

DIFFEOMORPHISMS AND POSITIVE CURVATURE

GEORG FRENCK

ABSTRACT. We prove the existence of elements of infinite order in the homotopy groups of the spaces $\mathcal{R}_{\text{Ric}>0}(M)$ and $\mathcal{R}_{\text{Sec}>0}(M)$ of positive Ricci and positive sectional curvature, provided that M is high-dimensional and Spin, admits such a metric and has a non-vanishing rational Pontryagin class.

1. INTRODUCTION

For a given closed oriented manifold M let $\mathcal{R}_{\text{Sec}>0}(M)$ and $\mathcal{R}_{\text{Ric}>0}(M)$ denote the spaces of Riemannian metrics of positive sectional or positive Ricci curvature. In contrast to the space $\mathcal{R}_{\text{scal}>0}(M)$ of positive scalar curvature metrics, rather little is known about the topology of those two spaces; especially if one is interested in rational homotopy groups.

In order to state our main result, let $\text{Diff}(M)$ denote the group of orientation preserving diffeomorphisms of M and let $\text{Diff}(M, D) \subset \text{Diff}(M)$ denote the subgroup of those diffeomorphisms that fix an embedded disk $D \subset M$ pointwise. Furthermore, let $\mathcal{R}_C(M) \subset \mathcal{R}_{\text{scal}>0}(M)$ be a $\text{Diff}(M)$ -invariant subset.

Theorem A. *Let M^d be closed, simply connected Spin-manifold that has at least one non-vanishing rational Pontryagin class and let $g \in \mathcal{R}_C(M)$. Let $k \geq 1$ be such that $(d+k)$ is divisible by 4 and $k \leq \min(\frac{d-1}{3}, \frac{d-5}{2})$. Then map*

$$\pi_{k-1}(\text{Diff}(M, D)) \otimes \mathbb{Q} \longrightarrow \pi_{k-1}(\mathcal{R}_C(M)) \otimes \mathbb{Q}$$

*induced by the orbit map $f \mapsto f^*g$ is nontrivial.*

In particular: $\pi_{k-1}(\mathcal{R}_{\text{Ric}>0}(M)) \otimes \mathbb{Q} \neq 0 \neq \pi_{k-1}(\mathcal{R}_{\text{Sec}>0}(M)) \otimes \mathbb{Q}$, provided these spaces are non-empty.

Remark 1.1 (State of the art concerning $\mathcal{R}_{\text{Sec}>0}(M)$). To the best of the author's knowledge, the following is all that is known about the homotopy type of $\mathcal{R}_{\text{Sec}>0}(M)$:

- (i) Kreck–Stolz have shown in [KS93], that there exists manifolds M such that $\mathcal{R}_{\text{Sec}>0}(M)$ is not connected. Their result remains true for the quotient $\mathcal{R}_{\text{Sec}>0}(M)/\text{Diff}(M)$, so those components do not originate from the orbit map.
- (ii) Crowley–Schick–Steimle have shown in [CSS18] that for every manifold M , the image of the orbit map $\pi_{k-1}(\text{Diff}(M)) \rightarrow \pi_{k-1}(\mathcal{R}_{\text{Sec}>0}(M))$ contains $\mathbb{Z}/2$ as a subgroup provided $d+k \equiv 1, 2 \pmod{8}$ and $d \geq 6$. This extends earlier results of Hitchin [Hit74] and Crowley–Schick [CS13].

I am supported by the DFG (German Research Foundation) – 281869850 (RTG 2229).

- (iii) Krannich–Kupers–Randal-Williams have proven the special case $M = \mathbb{H}\mathbb{P}^2$, $k = 4$ of [Theorem A](#) in [KKRW20]. Their proof delivers an excellent blueprint for our generalisations. Like in loc.cit., we will construct an M -bundle $E \rightarrow S^k$ with a Spin-structure on the vertical tangent bundle and non-vanishing \hat{A} -genus. Since [KKRW20] is written rather densely, we chose to give a more detailed account of their argument in [Section 2](#) before we go on to proving [Theorem A](#) in [Section 3](#).

Remark 1.2.

- (i) The bound on k can be improved if M is even-dimensional and ℓ -connected. In this case [Theorem A](#) holds true for $k \leq \min(d - 4, 2\ell - 1)$ (cf. [Remark 2.3](#)).
- (ii) As pointed out in [KKRW20] this answers a question of Schick [OWL, p. 30] and provides many examples for manifolds to which [BEW20, Theorem 2.1] is applicable.

