Abstract: We explore the hyperbolic band theory under a magnetic field for the first time. Our theory is a general extension of the conventional band theory defined on a Euclidean lattice into the band theory on a general hyperbolic lattice/Riemann surface. Our methods and results can be confirmed experimentally by circuit quantum electrodynamics (cQED), which enables us to create novel materials in a hyperbolic space. To investigate the band structures, we construct directly the hyperbolic magnetic Bloch states and find that they form Dirac cones on a coordinate neighborhood, by which they can be regarded as a global quantum gravity solution detectable in a laboratory. Besides this is the first explicit example of a massless Dirac state on a higher genus surface. Moreover we show that the energy spectrum exhibits an unusual fractal structure refracting the negative curvature, when plotted as a function of a magnetic flux.

1 Introduction

Circuit quantum electrodynamics (cQED) is an architecture for studying quantum information and quantum optics, in which artificial atoms/superconducting qubits are coupled to photon in a one-dimensional on-chip resonator [1–6]. The field of cQED provides a platform for quantum simulation of quantum many-body systems, and is a promising candidate for universal quantum computation. As those references show, quantum simulation with cQED has been considered for materials in the Euclidean geometry for more than a decade. More recently, a new experimental realization of hyperbolic lattices in cQED was presented [7]. This seminal work opens up a new direction for quantum simulation of materials in a curved space and implementation of holographic error correction codes [8, 9] is of a practical interest, not only for high energy physics but also for universal quantum computation. In fact a hyperbolic space, which has some negative curvature, cannot be isometrically embedded in the Euclidean space. Therefore there have been some technical difficulties in experimental study on materials in a hyperbolic space. So developing such a geometrically deformable quantum simulator endows us with a significant advantage in studying quantum physics in a curved space-time. In particular, understanding quantum mechanical phenomena in a non-Euclidean geometry in the presence of gravity is one of the most important challenges for the modern physicists. Furthermore information processing on a hyperbolic lattice has some practical and crucial meanings for information technology [10, 11], where it is argued that the connectivity of the internet is given by a hyperbolic map.

Motivated by this novel experimental environment of quantum simulation with cQED, we construct the first generalization of Bloch band theory on hyperbolic lattices under a magnetic field perpendicular to the system (Fig. 1). We aim at creating and investigating a theory of such a new class of materials, based on Riemann surface theory and algebraic geometry. In fact, the pairwise identification of sides of a unit cell of a hyperbolic $4g$-gon with the Fuchsian group gives a compact Riemann surface of genus $g \geq 2$. Band theory on a hyperbolic lattices without a magnetic field was studied in [12, 13] and recently developed in [14] more formally. So our theory is a natural, general and formal extension of the conventional band theory with Bloch states on a Euclidean lattice into that on a hyperbolic lattice. For any Hamiltonian with the $\{4g, 4g\}$ tessellation symmetry of the hyperbolic plane, we derive eigenstates associated with the magnetic Bloch conditions under the magnetic Fuchsian group of the tessellation, which is discrete but non-commutative. The magnetic Bloch states are generalized to automorphic functions. The construction of such a band theory on a hyperbolic lattice with a constant negative curvature is extremely non-trivial due to the absence of commutative translation symmetries. In fact, imposing the magnetic Bloch condition is not straightforwardly applicable to the hyperbolic band theory. To circumvent such a technical difficulty, we create the notion of magnetic Fuchsian group so that the Hamiltonian becomes simultaneously diagonalizable with the magnetic translations. Those mathematical and technical subjects are summarized in Sec. A. Although the Bloch wavefunctions were first introduced to describe the propagation of electrons in crystalline solids, this phenomenon applies to a generic propagation of wave-like phenomenon in a periodic system, including atomic matter waves in optical lattices, light in photonic crystals, and sound in acoustic systems. In fact the Bloch theorem states that solutions of the Schrödinger equation in a periodic potential correspond to plane waves. The periodicity of the underlying system is crucial for the existence of a Bloch state. In our case, the tessellation symmetry and the magnetic Fuchsian group guarantee this condition.

This study will contribute to a wide range of fields, including material design, condensed matter physics, quantum computation/simulation, high energy physics and mathematical physics. The rest of this article is organized as follows. In Sec. 2 we describe our system and prepare the Hamiltonian. In Sec. 3 we present our numerical results of band structures under a magnetic field. We report that they form Dirac cones, which implies that there are massless states obeying the Dirac equation.
on a coordinate neighborhood. This is the first explicit example of the Dirac states on a higher genus surface. We may link them to a theory of quantum gravity since they live in a hyperbolic space, which is a time slice of the three dimensional Anti-de Sitter (AdS$_3$) space, a solution of the Einstein equation. Since it is a massless state, we expect it to travel the hyperbolic plane as fast as light. Extracting some gravitational information will enhance our understanding on a quantum gravity theory. In Sec. 4 we present that the energy spectrum exhibits an unusual fractal pattern, where each stack of bands forms a Hofstadter butterfly. The existence of many stacks of butterflies clearly distinguishes the hyperbolic band theory from the conventional Euclidean band theory. In Sec. 5, we describe the Brillouin zone and the Hall Conductance.

