(Dated: May 21, 2021)

Coherence distillation is a central topic of the resource theory of coherence and various coherence distillation protocols were proposed. In this paper, we investigate the optimal probabilistic coherence distillation protocol, whose aim is to transform a coherent state into a set of $n$-level maximally coherent states by using strictly incoherent operations. Specifically, we accomplish this protocol by presenting an analytical expression for the maximal average distillable coherence for a general state and constructing the corresponding operation achieving this bound. Our protocol is a universal protocol since it can be applied to any coherence measure.

I. INTRODUCTION

Quantum coherence is an important feature of quantum mechanics which is responsible for the departure between the classical and quantum world. It is an essential component in quantum information processing \cite{1}, and plays a central role in various fields, such as quantum computing \cite{2,3}, quantum cryptography \cite{4}, quantum metrology \cite{5,6}, and quantum biology \cite{7}. Recently, the resource theory of coherence has attracted a growing interest due to the rapid development of quantum information science \cite{8–11}. The resource theory of coherence not only establishes a rigorous framework to quantify coherence but also provides a platform to understand quantum coherence from a different perspective.

Any quantum resource theory is characterized by two fundamental ingredients, namely, the free states and the free operations \cite{12–14}. For the resource theory of coherence, the free states are quantum states which are diagonal in a prefixed reference basis. However, the free operations are not uniquely specified. Motivated by suitable practical considerations, several free operations were presented \cite{8,9,15–21}. In this paper, we focus our attention on the strictly incoherent operations. The strictly incoherent operations are first proposed in Ref. \cite{16}. In Ref. \cite{17}, it was shown that these operations neither create nor use coherence and have a physical interpretation in terms of interferometry. Thus, the set of strictly incoherent operations is a physically well-motivated set of free operations for the resource theory of coherence.

When we perform a quantum information processing task, it is usually the pure coherent states playing the central role \cite{1}. However, a pure state easily becomes a mixed state due to the interaction with the environment. Thus, to obtaining pure coherent states, various coherence distillation protocols, that is, the protocols that transform a general coherent state into pure states by using various free operations, were proposed. These protocols can be divided into two classes: the asymptotic coherence distillation and the one-shot coherence distillation. The asymptotic coherence distillation of pure states and mixed states was studied in Refs. \cite{16,22}, where the coherence distillation of pure and mixed states by using incoherent operations was studied. Their results show that, in the asymptotic limit, infinite copies of a state can be transformed into copies of maximally coherent states by using collective incoherent operations. To relax several unreasonable assumptions of the asymptotic regime, i.e., unbounded number copies of identical states and collective operations, several one-shot coherence distillation protocols were proposed and explored \cite{23–39}.

We study one of the one-shot coherence distillation protocol, the optimal probabilistic coherence distillation in this paper. The aim of this protocol is to transform a given coherent state $\rho$ into a set of $n$-level maximally coherent states by using strictly incoherent operations as illustrated in Fig. 1 and, here, the optimal means that the average distillable coherence of the final ensemble is maximal. This protocol, inspired by an entanglement distillation protocol in Refs. \cite{40,41}, was first proposed in Ref. \cite{31}. Specifically, with the help of the $l_1$ norm of coherence, Torun et al. present an analytical expression for the maximal average distillable coherence by using strictly incoherent operations and construct the corresponding strategy for pure states \cite{31}. However, since we often encounter mixed states rather than pure states, an immediate question is how to extend this protocol to the mixed states case.

FIG. 1. Optimal probabilistic distillation of quantum coherence. This figure describes the protocol that transforms a general state $\rho$ into a set of $n$-level maximally coherent states $|\psi^n\rangle$ with $n = 1, \ldots, d$ by using strictly incoherent operations $\Lambda(\cdot)$.

