# Power-conjugate equations in symmetric groups 

Szilvia Homolya and Jenő Szigeti

#### Abstract

First we consider the solutions of the general "cubic" equation $$
\alpha_{1} \circ x^{r_{1}} \circ \alpha_{2} \circ x^{r_{2}} \circ \alpha_{3} \circ x^{r_{3}}=1
$$ (with $r_{1}, r_{2}, r_{3} \in\{1,-1\}$ ) in the symmetric group $\mathrm{S}_{n}$. In certain cases this equation can be rewritten as $\alpha \circ y \circ \alpha^{-1}=y^{2}$ or as $\alpha \circ y \circ \alpha^{-1}=y^{-2}$, where $\alpha \in \mathrm{S}_{n}$ depends on the $\alpha_{i}$ 's and the new unknown permutation $y \in \mathrm{~S}_{n}$ is a product of $x$ ( or $x^{-1}$ ) and one of the permutations $\alpha_{i}^{ \pm 1}$. Using combinatorial arguments and some basic number theoretical facts, we obtain results about the solutions of the so-called power-conjugate equation $\alpha \circ y \circ \alpha^{-1}=y^{e}$ in $\mathrm{S}_{n}$, where $e \in \mathbb{Z}$ is an integer exponent. A divisibility condition involving the type of $\alpha$ provide solutions with $\alpha \circ y \neq y \circ \alpha$ and a further condition gives the complete list of solutions. Some other divisibility assumptions concerning the type of $\alpha$ ensure that the solutions of $\alpha \circ y \circ \alpha^{-1}=y^{e}$ are exactly the solutions of $y^{e-1}=1$ in the centralizer of $\alpha$. Slightly stronger assumptions provide a complete answer to the question, when our equation has only the trivial solution $y=1$.

## 1. INTRODUCTION

One of the starting points of classical algebra is the solution of polynomial equations in fields. Thus, the investigation of equations in groups is a natural idea. Recently a good number of publications appeared that are related to complexity, taking an algorithmic approach to solving such equations. In the present paper we are interested only in the explicit solutions, so we restrict our consideration to the nonalgorithmic aspects. It is a surprising fact that the authors found only a limited number of results about the explicit solutions of equations in groups. One of the earliest results (due to Frobenius) is about the number of solutions of $x^{m}=1$ in a finite group (see [IR]). Further results concerning the equation $x^{m}=1$ in the symmetric group $\mathrm{S}_{n}$ consisting of all bijective $\{1,2, \ldots, n\} \longrightarrow\{1,2, \ldots, n\}$ functions can be found in [CHS], $[\mathrm{MW}]$ and $[\mathrm{FM}]$. A general equation (containing constants and group operations) for a single unknown permutation $x \in \mathrm{~S}_{n}$ is of the form:

$$
\alpha_{1} \circ x^{r_{1}} \circ \alpha_{2} \circ \cdots \circ \alpha_{k} \circ x^{r_{k}}=1
$$

where $k \geq 1, \alpha_{i} \in \mathrm{~S}_{n}$ and $r_{i} \in\{1,-1\}$ for each $1 \leq i \leq k$. Our first impression is that the complete solution of the above equation is hopeless, on the other hand to

[^0]deal with some special cases seems to be a challenging problem. We note that in the above equation $r_{1}=1$ can be assumed, otherwise $\alpha_{1} \circ x^{-r_{1}} \circ \alpha_{2} \circ \cdots \circ \alpha_{k} \circ x^{-r_{k}}=1$ is the same equation for the inverse $x^{-1}$ and $-r_{1}=1$.
The solutions in the "quadratic" case $k=2$ can easily be obtained by a simple procedure. If $1=r_{1}=r_{2}$, then $\alpha_{1} \circ x \circ \alpha_{2} \circ x=1$ is equivalent to
$$
\left(x \circ \alpha_{2}\right)^{2}=\alpha_{1}^{-1} \circ \alpha_{2}
$$

The above square root equation has a solution if and only if the number of the $2 i$-element cycles in $\alpha_{1}^{-1} \circ \alpha_{2}$ is even for all integers $i \geq 1$. If $1=r_{1}=-r_{2}$, then $\alpha_{1} \circ x \circ \alpha_{2} \circ x^{-1}=1$ is equivalent to

$$
x \circ \alpha_{2} \circ x^{-1}=\alpha_{1}^{-1} .
$$

The above equation has a solution if and only if the permutations $\alpha_{2}$ and $\alpha_{1}^{-1}$ are of the same type. The type of a permutation $\pi \in S_{n}$ is a sequence type $(\pi)=$ $\left\langle t_{1}, t_{2}, \ldots, t_{n}\right\rangle$ of integers, where $t_{i} \geq 0$ denotes the number of cycles in $\pi$ of length $i \geq 1$. A well-known fact is that for $\pi_{1}, \pi_{2} \in S_{n}$ the equality type $\left(\pi_{1}\right)=\operatorname{type}\left(\pi_{2}\right)$ is equivalent to the conjugate relation between $\pi_{1}$ and $\pi_{2}$ (there exists a permutation $\tau \in \mathrm{S}_{n}$ such that $\tau \circ \pi_{1} \circ \tau^{-1}=\pi_{2}$ ). Further details (about the complete solutions in the case $k=2$ ) are left to the readers.
The situation in the case $k \geq 3$ is far more complicated. A nice summary about the general situation can be found in [L]. An important direction of research is to find solutions of a given group-equation in an appropriate extension of the base group. The Kervaire-Laudenbach (KL) conjecture asserts that if the length $r_{1}+r_{2}+\cdots+r_{k}$ of the equation $\alpha_{1} \circ x^{r_{1}} \circ \alpha_{2} \circ \cdots \circ \alpha_{k} \circ x^{r_{k}}=1$ over an arbitrary group $G$ is nonzero, then this equation has a solution in a group $H$ containing $G$ (here we assume that $r_{i-1}+r_{i} \neq 0$ if $\left.\alpha_{i}=1,2 \leq i \leq k\right)$. A consequence of a general extension theorem of Gerstenhaber and Rothaus (see [GR]) is that (KL) holds for finite groups. For $k=5$ the conjecture (KL) is proved in [E].
Now consider the general "cubic" equation

$$
\begin{equation*}
\alpha_{1} \circ x^{r_{1}} \circ \alpha_{2} \circ x^{r_{2}} \circ \alpha_{3} \circ x^{r_{3}}=1 \tag{*}
\end{equation*}
$$

in $S_{n}$, where $r_{1}=1$. According to the choice of the exponents we have the following four possibilities

$$
\begin{aligned}
& (* 1) \alpha_{1} \circ x \circ \alpha_{2} \circ x \circ \alpha_{3} \circ x^{-1}=1, \quad(* 2) \alpha_{1} \circ x \circ \alpha_{2} \circ x^{-1} \circ \alpha_{3} \circ x=1 \\
& (* 3) \alpha_{1} \circ x \circ \alpha_{2} \circ x^{-1} \circ \alpha_{3} \circ x^{-1}=1, \quad(* 4) \alpha_{1} \circ x \circ \alpha_{2} \circ x \circ \alpha_{3} \circ x=1
\end{aligned}
$$

Clearly, the above equations can be rewritten as follows

$$
\begin{aligned}
& (* 1) \alpha \circ y \circ \beta=y^{2}, \text { where } y=x \circ \alpha_{2} \text { and } \alpha=\alpha_{1}^{-1}, \beta=\alpha_{2} \circ \alpha_{3}^{-1} \circ \alpha_{2}^{-1}, \\
& (* 2) \alpha \circ y \circ \beta=y^{2}, \text { where } y=x^{-1} \circ \alpha_{1}^{-1} \text { and } \alpha=\alpha_{2}, \beta=\alpha_{1} \circ \alpha_{3} \circ \alpha_{1}^{-1}, \\
& (* 3) \alpha \circ y \circ \beta=y^{2}, \text { where } y=x \circ \alpha_{3}^{-1} \text { and } \alpha=\alpha_{1}, \beta=\alpha_{3} \circ \alpha_{2} \circ \alpha_{3}^{-1}, \\
& (* 4) \alpha \circ y \circ \beta=y^{-2}, \text { where } y=\alpha_{3} \circ x \text { and } \alpha=\alpha_{1} \circ \alpha_{3}^{-1}, \beta=\alpha_{2} \circ \alpha_{3}^{-1} .
\end{aligned}
$$