According to [Zil14] there are the only known examples of positively manifolds curved in dimensions $4k + 3$ for $k \geq 2$ are spheres. Also, all 7-dimensional examples have finite fourth cohomology (cf. [Esc92; Goe14; GKS04]). Therefore, a positive answer to the following question would yield the first example of a manifold that admits infinitely many pairwise non-isotopic metrics of positive sectional curvature.

Question 1.3. *Is there a positively curved manifold of dimension $4k + 3$, $k \geq 1$ with a non-vanishing rational Pontryagin class?*

Acknowledgements. I would like to thank Jens Reinhold for comments on an earlier draft and Bernhard Hanke and Jost Eschenburg for valuable remarks.

2. SETTING THE STAGE

Let M be a closed oriented manifold of dimension d and let $\text{Diff}(M)$ denote the group of orientation preserving diffeomorphisms of M . We denote by $B\text{Diff}(M)$ the classifying space for fibre bundles with fibre M and oriented vertical tangent bundle.

2.1. Block diffeomorphisms. In this subsection we give a short overview of block diffeomorphisms and we explain how to compare them to diffeomorphisms. For $p \geq 0$ let Δ^p denote the standard topological p -simplex.

Definition 2.1. A *block diffeomorphism* of $\Delta^p \times M$ is a diffeomorphism of $\Delta^p \times M$ that for each face $\sigma \subset \Delta^p$ restricts to a diffeomorphism of $\sigma \times M$.

The set of all block diffeomorphisms forms a semisimplicial group denoted by $\widetilde{\text{Diff}}_{\bullet}(M)$ whose p -simplices are the block diffeomorphisms of $\Delta^p \times M$. The space $\widetilde{\text{Diff}}(M)$ of block bundles is defined as the geometric realisation of $\widetilde{\text{Diff}}_{\bullet}(M)$ and the associated classifying space is denoted by $B\widetilde{\text{Diff}}(M)$.

If we consider the semisimplicial subgroup $\text{Diff}_{\bullet}(M)$ of those block diffeomorphisms that commute with the projection $\Delta^p \times M \rightarrow \Delta^p$, we precisely get the p -simplices of the singular semisimplicial group $\text{Sing}_{\bullet}\text{Diff}(M)$. We have an inclusion $\text{Sing}_{\bullet}\text{Diff}(M) \subset \widetilde{\text{Diff}}_{\bullet}(M)$ and since the geometric realisation of

$\text{Sing}_\bullet(X)$ is homotopy equivalent to X for any space X ([HAT, pp. 8]), we get an induced map

$$B\text{Diff}(M) \longrightarrow B\widetilde{\text{Diff}}(M).$$

Next, let $\text{hAut}(M)$ denote the group-like¹ topological monoid of (orientation preserving) homotopy equivalences of M with classifying space $B\text{hAut}(M)$. Again, let $\widetilde{\text{hAut}}(M)$ be the realisation of the semisimplicial group of block homotopy equivalences defined analogously with $B\text{hAut}(M)$ and $B\widetilde{\text{hAut}}(M)$ the corresponding classifying spaces. By [Dol63, Thm 6.1] $\text{hAut}(M)$ and $\widetilde{\text{hAut}}(M)$ are homotopy equivalent. Consider the following maps induced by inclusions:

$$B\widetilde{\text{Diff}}(M) \rightarrow B\widetilde{\text{hAut}}(M) \simeq B\text{hAut}(M) \quad B\text{Diff}(M) \rightarrow B\text{hAut}(M)$$

and let $\text{hAut}(M)/\widetilde{\text{Diff}}(M)$ and $\text{hAut}(M)/\text{Diff}(M)$ denote the respective homotopy fibres. Note that $\text{hAut}(M)/\text{Diff}(M)$ classifies M -bundles that are homotopy equivalent to the trivial bundle through a homotopy that commutes with the projection of the bundle, i.e. *fibre homotopy trivial* M -bundles. We have the following comparison result which easily follows from [BL82, Corollary D].

Lemma 2.2. *If $k \leq \min(\frac{d-1}{3}, \frac{d-5}{2})$ then the map*

$$\pi_k \left(\frac{\text{hAut}(M)}{\text{Diff}(M)} \right) \left[\frac{1}{2} \right] \longrightarrow \pi_k \left(\frac{\text{hAut}(M)}{\widetilde{\text{Diff}}(M)} \right) \left[\frac{1}{2} \right]$$

is (split-)surjective.