In this paper, we address this question by extending the optimal probabilistic coherence distillation protocol to the mixed state case. Specifically, with the help of the simplex algorithm, we determine analytically the maximal average distillable coherence for an arbitrary state by using strictly incoherent operations and construct the corresponding operation

* suncp@gscaep.ac.cn
achieving this bound. The rest of this paper is organized as follows. We first recall some notions of the resource theory of coherence which are useful in this paper. Then, we present the protocol of optimal probabilistic coherence distillation for mixed states. Finally, we present our remarks and conclusions.

II. RESOURCE THEORY OF COHERENCE

Let $\mathcal{H}$ be the Hilbert space of a $d$-dimensional quantum system. A particular basis of $\mathcal{H}$ is denoted as $|i\rangle$, $i = 1, 2, \ldots, d$, which is chosen according to the physical problem under discussion. Coherence of a state is then measured based on the basis chosen. Specifically, a state is said to be incoherent if it is diagonal in the basis. Any state which cannot be written as a diagonal matrix is defined as a coherent state. For a pure state $|\varphi\rangle$, we will denote $|\varphi\rangle\langle\varphi|$ as $\varphi$, i.e., $\varphi := |\varphi\rangle\langle\varphi|$. And we will denote $|\psi^d\rangle = \frac{1}{\sqrt{n}} \sum_{i=1}^{d} |i\rangle$ as a $d$-dimensional maximally coherent state [9] and

$$|\psi^d\rangle = \frac{1}{\sqrt{n}} \sum_{i=1}^{n} |i\rangle, \text{ for } 1 \leq n \leq d$$

as an $n$-level maximally coherent state with $n = 1$ being an incoherent state.

A strictly incoherent operation is a completely positive trace preserving map, expressed as

$$\Lambda(\rho) = \sum_{a=1}^{N} K_{a}\rho K_{a}^{\dagger},$$

where the Kraus operators $K_{a}$ satisfy not only $\sum_{a=1}^{N} K_{a}^{\dagger}K_{a} = I$ but also $K_{a}IK_{a}^{\dagger} \subset I$ and $K_{a}IK_{a}^{\dagger} \subset I$ for every $K_{a}$, i.e., each $K_{a}$ as well $K_{a}^{\dagger}$ maps an incoherent state to an incoherent state [16, 17]. Here, $I$ represents the set of incoherent states. It is direct to prove that there is at most one nonzero element in each column (row) of $K_{a}$, and such a $K_{a}$ is called a strictly incoherent Kraus operator. With this definition, it is elementary to show that a projector is an incoherent operator if and only if it has the form $\mathbb{1}_{1} = \sum_{i=1}^{d} |i\rangle\langle i|$ with $1 \subset \{1, \ldots, d\}$. In what follows, we will denote $\mathbb{1}_{1}$ as strictly incoherent projective operators. The dephasing map, which we will denote it as $\Delta(\cdot)$, is defined as $\Delta(\rho) = \sum_{i=1}^{d} |i\rangle\langle i|\rho|i\rangle\langle i|$. A stochastic strictly incoherent operation is constructed by a subset of strictly incoherent Kraus operators. Without loss of generality, we denote the subset as $\{K_{1}, K_{2}, \ldots, K_{L}\}$. Otherwise, we may renumber the subscripts of these Kraus operators. Then, a stochastic strictly incoherent operation [25], denoted as $\Lambda_{s}(\rho)$, is defined by

$$\Lambda_{s}(\rho) = \frac{\sum_{a=1}^{L} K_{a}\rho K_{a}^{\dagger}}{\text{Tr}(\sum_{a=1}^{L} K_{a}\rho K_{a}^{\dagger})}$$

where $\{K_{1}, K_{2}, \ldots, K_{L}\}$ satisfies $\sum_{a=1}^{L} K_{a}^{\dagger}K_{a} \leq I$. Clearly, the state $\Lambda_{s}(\rho)$ is obtained with probability $P = \text{Tr}(\sum_{a=1}^{L} K_{a}\rho K_{a}^{\dagger})$ under a stochastic strictly incoherent operation $\Lambda_{s}$, while state $\Lambda(\rho)$ is fully deterministic under a strictly incoherent operation $\Lambda$.

