) \vee n_{m}(k)\right]: \\|M| \leq q_{i}+q_{k}-1}} \operatorname{Var}_{m}\left(U_{M}(i, k)\right) \leq\left(C_{q_{i}, q_{k}}+q_{k}\right) \max \left(\sigma_{m}^{2}(i) \varphi_{m}^{2}(k), \sigma_{m}^{2}(k) \varphi_{m}^{2}(i)\right)
$$

$$
\begin{align*}
& +\left(\mathbb{E}\left[V_{k}^{4}\right]-3 \sigma_{m}^{4}(k)+\kappa_{q_{k}} \sigma_{m}^{2}(k) \varphi_{m}^{2}(k)\right)^{1 / 2} \cdot\left(\mathbb{E}\left[V_{i}^{4}\right]-\sigma_{m}^{4}(i)\right)^{1 / 2} \\
& \leq\left(C_{q_{i}, q_{k}}+q_{k}\right) \max _{1 \leq u \leq d} \varrho_{m, u}^{2} \\
& +\left(\mathbb{E}\left[V_{k}^{4}\right]-3 \sigma_{m}^{4}(k)+\kappa_{q_{k}} \max _{1 \leq u \leq d} \varrho_{m, u}^{2}\right)^{1 / 2} \cdot\left(\mathbb{E}\left[V_{i}^{4}\right]\right)^{1 / 2}, \tag{29}
\end{align*}
$$

where we have applied (231) for the second inequality and used $\kappa_{q_{k}}$ to denote a finite constant depending only on $q_{k}$. By Lemma 3.2 and Condition 1.2, the right hand side of (29) thus converges to zero as $m \rightarrow \infty$.

Case 2: $a=a^{\prime}$ : In this case, we have $q_{i}=p_{a+1}=p_{a^{\prime}+1}=q_{k}$ and, hence, we are in the situation of Corollary 2.6. Thus, we have that

$$
\begin{align*}
& \quad \sum_{\substack{M \subseteq\left[n_{m}(i) \vee n_{m}(k)\right]:}} \operatorname{Var}_{m}\left(U_{M}(i, k)\right)=\sum_{\substack{M \subseteq q_{i}\left(n_{m}(k)\right]: \\
|M| \leq q_{i}+q_{k}-1}} \operatorname{Var}_{m}\left(U_{M}(i, k)\right) \\
& \leq \mathbb{E}\left[V_{i}^{4}\right]-3 \sigma_{m}^{4}(i)+2 q_{i} \sigma_{m}^{2}(i) \varphi_{m}^{2}(i)+\left(C_{q_{i}, q_{i}}+2 q_{i}\right) \varphi_{m}^{2}(k) \sigma_{m}^{2}(k) \\
& +\left(\mathbb{E}\left[V_{i}^{4}\right]-3 \sigma_{m}^{4}(i)+\kappa_{q_{i}} \sigma_{m}^{2}(i) \varphi_{m}^{2}(i)\right)^{1 / 2} \cdot\left(\mathbb{E}\left[V_{k}^{4}\right]-3 \sigma_{m}^{4}(k)+\kappa_{q_{k}} \sigma_{m}^{2}(k) \varphi_{m}^{2}(k)\right)^{1 / 2} \\
& \leq \mathbb{E}\left[V_{i}^{4}\right]-3 \sigma_{m}^{4}(i)+2 q_{i} \max _{1 \leq u \leq d} \varrho_{m, u}^{2}+\left(C_{q_{i}, q_{i}}+2 q_{i}\right) \max _{1 \leq u \leq d} \varrho_{m, u}^{2} \\
& +\left(\mathbb{E}\left[V_{i}^{4}\right]-3 \sigma_{m}^{4}(i)+\kappa_{q_{i}} \max _{1 \leq u \leq d} \varrho_{m, u}^{2}\right)^{1 / 2} \cdot\left(\mathbb{E}\left[V_{k}^{4}\right]-3 \sigma_{m}^{4}(k)+\kappa_{q_{k}} \max _{1 \leq u \leq d} \varrho_{m, u}^{2}\right)^{1 / 2} \tag{30}
\end{align*}
$$

where we have again applied (23) for the second inequality and used $\kappa_{q_{k}}$ and $\kappa_{q_{i}}$ to denote finite constants depending only on $q_{k}$ and $q_{i}$, respectively. Again, by Lemma 3.2 and Condition 1.2 , the right hand side of (30) thus converges to zero as $m \rightarrow \infty$.

