Abstract

We analyze the solution of the Schrödinger equation arising in the treatment of a geometric model introduced to explain the origin of the observed shallow levels in semiconductors threaded by a dislocation density. We show (contrary to what the authors claimed) that the model does not support bound states for any chosen set of model parameters. Assuming a fictitious motion in the $x-y$ plane there are bound states provided that $k \neq 0$ and not only for $k > 0$ as the authors believed. The truncation condition proposed by the authors yields only one particular energy for a given value of a chosen model parameter and misses all the others (conditionally solvable problem).

Key words: Schrödinger-Pauli equation; bound states; Frobenius method; three-term recurrence relation

Some time ago Bakke and Moraes [1] introduced a geometric model to explain the origin of the observed shallow levels in semiconductors threaded by dislocations.

¹ e-mail: fernande@quimica.unlp.edu.ar
a dislocation density. It leads to a Schrödinger-Pauli equation that can be re-
duced to a biconfluent Heun equation by means of suitable transformations. Through application of the Frobenius method the authors derived a three-
term recurrence relation for the expansion coefficients. They claimed that it 
was necessary to resort to a truncation condition in order to have bound states 
and in this way they obtained analytical expressions for the energies of the 
model. The purpose of this Comment is the analysis of the procedure proposed 
by Bakke and Moraes [1] for solving their eigenvalue equation.

The starting point is the time-dependent Schrödinger-Pauli equation

$$
\frac{i}{\hbar} \frac{\partial \psi}{\partial t} = -\frac{1}{2m} \left[ \frac{\partial^2}{\partial \rho^2} + \frac{1}{\rho} \frac{\partial}{\partial \rho} + \frac{1}{\rho^2} \frac{\partial^2}{\partial \varphi^2} - 2\Omega \frac{\partial^2}{\partial \varphi \partial z} + \left( 1 + \Omega^2 \rho^2 \right) \frac{\partial^2}{\partial z^2} \right] \psi + \frac{i \sigma^3}{2m \rho^2} \frac{\partial \psi}{\partial \varphi} - i \Omega \frac{\sigma^3}{2m} \frac{\partial \psi}{\partial z} + \frac{1}{8m \rho^2} \psi + \frac{\Omega^2}{8m} \psi + \frac{f}{\rho} \psi,
$$

(1)

where the meaning of the parameters can be seen in the authors’ paper. The 
form of the Laplacian operator $\nabla^2$ comes from the line element

$$
ds^2 = d\rho^2 + \rho^2 d\varphi^2 + \left( dz + \Omega \rho^2 d\varphi \right)^2,
$$

(2)

in cylindrical coordinates $0 \leq \rho < \infty$, $0 \leq \varphi \leq 2\pi$, $-\infty < z < \infty$. The 
authors argue as follows "We can see in Eq. (7) that $\psi$ is an eigenfunction of 
$\sigma^3$, whose eigenvalues are $s = \pm 1$ and the Hamiltonian of Eq. (7) commutes 
with the operators $\hat{J}_z = -i \partial_\varphi$ and $\hat{p}_z = -i \partial_z$, thus, we can write the solution 
of Eq. (7) in terms of the eigenfunctions of the operators $\hat{J}_z$ and $\hat{p}_z$, that is, 
$\psi_s = e^{-\xi t} e^{i \left( \frac{l}{2} + \frac{1}{2} \right) \varphi} e^{ikz} R_s(\rho)$, where $l = 0, \pm 1, \pm 2, \ldots$ and $k$ is a constant which 
corresponds to the momentum in the $z$-direction. We take $k > 0$ since, as 
we will see below in Eq. (10), for $k < 0$ the minus sign of the exponent of the Gaussian function becomes positive and we no longer have bound states. This asymmetry is due to the choice of the Burgers vector orientation." The statement about the allowed values of $k$ is wrong as we shall see in what
follows. To begin with $\psi_s(t, \rho, \varphi, z)$ is a bound state only if

$$\int \int \int |\psi_s(t, \rho, \varphi, z)|^2 \rho d\rho d\varphi dz < \infty,$$

(3)
as shown in any textbook on quantum mechanics [2]. In the example discussed here the improper integral over $z$ is obviously divergent and, consequently, there are no bound states for any chosen set of values of the model parameters.