A functional $C$ can be taken as a measure of coherence if it satisfies the four conditions [9, 17]: (C1) the coherence being zero for incoherent states; (C2) the monotonicity of coherence under incoherent operations or strictly incoherent operations; (C3) the monotonicity of coherence under selective measurements on average; and (C4) the non-increasing of coherence under mixing of quantum states. In accordance with the four conditions, various coherence measures have been put forward. Out of them, we consider the relative entropy of coherence $C_{r}$ [9], the $l_{1}$ norm of coherence $C_{I}$ [9], and the coherence rank $C_{R}$ [16, 42], which will be used in this paper. The relative entropy of coherence $C_{r}(\rho)$ of a state $\rho$ is defined as $C_{r}(\rho) = S(\Delta \rho) - S(\rho)$, where $S(\rho) = -\text{Tr}(\rho \ln \rho)$ is the von Neumann entropy. The $l_{1}$ norm of coherence is defined as $C_{I}(\rho) = \sum_{i} |\rho_{i}|$. The coherence rank $C_{R}$ of a pure state (not necessarily normalized), $|\varphi\rangle = \sum_{i=1}^{R} c_{i} |i\rangle$ with $c_{i} \neq 0$, is defined as the number of nonzero terms of $c_{i} \neq 0$ minus 1 [43], i.e., $C_{R}(\varphi) = R - 1$.

III. OPTIMAL PROBABILISTIC DISTILLATION OF QUANTUM COHERENCE

With the above notations, we are ready to present the main results of this paper. The protocol of the optimal probabilistic coherence distillation of quantum coherence can be formally posed as follows:

Given a $d$-dimensional state $\rho$, we want to transform it into a set of $n$-level maximally coherent states by using strictly incoherent operations, that is, we want to accomplish the transformation

$$\rho \xrightarrow{\text{SIO}} \{p_{n}, |\psi^{n}\rangle\}$$

with the coherence of the final ensemble, $C = \sum_{n} p_{n} C(\psi^{n})$, as large as possible. Here, $C$ is an arbitrary coherence measure fulfilling (C1)-(C4).

To present our main results more clearly, we will present it as the following three steps:

First, we show that, for a given state, it is the pure coherent-state subspaces that are useful in the optimal probabilistic distillation protocol.

The task of transforming a given state $\rho$ into a family of $n$-level maximally coherent states implies that we can obtain a special class of pure states from $\rho$ by using stochastic strictly incoherent operations. As we have shown that in Ref. [37], one can obtain a pure coherent state $|\varphi\rangle$ with its coherence rank being $m$ from a mixed state $\rho$ by using stochastic strictly incoherent operations and only if there is an incoherent projective operator $P$ such that

$$\frac{\mathbb{1}_{P\rho P}}{\text{Tr}(P\rho P)} = |\psi\rangle$$

is a pure state and the coherence rank of $|\psi\rangle$ is equal to or greater than $m$. This implies that it is the parts of $\rho$ such that $\frac{\mathbb{1}_{P\rho P}}{\text{Tr}(P\rho P)}$ being pure states are useful in this distillation protocol. For the sake of simplicity, we will call these parts as the pure coherent-state subspaces of $\rho$. More precisely, if there
is an incoherent projector \( P \) such that \( P \rho P = \varphi \) with the coherence rank of \( \varphi \) being \( n \geq 0 \), then we say that \( \rho \) has an \( n + 1 \)-dimensional pure coherent-state subspace corresponding to \( P \). Furthermore, we say that the pure coherent-state subspaces with the projector \( P \) for \( \rho \) is maximal if the pure coherent-state subspace cannot be expanded to a larger one with the incoherent projector \( P' \) such that \( P' \rho P' = \varphi' \), \( \varphi' \neq \varphi \), and \( P \varphi' P = \varphi \). For a state \( \rho \), we can identify the pure coherent-state subspaces of a mixed state with the aid of