Proof. By [BL82, Corollary D] there exists a space \mathcal{S} such that for $k \leq \min(\frac{d-1}{3}, \frac{d-5}{2})$ we have

$$\begin{aligned} \pi_k \left(\frac{\text{hAut}(M)}{\text{Diff}(M)} \right) \left[\frac{1}{2} \right] &\cong \pi_{k-1} \left(\Omega \left(\frac{\text{hAut}(M)}{\text{Diff}(M)} \right) \right) \left[\frac{1}{2} \right] \\ &\cong \pi_{k-1} \left(\Omega \left(\frac{\text{hAut}(M)}{\widetilde{\text{Diff}}(M)} \right) \times \Omega \mathcal{S} \right) \left[\frac{1}{2} \right] \twoheadrightarrow \pi_k \left(\frac{\text{hAut}(M)}{\widetilde{\text{Diff}}(M)} \right) \left[\frac{1}{2} \right] \quad \square \end{aligned}$$

Therefore, an element of $\pi_k(\text{hAut}(M)/\widetilde{\text{Diff}}(M)) \otimes \mathbb{Q}$ yields an M -bundle $E \rightarrow S^k$ that is fibre homotopy trivial, provided that the dimension of M is high enough. The advantage of working with $\text{hAut}(M)/\widetilde{\text{Diff}}(M)$ instead of $\text{hAut}(M)/\text{Diff}(M)$ stems from the fact, that the former is accessible through surgery theory as we will review in the succeeding section.

Remark 2.3. Another approach to compare $B\text{Diff}(M)$ and $B\widetilde{\text{Diff}}(M)$ is by using Morlet's lemma of disjunction as in [KKRW20, Lemma]. Let M^{2n} be even-dimensional and consider the following diagram of (homotopy) fibrations

¹A topological space X is called *group-like* if $\pi_0(X)$ is a group

$$\begin{array}{ccc}
\frac{\widetilde{\text{Diff}}_{\partial}(D^{2n})}{\text{Diff}_{\partial}(D^{2n})} & \longrightarrow & \frac{\widetilde{\text{Diff}}(M)}{\text{Diff}(M)} \\
\downarrow & & \downarrow \\
B\text{Diff}_{\partial}(D^{2n}) & \longrightarrow & B\text{Diff}(M) \\
\downarrow & & \downarrow \\
B\widetilde{\text{Diff}}_{\partial}(D^{2n}) & \longrightarrow & B\widetilde{\text{Diff}}(M)
\end{array}$$

If M is ℓ -connected with $\ell \leq 2n - 4$, then the induced map on homotopy fibres is $(2\ell - 2)$ -connected by Morlet's lemma of disjunction (cf. [BLR75, Corollary 3.2 on page 29]). Now $\pi_k(B\widetilde{\text{Diff}}_{\partial}(D^{2n})) \cong \pi_0(\text{Diff}_{\partial}(D^{2n+k-1}))$ is isomorphic to the finite group of exotic spheres in dimension $(2n + k)$ and $B\text{Diff}_{\partial}(D^{2n})$ is rationally $2n - 5$ -connected by [RW17, Theorem 4.1]. Therefore, $\widetilde{\text{Diff}}_{\partial}(D^{2n})/\text{Diff}_{\partial}(D^{2n})$ is rationally $(2n-5)$ -connected and $\widetilde{\text{Diff}}(M)/\text{Diff}(M)$ is rationally $\min(2n - 5, 2\ell - 2)$ -connected. This implies that the map

$$\pi_k(B\text{Diff}(M)) \otimes \mathbb{Q} \rightarrow \pi_k(B\widetilde{\text{Diff}}(M)) \otimes \mathbb{Q}$$

is surjective for $k \leq \min(2n - 4, 2\ell - 1)$.

2.2. Surgery theory. Let X be a simply connected manifold with boundary ∂X . The *structure set* $\mathcal{S}(X, \partial X)$ of $(X, \partial X)$ (sometimes written as $\mathcal{S}_{\partial}(X)$) is defined to be the set of equivalence classes of tuples $(W, \partial W, f)$ where W is a manifold with boundary ∂W and f is a homotopy equivalence² that restricts to a diffeomorphism on the boundary. Two such tuples $(W_0, \partial W_0, f_0)$ and $(W_1, \partial W_1, f_1)$ are equivalent, if there exists a diffeomorphism $\alpha: W_0 \rightarrow W_1$ such that $f_0 = f_1 \circ \alpha$.