2 Hamiltonian on Hyperbolic Surface under Magnetic Field

Here we show our band theory on a hyperbolic surface under a magnetic field perpendicular to the system. In the succeeding sections, we analyze the band structure (Fig. 2) and show that they exhibit the fractal structure (Fig. 5). Let $\mathbb{H} = \{ z = x + iy \in \mathbb{C} \mid y > 0 \}$ be the upper half-plane equipped with its usual Poincaré metric $ds^2 = \frac{dx^2 + dy^2}{y^2}$. Let $A \in \Omega^1(\mathbb{H})$ be a one-form on $\mathbb{H}$. Using the Laplace-Beltrami operator, we can write the Hamiltonian with a magnetic field as

$$
H = \frac{1}{2m} \frac{1}{\sqrt{g}} (p_{\mu} - A_{\mu}) \sqrt{g} g^{\mu\nu} (p_{\nu} - A_{\nu})
$$

$$
= \frac{1}{2m} y^2 ((p_x - A_x)^2 + (p_y - A_y)^2), \tag{2.1}
$$

where $p_{\mu} = -i \partial_{\mu}$. Since we are interested in the quantum Hall effect, we take the constant magnetic field that can be written as $dA = B \omega$, where $\omega = y^{-2} dx \wedge dy$ is the area element and $B \in \mathbb{R}$ is some fixed value. We use $A = \frac{2B}{y} dx$, then the Hamiltonian becomes

$$
H = \frac{y^2}{2m} \left( \left( \frac{p_x - B}{y} \right)^2 + p_y^2 \right)
$$

$$
= -\Delta + iB \frac{p_x}{m} + \frac{B^2}{2m} \tag{2.2}
$$
In what follows, we show a general procedure to address electron states in a hyperbolic surface under a uniform magnetic field. We address electron states on a lattice, so-called a Poincaré tile. Note that in a Euclidean lattice, the tight-binding Hamiltonian commutes with the translation operators, hence the Bloch states are their simultaneous eigenstates. In fact, the translation operators are commutative in the absence of a magnetic field. However in a hyperbolic lattice, the Fuchsian group is non-commutative. Therefore the construction of the magnetic Bloch state is quite non-trivial. Nevertheless, we verify their existence and give their concrete forms in Sec. A.2.

Our prescription for obtaining the band structure on a hyperbolic tiling is as follows:

1. Find a lattice Hamiltonian $H_{\text{lattice}}$ that converges into the original Hamiltonian as the lattice parameter goes to zero.

2. Deform the Hamiltonian $H_{\text{lattice}}$ in such a way that it respects the original tiling $\{4g, 4g\}$.

3. Diagonalize $H_{\text{lattice}}$.

In Sec. A we verify that our following arguments are mathematically valid and respect all of the procedure above. In what follows we demonstrate how this protocol works for the $g = 2$ case. For this purpose we define

\[
\hat{S}_B = (1 + x^2 - y^2) \frac{\partial}{\partial x} + 2xy \frac{\partial}{\partial y} + 2iBy,
\]

\[
\hat{T}_B = \frac{\partial}{\partial x},
\]

\[
\hat{U}_B = 2x \frac{\partial}{\partial x} + 2y \frac{\partial}{\partial y},
\]

and write

\[
\hat{J}_1 = \frac{1}{2}(2\hat{T}_B - \hat{S}_B), \quad \hat{J}_2 = i\hat{S}_B, \quad \hat{J}_3 = \frac{1}{2}\hat{U}_B,
\]

which satisfy the commutation relation

\[
[\hat{J}_i, \hat{J}_j] = i\epsilon_{ijk}\hat{J}_k.
\]

Using them, we can rewrite the Hamiltonian as

\[
H = \frac{1}{2m} \left( -\sum_{i=1}^{3} \hat{J}_i^2 + B^2 \right).
\]

Then we define the lattice Hamiltonian $H_{\text{lattice}}$ as

\[
H_{\text{lattice}} = -\sum_{i=1}^{3} \frac{1}{a_i^2} \left( \exp(a_i\hat{J}_i) + \exp(-a_i\hat{J}_i) \right),
\]

and find it converges into $H$ (2.6) (up to some constant) in the limit of $a_i \rightarrow 0$. We call the eigenstates of the lattice Hamiltonian the magnetic hyperbolic Bloch states, whose detailed theoretical formulation and analysis are given in Sec. A.2.

3 Band Structure and Quantum Gravity

Here we show some band structures in Fig. 2. We use a rational magnetic field $B = p/2q$, by which the energy bands split into $8q$. In general there are 8 stacks of $q$ bands, as shown in Fig. 5. Clearly there are some band crossing points and Dirac cones, which implies the existence of a
massless particle obeying the Dirac equation on a coordinate neighborhood. It is known that
the peculiar electronic states (linear dispersion and gapless states) exhibited by the Dirac electron
system appears on various materials such as graphene, an organic conductor with a two-dimensional
layered structure [15], and topological insulators. Dirac electrons, which move at high speed in
solids, are expected to be applied to electronic devices. Therefore, in recent years, substances
showing the Dirac electron system have been explored for both experimentally and theoretically.
Our work presents for the first time that a cQED system with a hyperbolic graph structure also
exhibits the Diac cones. Therefore we expect that the range of materials in which the massless Dirac
states appear will expand, and the development of new Dirac systems will progress. For example
it will be of interest to study connections with a symmetry protected topological (SPT) phase [16].