From (27), (23), (28), (29) and (30) we thus conclude that

$$
\lim _{m \rightarrow \infty}\left|\mathbb{E}_{m}[h(V)]-\mathbb{E}\left[h\left(N^{(m)}\right)\right]\right|=0
$$

and, thus, by (26) that

$$
\lim _{m \rightarrow \infty}\left|\mathbb{E}_{m}[h(V)]-\mathbb{E}[h(N)]\right|=0
$$

for each $h \in \mathcal{H}_{3}$. Note further that, by the definition of $\Sigma$, we have the distributional identity

$$
N \stackrel{\mathcal{D}}{=}\left(\mathbf{Z}_{t_{1}}(1), \ldots, \mathbf{Z}_{t_{l}}(1), \ldots, \mathbf{Z}_{t_{1}}(d), \ldots, \mathbf{Z}_{t_{l}}(d)\right)^{T}
$$

Hence, we have established the convergence of the finite dimensional distributions of $\mathbf{W}$ to those of $\mathbf{Z}$.
3.1.2. Conclusion of the argument. We will now finish the proof of Theorem 1.4 by proving tightness of the sequence $\left(\mathbf{W}^{(m)}\right)_{m \in \mathbb{N}}$ in $D[0,1]$. This will be done by verifying that

$$
\begin{equation*}
\omega\left(\mathbf{W}^{(m)}, \delta\right) \xrightarrow{\mathbb{P}_{m}} 0, \quad \text { as } m \rightarrow \infty \tag{31}
\end{equation*}
$$

where, for $x \in D[0,1]$ and $\delta>0$,

$$
\omega(x, \delta):=\sup \{|x(t)-x(s)|: s, t \in[0,1],|t-s|<\delta\}
$$

denotes the modulus of continuity of $x$. Since $\mathbf{W}_{0}^{(m)}=0$ for all $m \in \mathbb{N}$ and by the finite-dimensional distribution convergence established in Subsection [3.1.1 this will imply Theorem 1.4 by the Corollary to Bil99, Theorem 13.4]. Let us introduce the following notation: Fix $1 \leq l \leq d$ that we will from now on suppress from the notation whenever convenient, and, for $m \in \mathbb{N}$ and $0 \leq j \leq n_{m}$, define $\Delta_{j}^{(m)}:=\mathbf{W}_{\frac{j}{n_{m}}}^{(m)}(l)-\mathbf{W}_{\frac{j-1}{n_{m}}}^{(m)}(l), \mathcal{F}_{j}^{(m)}:=\sigma\left(X_{1}^{(m)}, \ldots, X_{j}^{(m)}\right)$ and $S_{j}^{(m)}:=\sum_{i=1}^{j} \Delta_{i}^{(m)}$. Then, by degeneracy, for each $m \in \mathbb{N},\left(S_{j}^{(m)}\right)_{1 \leq j \leq n_{m}}$ is an $\left(\mathcal{F}_{j}^{(m)}\right)_{0 \leq j \leq n_{m}}$ - martingale. Note that with this notation at hand, we
have $\mathbf{W}_{t}^{(m)}=S_{\left\lfloor n_{m} t\right\rfloor}^{(m)}$ for each $t \in[0,1]$ and Bil68, Theorem 8.4] and the Corollary to Bil99, Theorem 13.4] together imply that (31) holds, if, for each $k \in \mathbb{N}$ we have

$$
\begin{equation*}
\lim _{\lambda \rightarrow \infty} \limsup _{m \rightarrow \infty} \lambda^{2} \mathbb{P}_{m}\left(\max _{0 \leq i \leq n_{m}-k}\left|S_{k+i}^{(m)}-S_{k}^{(m)}\right| \geq \lambda\right)=0 \tag{32}
\end{equation*}
$$