It is a consequence of the h -cobordism theorem that we have the following isomorphism ([BM13, Section 3.2, pp.33])

$$\pi_k \left(\frac{\text{hAut}(M)}{\widetilde{\text{Diff}}(M)} \right) \cong \mathcal{S}_{\partial}(D^k \times M).$$

The main result of surgery theory is that the structure set $\mathcal{S}_{\partial}(D^k \times M)$ fits into an exact sequence of sets known as the *surgery exact sequence* (cf. [CLM, Theorem 10.21 and Remark 10.22]):

$$(1) \quad L_{k+d+1}(\mathbb{Z}) \longrightarrow \mathcal{S}_{\partial}(D^k \times M) \longrightarrow \mathcal{N}_{\partial}(D^k \times M) \xrightarrow{\sigma} L_{k+d}(\mathbb{Z})$$

Here, $\mathcal{N}_{\partial}(D^k \times M)$ is the set of *normal invariants* which is given by equivalence classes of tuples (W, f, \hat{f}, ξ) , where W is a $d + k$ -dimensional manifold with (stable) normal bundle ν_W , ξ is a stable vector bundle over $D^k \times M$ and $f: W \rightarrow D^k \times M$ is a map of degree 1 covered by a bundle map $\hat{f}: \nu_W \rightarrow \nu_{D^k \times M} \oplus \xi$ such that (f, \hat{f}) restricts to the identity on the boundary and the equivalence relation is given by cobordism.

²Since we assume X to be simply connected, every homotopy equivalence is simple and we do not need to require this in the definition.

Since we only consider simply connected manifolds, the relevant L -groups are 4-periodic and given by (cf. [CLM, Theorem 7.96])

$$L_n(\mathbb{Z}) \cong \begin{cases} \mathbb{Z} & \text{if } n \equiv 0 \pmod{4} \\ \mathbb{Z}/2 & \text{if } n \equiv 2 \pmod{4} \\ 0 & \text{otherwise} \end{cases}$$

and the map σ in the surgery exact sequence (1) is the so-called *surgery obstruction map*, which in degrees $d + k \equiv 0 \pmod{4}$ for simply connected M is given by

$$\sigma(W, f, \hat{f}, \xi) = \frac{1}{8} \left(\underbrace{\text{sign}(W \cup (D^k \times M))}_{=: W'} - \text{sign}(S^k \times M) \right) = \frac{1}{8} \text{sign}(W')$$

where sign denotes the signature (cf. [CLM, Lemma 7.170, Exercise 7.188]). The signature of W' can be computed via Hirzebruch's signature theorem, which constructs a power series

$$\begin{aligned} \mathcal{L}(x_1, x_2, \dots) = & 1 + s_1 x_1 + \dots + s_i x_i + \dots + s_{i,j} x_i \cdot x_j + \dots \\ & + s_{i_1, \dots, i_n} x_{i_1} \cdots x_{i_n} + \dots \end{aligned}$$

such that $\text{sign}(W') = \langle \mathcal{L}(p_1(TW'), p_2(TW'), \dots), [W'] \rangle$. Here $p_i(TW')$ are the Pontryagin classes of W' . Note that f, \hat{f} , and ξ can be extended trivially to W' . Since the map f is of degree one, evaluating the Pontryagin classes of W' against $[W']$ yields the same result as evaluating the Pontryagin classes of $-\xi \oplus T(S^k \times W)$, where $-\xi$ denotes the (stable) orthogonal complement to ξ .

In order to further analyse $\mathcal{N}_\partial(D^k \times M)$, let us define $G(n) = \{f: S^{n-1} \rightarrow S^{n-1} \text{ homotopy equivalence}\}$ and $BG := \text{colim}_{n \rightarrow \infty} BG(n)$. Note, that the index shift stems from the fact that one wants to have an inclusion $O(n) \subset G(n)$ of the orthogonal group. Analogously, let $BO := \text{colim}_{n \rightarrow \infty} BO(n)$. Note that BG is the classifying space for stable spherical fibrations whereas BO is the classifying space for stable vector bundles. The inclusion $O(n) \hookrightarrow G(n)$ induces a map $BO \rightarrow BG$ and we denote the homotopy fibre by G/O . By [CLM, Remark 10.28] there is an identification

$$\mathcal{N}_\partial(D^k \times M) \cong [S^k \wedge M_+, G/O]_*.$$

Here M_+ is M with a disjoint base point and \wedge denotes the smash product of pointed spaces given by $(X, x) \wedge (Y, y) := (X \times Y) / (X \times \{y\} \cup \{x\} \times Y)$. The functor $S^k \wedge (-)_+$ is adjoint to the k -fold loop space functor $\Omega^k(-)$ and so we get $[S^k \wedge M_+, G/O]_* \cong [M, \Omega^k G/O]$. Now $\Omega^{k+1} BG$ is the homotopy fibre of the map $\Omega^k G/O \rightarrow \Omega^k BO$. By obstruction theory (cf. [Hat02, p. 418]) the obstructions to the lifting problem