Thus, the solution of the "cubic" equation can be reduced to the solution of the equations

$$
\alpha \circ y \circ \beta=y^{2} \text { and } \alpha \circ y \circ \beta=y^{-2}
$$

where $\alpha, \beta \in \mathrm{S}_{n}$ are constants and the new unknown permutation is $y \in \mathrm{~S}_{n}$. In both cases we assume that $y=1$ is a solution of the given equation. Our requirement is quite natural, however the weaker assumption, that we have at least one solution in $\mathrm{S}_{n}$ is even more natural. The condition that $y=1$ is a solution is equivalent
to the fact that $\beta=\alpha^{-1}$ is the inverse of $\alpha$ (in both cases). In view of the above observations, we consider the power-conjugate equation

$$
(e * \alpha): \alpha \circ y \circ \alpha^{-1}=y^{e},
$$

where $e \in \mathbb{Z}$ is an integer exponent. If $e \in\{-1,1\}$, then $(e * \alpha)$ is quadratic and the case $e=0$ is trivial. Therefore in the rest of the paper we assume that $e \notin\{-1,0,1\}$. Using combinatorial arguments and some basic number theoretical facts, in certain cases (depending on the type of $\alpha$ ) we are able to obtain essential information about the solutions of $(e * \alpha)$ in $S_{n}$. Solutions with $\alpha \circ y \neq y \circ \alpha$ appear in Theorems 3.1, 3.6 as well as in Corollaries 3.2, 3.3, while solutions with $\alpha \circ y=y \circ \alpha$ appear in Theorems 4.5 and 4.8. One of our main results reveals that under certain mild divisibility assumptions involving the type of $\alpha$, the solutions of $(e * \alpha)$ are exactly the solutions of $y^{e-1}=1$ in the centralizer of $\alpha$ (see 4.5). Using slightly stronger assumptions, we obtain a complete answer to the question, when $(e * \alpha)$ has only the trivial solution $y=1$ (see 4.8).

## 2. PRELIMINARY LEMMAS

Let $\delta=\tau \circ \alpha \circ \tau^{-1}$ be a conjugate of $\alpha$ (here $\tau \in \mathrm{S}_{n}$ is fixed). Since the conjugation is an automorphism of $\mathrm{S}_{n}$, the solutions of $(e * \delta): \delta \circ z \circ \delta^{-1}=z^{e}$ can be obtained as the conjugates $z=\tau \circ y \circ \tau^{-1}$ of the solutions of $(e * \alpha)$. Thus, the number of solutions of $(e * \alpha)$ depends only on the conjugacy class (or the type) of $\alpha$.
For a given permutation $\alpha \in \mathrm{S}_{n}$ with type $(\alpha)=\left\langle g_{1}, g_{2}, \ldots, g_{n}\right\rangle$ and for an integer $1 \leq d \leq n$ we define a set of integers (the $d$-range of $\alpha$ ) as

$$
\begin{gathered}
F_{d}(\alpha)=\left\{\sum_{1 \leq j \leq n, d \mid j} q_{j} \cdot j \mid 0 \leq q_{j} \leq g_{j} \text { for all } 1 \leq j \leq n\right\}= \\
\left\{q_{d} \cdot d+q_{2 d} \cdot 2 d+\cdots+q_{\lfloor n / d\rfloor d} \cdot\lfloor n / d\rfloor d \mid 0 \leq q_{i d} \leq g_{i d} \text { for all } 1 \leq i \leq\lfloor n / d\rfloor\right\}
\end{gathered}
$$

Now $g_{1} \cdot 1+g_{2} \cdot 2+\cdots+g_{n} \cdot n=n$ gives that $F_{d}(\alpha) \subseteq\{d, 2 d, \ldots,\lfloor n / d\rfloor d\}$ and $g_{n}=1$ implies that $g_{1}=g_{2}=\cdots=g_{n-1}=0$, whence $F_{1}(\alpha)=\{0, n\}$ follows. Clearly, the divisibility $d_{1} \mid d_{2}$ implies that $F_{d_{2}}(\alpha) \subseteq F_{d_{1}}(\alpha)$.
2.1. Lemma. If the containment $\alpha(H) \subseteq H$ holds for some subset $H \subseteq\{1,2, \ldots, n\}$, then $\alpha(H)=H$ and $H=D_{1} \cup D_{2} \cup \cdots \cup D_{m}$ is a union of certain pairwise disjoint cycles of $\alpha$. If $1 \leq d \leq n$ and $d\left|\left|D_{j}\right|\right.$ holds for all $1 \leq j \leq m$, then for the number of elements we have

$$
|H|=\left|D_{1}\right|+\left|D_{2}\right|+\cdots+\left|D_{m}\right| \in F_{d}(\alpha)
$$

Proof. Obvious.
2.2. Lemma. If $\alpha \circ y \circ \alpha^{-1}=z$ holds for $\alpha, y, z \in \mathrm{~S}_{n}$ and $\left(c_{1}, c_{2}, \ldots, c_{r}\right)$ is a cycle of $y$, then $\left(\alpha\left(c_{1}\right), \alpha\left(c_{2}\right), \ldots, \alpha\left(c_{r}\right)\right)$ is a cycle of $z$.

Proof. Clearly, $z\left(\alpha\left(c_{i}\right)\right)=(z \circ \alpha)\left(c_{i}\right)=(\alpha \circ y)\left(c_{i}\right)=\alpha\left(y\left(c_{i}\right)\right)=\alpha\left(c_{i+1}\right)$ (indices $1 \leq i \leq r$ are considered modulo $r$ ).
2.3. Lemma. Consider the union $\{1,2, \ldots, n\}=H_{1} \cup H_{2} \cup \cdots \cup H_{s}$ of the pairwise disjoint fixed subsets $H_{k} \subseteq\{1,2, \ldots, n\}, 1 \leq k \leq s$ of $\alpha \in \mathrm{S}_{n}$ (now $\alpha\left(H_{k}\right)=H_{k}$ for each $1 \leq k \leq s$ ) and let $y_{k} \in \mathrm{~S}_{H_{k}}$ (here $y_{k}: H_{k} \longrightarrow H_{k}$ is a permutation) be a solution of $\left(e *\left(\alpha \upharpoonright H_{k}\right)\right)$, where $\left(\alpha \upharpoonright H_{k}\right): H_{k} \longrightarrow H_{k}$ is the restriction of $\alpha$ to
$H_{k}$. Now the disjoint union $y_{1} \sqcup y_{2} \sqcup \cdots \sqcup y_{s}$ of the permutations $y_{k}(1 \leq k \leq s)$ is a solution of $(e * \alpha)$ in $\mathrm{S}_{n}$. Notice that for $i \in\{1,2, \ldots, n\}$
$\left(y_{1} \sqcup y_{2} \sqcup \cdots \sqcup y_{s}\right)(i)=y_{k}(i)$, where $1 \leq k \leq s$ is the unique index with $i \in H_{k}$.

Proof. Obvious.
2.4. Lemma. If $y_{1}, y_{2} \in \mathrm{~S}_{n}$ are solutions of $(e * \alpha)$ such that $y_{1} \circ y_{2}=y_{2} \circ y_{1}$, then the product $y_{1} \circ y_{2}$ is also a solution of $(e * \alpha)$. If $y \in \mathrm{~S}_{n}$ is a solution of $(e * \alpha)$, then $y^{-1} \in \mathrm{~S}_{n}$ is also a solution of $(e * \alpha)$ and for all $i \in \mathbb{Z}$ and $k \geq 0$ we have

$$
\alpha^{k} \circ y^{i}=y^{e^{k} i} \circ \alpha^{k}
$$

Proof. Since $\alpha \circ y_{1} \circ \alpha^{-1}=y_{1}^{e}$ and $\alpha \circ y_{2} \circ \alpha^{-1}=y_{2}^{e}$ hold, the multiplicative property of the conjugation gives that

$$
\alpha \circ y_{1} \circ y_{2} \circ \alpha^{-1}=\left(\alpha \circ y_{1} \circ \alpha^{-1}\right) \circ\left(\alpha \circ y_{2} \circ \alpha^{-1}\right)=y_{1}^{e} \circ y_{2}^{e}=\left(y_{1} \circ y_{2}\right)^{e} .
$$