Besides the interests from the material physics, we explain some impact of our results from a
view point of high energy physics as follows. As our geometry has a negative curvature, the particle
should have some information of a quantum gravity. In fact a hyperbolic tiling has desirable symme-
tries for constructing a toy model of a gravity theory, known as the AdS/CFT correspondence [17].
For example the three-dimensional AdS space is a product of a hyperbolic disc and one-dimensional
time. As pointed out in [9], they are discretely scale-invariant, and there exist graph isomorphisms
that map any point in the graph to the center while preserving the local structure of the tiling.
The AdS space is an exact solution of the Einstein equation, and we may understand an eigenstate
of our Hamiltonian as a state relevant to quantum gravity. In fast, since it is massless, we expect
it to travel the hyperbolic plane as fast as light. Extracting some gravitational information will
lead to understanding a quantum gravity theory. We construct such a solution in a direct way for
the first time. A string theoretical top down approach for linking AdS/CFT correspondence with
topological materials is given in [18], whereas bottom up approaches have not been developed yet.
In fact, many known low dimensional quantum gravity analysis have been limited to some strongly
chaotic models dual to the black hole physics in AdS [19, 20]. Therefore our proposing solutions and
methods will open up a new direction for investigating quantum gravity solutions in a laboratory.

Figure 2: Band structure of the electrons on the \{8,8\} hyperbolic tiling. Unspecified wave numbers
are set to 0. The figures correspond to some lower energy bands at $B = 1/8$.

4 Hofstadter Problem on Hyperbolic Tiling

Here we study the energy spectra of electrons under a magnetic field from another viewpoint. The
Hofstadter problem [21] is a well-known and established problem on the energy spectrum of Bloch
electrons moving in a two-dimensional lattice under a uniform magnetic field. As a function of
magnetic flux, the energy spectra exhibit the fractal structure, called the Hofstadter butterfly. Due to such an extremely non-trivial fractal structure, many authors have considered this problem from various theoretical viewpoints [22–27]. Many experimental evidences of the fractal structure of the Hofstadter spectrum were reported in a lot of systems, such as GaAs-AlGaAs heterostructures with superlattices [28–30], ultracold atoms in optical lattices [31–33], moiré superlattices [34–36], the superconducting qubits [37] and 1D acoustic array [38–40]. In Fig. 5, we present our solution of the Hofstadter problem. The figure exhibits the unusual self-similar structure. This may be expected since our theory is a natural and general extension of the conventional works on a Euclidean lattice. Much more crucial and surprising fact for us is that there are more than 1 stacks of butterflies that appear in a pattern while keeping some band gaps. We fix \( q = 499 \) and run \( p \) from 1 to \( 2q - 1 \). Then each stack of bands constitutes of \( q \) eigenenergies of the Hamiltonian, thereby there are \( 8q \) bands in total. "8" comes from \( 4 \times g \) \((g = 2)\) and we expect this formula should be true in general for \( g \geq 2 \). It is important to recall that the \( g = 1 \) case, namely the standard torus case, is exceptional. This is based on the fact that any closed and oriented two-dimensional manifold is classified by its curvature: positive \((g = 0)\), zero \((g = 1)\) and negative \((g \geq 2)\). So our finding on the difference in the fractal structures clearly shows that the band theory on the hyperbolic geometry \((g \geq 2)\) is essentially different from that on the Euclidean geometry, even at some quantum scale.
Figure 3: Spectrum of an electron on a hyperbolic surface \((g = 2)\) under a uniform magnetic field, plotted as a function of a rational flux. The plot is generated with the lattice Hamiltonian \((2.7)\).
5 Remarks on the Hall Conductance and the Brillouin Zone

Here we give a general description of the Hall conductance based on \[41–44\]. A study of the Hall conductance on a hyperbolic surface is given by \[45\]. Our theory is a \(U(1)\)-gauge theory on a compact Riemann surface \(H/\Gamma \cong \Sigma_g\) of genus \(g \geq 2\), where \(\Gamma \subset PSL(2, \mathbb{R})\) is the the discrete Fuchsian group associated with the tiling of Poincaré disk. The geometric Langlands correspondence is an equivalence between the derived category of quasicoherent sheaves on the local systems and the derived category of \(D\)-modules on the Picard variety \(\text{Pic} = \bigcup_d \{L : d = c_1(L)\}\) of \(\Sigma_g\) classifying line bundles on \(\Sigma_g\). Here \(c_1(L)\) is the Chern number of a line bundle \(L\) on \(\Sigma_g\).