$$\begin{array}{ccc} & & \Omega^k G/O \\ & \nearrow \text{dashed} & \uparrow \\ M & \xrightarrow{\quad} & \Omega^k BO \end{array}$$

live in the groups $H^{i+1}(M; \pi_i(\Omega^{k+1} BG)) \cong H^{i+1}(M; \pi_{k+i+1}(BG))$. The homotopy groups of $\pi_k(BG)$ are isomorphic to the shifted stable homotopy groups of spheres π_{k-1}^{st} by [CLM, p. 135]. By Serre's finiteness theorem,

these groups are finite for $k \geq 2$ and hence all obstruction groups vanish rationally, since we assumed that $k \geq 1$. Since $\text{maps}_*(M, \Omega^k BO)$ is an H -space, we see that for every (pointed) map $f: M \rightarrow \Omega^k BO$, some multiple of f can be lifted to $\Omega^k G/O$. Therefore it suffices for us to specify an element in

$$[S^k \wedge M_+, BO]_* = \widetilde{KO}^0(S^k \wedge M_+)$$

in order to get a normal invariant. Next, consider the isomorphism given by the Pontryagin character:

$$\begin{aligned} \text{ph}(-) := \text{ch}(- \otimes \mathbb{C}): \widetilde{KO}^0(S^k \wedge M_+) \otimes \mathbb{Q} &\xrightarrow{\cong} \bigoplus_{i \geq 0} \widetilde{H}^{4i}(S^k \wedge M_+; \mathbb{Q}) \\ &\cong u_k \cdot \bigoplus_{i \geq 0} H^{4i-k}(M; \mathbb{Q}) \end{aligned}$$

for u_k the cohomological fundamental class in $H^k(S^k)$. The i -th component of the Pontryagin character is given by

$$\begin{aligned} \text{ph}_i(\xi) &= \text{ch}_{2i}(\xi \otimes \mathbb{C}) = \frac{1}{(2i)!} \left((-2i)c_{2i}(\xi) + f(c_1(\xi), \dots, c_{2i-1}(\xi)) \right) \\ &= \frac{(-1)^{i+1}}{(2i-1)!} p_i(\xi) \end{aligned}$$

where $f(c_1(\xi), \dots, c_{2i-1}(\xi))$ is a polynomial in Chern classes of ξ homogenous of degree $2i$ which vanishes since all products in $\widetilde{H}^*(S^k \wedge M_+; \mathbb{Q})$ are trivial. Hence, for any collection $(x_i) \in H^{4i-k}(M; \mathbb{Q})$ and $(A_i) \in \mathbb{Q}$ there exists a $\lambda \in \mathbb{Z} \setminus \{0\}$ and a normal invariant $(W, f, \hat{f}, \xi) \in \mathcal{N}_\partial(D^k \times M)$ such that

$$p_i(\xi') = (-1)^{i+1} (2i-1)! \lambda A_i \cdot u_k \cdot x_i,$$

where u_k denotes the cohomological fundamental class of S^k . This allows us to construct a normal invariant such that the underlying stable vector bundle has prescribed Pontryagin classes, which we will do in the succeeding section.

3. PROOF OF MAIN THEOREM

3.1. Prescribing Pontryagin classes. Let M^d be as in [Theorem A](#) and let $m := \frac{d+k}{4}$. Let $j := \min\{i \geq 1: p_i(TM) \neq 0 \in H^{4i}(M; \mathbb{Q})\} \in \{1, \dots, \lfloor \frac{d}{4} \rfloor\}$, where $p_i(TM)$ denotes the i -th Pontryagin class of M .

Lemma 3.1. *There exists a normal invariant $\eta \in \mathcal{N}_\partial(D^k \times M)$ with underlying stable vector bundle $\xi \rightarrow D^k \times M$ with the following property: For ξ' the extension of ξ by the trivial bundle to $S^k \times M$, we have*

$$\langle p_j(TM \oplus -\xi') \cdot p_{m-j}(TM \oplus -\xi'), [S^k \times M] \rangle \neq 0 \neq \langle p_m(TM \oplus -\xi'), [S^k \times M] \rangle$$

are the only non-vanishing elementary Pontryagin numbers of $TM \oplus -\xi$, and $\sigma(\eta) = 0$.