If $y \in \mathrm{~S}_{n}$ is a solution of $(e * \alpha)$, then

$$
\alpha \circ y^{-1} \circ \alpha^{-1}=\left(\alpha \circ y \circ \alpha^{-1}\right)^{-1}=\left(y^{e}\right)^{-1}=\left(y^{-1}\right)^{e} .
$$

Since $y^{i}$ is also a solution of $(e * \alpha)$, we have $\alpha \circ y^{i} \circ \alpha^{-1}=\left(y^{i}\right)^{e}$, whence $\alpha \circ y^{i}=y^{e i} \circ \alpha$ follows for all $i \geq 0$. For $k \geq 0$ we use an induction:
$\alpha^{k+1} \circ y^{i}=\alpha \circ\left(\alpha^{k} \circ y^{i}\right)=\alpha \circ\left(y^{e^{k} i} \circ \alpha^{k}\right)=\left(\alpha \circ y^{e^{k} i}\right) \circ \alpha^{k}=\left(y^{e\left(e^{k} i\right)} \circ \alpha\right) \circ \alpha^{k}=y^{e^{k+1} i} \circ \alpha^{k+1} \square$
2.5. Lemma. If $y \in \mathrm{~S}_{n}$ is a solution of $(e * \alpha)$, then $y$ and $y^{e}$ are of the same type $\left\langle t_{1}, t_{2}, \ldots, t_{n}\right\rangle, y^{e^{w}-1}=1$ and for any cycle $\left(c_{1}, c_{2}, \ldots, c_{r}\right)$ of $y$ the cycle length $r \geq 1$ is a divisor of $e^{w}-1$ (i.e. $r \mid e^{w}-1$ ), where type $(\alpha)=\left\langle g_{1}, g_{2}, \ldots, g_{n}\right\rangle$ and

$$
w=\operatorname{ord}(\alpha)=\operatorname{lcm}\left\{a \mid 1 \leq a \leq n, g_{a} \neq 0\right\}
$$

is the order of $\alpha$. We also have $\operatorname{gcd}(r, e)=1$ and $\left(c_{1}, c_{e+1}, c_{2 e+1}, \ldots, c_{(r-1) e+1}\right)$ is a cycle of $y^{e}$, where the indices ie $+1,0 \leq i \leq r-1$ are taken in $\{1,2, \ldots, r\}$ modulo $r$. This cycle of $y^{e}$ has the same elements as the original cycle and each cycle of $y^{e}$ can be obtained by the above construction, starting from a uniquely determined cycle of $y$.

Proof. According to $(e * \alpha)$, the permutation $y^{e}$ is the conjugate of $y$ (by $\alpha$ ), whence $\operatorname{type}(y)=\operatorname{type}\left(y^{e}\right)$ follows. The application of Lemma 2.4 gives that $\alpha^{w} \circ y=$ $y^{e^{w}} \circ \alpha^{w}$. Now $\alpha^{w}=1$ implies that $y^{e^{w}-1}=1$, whence we obtain that any cycle length $r \geq 1$ of $y$ is a divisor of $e^{w}-1$. Clearly, $\operatorname{gcd}(r, e)=1$ is a consequence of $r \mid e^{w}-1$. If $\left(c_{1}, c_{2}, \ldots, c_{r}\right)$ is a cycle of $y$, then $\left(c_{1}, c_{e+1}, c_{2 e+1}, \ldots, c_{(r-1) e+1}\right)$ is obviously a cycle of $y^{e}$ of the same length $r$ (notice that $c_{i e+1} \neq c_{j e+1}$ follows from $r \nmid(j-i) e$ for all $1 \leq i<j \leq r-1)$. If $\left(c_{1}, y^{e}\left(c_{1}\right), \ldots, y^{(r-1) e}\left(c_{1}\right)\right)$ is a cycle of $y^{e}$ of length $r \geq 1$, then $y^{r e}\left(c_{1}\right)=c_{1}$ and $s \mid r e$, where $y^{s}\left(c_{1}\right)=c_{1}$ and $1 \leq s \leq n$ is the length of the $y$-cycle strating with $c_{1}$. Since $\operatorname{gcd}(s, e)=1$, we obtain that $s \mid r$. The containment $\left\{c_{1}, y^{e}\left(c_{1}\right), \ldots, y^{(r-1) e}\left(c_{1}\right)\right\} \subseteq\left\{c_{1}, y\left(c_{1}\right), \ldots, y^{s-1}\left(c_{1}\right)\right\}$ implies that $r \leq s$, whence $r=s$ follows. Thus, the above cycle of $y^{e}$ can be constructed by the given process starting from the cycle $\left(c_{1}, y\left(c_{1}\right), \ldots, y^{r-1}\left(c_{1}\right)\right)$ of $y$.
2.6. Lemma. Let $y \in \mathrm{~S}_{n}$ be a solution of $(e * \alpha)$ with type $(y)=\left\langle t_{1}, t_{2}, \ldots, t_{n}\right\rangle$ and for a given $1 \leq r \leq n$ with $t_{r} \geq 1$ consider the base sets

$$
C_{i}^{(r)} \subseteq\{1,2, \ldots, n\}, 1 \leq i \leq t_{r}
$$

of all r-element cycles of $y\left(\left|C_{i}^{(r)}\right|=r\right.$ for all $\left.1 \leq i \leq t_{r}\right)$. Then there exists $a$ permutation $\gamma$ of the index set $\left\{1,2, \ldots, t_{r}\right\}$ such that

$$
\alpha\left(C_{i}^{(r)}\right)=C_{\gamma(i)}^{(r)} .
$$

Since $\gamma$ is uniquely determined by $\alpha$, it is natural to use the notation $\gamma=\alpha^{(r)}$. Now $t_{r} r \in F_{1}(\alpha)$ and if $\alpha^{(r)}$ has a cycle $\left(i_{1}, i_{2}, \ldots, i_{d}\right)$ of length $1 \leq d \leq t_{r}$, then $d \mid w=\operatorname{ord}(\alpha)$ and $d r \in F_{d}(\alpha)$.

Proof. In view of Lemmas 2.2 and 2.5, any $r$-element cycle of $y^{e}$ can be obtained as the $\alpha$ image of a unique $r$-element cycle of $y$. Since the base sets of the $r$-element cycles in $y$ and in $y^{e}$ coincide, we obtain that $\alpha\left(C_{i}^{(r)}\right)=C_{\gamma(i)}^{(r)}$ for some permutation $\gamma$ of the indices. Now $H=C_{1}^{(r)} \cup C_{2}^{(r)} \cup \cdots \cup C_{t_{r}}^{(r)}$ is a fixed set of $\alpha$, whence $t_{r} r=|H| \in F_{1}(\alpha)$ follows by Lemma 2.1. If $\left(i_{1}, i_{2}, \ldots, i_{d}\right)$ is a cycle of $\alpha^{(r)}$, then

$$
\alpha\left(C_{i_{1}}^{(r)}\right)=C_{i_{2}}^{(r)}, \alpha\left(C_{i_{2}}^{(r)}\right)=C_{i_{3}}^{(r)}, \ldots, \alpha\left(C_{i_{d-1}}^{(r)}\right)=C_{i_{d}}^{(r)}, \alpha\left(C_{i_{d}}^{(r)}\right)=C_{i_{1}}^{(r)}
$$

Now $H(d)=C_{i_{1}}^{(r)} \cup C_{i_{2}}^{(r)} \cup \cdots \cup C_{i_{d}}^{(r)}$ is a fixed set of $\alpha$ and the above property of $\alpha$ (or $\alpha^{(r)}$ ) gives that

$$
H(d)=D_{1} \cup D_{2} \cup \cdots \cup D_{m},
$$

where $D_{1}, D_{2}, \ldots, D_{m}$ are certain pairwise disjoint cycles of $\alpha$ such that $d\left|\left|D_{j}\right|\right.$ and $\left|D_{j}\right| \mid w$ hold for all $1 \leq j \leq m$. Thus, $d \mid w$ and

$$
d r=|H(d)|=\left|D_{1}\right|+\left|D_{2}\right|+\cdots+\left|D_{m}\right| \in F_{d}(\alpha)
$$

follows by the repeated application of Lemma 2.1.
2.7. Lemma. Let $y \in S_{n}$ be a solution of $(e * \alpha)$ with type $(y)=\left\langle t_{1}, t_{2}, \ldots, t_{n}\right\rangle$. If $t_{r} \neq 0$ and the induced permutation $\alpha^{(r)}$ of the indices $\left\{1,2, \ldots, t_{r}\right\}$ (see Lemma 2.6) has a cycle $\left(i_{1}, i_{2}, \ldots, i_{d}\right)$ of length $1 \leq d \leq t_{r}$ and $\operatorname{gcd}\left(e^{d}-1, r\right)=1$, then $\alpha$ also has a cycle of length $d$ in $C_{i_{1}}^{(r)} \cup C_{i_{2}}^{(r)} \cup \cdots \cup C_{i_{d}}^{(r)}$.