As pointed out by \[14\], the generalized Brillouin zone \(\text{Jac}(\Sigma_g)\) is the Jacobian of \(\Sigma_g\) and parametrizes distinct \(U(1)\)-representations of \(\pi_1(\Sigma_g)\). The degree zero component \(\text{Pic}_0\) of \(\text{Pic}\) corresponds to \(\text{Jac}(\Sigma_g)\). In general the Hall conductance is given by the sum of the Chern number of line bundles \(L_i \in \text{Pic}\) below the Landau level

\[
\sigma_{xy} = \sum_i c_1(L_i).
\]  

(5.1)

We consider the Abel-Jacobi map \(j: \Sigma_g \to \text{Jac}(\Sigma_g)\) sending \(p \in \Sigma_g\) to the line bundle for some fixed reference point \(p_0 \in \Sigma_g\):

\[
j(x) = \left(\int_{p_0}^p \omega_1, \cdots, \int_{p_0}^p \omega_g\right),
\]

(5.2)

where \(\omega_1, \cdots, \omega_g\) are bases of the space of holomorphic differentials on \(\Sigma_g\). By the Abel-Jacobi there is an isomorphism as complex manifolds \(\mathbb{C}^g/\Lambda \cong \text{Jac}(\Sigma_g)\), where \(\Lambda\) is the lattice spanned by the integrals of \(\omega_i\)'s over the one-cycles in \(\Sigma_g\).

Now we consider a holomorphic line bundle \(L\) with connection on \(\Sigma_g\). A local system is a pair \(L = (L, \nabla)\) of holomorphic line bundle \(L\) and a holomorphic connection \(\nabla\) on \(L\). By the Fourier-Mukai transformation, \(L = (L, \nabla)\) is mapped to a \(D\)-module \(F = (\mathcal{F}, \tilde{\nabla})\), where \(\mathcal{F}\) is a holomorphic line bundle on \(\text{Jac}\) and \(\tilde{\nabla}\) is a flat holomorphic connection on \(\mathcal{F}\), which is a Hecke eigensheaf with respect to \(L\). A Berry connection would correspond to \(\tilde{\nabla}\) and the Hecke functor should be regarded as the Wilson loop given by the Berry connection. Besides we can consider a generic Abel-Jacobi map and discuss the sheaves on the other components \(\text{Pic}_d\) which gives a non-zero quantized Hall conductance and respects the Hecke eigensheaf feature.

6 Conclusion and Discussion

In this article we considered the hyperbolic band theory in the presence of a magnetic field. We analyzed the energy spectrum of the magnetic hyperbolic Bloch states (Sec. 3) and investigated the Hofstadter problem (Sec. 4). Our proposed method is a natural and general extension of the conventional band theory on a Euclidean lattice under a magnetic field to that on a hyperbolic lattice.

For further research directions, it will be meaningful to consider the theory with impurities or defects, by which we can address the problems under more realistic conditions. In our recent study \[46, 47\], we showed that the fractal scaling nature of the localized length of the Bloch states localizing around a defect. Studying the localized length can be a powerful method to investigate the fractal nature of the Hofstadter butterfly as well as the energy spectrum. As our previous methods are generally true in Euclidean lattices, we expect the same logic is applicable to the hyperbolic cases. Furthermore, by identifying the boundaries by tessellation \(\Gamma\), the current has some isolated zeros, due to the Poincaré-Hopf theorem \[48\]. This fact is different from the conventional band theory on a square lattice or a tours, where current without an isolated zero can exits. So investigating some physical meaning of a vortex associated with such an isolated zero will be meaningful. Besides it
will be yet another interesting problem to complete the classification table of topological materials on hyperbolic plane, as did for the case of the Euclidean band theory [49–51].

References

A Supplemental Information

In what follows we state some detailed theoretical descriptions of the main text and provide the corresponding mathematical proofs. Sec. A.1 includes a brief review of the translation group of the hyperbolic plane. Our original theoretical contributions are summarized in Sec. A.2 and A.3.

A.1 Review on the Fuchsian Group

In this section we give a brief review on some basic things about a transformation group that acts on the hyperbolic plane. A discrete subgroup of the transformation group is called the Fuchsian group, and it determines the tiling of the hyperbolic plane.

**Definition A.1 (Hyperbolic plane).** Let $\mathbb{H}$ be a Riemann manifold with a metric $ds^2 = \frac{1}{y^2}(dx^2 + dy^2)$ on upper half-plane $\{ z = x + iy \in \mathbb{C} \mid y > 0 \}$.

Let $SL_2(\mathbb{R})$ be a special linear group defined by

\[ SL_2(\mathbb{R}) = \left\{ g = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \mid \det g = 1 \right\}. \quad (A.1) \]

This group acts on the hyperbolic plane $\mathbb{H}$ as follows:

\[ g \cdot z = \frac{az + b}{cz + d} \quad (g \in SL_2(\mathbb{R}), \ z \in \mathbb{H}). \quad (A.2) \]

This action satisfies

\[ g_1 \cdot (g_2 \cdot z) = (g_1g_2) \cdot z \]
\[ g \cdot z = (-g) \cdot z \quad (A.3) \]

for arbitrary $g_1, g_2, g \in SL_2(\mathbb{R})$ and $z \in \mathbb{H}$. Throughout this work we omit ",,\" accordingly.