\[
\mathcal{A} = (\Delta \rho)^{-\frac{1}{2}} |\psi(\Delta \rho)^{-\frac{1}{2}},
\]

which was presented in Ref. [25]. Here, for \( \rho = \sum_{ij} \rho_{ij} |i\rangle \langle j| \), the \( |\psi\rangle \) reads \( |\psi\rangle = \sum_{ij} |\psi_{ij}| |i\rangle \langle j| \) and \((\Delta \rho)^{-\frac{1}{2}} \) is a diagonal matrix with elements

\[
(\Delta \rho)^{-\frac{1}{2}}_{ii} = \begin{cases} \rho_{ii}^{-\frac{1}{2}}, & \text{if } \rho_{ii} \neq 0; \\ 0, & \text{if } \rho_{ii} = 0. \end{cases}
\]

It is straightforward to show that \( \rho \) is a pure state if and only if all the elements of \( \mathcal{A} \) are 1 [25]. From this, we can obtain that if there is a \( n \)-dimensional principal submatrices \( \mathcal{A}_n \) of \( \mathcal{A} \) with all its elements being 1, then the corresponding subspace of \( \rho \) is an \( n \)-dimensional pure coherent-state subspace. By using this result, one can easily identify the pure coherent-state subspaces of \( \rho \).

Second, we show that, to obtain the optimal probabilistic distillation protocol, we only need to consider the maximal pure coherent-state subspaces of \( \rho \).

To show this, let us recall the necessary and sufficient conditions for transforming a pure coherent state \( |\varphi\rangle \) into a set of pure coherent states \( \{|\varphi_n\rangle\}_{n=1}^k \) by using strictly incoherent operations. These conditions, which were presented in Ref. [19], say that the transformation \( |\varphi\rangle \rightarrow \{|\varphi_n\rangle\}_{n=1}^k \) is possible by using strictly incoherent operations if and only if there are \( C_i(\varphi) \geq \sum_{l=1}^d p_l C_i(\varphi_l) \), \( 1 \leq i \leq d \), where \( |\varphi_l\rangle = \sum_{i=1}^d c_i |i\rangle \) with the assumption that \( |c_1| \geq |c_2| \geq \cdots \geq |c_d| \),

\[
C_i(\varphi) := \sum_{j=1}^d |c_j|^2, \quad 1 \leq i \leq d.
\]

In our protocol, as we want to obtain a set of \( n \)-level maximally coherent states, thus we only consider the final states are \( \{|\varphi_n\rangle\}_{n=1}^k \). Hence, the conditions presented above become \( C_i(\varphi) \geq \sum_{n=1}^k p_n C_i(\varphi_n) \), that is,

\[
\sum_{j=1}^d |c_j|^2 \geq \sum_{n=1}^k \sum_{j=1}^d p_n \left( \frac{n-j+1}{n} \right).
\]

With the constraints in Eq. (8), the average amount distillable coherence, is

\[
\overline{C}(\varphi) = \sum_{n=1}^k p_n f(n),
\]

where \( f(n) \) is the value of \(|\varphi_n\rangle\) under some specific coherence measure, e.g., \( f(n) = \ln_2 n \) for the relative entropy of coherence, with \( f(n) \geq f(n-1) \geq \cdots \geq f(2) > f(1) = 0 \). Thus, the problem of maximal \( \overline{C}(\varphi) \) with the constraints in Eq. (8) can be expressed as the following linear programming problem

\[
\begin{align*}
\text{maximize} & \quad \mathbf{c}^T \mathbf{p} \\
\text{subject to} & \quad \mathbf{A}\mathbf{p} \leq \mathbf{q}, \quad \mathbf{p} \geq 0
\end{align*}
\]

where, with the superscript \( T \) being transpose, \( \mathbf{c}, \mathbf{p}, \) and \( \mathbf{q} \) are