Proof. Let $C_{i_{1}}^{(r)}=\left\{c_{1}, c_{2}, \ldots, c_{r}\right\}$ be the set of all elements in a cycle $\left(c_{1}, c_{2}, \ldots, c_{r}\right)$ of $y$ (notice that $r \mid e^{w}-1$ by Lemma 2.5). Since $c_{1} \in C_{i_{1}}^{(r)}$ and

$$
\alpha\left(C_{i_{1}}^{(r)}\right)=C_{i_{2}}^{(r)}, \alpha\left(C_{i_{2}}^{(r)}\right)=C_{i_{3}}^{(r)}, \ldots, \alpha\left(C_{i_{d-1}}^{(r)}\right)=C_{i_{d}}^{(r)}, \alpha\left(C_{i_{d}}^{(r)}\right)=C_{i_{1}}^{(r)},
$$

the containment $\alpha^{d}\left(c_{1}\right) \in C_{i_{1}}^{(r)}$ holds, whence $\alpha^{d}\left(c_{1}\right)=y^{s}\left(c_{1}\right)$ follows for some $1 \leq s \leq r$. Now $\operatorname{gcd}\left(e^{d}-1, r\right)=1$ implies that $\left(e^{d}-1\right) u+s=r v$ for some $u, v \in \mathbb{Z}$ and $y^{u}\left(c_{1}\right)$ is a fixed point of $\alpha^{d}$. Indeed, the application of Lemma 2.4 gives that

$$
\begin{gathered}
\alpha^{d}\left(y^{u}\left(c_{1}\right)\right)=\left(\alpha^{d} \circ y^{u}\right)\left(c_{1}\right)=\left(y^{e^{d} u} \circ \alpha^{d}\right)\left(c_{1}\right)=y^{e^{d} u}\left(\alpha^{d}\left(c_{1}\right)\right)=y^{e^{d} u}\left(y^{s}\left(c_{1}\right)\right)= \\
y^{e^{d} u+s}\left(c_{1}\right)=y^{u+r v}\left(c_{1}\right)=y^{u}\left(c_{1}\right) .
\end{gathered}
$$

Thus, $\left(y^{u}\left(c_{1}\right), \alpha\left(y^{u}\left(c_{1}\right)\right), \ldots, \alpha^{d-1}\left(y^{u}\left(c_{1}\right)\right)\right)$ is a $d$-element cycle of $\alpha$.

## 3. NON-COMMUTING SOLUTIONS OF $\alpha \circ y \circ \alpha^{-1}=y^{e}$

If $y \in \mathrm{~S}_{n}$ is a solution of $\alpha \circ y \circ \alpha^{-1}=y^{e}$, then the conditions $\alpha \circ y=y \circ \alpha$ and $y^{e-1}=1$ are obviously equivalent to each other. A solution of $(e * \varepsilon)$ is called commuting if one of these two equivalent conditions holds. On the other hand, if $y \in S_{n}$ is a permutation with $y^{e-1}=1$ and $\alpha \circ y=y \circ \alpha$, then $y$ is a solution of $(e * \alpha)$ : we have $y^{e}=y$ and $\alpha \circ y \circ \alpha^{-1}=y=y^{e}$.
3.1. Theorem. For any integer $r \geq 2$ dividing $n \geq 3$ and $e^{\frac{n}{r}}-1$ and any $n$-cycle $\alpha \in \mathrm{S}_{n}$, the equation $\alpha \circ y \circ \alpha^{-1}=y^{e}$ has a solution $y \in \mathrm{~S}_{n}$, which is a product of $n / r$ disjoint $r$-cycles. If the additional condition that $r$ is not a divisor of $e-1$ holds, then $y^{e-1} \neq 1$ and $y$ is a non-commuting solution of $(e * \alpha)$.

Proof. Take $q=n / r$ and define an $n$-element set $P_{n}$ of ordered pairs and a function $\varepsilon: P_{n} \longrightarrow P_{n}$ as follows:

$$
\begin{gathered}
P_{n}=\{(i, j) \mid 1 \leq i \leq q \text { and } 1 \leq j \leq r\} \\
\varepsilon(i, j)=\left\{\begin{array}{c}
(i+1, e j) \text { if } 1 \leq i \leq q-1 \text { and } 1 \leq j \leq r \\
(1, e j+1) \text { if } i=q \text { and } 1 \leq j \leq r
\end{array}\right.
\end{gathered}
$$

where $e j$ and $e j+1$ are taken in $\{1,2, \ldots, r\}$ modulo $r$. It is straightforward to check that $\varepsilon$ is injective (hence a permutation of $P_{n}$ ). Clearly, the definition of $\varepsilon$ immediately gives that the length of a cycle in $\varepsilon$ is a multiple of $q$. If $1 \leq k \leq q-1$ and $1 \leq j \leq r$, then $\varepsilon^{k}(1, j)=\left(1+k, e^{k} j\right)$ and $r \mid e^{q}-1$ ensures that $\varepsilon^{q}(1, j)=$ $\left(1, e^{q} j+1\right)=(1, j+1)$. Thus,

$$
\varepsilon^{q}(1, j)=(1, j+1), \varepsilon^{2 q}(1, j)=(1, j+2), \ldots, \varepsilon^{(r-1) q}(1, j)=(1, j+r-1)
$$

are distinct elements and $\varepsilon^{r q}(1, j)=(1, j+r)=(1, j)$ (in $P_{n}$ ). It follows that $\varepsilon$ has exactly one cycle of length $n=r q$. Now define a permutation $y: P_{n} \longrightarrow P_{n}$ as follows:

$$
y(i, j)=(i, j+1)
$$

where $1 \leq i \leq q, 1 \leq j \leq r$ and $j+1$ is taken in $\{1,2, \ldots, r\}$ modulo $r$. The number of cycles in $y$ is exactly $q$ and each cycle of $y$ is of the form

$$
((i, 1),(i, 2), \ldots,(i, r))
$$

An easy calculation shows that $\varepsilon \circ y=y^{e} \circ \varepsilon$. If $1 \leq i \leq q-1$ and $1 \leq j \leq r$, then

$$
\varepsilon(y(i, j))=\varepsilon((i, j+1))=(i+1, e j+e)
$$

and

$$
y^{e}(\varepsilon(i, j))=y^{e}((i+1, e j))=(i+1, e j+e)
$$

If $i=q$ and $1 \leq j \leq r$, then

$$
\varepsilon(y(q, j))=\varepsilon((q, j+1))=(1, e j+e+1)
$$

and

$$
y^{e}(\varepsilon(q, j))=y^{e}((1, e j+1))=(1, e j+1+e)
$$

Thus, $y$ is a required solution of $(e * \varepsilon)$. If $r$ is not a divisor of $e-1$, then $y^{e-1} \neq 1$. Finally, we deduce, that $(e * \alpha)$ has similar solutions for any permutation $\alpha \in \mathrm{S}_{n}$ with $\operatorname{type}(\alpha)=\operatorname{type}(\varepsilon)$.
3.2. Corollary. If $\alpha \in \mathrm{S}_{n}$ is an $n$-cycle and $p \geq 2$ is a prime divisor of $d=$ $\operatorname{gcd}\left(n, e^{n}-1\right) \neq 1$, then $(e * \alpha)$ has a solution $y \in \mathrm{~S}_{n}$, wich is a product of $n / p$
disjoint p-cycles (and $y^{d}=1$ ). If the additional condition $d \nmid(e-1)^{d}$ holds, then $p$ can be chosen as a non-divisor of $e-1$. In this case $y^{e-1} \neq 1$ and $y$ is $a$ non-commuting solution of $(e * \alpha)$.