$SL_2(\mathbb{R})$ is generated by the following three elements:

\[ S = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}, \quad T = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}, \quad U = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}. \quad (A.4) \]

$S, T,$ and $U$ denote rotation, translation, and scaling, respectively. The commutation relations are given by

\[ [U, T] = 2T, \quad [U, S] = 4T - 2S, \quad [S, T] = U. \quad (A.5) \]
The generator $S$ produces one-parameter family
\[
    e^{\theta S} = \begin{pmatrix} \cos \theta & \sin \theta \\ -\sin \theta & \cos \theta \end{pmatrix}
\] (A.6)
in $SL_2(\mathbb{R})$ and $e^{\theta S}$ acts on $z_0 \in \mathbb{H}$ as
\[
e^{\theta S} z_0 = \frac{\cos \theta z_0 + \sin \theta}{-\sin \theta z_0 + \cos \theta}.
\] (A.7)
We consider an orbital that is described by moving the parameter $\theta$.

**Proposition A.2.** For arbitrary $z_0 \in \mathbb{H}$, an orbit $\{ e^{\theta S} z_0 \mid \theta \in \mathbb{R} \}$ is equal to
\[
C = \{ z = x + iy \in \mathbb{H} \mid x^2 + (y - a)^2 = b^2 \},
\] (A.8)
where
\[
a = \frac{x_0^2 + y_0^2 + 1}{2y_0}, \quad b = \sqrt{a^2 - 1}.
\] (A.9)
Therefore the orbit generated by $S$ is a circle with center $z = ia$ and radius $b$.

**Proof.** Let $z(\theta) = e^{\theta S} z_0 = x(\theta) + iy(\theta)$, $z(0) = z_0$. To find a differential equation that $z(\theta)$ should satisfy, differentiate $z(\theta)$ by $\theta$. Since $z(\theta)$ satisfies $z(\theta_1 + \theta_2) = e^{\theta_1 S} z(\theta_2)$, it is sufficient to consider a derivative of $z(\theta)$ near $\theta = 0$. From
\[
\left. \frac{d}{d\theta} z(\theta) \right|_{\theta = 0} = 1 + x_0^2 - y_0^2 + i2x_0y_0,
\] (A.10)
the equation to be satisfied by $x, y$ is
\[
\frac{d}{d\theta} x = 1 + x^2 - y^2,
\] \[\frac{d}{d\theta} y = 2xy. \] (A.11)
For $x, y$ satisfying eq. (A.11), let $f(\theta) = x(\theta)^2 + (y(\theta) - a)^2 - b^2$ be a function of $\theta$, where $a, b$ are constants. Differentiating $f$ by $\theta$, we obtain
\[
f'(\theta) = 2x(1 + b^2 - a^2 + f).
\] (A.12)
Suppose $f$ satisfies the equation above along with conditions $f = 0$ and $a^2 - b^2 = 1$. Then a closed loop defined by $x^2 + (y - a)^2 = b^2, a^2 - b^2 = 1$ is the orbit of (A.11). If the loop contains $z_0$, then the parameters satisfy
\[
a = \frac{x_0^2 + y_0^2 + 1}{2y_0}, \quad b = \sqrt{a^2 - 1}.
\] (A.13)
\[\square\]
It is important to note that $T$ and $U$ generate
\[
e^{tT} = \begin{pmatrix} 1 & t \\ 0 & 1 \end{pmatrix}, \quad e^{\mu U} = \begin{pmatrix} e^\mu & 0 \\ 0 & e^{-\mu} \end{pmatrix}
\] (A.14)
and they act on $z_0 \in \mathbb{H}$ as
\[
e^{tT} z_0 = z_0 + t, \quad e^{\mu U} z_0 = e^{2\mu} z_0.
\] (A.15)
Then one would confirm that any \( g \in SL_2(\mathbb{R}) \) can be uniquely decomposed as
\[
g = e^{\mu U} e^{iT} e^{\theta S}.
\] (A.16)

Let \( \Gamma \) be a discrete subgroup of \( SL_2(\mathbb{R}) \), known as the Fuchsian group. Here discrete means that there is no element in \( \Gamma \) near the identity element. For example, \( SL_2(\mathbb{Z}) \) is a Fuchsian group, but \( SL_2(\mathbb{Q}) \) is not. The following statement is a well-known fact.

**Proposition A.3.** Let \( \Gamma \) be a Fuchsian group of \( SL_2(\mathbb{R}) \). Then there exists a subset \( D \) in \( \mathbb{H} \) that satisfy the following:

1. \( \mathbb{H} = \bigcup_{\gamma \in \Gamma} \gamma D \).
2. If \( \gamma \in \Gamma, \gamma \neq \pm 1 \), then a measure of \( D \cap \gamma D \) is zero.
3. The edges of \( D \) are geodesics.

Such a \( D \) is called by a fundamental domain of \( \Gamma \).

This proposition means that \( \mathbb{H} \) can be divided by \( D \). Here we can take \( D \) to be a regular \( p \)-gon and put it on \( \mathbb{H} \) so that \( q \) fundamental domains share a single vertex. We call such a partition \( \{p, q\} \) tiling.