Note that the additional $\sqrt{n}$ appearing in the statement of [Bil68, Theorem 8.4] does not appear here, since our processes are already normalized at time $t=1$. Let us thus fix $k \in \mathbb{N}$. Then, the sequence $\left(S_{k+i}^{(m)}-S_{k}^{(m)}\right)_{0 \leq i \leq n_{m}-k}$ is an $\left(\mathcal{F}_{k+i}^{(m)}\right)_{0 \leq i \leq n_{m}-k^{-}}$martingale. Thus, by first applying Markov's and then Doob's $L^{4}$-inequality, we have that

$$
\begin{align*}
& \lambda^{2} \mathbb{P}_{m}\left(\max _{0 \leq i \leq n_{m}-k}\left|S_{k+i}^{(m)}-S_{k}^{(m)}\right| \geq \lambda\right) \\
& \leq \mathbb{E}_{m}\left[\left(\max _{0 \leq i \leq n_{m}-k}\left|S_{k+i}^{(m)}-S_{k}^{(m)}\right|\right)^{2} \mathbb{1}_{\left\{\max _{0 \leq i \leq n_{m}-k}\left|S_{k+i}^{(m)}-S_{k}^{(m)}\right| \geq \lambda\right\}}\right] \\
& \leq \frac{1}{\lambda^{2}} \mathbb{E}_{m}\left[\left(\max _{0 \leq i \leq n_{m}-k}\left|S_{k+i}^{(m)}-S_{k}^{(m)}\right|\right)^{4}\right] \leq\left(\frac{4}{3}\right)^{4} \frac{1}{\lambda^{2}} \mathbb{E}_{m}\left[\left|S_{n_{m}}^{(m)}-S_{k}^{(m)}\right|^{4}\right] \\
& \leq\left(\frac{4}{3}\right)^{4} \frac{8}{\lambda^{2}}\left(\mathbb{E}_{m}\left|S_{n_{m}}^{(m)}\right|^{4}+\mathbb{E}_{m}\left|S_{k}^{(m)}\right|^{4}\right) \tag{33}
\end{align*}
$$

Now, firstly, by Condition 1.3, we have

$$
\begin{equation*}
\lim _{m \rightarrow \infty} \mathbb{E}_{m}\left|S_{n_{m}}^{(m)}\right|^{4}=\lim _{m \rightarrow \infty} \mathbb{E}_{m}\left[W^{(m)}(l)^{4}\right]=3 \tag{34}
\end{equation*}
$$

Secondly, using the inequality $\left|\sum_{i=1}^{n} a_{i}\right|^{4} \leq n^{3} \sum_{i=1}^{n}\left|a_{i}\right|^{4}$, and by Condition 1.2 we obtain that

$$
\begin{align*}
\mathbb{E}_{m}\left|S_{k}^{(m)}\right|^{4} & =\mathbb{E}_{m}\left|\sum_{J \in D_{p_{l}}(k)} W_{J}^{(m)}(l)\right|^{4} \leq\binom{ k}{p}^{3} \sum_{J \in D_{p_{l}}(k)} \mathbb{E}_{m}\left|W_{J}^{(m)}(l)\right|^{4} \\
& \leq\binom{ k}{p_{l}}^{3} D_{m, l} \sum_{J \in D_{p_{l}}(k)}\left(\mathbb{E}_{m}\left|W_{J}^{(m)}(l)\right|^{2}\right)^{2} \\
& \leq\binom{ k}{p_{l}}^{3} D_{m, l} \varrho_{m, l}^{2} \sum_{J \in D_{p_{l}}(k)} \mathbb{E}_{m}\left|W_{J}^{(m)}(l)\right|^{2} \\
& \leq\binom{ k}{p_{l}}^{3} D_{m, l} \varrho_{m, l}^{2} \xrightarrow{m \rightarrow \infty} 0 \tag{35}
\end{align*}
$$

where we have used the fact that $\mathbb{E}_{m}\left|W_{J}^{(m)}(l)\right|^{2} \leq \varrho_{m, l}^{2}$ for all $J \in D_{p_{l}}(k)$. Thus, (33)-(35) imply that

$$
\limsup _{m \rightarrow \infty} \lambda^{2} \mathbb{P}_{m}\left(\max _{0 \leq i \leq n_{m}-k}\left|S_{k+i}^{(m)}-S_{k}^{(m)}\right| \geq \lambda\right) \leq\left(\frac{4}{3}\right)^{4} \frac{24}{\lambda^{2}}=\frac{2048}{27} \frac{1}{\lambda^{2}}
$$