Proof. Now $n=n_{1} p$ and

$$
e^{\frac{n}{p}}-1=e^{n_{1}}-1=\left(e^{n_{1} p}-1\right)-e^{n_{1}}\left(e^{n_{1}(p-1)}-1\right)=\left(e^{n}-1\right)-e^{n_{1}}\left(e^{n_{1}(p-1)}-1\right)
$$

is divisible by $p$ (i.e. $p \left\lvert\, e^{\frac{n}{p}}-1\right.$ ) by Fermat's divisibility $p \mid e^{p-1}-1$. The application of Theorem 3.1 gives the existence of a solution $y \in \mathrm{~S}_{n}$ of $(e * \alpha)$ such that $y$ is a product of $n / p$ disjoint $p$-cycles. Clearly, $p \mid d$ implies that $y^{d}=1$. In the additional case $p \nmid e-1$ implies that $y^{e-1} \neq 1$.
3.3. Corollary. If $\alpha \in \mathrm{S}_{n}$ is a permutation of type $(\alpha)=\left\langle g_{1}, g_{2}, \ldots, g_{n}\right\rangle$ such that $g_{a} \neq 0$ and $p \geq 2$ is a prime divisor of $d=\operatorname{gcd}\left(a, e^{a}-1\right) \neq 1$ for some $2 \leq a \leq n$, then $(e * \alpha)$ has a solution $y \in \mathrm{~S}_{n}$ wich is a product of $a / p$ disjoint $p$-cycles (and $y^{d}=1$ ). If the additional condition $d \nmid(e-1)^{d}$ holds, then $p$ can be chosen as a non-divisor of $e-1$. In this case $y^{e-1} \neq 1$ and $y$ is a non-commuting solution of $(e * \alpha)$.

Proof. If $\left(i, \alpha(i), \ldots, \alpha^{a-1}(i)\right)$ is an $a$-element cycle of $\alpha$, then $\{1,2, \ldots, n\}=$ $H_{1} \cup H_{2}$, where $H_{1}=\left\{i, \alpha(i), \ldots, \alpha^{a-1}(i)\right\}$ and $H_{2}=\{1,2, \ldots, n\} \backslash H_{1}$ are disjoint fixed sets of $\alpha$. Now Corollary 3.2 ensures the existence of a solution $y_{1} \in S_{H_{1}}$ of $\left(e *\left(\alpha \upharpoonright H_{1}\right)\right)$ (here $y_{1}: H_{1} \longrightarrow H_{1}$ is a permutation and $\left(\alpha \upharpoonright H_{1}\right): H_{1} \longrightarrow H_{1}$ is the restriction of $\alpha$ to $H_{1}$ ) wich is a product of $a / p$ disjoint $p$-cycles. If $y_{2}=1$ is the identity permutation on $H_{2}$, then $y=y_{1} \sqcup y_{2}$ is also a product of $a / p$ disjoint $p$-cycles and $\left(y_{1} \sqcup y_{2}\right)^{d}=1$. The application of Lemma 2.3 gives that $y \in \mathrm{~S}_{n}$ is a solution of $(e * \alpha)$. In the additional case Corollary 3.2 gives that $y_{1}$ is non-commuting, whence the non-commuting property of $y_{1} \sqcup y_{2}$ follows.
3.4. Proposition. Let $\alpha=(1,2, \ldots, n) \in S_{n}$ be a cyclic permutation and $r \geq 2$ be a divisor of $n$ such that $\operatorname{gcd}\left(\frac{n}{r}, e^{n}-1\right)=1$. If $1 \neq y \in \mathrm{~S}_{n}$ is a solution of $(e * \alpha)$ with $\operatorname{type}(y)=\left\langle t_{1}, t_{2}, \ldots, t_{n}\right\rangle$ and $t_{s} \neq 0$ for some $2 \leq s \leq n$, then $s$ is a divisor of $r$ (i.e. any cycle length of $y$ is a divisor of $r$ ), $t_{s}$ is a multiple of $\frac{n}{r}$ and $y^{r}=1$. If $r=p$ is a prime number, then $s=p, t_{p}=\frac{n}{p}$ and $t_{k}=0$ for each $1 \leq k \leq n$, $k \neq p$, thus $y$ is a product of $n / p$ disjoint $p$-cycles.

Proof. Since $s \geq 2$ is a cycle of length of $y$, Lemma 2.5 ensures that $s \mid e^{n}-1$, where $n=\operatorname{ord}(\alpha)$. Let $C_{i}^{(s)} \subseteq\{1,2, \ldots, n\}, 1 \leq i \leq t_{s}$ be the pairwise disjoint base sets of the $s$-element cycles of $y$. The type of $\alpha$ and Lemma 2.6 ensure that $t_{s} s \in$ $F_{1}(\alpha)=\{0, n\}=\left\{0, r \cdot \frac{n}{r}\right\}$. in view of $t_{s} s=r \cdot \frac{n}{r}, s \mid e^{n}-1$ and $\operatorname{gcd}\left(\frac{n}{r}, e^{n}-1\right)=1$, we deduce that $s \mid r$ and $\left.\frac{n}{r} \right\rvert\, t_{s}$. If $r=p$ is prime, then $s=p$ and $t_{p}=\frac{n}{p}$ follow from the divisibility $s \mid p$ and $t_{s} s=p \cdot \frac{n}{p}$.
3.5. Corollary. If $\alpha=(1,2, \ldots, n) \in \mathrm{S}_{n}$ is a cyclic permutation and $p \geq 2$ is a prime divisor of $n$ such that $\operatorname{gcd}\left(\frac{n}{p}, e^{n}-1\right)=1$ and $p \nmid e-1$, then $y=1$ is the only commuting solution of $(e * \alpha)$.

Proof. For any solution $1 \neq y \in \mathrm{~S}_{n}$ of $(e * \alpha)$ Proposition 3.4 gives that $y$ is a product of $n / p$ disjoint $p$-cycles. Now $y^{e-1} \neq 1$ is a consequence of $p \nmid e-1$.
3.6. Theorem. Let $\alpha=(1,2, \ldots, n) \in \mathrm{S}_{n}$ be a cyclic permutation, $p \geq 2$ be $a$ prime divisor of $n$ such that $p \left\lvert\, e^{\frac{n}{p}}-1\right.$ and $\operatorname{gcd}\left(\frac{n}{p}, e^{n}-1\right)=1$. Now the existence of a non-trivial solution $1 \neq y \in \mathrm{~S}_{n}$ of $(e * \alpha)$ follows from Theorem 3.1. If $y \neq 1$ is an arbitrary solution of $(e * \alpha)$, then the powers $y, y^{2}, \ldots, y^{p-1}, y^{p}=1$ provide the complete list of solutions of $(e * \alpha)$.

Proof. Let $1 \neq y \in S_{n}$ be an arbitrary solution of $(e * \alpha)$ with type $(y)=$ $\left\langle t_{1}, t_{2}, \ldots, t_{n}\right\rangle$. Proposition 3.4 ensures that $y$ is a product of $q=n / p$ disjoint $p$-cycles and the powers $y, y^{2}, \ldots, y^{p-1}, y^{p}=1$ are distinct solutions of $(e * \alpha)$.
If $1 \leq d \leq t_{p}=q$ is the length of a cycle $\left(i_{1}, i_{2}, \ldots, i_{d}\right)$ of the induced permutation $\alpha^{(p)}$, then Lemma 2.6 gives $d p \in F_{d}(\alpha) \subseteq F_{1}(\alpha)=\{0, p \cdot q\}$ and $d=q$. It follows that $\alpha^{(p)}$ has only one cycle of length $d=q$ and we can assume that $\alpha^{(p)}=(1,2, \ldots, q)$ (hence $\alpha\left(C_{j}^{(p)}\right)=C_{j+1}^{(p)}$ for $1 \leq j \leq q-1$ and $\left.\alpha\left(C_{q}^{(p)}\right)=C_{1}^{(p)}\right)$. Now fix an element $a \in C_{1}^{(p)}$. The above cyclic property of $\alpha^{(p)}$ and $1 \leq q=n / p \leq n-1$ ensure that $a \neq \alpha^{q}(a) \in C_{1}^{(p)}$, whence $\alpha^{q}(a)=y^{s}(a)$ follows for some $1 \leq s \leq p-1$ (s depends on the choice of $a)$. We claim that $y\left(\alpha^{i}(a)\right)=\alpha^{\bar{s}(i) q+i}(a)$ holds for all integers $0 \leq i \leq p q=n$, where $1 \leq \bar{s}(i) \leq p-1$ denotes the multiplicative inverse (reciprocal) of $e^{i} s$ in the prime field $\mathbb{Z}_{p}$ (notice that $p \mid e^{i} s$ would contradict to $1 \leq s \leq p-1$ and $\left.p \left\lvert\, e^{\frac{n}{p}}-1\right.\right)$.
First we use $\alpha^{i} \circ y^{s}=y^{e^{i} s} \circ \alpha^{i}$ (in Lemma 2.4) to get