The function $R_s(\rho)$ satisfies the eigenvalue equation

$$-\frac{1}{2m} \left( \frac{\partial^2 R_s}{\partial \rho^2} + \frac{1}{\rho} \frac{\partial R_s}{\partial \rho} \right) + \frac{\gamma_s^2}{2\rho^2} R_s - \frac{\Omega k \gamma_s}{m} R_s + \frac{1}{2m} \left( k + \frac{\Omega}{2} \right)^2 R_s +$$

$$\Omega^2 k^2 \rho^2 R_s + \frac{f}{\rho} R_s = E R_s,$$

(4)

where $\gamma_s = l + \frac{1}{2}(1 - s)$. The authors claimed to have obtained the equation

$$\frac{d^2 R_s}{d\zeta^2} + \frac{1}{\zeta} \frac{dR_s}{d\zeta} - \frac{\gamma_s^2}{\zeta^2} R_s - \zeta^2 R_s - \frac{f'}{\sqrt{\Omega k \zeta}} R_s + \frac{\beta_s}{\Omega k} R_s = 0,$$

(5)

by means of the change of variables $\zeta = \sqrt{\Omega k \rho}$. Here the authors made two mistakes, the first one coming from ignoring the fact that they multiplied the whole equation by $2m$; therefore, the resulting harmonic term should be $-2m \zeta^2 R_s$ instead of the fourth term of this equation. The correct transformation that leads to that fourth term is $\zeta = (2m \Omega^2 k^2)^{1/4} \rho = (2m)^{1/4} \sqrt{|\Omega |} \rho$, provided that $k \neq 0$ (see a recent pedagogical article on deriving dimensionless equations [3]). The second mistake is that $\sqrt{k^2} = |k|$ (and not $k$) so that the sign of $k$ does not affect the form of the Gaussian function as the authors believed. The result of these mistakes is that most of the parameters in equation (5) are wrong; however, their precise form is not relevant for the following discussion.

By means of the transformation

$$R_s(\zeta) = \zeta |\gamma_s| e^{-\frac{\zeta^2}{2}} \sum_{j=0}^{\infty} a_j \zeta^j,$$

(6)
the authors derived the three-term recurrence relation

\[
a_{m+2} = \frac{b}{(m+2)(m+\alpha+1)}a_{m+1} + \frac{2m-g}{(m+2)(m+\alpha+1)}a_m,
\]

\[m = -1, 0, 1, 2, \ldots, a_{-1} = 0, a_0 = 1,\]

(7)

where \(\alpha = 2|\gamma_s|+1\). The parameters \(b\) and \(g\) are given in the authors’ paper but their form is incorrect because of the unsuitable change of variable discussed above. However, their precise form is not relevant for the following discussion (as stated above).

The authors reasoned that “Note that the recurrence relation (14) is valid for both signs of the Coulomb-like potential, that is, we can specify the signs of the Coulomb-like potential by making \(f \to \pm|f|\) in (14). Hence, in order to obtain finite solutions everywhere, which represent bound state solutions, we need that the power series expansion (13) or the Heun biconfluent series become a polynomial of degree \(n\). Through expression (14), we can see that the power series expansion (13) becomes a polynomial of degree \(n\) if we impose the conditions:

\[g = 2n \text{ and } a_{n+1} = 0,\]

(8)

where \(n = 1, 2, 3, \ldots\)”. From the first truncation condition the authors derived an analytical expression for the energy \(E_{n,l,s}\) and stated that “where the angular frequency is given by \(\omega_{n,l,s} = \frac{\Omega}{m}\). On the other hand, the condition \(a_{n+1} = 0\) allows us to obtain an expression involving the angular frequency and the quantum numbers \(n, l\) and \(s\). Observe that we have considered \(k\) being a positive constant, thus, we can choose any value of \(k\) in such a way that the condition \(a_{n+1} = 0\) and write \(k = k_{n,l,s}\). We should note that writing \(k\) in terms of the quantum numbers \(n, l\) and \(s\), that is, \(k = k_{n,l,s}\), it does not mean that \(k\) is quantized. Writing \(k = k_{n,l,s}\) means that the choice of the values of \(k > 0\) depends on the quantum numbers \(n, l\) and \(s\) in order to
satisfy the condition \( a_{n+1} = 0 \). Then, we can write the angular frequency as
\[
\omega_{n,l,s} = \Omega_{k_n,l,s} \frac{\hbar}{m}.
\]

The authors appear to believe that there are bound states only when the truncation conditions (8) are satisfied and only for \( k > 0 \). Besides, they said that the truncation conditions (8) require that \( k \) take some particular values \( k = k_{n,l,s} > 0 \) without being understood as a quantization of \( k \). These statements are wrong as we show in what follows (we have already shown above that the only restriction is that \( k \neq 0 \)).