**Proposition A.4.** Let
\[
\gamma_j = \begin{pmatrix}
\cos \left( \frac{j-1}{4g} \pi \right) & -\sin \left( \frac{j-1}{4g} \pi \right) \\
\sin \left( \frac{j-1}{4g} \pi \right) & \cos \left( \frac{j-1}{4g} \pi \right)
\end{pmatrix}
\begin{pmatrix}
ev^\mu & 0 \\
0 & e^{-\mu}
\end{pmatrix}
\begin{pmatrix}
\cos \left( \frac{j-1}{4g} \pi \right) & -\sin \left( \frac{j-1}{4g} \pi \right) \\
\sin \left( \frac{j-1}{4g} \pi \right) & \cos \left( \frac{j-1}{4g} \pi \right)
\end{pmatrix}
\]
\[
= \exp \left( \mu \left( U \cos \left( \frac{j-1}{4g} \pi \right) - (2T - S) \sin \left( \frac{j-1}{4g} \pi \right) \right) \right)
\] (A.17)
be generators of a Fuchsian group \( \Gamma \), where \( j = 1, \cdots, 2g \) and \( \mu \) satisfies
\[
e^\mu = \cos \frac{\pi}{4g} + \sqrt{\frac{\cos^2 \frac{\pi}{4g}}{\sin^2 \frac{\pi}{4g}} - 1}.
\] (A.18)

This \( \Gamma \) gives the \( \{4g, 4g\} \) tiling. The fundamental domain \( D \) is a regular \( 4g \)-gon and the vertices \( v_1, \cdots v_{4g} \) are located at
\[
v_{4g} = \cos \frac{\pi}{4g} e^\mu - \sin \frac{\pi}{4g} + ie^\mu \sin \frac{\pi}{4g} \cos \frac{\pi}{4g}
\] (A.19)
\[
v_j = e^{\frac{j}{8g}S} v_{4g} \ (j = 1, \cdots, 4g - 1).
\]

In particular the Fuchsian group \( \Gamma \) corresponding to the \( \{8, 8\} \) tiling is a group generated by the following four elements:
\[
\gamma_j = \begin{pmatrix}
\cos \left( \frac{j-1}{8} \pi \right) & -\sin \left( \frac{j-1}{8} \pi \right) \\
\sin \left( \frac{j-1}{8} \pi \right) & \cos \left( \frac{j-1}{8} \pi \right)
\end{pmatrix}
\begin{pmatrix}
ev^\mu & 0 \\
0 & e^{-\mu}
\end{pmatrix}
\begin{pmatrix}
\cos \left( \frac{j-1}{8} \pi \right) & -\sin \left( \frac{j-1}{8} \pi \right) \\
\sin \left( \frac{j-1}{8} \pi \right) & \cos \left( \frac{j-1}{8} \pi \right)
\end{pmatrix}
\]
\[
= \exp \left( \mu \left( U \cos \left( \frac{j-1}{4} \pi \right) - (2T - S) \sin \left( \frac{j-1}{4} \pi \right) \right) \right)
\] (A.20)

\[\Box\]
Figure 4: The fundamental domain of \{8, 8\} tiling.

where \( j = 1, \cdots, 4 \) and

\[
e^\mu = \frac{\cos \frac{\pi}{4}}{\sin \frac{\pi}{8}} + \sqrt{\frac{\cos^2 \frac{\pi}{4}}{\sin^2 \frac{\pi}{8}} - 1} = (1 + \sqrt{2}) \left( 1 + \sqrt{2} \sqrt{\sqrt{2} - 1} \right). \tag{A.21}
\]

This Fuchsian group \( \Gamma \) generates a fundamental domain as shown in Fig. 4.

In what follows we consider the Fuchsian group \( \Gamma \) associated with the \{4g, 4g\} tiling, where \( g \geq 2 \) is an integer corresponding to genus of a surface. The generators of \( \Gamma \) satisfy

\[
\gamma_1 \gamma_2^{-1} \cdots \gamma_{2g}^{-1} \gamma_1^{-1} \gamma_2 \cdots \gamma_{2g} = 1. \tag{A.22}
\]

This formula allows us to identify the opposite edges of \( D \). Let \( C_j \ (j = 1, \cdots, 4g) \) be edges of \( D \) that connect \( v_{j-1} \) and \( v_j \), where \( v_{-1} = v_{4g} \). Then each \( C_j \) fulfill

\[
\gamma_j C_{j+2g} = C_j. \tag{A.23}
\]

The fundamental domain is a regular \( 4g \)-gon, and the Riemann surface of genus \( g \) can be constructed by identifying the facing edges. Since the metric \( ds^2 = \frac{1}{y^2} (dx^2 + dy^2) \) is invariant under \( \Gamma \subset SL_2(\mathbb{R}) \), the metric naturally gives a Riemann surface.