Proof. Let $u_M \in H^{4m-k}(M; \mathbb{Q})$ denote the cohomological fundamental class of M . Since the cup product induces a perfect pairing

$$H^{4j}(M; \mathbb{Q}) \times H^{4(m-j)-k}(M; \mathbb{Q}) \rightarrow \mathbb{Q},$$

there exists a class $x \in H^{4(m-j)-k}(M; \mathbb{Q})$ such that $x \cdot p_j(TM) = u_M$. By the discussion in section 2 for every $A \in \mathbb{Q}$ there exists a $\lambda \in \mathbb{Z} \setminus \{0\}$ and a normal

invariant $\eta = (W, f, \hat{f}, \xi)$ such that the (extended) stable vector bundle ξ' has only 2 higher non-vanishing rational Pontryagin classes, namely:

$$\begin{aligned} p_0(\xi') &= 1 \\ p_{m-j}(\xi') &= -(-1)^{m-j+1}(2m-2j)!\lambda \cdot u_k \cdot x \\ p_m(\xi') &= -(-1)^{m+1}(2m)!\lambda A \cdot u_k \cdot u_M \end{aligned}$$

Since $j < m$ and $p_i(TM) = 0$ for all $0 < i < j$, we have³

$$\begin{aligned} p_n(TM \oplus -\xi') &= \sum_{i=0}^n p_i(TM) \cdot p_{n-i}(-\xi') \\ &= \begin{cases} p_m(TM) + p_j(TM) \cdot p_{m-j}(-\xi') + p_m(-\xi') & \text{if } n = m \\ p_{m-j}(TM) + p_{m-j}(-\xi') & \text{if } n = m - j \\ p_n(TM) & \text{otherwise} \end{cases} \\ \langle p_j(TM \oplus -\xi') \cdot p_{m-j}(TM \oplus -\xi'), [S^k \times M] \rangle &= \langle p_j(TM) \cdot (p_{m-j}(TM) + p_{m-j}(-\xi')), [S^k \times M] \rangle \\ &= \langle p_j(TM) \cdot (-1)^{m-j+1}(2m-2j)!\lambda \cdot x \cdot u_k, [S^k \times M] \rangle \\ &= (-1)^{m-j+1}(2m-2j)!\lambda =: b \neq 0 \end{aligned}$$

$$\begin{aligned} \langle p_m(TM \oplus -\xi'), [S^k \times M] \rangle &= \langle p_m(TM) + p_j(TM) \cdot (p_{m-j}(TM) + p_{m-j}(-\xi')) + p_m(-\xi'), [S^k \times M] \rangle \\ &= (-1)^{m-j+1}(2m-2j)!\lambda + \langle (-1)^{m+1}(2m)!\lambda A \cdot u_k \cdot u_M, [S^k \times M] \rangle \\ &= \underbrace{(-1)^{m-j+1}\lambda(2m-2j)!}_{=b} + \underbrace{(-1)^{m+1}\lambda(2m)! \cdot A}_{=:c \neq 0} = b + c \cdot A \end{aligned}$$

We will choose A later. Note that every non-vanishing elementary Pontryagin number of $TM \oplus -\xi$ must contain a Pontryagin class of ξ . Otherwise it would be a Pontryagin number of TM of total degree $d+k$ which would evaluate trivially against $[S^k \times M]$. Therefore, any non-vanishing elementary Pontryagin-number of $TM \oplus -\xi$ must either contain p_{m-j} or p_m and since $p_i(TM) = 0$ for all $0 < i < j$, the above are the only possibly non-vanishing ones. It remains to compute the surgery obstruction using Hirzebruch's signature theorem:

$$\begin{aligned} \sigma(\eta) &= \text{sign}(W') = \langle \mathcal{L}(W'), [W'] \rangle = \langle \mathcal{L}(W'), f_*[S^k \times M] \rangle \\ &= \langle \mathcal{L}(S^k) \cdot \mathcal{L}(TM \oplus \xi), [S^k \times M] \rangle \\ &= \langle s_{j,m-j}p_j(TM \oplus \xi)p_{m-j}(TM \oplus \xi) + s_m p_m(TM), [S^k \times M] \rangle \\ &= (s_{j,m-j} + s_m)b + s_m \cdot c \cdot A. \end{aligned}$$

Since all coefficients s_{\dots} in the \mathcal{L} -polynomial are nonzero by [BB18], it follows that we can choose $A \neq 0$ such that $\sigma(\eta) = 0$. \square

³Since we are only interested in rational Pontryagin classes we have $p(V \oplus W) = p(V) \cdot p(W)$.

By the discussion in [Section 2](#), there exists a bundle $E \rightarrow S^k$ with the same two non-vanishing elementary Pontryagin numbers and by [\[FR21, Lemma 2.5\]](#) the \hat{A} -genus of E does not vanish. Also note that E is fibre homotopy equivalent to the trivial bundle.