\[
\mathbf{c} = (f(1), f(2), \cdots, f(d))^T, \\
\mathbf{p} = (p_1, p_2, \cdots, p_d)^T, \\
\mathbf{q} = (C_1(\varphi), C_2(\varphi), \cdots, C_d(\varphi))^T,
\]

and from Eq. (8) the matrix \( \mathbf{A} \) can be expressed as

\[
\mathbf{A} = \begin{pmatrix}
1 & 1 & 1 & \cdots & 1 \\
0 & \frac{1}{2} & \frac{1}{2} & \cdots & \frac{1}{2} \\
0 & 0 & \frac{3}{2} & \cdots & \frac{3}{2} \\
\vdots & \vdots & \vdots & \ddots & \vdots \\
0 & 0 & 0 & \cdots & 1
\end{pmatrix}
\]

(11)

Next, we obtain the maximum in Eq. (10) i.e., the maximal \( \overline{C}(\varphi) \), by using the simplex algorithm [44]. To this end, let us reformulate this problem into the standard form where all the constraints are expressed as equalities by introducing variables \( p_i, \geq 0 \), that is, converted \( a_{i1} p_1 + a_{i2} p_2 + \cdots + a_{id} p_d \leq \overline{C}_i(\varphi) \) into \( a_{i1} p_1 + a_{i2} p_2 + \cdots + a_{id} p_d + p_i = \overline{C}_i(\varphi) \), where \( p_i \geq 0 \) with \( n+1 \leq i \leq 2n \). Here, \( p_i \) are called slack variables. With the help of \( p_i \), the problem in Eq. (10) can be reexpressed as

\[
\begin{align*}
\text{maximize} & \quad \mathbf{c}'^T \mathbf{p}' \\
\text{subject to} & \quad \mathbf{B}\mathbf{p}' = \mathbf{q}, \quad \mathbf{p}' \geq 0
\end{align*}
\]

where \( \mathbf{c}' = (f(1), f(2), \cdots, f(d), 0, 0, \cdots, 0)^T, \)

\[
\mathbf{B} = \begin{pmatrix}
1 & 1 & 1 & \cdots & 1 & 1 & 0 & 0 & \cdots & 0 \\
0 & \frac{1}{2} & \frac{1}{2} & \cdots & \frac{1}{2} & 0 & 1 & 0 & \cdots & 0 \\
0 & 0 & \frac{3}{2} & \cdots & \frac{3}{2} & 0 & 0 & 1 & \cdots & 0 \\
\vdots & \vdots & \vdots & \ddots & \vdots & \vdots & \vdots & \vdots & \ddots & \vdots \\
0 & 0 & 0 & \cdots & 1 & 0 & 0 & 0 & \cdots & 1
\end{pmatrix}
\]

(13)

and \( \mathbf{p}' = (p_1, p_2, \cdots, p_d, p_{d+1}, \cdots, p_{2d})^T \). The standard form in Eq. (12) can be further converted to a table as shown in Table I. In Table I, \( b_{ij} \) is the \( j \)-th column of the matrix \( \mathbf{B} \) in Eq. (13), the left-most column indicates the basic variables, the next \( 2d \) columns contain the coefficients for the \( d \) original variables and the \( d \) slack variables, and the right most column is for constants \( q_i \) with \( i = 1, \ldots, d \). The variables corresponding to the columns of the identity matrix are called basic variables, as shown in the left-most column, such as \( p_{d+1}, \cdots, p_{2d} \), while the remaining variables are called free variables, such as \( p_1, \cdots, p_d \). A feasible solution of Eq. (12) is a vector \( \mathbf{p}' \) fulfilling both \( \mathbf{B}\mathbf{p}' = \mathbf{q} \) and \( \mathbf{p}' \geq 0 \).