The action of \( SL_2(\mathbb{R}) \) on a function \( f \) on \( \mathbb{H} \) is determined by

\[
(\rho(g)f)(z) = f(gz) \quad g \in SL_2(\mathbb{R}), \quad z \in \mathbb{H}, \tag{A.24}
\]

where \( \rho \) is a representation to a function space. This \( \rho \) reverses the order of products as

\[
(\rho(g_1)\rho(g_2)f)(z) = f(g_2g_1z) = (\rho(g_2g_1)f)(z) \tag{A.25}
\]

for any \( g_1, g_2 \in SL_2(\mathbb{R}) \).
To find the generators of this transformation, we take \( g = e^{\theta S}, e^{t T}, e^{\mu U} \) and differentiate by a parameter, respectively. Then we obtain
\[
\begin{align*}
\frac{d}{d\theta} (\rho(e^{\theta S}) f(z)) \bigg|_{\theta=0} &= \frac{d}{d\theta} f(e^{\theta S} z) \bigg|_{\theta=0} = (1 + x^2 - y^2) \frac{\partial}{\partial x} f + 2xy \frac{\partial}{\partial y} f \\
\frac{d}{dt} (\rho(e^{t T}) f(z)) \bigg|_{\theta=0} &= \frac{d}{dt} f(e^{t T} z) \bigg|_{\theta=0} = \frac{\partial}{\partial x} f \\
\frac{d}{d\mu} (\rho(e^{\mu U}) f(z)) \bigg|_{\theta=0} &= \frac{d}{d\mu} f(e^{\mu U} z) \bigg|_{\theta=0} = 2x \frac{\partial}{\partial x} f + 2y \frac{\partial}{\partial y} f.
\end{align*}
\] (A.26)

We define the generators of the transformation as
\[
\begin{align*}
\hat{S} &= (1 + x^2 - y^2) \frac{\partial}{\partial x} + 2xy \frac{\partial}{\partial y} \\
\hat{T} &= \frac{\partial}{\partial x} \\
\hat{U} &= 2x \frac{\partial}{\partial x} + 2y \frac{\partial}{\partial y}.
\end{align*}
\] (A.27)

The commutation relation of \( \{\hat{S}, \hat{T}, \hat{U}\} \) is
\[
[\hat{U}, \hat{T}] = -2\hat{T}, \quad [\hat{U}, \hat{S}] = -4\hat{T} + 2\hat{S}, \quad [\hat{S}, \hat{T}] = -\hat{U}. \tag{A.28}
\]

This commutation relation differs in sign from the commutation relation (A.4). This fact reflects that \( \rho \) reverses the order of the products. Therefore the transformation corresponding to \( g = \exp(X) \in SL_2(\mathbb{R}) \) is written by
\[
\hat{g} = \rho(g) = \exp(\hat{X}) = \sum_{n=0}^{\infty} \frac{1}{n!} \hat{X}^n. \tag{A.29}
\]

We can define the transformation groups corresponding to the generators \( \gamma_1 \cdots \gamma_4 \) of the Fuchsian group associated with the \( \{8, 8\} \) tiling in such a way that
\[
\gamma_j = \rho(\gamma_j) = \exp \left( \mu \left( \hat{U} \cos \left( j \frac{3}{4} \pi \right) - (2\hat{T} - \hat{S}) \sin \left( j \frac{3}{4} \pi \right) \right) \right)
= \exp \left( -j \frac{1}{8} \pi \hat{S} \right) \exp(\mu \hat{U}) \exp \left( j \frac{1}{8} \pi \hat{S} \right).
\] (A.30)

Then these \( \tilde{\gamma}_1, \cdots \tilde{\gamma}_4 \) satisfy
\[
\tilde{\gamma}_4 \tilde{\gamma}_3^{-1} \tilde{\gamma}_2 \tilde{\gamma}_1^{-1} \tilde{\gamma}_4^{-1} \tilde{\gamma}_3 \tilde{\gamma}_2^{-1} \tilde{\gamma}_1 = 1. \tag{A.31}
\]

Finally we discuss a group generated by \( \{\hat{S}, \hat{T}, \hat{U}\} \). For arbitrary function \( f \), the transformation \( e^{\pi \hat{S}} \) act as
\[
(e^{\pi \hat{S}} f)(z) = f(e^{\pi \hat{S} \cdot z}) = f((-1) \cdot z) = f(z) \quad (z \in \mathbb{H}). \tag{A.32}
\]
Therefore \( \{\hat{S}, \hat{T}, \hat{U}\} \) generate
\[
PSL_2(\mathbb{R}) \simeq SL_2(\mathbb{R})/\{\pm 1\}. \tag{A.33}
\]
A.2 Magnetic Fuchsian Group

The purpose of this section is to give a general prescription for analyzing electrons on a hyperbolic surface under a magnetic field. For this purpose, we show and demonstrate how the following protocols work:

1. We propose the magnetic Fuchsian group, that commutes with the Hamiltonian (2.1) on the hyperbolic lattice. For this, we prepare the generators of $SL_2(\mathbb{R})$ so that they commute with the Hamiltonian (2.1) and consider the magnetic translation.

2. We construct the magnetic hyperbolic Bloch state, which is a Bloch-like state on a hyperbolic lattice. This can be done by imposing the magnetic Bloch condition.

With respect to the gauge field $A = B \frac{dy}{dx}$ obeying $dA = B \text{vol}$, we work in Landau gauge. We first consider the $B = 0$ case. By using eq. (A.27), we can write the Hamiltonian as

$$H = \frac{1}{2m} \left( \hat{T}(\hat{S} - \hat{T}) - \frac{1}{4} \hat{U}^2 - \frac{1}{2} \hat{U} \right).$$

(A.34)

Now let us consider the $B \neq 0$ case.