First of all we want to make it clear that the model chosen by the authors does not support bound states as argued above. For this reason, in what follows we assume that the eigenvalue equation (4) applies only to the motion of a particle in the \( x - y \) plane (with \( k \neq 0 \! \! \! \! \)!) so that we can speak of bound states. In such a case we have bound states for all values of \( f \) if \( k \neq 0 \) and for \( f < 0 \) when \( k = 0 \). It is plain that it is not necessary to restrict the analysis only to positive values of \( k \).

In order to make the analysis simpler we rewrite equation (5) as follows
\[
\frac{d^2 R_s}{d\zeta^2} + \frac{1}{\zeta} \frac{dR_s}{d\zeta} - \frac{\gamma_s^2}{\zeta^2} R_s - \zeta^2 R_s - \frac{b}{\zeta} R_s + W R_s = 0,
\]
that is obviously valid only for \( k \neq 0 \). As stated above there are bound states for all values of \( b \) because the harmonic term determines the behaviour at infinity and \( \gamma_s^2/\zeta^2 \) the behaviour at origin. Any textbook on quantum mechanics [2] shows that bound states occur for those values of \( W \) such that
\[
\int_0^\infty |R_s(\zeta)|^2 \zeta d\zeta < \infty.
\]

On the other hand, the truncation condition (8) yields bound states for particular values of \( b = b_{n,l,s} \) and for each of them they provide just one eigenvalue \( W_{n,l,s} \). Equation (9) leads to the three-term recurrence relation (7) with \( g = W - 2|\gamma_s| - 2 \); so that from the truncation conditions (8) for \( n = 1 \) we obtain \( b = \pm \sqrt{\alpha g} \). Therefore, when \( s = 1 \) and \( l = 1 \) we have \( \gamma_1 = 1 \), \( g = 2 \),
\[ b = \pm \sqrt{6} \text{ and } W = 6. \]

Let us solve the eigenvalue equation (9) by means of standard approximate methods; for example, the reliable Rayleigh-Ritz variational method that is known to yield upper bounds to all states [3]. For simplicity we choose the basis set of (un-normalized) functions \[ \{ u_j(\zeta) = \zeta^{\gamma} e^{-\frac{\zeta^2}{2}}, j = 0, 1, \ldots \}. \]

In order to test the accuracy of the variational results we resort to the powerful Riccati-Padé method [7]. For \[ b = \sqrt{6} \text{ and } \gamma_1 = 1 \] the three lowest eigenvalues given by both methods are \[ W_{0,1,1} = 1.600357154, W_{1,1,1} = 6, W_{2,1,1} = 10.21072810. \] Since the differential equation (9) is invariant under the transformation \((b, \zeta) \rightarrow (-b, -\zeta)\) we conclude that \(W(-b) = W(b)\) and the numerical calculations just mentioned with \(b = -\sqrt{6}\) confirm this general result. The important point here is that the method proposed by Bakke and Moraes [1] only yields one eigenvalue for a particular value \(b_{n,l,s}\) of the model parameter \(b\) and misses all the other ones. This fact is not surprising as it is expected of the exact solutions to conditionally-solvable models [4, 5] (and references therein) and is confirmed by the numerical calculation discussed above. It is obvious that each of the energies \(E_{n,l,s}\) reported by those authors correspond to a particular model with the parameter \(b_{n,l,s}\) (of course if we omit the fact that almost all the relevant parameters, energy included, appearing in the equations below their equation (8) are wrong).

Summarizing: the model proposed by Bakke and Moraes [1] does not support bound states (for any chosen set of model parameters) in contradiction with what they claimed. Assuming a fictitious motion in the \(x - y\) plane there are bound states provided that \(k \neq 0\) and not only for \(k > 0\) as they stated. The truncation condition proposed by the authors yields only one particular energy for a given value of a chosen model parameter and misses all the other eigenvalues (conditionally solvable problem).