With these notions, we can give a sketch of the steps of the simplex algorithm (See [44] for details). The first step of the simplex algorithm is to set the basic variables, \( p_{d+i} = q_i \) for \( i = 1, \cdots, d \), while the free variables are set to \( p_i = 0 \) for \( i = 1, \cdots, d \). It is obvious that the value of the objective function is 0 at this time. Next, by carrying out Gaussian elimination, we can generate a new feasible solution.
from an old one by replacing one basic variable by a free variable while preserving the nonnegativity of the solution Ref. [45]. For example, let us transform $p_2$ from a non-basic variable into a basic variable. Without loss of generality, we assume that there is $q_1 \geq 2q_2$. Then, by direct calculation, we obtain the Table II. In Table II, there are $c_i = -f(i)+2(\frac{i}{d})$ with $i=3, \cdots, d$. We note that, at this time, the basic variables transform from $p_{d+1}, p_{d+2}, p_{d+3}, \cdots, p_{2d}$ into $p_{d+1}, p_2, p_{d+3}, \cdots, p_{2d}$. The value of the objective function has turned into $2q_2$. The procedure continues until all elements $c_i$ with $i=1, \cdots, 2d-1$ of the last lines are all nonnegative, which is a sufficient condition for obtaining the maximum in Eq. (12) [44]. For the problem in Eq. (12), let us consider a special form of it where we select $p_1, p_2, \cdots, p_d$ as basic variables. By direct calculation, we can obtain the table III. In Table III, there are $c_{d+i} = f(i)$, responds to the $i$-th element of the vector $b_j$. With these relations, we further obtain $Q_j = \sum_{i=1}^{d} c_i |i|$. Thus, we cannot obtain a larger value than that in Eq. (14). We assume there is $m = 2$, the generalization to $m > 2$ is straightforward, that is, divide $|\varphi_i| = \sum_{i=1}^{d} c_i |i|$ into $|\varphi_1| = \frac{1}{\sqrt{1-p}} \sum_{i=1}^{m} c_i |i|$ with probability $p = \frac{m}{\sum_{i=1}^{d} c_i ^2}$ and $|\varphi_2| = \frac{1}{\sqrt{1-p}} \sum_{i=m+1}^{d} c_i |i|$ with probability $1-p$. Then, by direct calculations, the maximal average distillable coherence we can obtain is $\bar{C} = \frac{m}{\sum_{i=1}^{d} c_i ^2} \sum_{i=1}^{m} c_i |i| f(i) + \sum_{i=m+1}^{d} c_i |i| (i-m) f(i) - m f(n)$, where we have used $f(n) \geq f(n-1) \geq \cdots \geq f(2) > f(1) = 0$. From this, it is straightforward to examine the relation that $Q \geq \bar{C}$. Thus, we have obtained that, to obtain the optimal probabilistic distillation protocol, we only need to consider the maximal pure coherent-state subspaces of $\rho$.

Third, we present the maximal average distillable coherence and an explicit protocol achieving this bound.

For a state $\rho$, the corresponding Hilbert subspaces of principal submatrices $\mathcal{A}_i$ with $\mu = 1, \cdots, \mathcal{U}$ be $\mathcal{H}_\mu$, which is spanned by $\{|\ell'_1\rangle, |\ell'_2\rangle, \cdots, |\ell'_d\rangle\} \subset \{|1\rangle, |2\rangle, \cdots, |d\rangle\}$. And we denote the corresponding incoherent projective operators as $\rho_\mu$, with the rank of it being $d_\mu$, i.e.,

$$\rho_\mu = |\ell'_1\rangle \langle \ell'_1| + |\ell'_2\rangle \langle \ell'_2| + \cdots + |\ell'_d\rangle \langle \ell'_d|.$$  

Performing $\{\rho_\mu\}$ on the state $\rho$, we then obtain the set $\{\varphi_\mu\}_{\mu=1}^U$, which have the form as

$$\frac{\langle \rho_\mu \varphi_\mu \rangle}{\text{Tr}(\rho_\mu \rho_\mu)} = \varphi_\mu.$$  