Lemma 3.2. *If $j := \min\{i \geq 1 : p_i(TM) \neq 0\}$ is smaller than $d/4$, then there exists a bundle $E \rightarrow S^k$ as above that has a cross-section with trivial normal bundle.*

Proof. Let $\text{triv}: S^k \hookrightarrow S^k \times M$ be the trivial section. Since the bundle E constructed in [Lemma 3.1](#) is fibre homotopy equivalent to the trivial bundle via $f: S^k \times M \simeq E$ we get a section $s := f \circ \text{triv}: S^k \rightarrow E$. We have

$$\begin{aligned} s^*p_n(TE) &= \text{triv}^* \left(\sum_{i=0}^n p_i(TM) \cdot p_{n-i}(-\xi) \right) \\ &= \sum_{i=0}^n \underbrace{\text{triv}^* p_i(TM)}_{=0 \text{ for } i \geq 1} \cdot \text{triv}^* p_{n-i}(-\xi) = \text{triv}^* p_n(-\xi) \end{aligned}$$

Recall, that the only non-vanishing Pontryagin classes of ξ are p_{m-j} and p_m and let ν_s denote the normal bundle of s . Since the rank of this bundle is bigger than k , the bundle ν_s is stable in the sense that it is classified by an element in

$$\pi_k(BO) = \text{KO}^{-k}(\text{pt}) \cong \begin{cases} \mathbb{Z} & \text{for } k \equiv 0 \pmod{4} \\ \mathbb{Z}/2 & \text{for } k \equiv 1, 2 \pmod{8} \\ 0 & \text{otherwise} \end{cases}.$$

Since we are only interested in the problem rationally, it suffices to consider the case $k \equiv 0 \pmod{4}$. It follows, that ν_s is trivial if $p_{k/4}(\nu_s) = 0$ and as $p(S^k) = 1$, the Pontryagin class $p_{k/4}$ of ν_s satisfies

$$p_{k/4}(\nu_s) = p_{k/4}(s^*TE) = s^*p_{k/4}(TE) = \text{triv}^*p_{k/4}(\xi) = 0$$

since by our assumption $k/4 < \frac{d+k}{4} - j = m - j$ and p_{m-j} and p_m are the only Pontryagin classes of ξ . \square

Remark 3.3. If $d \not\equiv 0 \pmod{4}$, the requirement from the lemma is automatically full-filled. If $d \equiv 0 \pmod{4}$ and $j = d/4$, then M has only one non-vanishing Pontryagin number, namely $\langle p_{d/4}(TM), [M] \rangle$. Since all coefficients in the \hat{A} -polynomial are nonzero by [\[BB18\]](#), we have $\hat{A}(M) = a \cdot \langle p_{d/4}(TM), [M] \rangle \neq 0$ for some $a \in \mathbb{Z} \setminus \{0\}$. If additionally M admits a Spin-structure, then by the Lichnerowicz-formula and the Atiyah–Singer index theorem [\[AS63; Lic63\]](#), M does not support a metric of positive scalar curvature. Hence, for a Spin-manifold of positive scalar curvature, we have $j < d/4$ and [Lemma 3.2](#) applies.

From the discussion in the preceding section we get:

Proposition 3.4. *Let $k \geq 1$ and let M be an oriented, simply connected manifold of dimension $d \geq \max(3k + 1, 2k + 5)$ that has at least one non-vanishing Pontryagin class. If $d + k \equiv 0 \pmod{4}$, then there exists a smooth, oriented M -bundle $E \rightarrow S^k$ that is fibre homotopy equivalent to the trivial bundle and satisfies $\hat{A}(E) \neq 0$. If M admits a Spin-structure and a metric of*

positive scalar curvature, then the bundle admits a cross-section with trivial normal bundle.

- Remark 3.5.* (i) This recovers [HSS14, Theorem 1.4] and provides an upgrade: the result in loc.cit. is “based on abstract existence results [and] does not yield an explicit description of the diffeomorphism type of the fibre manifold” [HSS14, p. 337]. In contrast, our result states, that it is correct for generic manifolds.
- (ii) By [HSS14, Proposition 1.9] and [Wie19, Lemma 2.3] a bundle $M \rightarrow E \rightarrow S^k$ is rationally nullcobordant, if all rational Pontryagin classes vanish or if $\dim(M) < \frac{k}{2}$. This shows that both assumptions on M from Proposition 3.4 (and hence from Theorem A) are actually necessary, even though the dimension bound is not optimal (cf. Remark 2.3).

Recall that an oriented manifold M is called $\hat{\mathcal{A}}$ -multiplicative fibre in degree k if for every oriented M -bundle $E \rightarrow S^K$ we have $\hat{\mathcal{A}}(E) = 0$ (cf. [HSS14, Definition 1.8]). From Proposition 3.4 and Remark 3.5 (ii) we deduce the following corollary.