$$
\alpha^{q}\left(\alpha^{i}(a)\right)=\alpha^{i}\left(\alpha^{q}(a)\right)=\alpha^{i}\left(y^{s}(a)\right)=y^{e^{i} s}\left(\alpha^{i}(a)\right)
$$

and then we prove by induction, that

$$
\alpha^{k q}\left(\alpha^{i}(a)\right)=y^{k e^{i} s}\left(\alpha^{i}(a)\right)
$$

holds for all integers $k \geq 0$. Lemma 2.4 gives that $\alpha^{k q} \circ y^{e^{i} s}=y^{e^{k q} e^{i} s} \circ \alpha^{k q}$ and $e^{k q} e^{i} s-e^{i} s=\left(e^{k q}-1\right) e^{i} s$ is divisible by $e^{q}-1$ and hence by $p$. Now $e^{k q} e^{i} s-e^{i} s=p v$ and the validity of the above equality for $k+1$ can be derived as

$$
\begin{gathered}
\alpha^{(k+1) q}\left(\alpha^{i}(a)\right)=\alpha^{k q}\left(\alpha^{q}\left(\alpha^{i}(a)\right)\right)=\alpha^{k q}\left(y^{e^{i} s}\left(\alpha^{i}(a)\right)\right)= \\
y^{e^{k q} e^{i} s}\left(\alpha^{k q}\left(\alpha^{i}(a)\right)\right)=y^{e^{k q} e^{i} s}\left(y^{k e^{i} s}\left(\alpha^{i}(a)\right)\right)=y^{e^{k q} e^{i} s-e^{i} s}\left(y^{(k+1) e^{i} s}\left(\alpha^{i}(a)\right)\right)= \\
y^{p v}\left(y^{(k+1) e^{i} s}\left(\alpha^{i}(a)\right)\right)=y^{(k+1) e^{i} s}\left(\alpha^{i}(a)\right) .
\end{gathered}
$$

In view of $\bar{s}(i) e^{i} s=1+p u$, the substitution $k=\bar{s}(i)$ into $\alpha^{k q}\left(\alpha^{i}(a)\right)=y^{k e^{i} s}\left(\alpha^{i}(a)\right)$ gives our claim

$$
y\left(\alpha^{i}(a)\right)=y^{\bar{s}(i) e^{i} s}\left(\alpha^{i}(a)\right)=\alpha^{\bar{s}(i) q}\left(\alpha^{i}(a)\right)=\alpha^{\bar{s}(i) q+i}(a) .
$$

Since $\left\{\alpha^{i}(a) \mid 0 \leq i \leq n-1\right\}=\{1,2, \ldots, n\}$, the permutation $y$ is completely determined by $s$. The fact that $1 \leq s \leq p-1$ can be chosen in $p-1$ different ways implies that the number of non-trivial solutions of $(e * \alpha)$ is at most $p-1$. It follows that $y, y^{2}, \ldots, y^{p-1}, y^{p}=1$ is the complete list of solutions.
3.7. Examples. The following integers satisfy the conditions in $3.1,3.5$ and 3.6 . If $e=2$ and $n=20,21$, then we have $5 \left\lvert\, 2^{\frac{20}{5}}-1\right., \operatorname{gcd}\left(\frac{20}{5}, 2^{20}-1\right)=1,5 \nmid 2-1$ and $7 \left\lvert\, 2^{\frac{21}{7}}-1\right., \operatorname{gcd}\left(\frac{21}{7}, 2^{21}-1\right)=1,7 \nmid 2-1$. If $e=-2$ and $n=55$, then we have $11 \left\lvert\,(-2)^{\frac{55}{11}}-1\right., \operatorname{gcd}\left(\frac{55}{11}, 2^{55}-1\right)=1,11 \nmid(-2)-1$.
4. COMMUTING SOLUTIONS OF $\alpha \circ y \circ \alpha^{-1}=y^{e}$
4.1. Theorem. Let $w=\operatorname{ord}(\alpha)=\operatorname{lcm}\left\{a \mid 1 \leq a \leq n, g_{a} \neq 0\right\}$ be the order of the permutation $\alpha \in \mathrm{S}_{n}$ of type $(\alpha)=\left\langle g_{1}, g_{2}, \ldots, g_{n}\right\rangle$ with $g_{1}=0$. Assume that for any choice of the integers $r \geq 2$ and $d \geq 2$ with $\operatorname{gcd}(e-1, r)=1, r\left|e^{w}-1, d\right| w$ and $d r \in F_{d}(\alpha)$ we have $g_{d}=0$ and $\operatorname{gcd}\left(e^{d}-1, r\right)=1$. If $y$ is a solution of $(e * \alpha)$ such that $\operatorname{gcd}(e-1, s)=1$ for any cycle length $s \geq 2$ of $y$, then $y=1$.

Proof. Let $y \in S_{n}$ be a solution of $(e * \alpha)$ with type $(y)=\left\langle t_{1}, t_{2}, \ldots, t_{n}\right\rangle$. Assume that $y \neq 1$, then $y$ has at least one cycle of length $r \geq 2$. Now we have $\operatorname{gcd}(e-1, r)=$ 1 and Lemma 2.5 ensures that $r \mid e^{w}-1$. Let $C_{i}^{(r)} \subseteq\{1,2, \ldots, n\}, 1 \leq i \leq t_{r}$ be the pairwise disjoint base sets of the $r$-element cycles of $y$. In view of Lemma 2.6 we have $\alpha\left(C_{i}^{(r)}\right)=C_{\gamma(i)}^{(r)}, 1 \leq i \leq t_{r}$, where $\gamma=\alpha^{(r)}$ is the induced permutation of the indices $\left\{1,2, \ldots, t_{r}\right\}$. Consider an arbitrary cycle $\left(i_{1}, i_{2}, \ldots, i_{d}\right)$ of $\alpha^{(r)}$, then $1 \leq d \leq t_{r}$ and Lemma 2.6 gives $d \mid w$ and $d r \in F_{d}(\alpha)$. If $d \geq 2$, then we have $g_{d}=0$ and $\operatorname{gcd}\left(e^{d}-1, r\right)=1$. If $d=1$, then we also have $\operatorname{gcd}\left(e^{d}-1, r\right)=1$. Thus, the application of Lemma 2.7 gives that $\alpha$ also has a cycle of length $d$, in contradiction with $g_{d}=0$.
4.2. Corollary. Let $\alpha=(1,2, \ldots, a) \circ(a+1, a+2, \ldots, a+b) \in \mathrm{S}_{n}$ be a product of two cyclic permutations, where $2 \leq a<b \leq n=a+b$. If $a$ is not $a$ divisor of $b$ and $\operatorname{gcd}\left(u, e^{u}-1\right)=1$ for any choice of $u \in\{a, b, a+b\}$, then $(e * \alpha)$ has only the trivial solution $y=1$.