From the analysis in the second step, we get that in order to obtaining the optimal protocol, we should seek out each maximal pure coherent-state subspaces. Let the pure states corresponding to maximal pure coherent-state subspaces be

$$\rho_\mu = \frac{\langle \rho_\mu \varphi_\mu \rangle}{\text{Tr}(\rho_\mu \rho_\mu)} = \varphi_\mu.$$  

Here, $\rho_\mu$ are the incoherent projectors corresponding to maximal pure coherent-state subspaces. Then, after applying the incoherent projectors $\{\rho_\mu\}$ to $\rho$, we obtain a set of pure states $\varphi_\mu$ with probability $p_\mu = \text{Tr}(\rho_\mu \rho_\mu)$, i.e., there is

$$\Lambda_\mu(\rho) = \frac{q_\mu}{\mu=1} \frac{\rho_\mu}{\text{Tr}(\rho_\mu \rho_\mu)} = \frac{q_\mu}{\mu=1} \rho_\mu \varphi_\mu.$$

| 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | $Q_5$ |

$$Q_i = b_{(d+i)} q_i + b_{(d+i+1)} q_{i+1} + b_{(d+i+2)} q_{i+2}, \text{ where } b_{(d+i)} = i, b_{(d+i+1)} = -2i, \text{ and } b_{(d+i+2)} = i, c_{d+i} = f(i). \text{ Here, } b_i \text{ corres}$
For every $|\varphi_\mu^m\rangle = \sum_{n=1}^{d_\mu} c_n^\mu |i\rangle$, we can construct a strictly incoherent operation as

$$\Lambda_\mu(\cdot) = \sum_{n=1}^{d_\mu} K_n^\mu (\cdot) K_n^\mu,$$

where $K_n^\mu = \sqrt{p_n (\sum_{i=1}^{d_n} |\varphi_i^\mu\rangle \langle \varphi_i^\mu|)}$ with $p_n = d_n |c_n^\mu|^2$ and $p_n = n(|c_n^\mu|^2 - |c_{n+1}^\mu|^2)$ for $n = 1, \cdots, d_n - 1$. With the help of $\Lambda_\mu(\cdot)$, we arrive at the corresponding operation acting on $\rho$ which has the form as

$$\Lambda(\cdot) = \oplus_{\mu=1}^{q} \Lambda_\mu(\cdot).$$

As it is straightforward to examine that $\sum_{n=1}^{d_n} K_n^\mu K_n^\mu = I_{d_n}$ and there is at most one nonzero element in each column and row of $K_n^\mu$, thus $\Lambda(\cdot)$ is a strictly incoherent operation. By using the analysis of the first and second steps, we obtain that maximal average distillable coherence of the state in Eq. (15) corresponds to the maximal average distillable coherence of $\rho$. Since, in the optimal protocol, we obtain the $n$-level maximally coherent state with probability $p_n = \sum_{\mu=1}^{q} p_\mu (n(|c_n^\mu|^2 - |c_{n+1}^\mu|^2))$ from $\rho$, then the optimal average distilled coherence of $\rho$ is

$$\overline{C}_{\text{max}}(\rho) = \sum_{\mu=1}^{q} \sum_{n=1}^{d_n} p_\mu (|c_n^\mu|^2 - |c_{n+1}^\mu|^2) n f(n).$$

We can then summarize the above results as the following Theorem.

Theorem. For any state $\rho$, let the state corresponding to its maximal pure coherent-state subspaces be $\Lambda(\rho) = \bigoplus_{\mu=1}^{q} p_\mu \varphi_\mu^m$, then the maximal average distillable coherence of it is

$$\overline{C}_{\text{max}}(\rho) = \sum_{\mu=1}^{q} \sum_{n=1}^{d_n} p_\mu (|c_n^\mu|^2 - |c_{n+1}^\mu|^2) n f(n).$$

The corresponding strictly incoherent operation is

$$\Lambda(\cdot) = \bigoplus_{\mu=1}^{q} \sum_{n=1}^{d_n} K_n^\mu (\cdot) K_n^\mu,$$

where $K_n^\mu = \sqrt{p_n (\sum_{i=1}^{d_n} |\varphi_i^\mu\rangle \langle \varphi_i^\mu|)}$ with $p_n = d_n |c_n^\mu|^2$ and $p_n = n(|c_n^\mu|^2 - |c_{n+1}^\mu|^2)$ for $n = 1, \cdots, d_n - 1$.