for each $\lambda>0$ and $k \in \mathbb{N}$ fixed, so that (32) is indeed satisfied. This finishes the argument for tightness.
3.2. An additional argument explaining the continuity of the limiting process $\mathbf{Z}$. Note that, by Bil99, Theorem 13.4] our conditions necessarily entail the remarkable fact that the limiting Gaussian process $\mathbf{Z}$ has continuous paths, which might be quite surprising at first glance. Thus, we will now give another argument for this fact, which additionally explains why it is true. To this end, define the vector $\mathbf{V}^{(m)}=\left(\mathbf{V}^{(m)}(1), \ldots, \mathbf{V}^{(m)}(d)\right)$ of continuous processes, defined by linear interpolation, i.e. for $1 \leq l \leq d$ we let

$$
\mathbf{V}_{t}^{(m)}(l):=\mathbf{W}_{\frac{i-1}{n_{m}}}^{(m)}(l)+\left(n_{m} t-(i-1)\right)\left(\mathbf{W}_{\frac{i}{n_{m}}}^{(m)}(l)-\mathbf{W}_{\frac{i-1}{n_{m}}}^{(m)}(l)\right), \quad \frac{i-1}{n_{m}} \leq t<\frac{i}{n_{m}}
$$

and $\mathbf{V}_{1}^{(m)}(l)=\mathbf{W}_{1}^{(m)}(l)=W^{(m)}(l)$. Then, for fixed $1 \leq l \leq d$ and with the same notation as above, it is easy to see that

$$
\left\|\mathbf{V}^{(m)}(l)-\mathbf{W}^{(m)}(l)\right\|_{\infty}=\max _{1 \leq i \leq n_{m}}\left|\Delta_{i}^{(m)}\right| .
$$

Thus, using e.g. [IS02, Theorem 3] in the third inequality below, for $\varepsilon>0$ we can bound

$$
\begin{aligned}
& \mathbb{P}_{m}\left(\left\|\mathbf{V}^{(m)}(l)-\mathbf{W}^{(m)}(l)\right\|_{\infty}>\varepsilon\right)=\mathbb{P}_{m}\left(\max _{1 \leq i \leq n_{m}}\left|\Delta_{i}^{(m)}\right|>\varepsilon\right) \leq \sum_{i=1}^{n_{m}} \mathbb{P}_{m}\left(\left|\Delta_{i}^{(m)}\right|>\varepsilon\right) \\
& \leq \varepsilon^{-4} \sum_{i=1}^{n_{m}} \mathbb{E}_{m}\left|\sum_{\substack{J \in \mathcal{D}_{p_{p}}(i): \\
i \in J}} W_{J}^{(m)}(l)\right|^{4} \leq B\left(p_{l}\right) \varepsilon^{-4} \sum_{i=1}^{n_{m}} \mathbb{E}_{m}\left[\left(\sum_{\substack{J \in \mathcal{D}_{p_{l}}(i): \\
i \in J J}} W_{J}^{(m)}(l)^{2}\right)^{2}\right] \\
& =B\left(p_{l}\right) \varepsilon^{-4} \sum_{i=1}^{n_{m}} \sum_{\substack{J, K \in \mathcal{D}_{p_{l}}(i): \\