Proof. In order to use Theorem 4.1 take the integers $r \geq 2$ and $d \geq 2$ such that $\operatorname{gcd}(e-1, r)=1, r\left|e^{w}-1, d\right| w$ and

$$
u=d r \in F_{d}(\alpha) \subseteq F_{1}(\alpha)=\{0, a, b, a+b\}
$$

where $w=\operatorname{ord}(\alpha)=\operatorname{lcm}(a, b)$. Clearly, $d \notin\{a, b\}$ is a consequence of the fact that $a$ is not a divisor of $b$. It follows that $g_{1}=g_{d}=0$ in type $(\alpha)$ and $\operatorname{gcd}\left(e^{d}-1, r\right)=1$ is a consequence of $\operatorname{gcd}\left(e^{d r}-1, d r\right)=\operatorname{gcd}\left(e^{u}-1, u\right)=1$.
If $y$ is a solution of $(e * \alpha)$ with type $(y)=\left\langle t_{1}, t_{2}, \ldots, t_{n}\right\rangle$ and $s \geq 2$ is a cycle length of $y$, then $t_{s} s \in F_{1}(\alpha)=\{0, a, b, a+b\}$ by Lemma 2.6. In view of $\operatorname{gcd}(e-1, a)=$ $\operatorname{gcd}(e-1, b)=\operatorname{gcd}(e-1, a+b)=1$, we obtain that $\operatorname{gcd}(e-1, s)=1$. Thus Theorem 4.1 ensures that $y=1$.
4.3. Corollary. Let $\alpha=(1,2, \ldots, a) \circ(a+1, a+2, \ldots, a+b) \in \mathrm{S}_{n}$ be a product of two cyclic permutations, where $2 \leq a \leq b \leq n=a+b$. If $a$ is a divisor of $b$, $\operatorname{gcd}\left(b, e^{b}-1\right)=\operatorname{gcd}(a+b, e-1)=1$ and $\frac{a+b}{a}$ is not a divisor of $e^{b}-1$, then $(e * \alpha)$ has only the trivial solution $y=1$.

Proof. In order to use Theorem 4.1 take the integers $r \geq 2$ and $d \geq 2$ such that $\operatorname{gcd}(e-1, r)=1, r\left|e^{w}-1, d\right| w$ and

$$
u=d r \in F_{d}(\alpha) \subseteq F_{1}(\alpha)=\{0, a, b, a+b\}
$$

where $w=\operatorname{ord}(\alpha)=\operatorname{lcm}(a, b)$. The fact that $a$ is a divisor of $b$ implies that $w=b$. Since $\frac{a+b}{a}$ is not a divisor of $e^{b}-1$, there are no integers $r \geq 2$ and $d \geq 2$ with the above properties. Indeed, $d r \in\{a, b\}$ is in contradiction with $r\left|e^{b}-1, r\right| b$ and $\operatorname{gcd}\left(e^{b}-1, b\right)=1$. If $d r=a+b$, then $d \mid b$ implies that $d \mid a$ and $\left.\frac{a+b}{a} \right\rvert\, \frac{a+b}{d}$. Now
$r=\frac{a+b}{d}$ is in contradiction with $\frac{a+b}{a} \nmid e^{b}-1$. Thus, we do not have to check $g_{d}=0$ and $\operatorname{gcd}\left(e^{d}-1, r\right)=1$.
If $y$ is a solution of $(e * \alpha)$ with type $(y)=\left\langle t_{1}, t_{2}, \ldots, t_{n}\right\rangle$ and $s \geq 2$ is a cycle length of $y$, then $t_{s} s \in F_{1}(\alpha)=\{0, a, b, a+b\}$ by Lemma 2.6. In view of $\operatorname{gcd}(e-1, a)=$ $\operatorname{gcd}(e-1, b)=\operatorname{gcd}(e-1, a+b)=1$, we obtain that $\operatorname{gcd}(e-1, s)=1$. Thus Theorem 4.1 ensures that $y=1$.
4.4. Examples. If $e=2$, then $a=10$ and $b=15$ satisfy the conditions in Corollary 4.2. If $e=-2$, then $a=35$ and $b=77$ satisfy the conditions in Corollary 4.2. If $e=2$, then $a=5$ and $b=25$ satisfy the conditions in Corollary 4.3. If $e=-2$, then $a=2$ and $b=14$ satisfy the conditions in Corollary 4.3.

For an integer $2 \leq v$ with $\operatorname{gcd}(v, e-1)=1$ let $q(e, v)$ denote the smallest prime divisor of $e^{v}-1$ not dividing $e-1$ (if there is no such prime, then take $q(e, v)=+\infty$ ). If $v$ is odd, then $7 \leq q(2, v)$. Similarly, if $v$ is not divisible by 2 and 3 , then $23 \leq q(2, v)$. Indeed, $2 \nmid v$ and $3 \nmid v$ imply that $2,3,5,7,11,13,17,19 \nmid 2^{v}-1$. Notice that $q(2,2)=2^{2}-1, q(2,3)=2^{3}-1, q(2,4)=3, q(2,5)=2^{5}-1, q(2,6)=3$, $q(2,7)=2^{7}-1, q(2,8)=3, q(2,9)=7, q(2,10)=3$ and $q(2,11)=23 \neq 2^{11}-1$ (clearly, $2^{11}-1$ is not a Mersenne prime). We also note that $q(-2,2)=+\infty$, $q(-2,4)=5, q(-2,5)=11, q(-2,7)=43, q(-2,8)=5, q(-2,10)=11$ and $q(-2,11)=683$.
4.5. Theorem. Let $w=\operatorname{ord}(\alpha)=\operatorname{lcm}\left\{a \mid 1 \leq a \leq n, g_{a} \neq 0\right\}$ be the order of the permutation $\alpha \in \mathrm{S}_{n}$ of type type $(\alpha)=\left\langle g_{1}, g_{2}, \ldots, g_{n}\right\rangle$ such that $g_{1}=0$ and $\operatorname{gcd}(a, b)=1$ for all $1 \leq a<b \leq n$ with $g_{a} \neq 0 \neq g_{b}$ (two different cycle lengths are relative primes). Assume that $1 \leq g_{a} \leq q(e, w)-1$ and $\operatorname{gcd}\left(a, e^{a}-1\right)=1$ hold for all $1 \leq a \leq n$ with $g_{a} \neq 0$. If $y \in \mathrm{~S}_{n}$ is a solution of $(e * \alpha)$, then $y^{e-1}=1$ (i.e. y is commuting).

Proof. Let $y \in S_{n}$ be a solution of $(e * \alpha)$. Any cycle $C$ of $y^{(e-1)^{n}}$ can be obtained from a uniquely determined cycle $D$ of $y$ (notice that $C \subseteq D$ ). If $s=|D|$ is the length of $D$, then $|C|=\frac{s}{d}$ with $d=\operatorname{gcd}\left((e-1)^{n}, s\right)$. Since $\operatorname{gcd}\left(e-1, \frac{s}{d}\right)=1$, we can apply Theorem 4.1 on $y^{(e-1)^{n}}$. Let $r \geq 2$ and $d \geq 2$ be integers such that $\operatorname{gcd}(e-1, r)=1, r\left|e^{w}-1, d\right| w$ and $d r \in F_{d}(\alpha)$. Our conditions on the type of $\alpha$ ensure the existence of a unique integer $k \geq 1$ such that $1 \leq d k \leq n$ and $g_{d k} \neq 0$, whence $F_{d}(\alpha)=F_{d k}(\alpha)=\left\{0, d k, 2 d k, \ldots, g_{d k} d k\right\}$ follows. Now we have $d r=j d k$ as well as $r=j k$ for some $1 \leq j \leq g_{d k}$. Since $r \mid e^{w}-1$, we obtain that $j \mid e^{w}-1$. Clearly, $\operatorname{gcd}(e-1, j)=1$ and $2 \leq j \leq g_{d k} \leq q(e, w)-1$ would contradict to the definition of $q(e, w)$. It follows that $j=1$ and $g_{d r}=g_{d k} \neq 0$. Thus, $g_{d}=0$ and $\operatorname{gcd}\left(e^{d r}-1, d r\right)=1$ are also consequences of our conditions on the type of $\alpha$, whence $\operatorname{gcd}\left(e^{d}-1, r\right)=1$ follows. The application of Theorem 4.1 gives that $y^{(e-1)^{n}}=1$. We also have $y^{e^{w}-1}=1$ by Lemma 2.5. Since $\operatorname{gcd}(a, e-1)=1$ holds for all $1 \leq a \leq n$ with $g_{a} \neq 0$ (our assumption that $\operatorname{gcd}\left(a, e^{a}-1\right)=1$ is stronger) and $w=\operatorname{lcm}\left\{a \mid 1 \leq a \leq n, g_{a} \neq 0\right\}$, we obtain that $\operatorname{gcd}(w, e-1)=1$. In view of

$$
e^{w}-1=(e-1)\left(w+(e-1)+\left(e^{2}-1\right)+\cdots+\left(e^{w-1}-1\right)\right)
$$

$\operatorname{gcd}\left(e^{w}-1,(e-1)^{n}\right)=e-1$ can be derived, whence $\left(e^{w}-1\right) u+(e-1)^{n} v=e-1$ follows for some $u, v \in \mathbb{Z}$. As a consequence we have

$$
y^{e-1}=y^{\left(e^{w}-1\right) u+(e-1)^{n} v}=\left(y^{e^{w}-1}\right)^{u} \circ\left(y^{(e-1)^{n}}\right)^{v}=1
$$