In particular, if the initial state is a pure state and the coherence measure we chosen is the $l_1$ norm of coherence, i.e., $f(n) = C_{l_1}(\psi^n) = n - 1$, then we can obtain the results in Ref. [31].

Before concluding, we would like to stress that, although the performance of pure states in the above protocol is identical for incoherent operations, which was given in [9], and strictly incoherent operations [31], there is an operational gap between them when the state is a mixed one. To show this, let us consider the state

$$\rho = \begin{pmatrix}
\frac{1}{4} & 0 & \frac{1}{4} \\
0 & \frac{1}{4} & \frac{1}{4} \\
\frac{1}{4} & \frac{1}{4} & 0
\end{pmatrix}.$$

It is straightforward to examine that there is not an incoherent projective operator $\mathbb{P}$ such that the coherence rank of $\mathbb{P} \rho \mathbb{P}$ is equal to or larger than 1. This means that, from the Theorem, we cannot obtain any $n(\ge 2)$-level maximally coherent state with nonzero probability from it by using strictly incoherent operations. However, this is not the case if we choose incoherent operations. To see this, let the operation be $\Lambda(\cdot) = K_1(\cdot) K_1^\dagger + K_2(\cdot) K_2^\dagger$, where

$$K_1 = \begin{pmatrix}
\frac{1}{4} & \frac{1}{4} & 0 & 0 \\
0 & \frac{1}{4} & \frac{1}{4} & \frac{1}{4} \\
0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0
\end{pmatrix}, \quad K_2 = \begin{pmatrix}
\frac{-1}{2} & \frac{1}{2} & 0 & 0 \\
0 & \frac{-1}{2} & \frac{1}{2} & \frac{1}{2} \\
0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0
\end{pmatrix}.$$

By applying $\Lambda$ to $\rho$, we obtain that $\Lambda(\rho) = \psi^2$. This implies that the maximal average distillable coherence of $\rho$, $\overline{C}(\rho)_{\text{max}}$, is equal to or larger than $f(2) > 0$. This example tells us that incoherent operations are stronger than strictly incoherent operations when we preform this protocol.

IV. CONCLUSIONS

Quantum coherence is a useful physical resource, describing the ability of quantum system to perform quantum information tasks. Since it is usually the pure states play the central role when we perform a quantum information task, various coherence distillation protocols were proposed. In this paper, we have studied the optimal probabilistic coherence distillation, where the optimal means that the average distillable coherence of the final ensemble is maximal. With the help of the simplex algorithm, we have accomplished this protocol by extending it to the mixed states case. Specifically, we have presented an analytical expression for the maximal average distillable coherence for a general state and constructed the corresponding operation. Interestingly, our protocol can be applied to any coherence measure. Our protocol provides a practical protocol for efficient quantum coherence manipulation of mixed states. Finally, we would like to point out that strictly incoherent operations can always be constructed by the system interacting with an ancilla and a general experimental setting has been suggested based on an interferometer in Ref. [17]. Thus, our scheme of the optimal probabilistic coherence distillation of a state may be experimentally demonstrated.

[43] We should note that the coherence rank defined in [16], $C_\epsilon(\varphi) = R$, does not fulfill (C1). Thus, in this paper, we defined it as $C_\epsilon(\varphi) = R - 1$ to avoid this (See [42]).

[45] To avoid the negativity, we may transform the $p_i$ corresponding to $|i\rangle \min \frac{q_i}{|b_i|}$ with $|b_i| > 0$ from a free variable into a basic variable (See Ref. [44] for details).