\end{aligned}
$$

where $B\left(p_{l}\right)$ is a finite constant only depending on $p_{l}$, see [IS02, Theorem 3]. Thus, we have proved that, for each $1 \leq l \leq d,\left\|\mathbf{V}^{(m)}(l)-\mathbf{W}^{(m)}(l)\right\|_{\infty}$ and, a fortiori their Skorohod distance, converges to zero in probability as $m \rightarrow \infty$, so that Bil99, Theorem 3.1] implies that the processes $\mathbf{V}^{(m)}(l)$ and $\mathbf{W}^{(m)}(l)$ must indeed have the same distributional limit, if any.
3.3. Proof of Theorem 1.5. Suppose that Conditions 1.2 and 1.3 hold for the sequence $\left(\mathbf{W}^{(m)}\right)_{m \in \mathbb{N}}$. Since the above argument for tightness does not make use of Condition [1.1 tightness still holds. Let $\left(\mathbf{W}^{\left(m_{l}\right)}\right)_{l \in \mathbb{N}}$ be a given subsequence. By relative compactness, there is a further subsequence $\left(\mathbf{W}^{\left(m_{l_{k}}\right)}\right)_{k \in \mathbb{N}}$ that converges in distribution to some process Z. Again by [Bil99, Theorem 13.4] we can conclude that Z has values in $C\left([0,1] ; \mathbb{R}^{d}\right)$. Thus, the projections $\pi_{t}: D\left([0,1] ; \mathbb{R}^{d}\right) \rightarrow \mathbb{R}^{d}, x \mapsto x(t), t \in[0,1]$, are $\mathbb{P}_{\mathbf{Z}}$-a.s. continuous, where $\mathbb{P}_{\mathbf{Z}}$ denotes the law of $\mathbf{Z}$ on $D\left([0,1] ; \mathbb{R}^{d}\right)$. Hence, the continuous mapping theorem implies that the finite-dimensional distributions of $\left(\mathbf{W}^{\left(m_{l_{k}}\right)}\right)_{k \in \mathbb{N}}$ converge to those of $\mathbf{Z}$ and, e.g. by a uniform integrability argument, one makes sure that the covariance matrices of the finite dimensional distributions of $\left(\mathbf{W}^{\left(m_{l_{k}}\right)}\right)_{k \in \mathbb{N}}$ also converge to the respective ones of $\mathbf{Z}$. Thus, the argument leading to (25) goes through with the right hand side replaced by the variance of the corresponding coordinate of $\mathbf{Z}$ at $t_{b}$. Now, since Lemma 3.2 applies under Conditions 1.2 and 1.3, the same reasoning as in Subsubsection 3.1.1 ensures that the finite dimensional distributions of $\left(\mathbf{W}^{\left(m_{l_{k}}\right)}\right)_{k \in \mathbb{N}}$ have a Gaussian limit, implying that $\mathbf{Z}$ is indeed a continuous, centered Gaussian process. The non-correlation, and therefore the independence, of the components of $\mathbf{Z}$ follows from the fact that Hoeffding degenerate $U$-statistics of distinct orders are orthogonal in $L^{2}$. The proof is complete.
3.4. Proof of relation (11). We fix $p \geq 3$ and $2 \leq a \leq p-1$ as in Example 1.12, and adopt the notation introduced therein. It is sufficient to show that

$$
\begin{equation*}
\left|F_{m}^{0} \cap[\lfloor t m\rfloor]^{p}\right| \sim\left|F_{\lfloor t m\rfloor}^{0}\right|, \tag{36}
\end{equation*}
$$

a relation that is implied by the next statement.
Lemma 3.4. Consider a nondecreasing integer-valued sequence $(\ell(m))_{m \geq 1}$ such that, as $m \rightarrow \infty, \ell(m) \sim$ $\alpha \cdot m$, for some $\alpha \in(0,1)$. Then

$$
\left|F_{m}^{0} \cap[\ell(m)]^{p}\right| \sim\left|F_{\ell(m)}^{0}\right| .
$$

Proof. For every $\ell \geq 1$ we write $k=k(\ell)$ to denote the unique integer such that $\ell \in\left[k^{a},(k+1)^{a}\right)$, in such a way that $F_{\ell}=F_{k^{a}(\ell)}$. We have that

$$
\left|F_{m}^{0} \cap[\ell(m)]^{p}\right|=\left|F_{\ell(m)}^{0}\right|+\left|\left(F_{m}^{0} \cap[\ell(m)]^{p}\right) \backslash F_{k^{a}(\ell(m))}^{0}\right| .
$$

Using the relations

$$
\left|\left(F_{m}^{0} \cap[\ell(m)]^{p}\right) \backslash F_{k^{a}(\ell(m))}^{0}\right| \leq\left|F_{(k(\ell(m))+1)^{a}}^{0}\right|-\left|F_{k^{a}(\ell(m))}^{0}\right| \sim k(\ell(m))^{p-1} \leq \ell(m)^{(p-1) / a}=o\left(m^{p / a}\right),
$$

we immediately deduce the desired conclusion.