Thus, $y$ is a commuting solution of $(e * \alpha)$.
4.6. Examples. If we omit any one of the three conditions $\operatorname{gcd}(a, b)=1$,
$1 \leq g_{a} \leq q(e, w)-1$ and $\operatorname{gcd}\left(a, e^{a}-1\right)=1$ from Theorem 4.5, then we loose the validity of 4.5 .
(i) The cycle lengths 2 and 4 in $\alpha=(1,2) \circ(3,4,5,6) \circ(7,8,9,10) \in \mathrm{S}_{10}$ are not relative primes, while the other two conditions with $e=2$ in 4.5 hold for $\alpha$ $\left(w=\operatorname{ord}(\alpha)=4, q(2,4)=3\right.$ and $\left.\operatorname{gcd}\left(2,2^{2}-1\right)=\operatorname{gcd}\left(4,2^{4}-1\right)=1\right)$. Now it is straightforward to check that $y=(1,10,4,6,8) \circ(2,3,7,9,5) \in \mathrm{S}_{10}$ is a noncommuting solution of $(e * \alpha): y^{e-1} \neq 1$.
(ii) The only cycle length is 2 in $\alpha=(1,2) \circ(3,4) \circ(5,6) \in \mathrm{S}_{6}$ and $g_{2}=3 \not \leq$ $q(2,2)-1=2$, while the other two conditions with $e=2$ in 4.5 hold for $\alpha(w=$ $\operatorname{ord}(\alpha)=2$ and $\left.\operatorname{gcd}\left(2,2^{2}-1\right)=1\right)$. Now it is straightforward to check that $y=(1,3,5) \circ(2,6,4) \in \mathrm{S}_{6}$ is a non-commuting solution of $(e * \alpha): y^{e-1} \neq 1$.
(iii) If $d=\operatorname{gcd}\left(a, e^{a}-1\right) \neq 1$ for some $1 \leq a \leq n$ with $g_{a} \neq 0$, then the weak additional condition $d \nmid(e-1)^{d}$ in Corollary 3.3 ensures the existence of a noncommuting solution of $(e * \alpha)$.
4.7. Remarks. Theorem 4.5 reveals that under certain mild assumptions, the solutions of $(e * \alpha)$ are exactly the solutions of $y^{e-1}=1$ in the centralizer of $\alpha$. If $a=p^{t}$ is a prime power and $p \nmid e-1$, then it is straightforward to check that

$$
e=e^{p^{0}} \equiv e^{p^{1}} \equiv \cdots \equiv e^{p^{t-1}} \equiv e^{p^{t}} \bmod (p)
$$

whence $\operatorname{gcd}\left(a, e^{a}-1\right)=1$ follows. As $\operatorname{gcd}(w, e-1)$ appears in the above proof of 4.5, we add the following simple observation. If $\alpha \in \mathrm{S}_{n}$ is arbitrary and $\operatorname{gcd}(w, e-1)=$ $d \neq 1$, then $y=\alpha^{\frac{w}{d}} \neq 1$ is a non-trivial commuting solution of $(e * \alpha)$ such that $y^{d}=1$.

The replacement of $1 \leq g_{a} \leq q(e, w)-1$ in Theorem 4.5 by the stronger condition $g_{a}=1$ helps to give a complete answer when our equation $(e * \alpha)$ has only the trivial solution $y=1$. If $g_{1}=0$ and $0 \leq g_{a} \leq 1$, then our next result shows that $\operatorname{gcd}\left(a, e^{a}-1\right) \neq 1$ in Corollary 3.3 is essential for the existence of a non-trivial solution.
4.8. Theorem. Let $\alpha \in \mathrm{S}_{n}$ be a permutation such that type $(\alpha)=\left\langle g_{1}, g_{2}, \ldots, g_{n}\right\rangle$, $g_{1}=0,0 \leq g_{a} \leq 1$ and $\operatorname{gcd}(a, b)=1$ for all $1 \leq a, b \leq n$ with $a \neq b$ and $g_{a}=g_{b}=1$ (two different cycle lengths are relative primes). Now the following conditions are equivalent:
(i) $\operatorname{gcd}\left(a, e^{a}-1\right)=1$ holds for all $1 \leq a \leq n$ with $g_{a}=1$.
(ii) The only solution $y \in \mathrm{~S}_{n}$ of $(e * \alpha)$ is $y=1$.

Proof. (i) $\Longrightarrow\left(\right.$ ii): Now $\alpha=\alpha_{1} \circ \alpha_{2} \circ \cdots \circ \alpha_{k}$ is a product of pairwise disjoint cycles $\alpha_{1}, \alpha_{2}, \ldots, \alpha_{k} \in S_{n}$ such that

$$
2 \leq a_{1}=\operatorname{ord}\left(\alpha_{1}\right)<a_{2}=\operatorname{ord}\left(\alpha_{2}\right)<\cdots<a_{k}=\operatorname{ord}\left(\alpha_{k}\right) \leq n
$$

and $a_{1}+a_{2}+\cdots+a_{k}=n$. If $y \in \mathrm{~S}_{n}$ is a solution of $(e * \alpha)$, then Theorem 4.5 gives that $y$ is commuting: $y^{e-1}=1$ and $\alpha \circ y=y \circ \alpha$. The type of $\alpha$ (no two cycles of the same length) ensures that

$$
\operatorname{Cen}(\alpha)=\left\{\alpha_{1}^{t_{1}} \circ \alpha_{2}^{t_{2}} \circ \cdots \circ \alpha_{k}^{t_{k}} \mid 0 \leq t_{i} \leq a_{i}-1 \text { for each } 1 \leq i \leq k\right\}
$$

In view of $y \in \operatorname{Cen}(\alpha)$, we have $y=\alpha_{1}^{t_{1}} \circ \alpha_{2}^{t_{2}} \circ \cdots \circ \alpha_{k}^{t_{k}}$ for some integers $0 \leq t_{i} \leq a_{i}-1$, $1 \leq i \leq k$. Clearly, $y^{e-1}=1$ implies that the divisibility $a_{i} \mid(e-1) t_{i}$ holds for each $1 \leq i \leq k$. Since $\operatorname{gcd}\left(a_{i}, e-1\right)=1$ is a consequence of $\operatorname{gcd}\left(a_{i}, e^{a_{i}}-1\right)=1$, we deduce that $t_{i}=0$ for each $1 \leq i \leq k$. It follows that $y=1$.
(ii) $\Longrightarrow$ (i): If $\operatorname{gcd}\left(a, e^{a}-1\right) \neq 1$ holds for some $1 \leq a \leq n$ with $g_{a}=1$ and $p \geq 2$ is a prime divisor of $\operatorname{gcd}\left(a, e^{a}-1\right)$, then Corollary 3.3 gives the existence of a solution $1 \neq y \in S_{n}$ of $(e * \alpha)$ which is a product of $a / p$ disjoint $p$-cycles.
4.9. Remarks. The following observations are closely related to some of the conditions in Theorems 4.5 and 4.8. If $\alpha \in S_{n}$ is a permutation such that type $(\alpha)=$ $\left\langle g_{1}, g_{2}, \ldots, g_{n}\right\rangle$ and $g_{1}=0$, then we have the following inequalities:

$$
w=\operatorname{ord}(\alpha) \leq \prod_{1 \leq a \leq n} a^{g_{a}} \leq|\operatorname{Cen}(\alpha)|
$$

Since $w=\operatorname{ord}(\alpha)=\operatorname{lcm}\left\{a \mid 1 \leq a \leq n, g_{a} \neq 0\right\}$, it is clear that $\operatorname{ord}(\alpha)=\prod_{1 \leq a \leq n} a^{g_{a}}$ holds if and only if $0 \leq g_{a} \leq 1$ and $\operatorname{gcd}(a, b)=1$ for all $1 \leq a, b \leq n$ with $a \neq b$ and $g_{a}=g_{b}=1$. It is not difficult to show that $\prod_{1 \leq a \leq n} a^{g_{a}}=|\operatorname{Cen}(\alpha)|$ holds if and only if $0 \leq g_{a} \leq 1$ for all $1 \leq a \leq n$.