Corollary 3.6. *A manifold M of dimension $d \geq \max(3k+1, 2k+5)$ is an $\hat{\mathcal{A}}$ -multiplicative fibre in degree k if and only if all its rational Pontryagin classes vanish.*

3.2. Spin-structures and positive (scalar) curvature. Let M be Spin and let $B\text{Diff}^{\text{Spin}}(M)$ be the classifying space for M -bundles with a Spin-structure on the vertical tangent bundle⁴. By [Ebe06, Lemma 3.3.6] the homotopy fibre of the forgetful map $B\text{Diff}^{\text{Spin}}(M) \rightarrow B\text{Diff}(M)$ is a $K(\mathbb{Z}/2, 1)$ if M is simply connected. Therefore the induced map

$$\pi_n(B\text{Diff}^{\text{Spin}}(M)) \otimes \mathbb{Q} \longrightarrow \pi_n(B\text{Diff}(M)) \otimes \mathbb{Q}$$

is an isomorphism and we may assume without loss of generality that the bundles from Section 3 carry a Spin-structure on the vertical tangent bundle and hence on the total space, provided that M admits one.

It is a well known consequence of the Atiyah–Singer Index theorem and the Lichnerowicz formula that Spin-manifolds with non-vanishing $\hat{\mathcal{A}}$ -genus do not admit a metric of positive scalar curvature [AS63; Lic63]. Theorem A then follows from another standard argument that goes back to Hitchin [Hit74] (see [HSS14, Remark 1.5] or [FR21, Proposition 3.7]) from Proposition 3.4. Together with [Fre19a, Theorem A] (see also [Fre19b, Corollary E]) we also derive the following result.

Corollary 3.7. *Let M be a simply connected Spin-manifold of dimension at least 6 that admits a metric of positive scalar curvature. Then the action*

$$\pi_0(\text{Diff}(M)) \longrightarrow \pi_0 \text{hAut}(\mathcal{R}_{\text{scal}>0}(M))$$

factors through a finite group if and only if $d \not\equiv 3(4)$ or $d \equiv 3(4)$ and all Pontryagin classes of M vanish.

⁴A model for $B\text{Diff}^{\text{Spin}}(M)$ is given by

$$B\text{Diff}^{\text{Spin}}(M) := \{(N, \hat{\ell}_N), M \cong N \subset \mathbb{R}^\infty, \hat{\ell}_N \in \text{Bun}(TN, \theta^* U_d)\}$$

for $\theta: B\text{Spin}(d) \rightarrow BSO(d)$ the 2-connected cover, $U_d \rightarrow BSO(d)$ the universal oriented vector bundle and $\text{Bun}(_, _)$ the space of bundle maps.

[Theorem A](#) also recovers [HSS14, Theorem 1.1 a)]:

Corollary 3.8. *Let $k \geq 1$ and let N be a Spin-manifold with $\dim(N) = d \geq \max(3k + 1, 2k + 5)$ and $d + k \equiv 0 \pmod{4}$. Then $\pi_{k-1}(\mathcal{R}_{\text{scal}>0}(N))$ contains an element of infinite order.*

Proof. Let K be a $K3$ -surface. Then for $n := d - 4 \geq 2$, the manifold $K \times S^n$ satisfies the hypothesis of [Theorem A](#) and there is a $K \times S^n$ -bundle $E \rightarrow S^k$ that has non-vanishing $\hat{\mathcal{A}}$ -genus and admits a cross section with trivial normal bundle. If N is an arbitrary Spin-manifold of dimension $d \geq 6$, then gluing in the trivial $N \setminus D^d$ -bundle along this cross section yields a $N \# (K \times S^{d-4})$ -bundle over S^k with non-vanishing $\hat{\mathcal{A}}$ -genus. Hence the group $\pi_{k-1}(\mathcal{R}_{\text{scal}>0}(N \# (K \times S^{d-4})))$ contains an element of infinite order. Since N is cobordant to $N \# (K \times S^{d-4})$ in $\Omega_{\text{Spin}}^d(B\pi_1(N))$, the corresponding spaces of positive scalar curvature metrics are homotopy equivalent. \square

Remark 3.9. A more general result without any dimension restriction has been proven by Botvinnik–Ebert–Randal-Williams [BERW17]. The methods from loc.cit. are however not constructive and do not give a way to decide if the obtained elements arise from the orbit of the action $\text{Diff}(M) \curvearrowright \mathcal{R}_{\text{scal}>0}(M)$.