**Definition A.5.** We put

$$\hat{S}_B = (1 + x^2 - y^2) \frac{\partial}{\partial x} + 2xy \frac{\partial}{\partial y} + 2iBy$$

$$\hat{T}_B = \frac{\partial}{\partial x} = \hat{T}$$

$$\hat{U}_B = 2x \frac{\partial}{\partial x} + 2y \frac{\partial}{\partial y} = \hat{U},$$

(A.35)

and call them generators of the magnetic $PSL_2(\mathbb{R})$.

They satisfy the commutation relations

$$[\hat{U}_B, \hat{T}_B] = -2\hat{T}_B, \quad [\hat{U}_B, \hat{S}_B] = -4\hat{T}_B + 2\hat{S}_B, \quad [\hat{S}_B, \hat{T}_B] = -\hat{U}_B$$

(A.36)

Consequently the Lie algebra $\mathfrak{sl}_2(\mathbb{R})$ of $PSL_2(\mathbb{R})$ and the Lie algebra $\mathfrak{sl}_2(\mathbb{R})[B]$ generated by $\{S_B, T_B, U_B\}$ are isomorphic. We write $PSL_2(\mathbb{R})[B]$ for the magnetic $PSL_2(\mathbb{R})$, that is the Lie group corresponding to $\mathfrak{sl}_2(\mathbb{R})[B]$.

**Lemma A.6.** The Hamiltonian (2.1) commutes with $\hat{S}_B, \hat{T}_B, \hat{U}_B$.

One can show this statement by rewriting the Hamiltonian as

$$H = \frac{1}{2m} \left( \hat{T}_B(\hat{S}_B - \hat{T}_B) - \frac{1}{4} \hat{U}_B^2 - \frac{1}{2} \hat{U}_B + B^2 \right).$$

(A.37)

Topologically $PSL_2(\mathbb{R}) \simeq S^1 \times \mathbb{R}^2$, thereby $PSL_2(\mathbb{R})$ is a covering group of $PSL_2(\mathbb{R})[B]$ if an appropriate $B$ is chosen. So we consider $\hat{S}_B$, which corresponds to a direction of $S^1$.

**Proposition A.7.** $e^{i\hat{S}_B}$ acts on any $f \in C^\infty(\mathbb{H})$ as

$$(e^{i\hat{S}_B}f)(z_0) = \exp \left( \int_0^t 2iBy(t') dt' \right) (e^{i\hat{T}}f)(z_0) \quad (z_0 \in \mathbb{H}),$$

(A.38)

where $y(t') = \text{Im} \left\{ e^{iS} z_0 \right\}$. Consequently $e^{i\hat{S}_B}$ changes not only the position but also the phase. □
Proof. We define

\[(\Psi_t f)(z_0) = \exp\left( \int_0^t 2iBy(t')dt' \right)(e^{tS} f)(z_0)\]

\[= \exp\left( \int_0^t 2iBy(t')dt' \right)f(e^{tS}z_0),\]

(A.39)

and find

\[(\Psi_{t_1} \Psi_{t_2} f)(z_0) = \exp\left( \int_0^{t_1+t_2} 2iBy(t)dt \right)(\Psi_{t_2} f)(e^{t_1S}z_0)\]

\[= \exp\left( \int_0^{t_1+t_2} 2iBy(t)dt \right)\exp\left( \int_0^{t_2} 2iBy_2(t)dt \right)f(e^{t_2S}e^{t_1S}z_0),\]

(A.40)

where \(y_1(t) = \text{Im}\{e^{tS}z_0\}\), \(y_2(t) = \text{Im}\{e^{tS}e^{t_1S}z_0\}\). We define a new curve \(y(t) = \text{Im}\{e^{tS}z_0\}\) \((0 \leq t \leq t_1 + t_2)\) obeying

\[y(t) = \text{Im}\{e^{tS}z_0\} = \begin{cases} y_1(t) & (0 \leq t \leq t_1) \\ y_2(t-t_1) & (t_1 \leq t \leq t_2).\end{cases}\]

(A.41)

Therefore we obtain

\[(\Psi_{t_1} \Psi_{t_2} f)(z_0) = \exp\left( \int_0^{t_1+t_2} 2iBy(t)dt \right)f(e^{(t_1+t_2)S}z_0) = (\Psi_{t_1+t_2} f)(z_0),\]

(A.42)

by which we find that it satisfies \(\Psi_{t_1} \Psi_{t_2} = \Psi_{t_1+t_2}\) and generates a one-parameter transformation \(\{\Psi_t\}_{t \in \mathbb{R}}\). Moreover we find \(\Psi_t = e^{tS_B}\) since it obeys

\[\frac{d}{dt}(\Phi_t f)(z) \bigg|_{t=0} = (\dot{S}_B)f(z), \ \forall z \in H.\]

(A.43)

Let

\[j(e^{tS_B}, z) = \exp\left( \int_0^t 2iBy(t')dt' \right)\]

(A.44)

be the variation of the phase factor by acting \(e^{tS_B}\). This is crucial for discussing how many times \(PSL_2(\mathbb{R})\) covers \(PSL_2(\mathbb{R})[B]\).

Theorem A.8. \(PSL_2(\mathbb{R})\) is a q-fold covering of \(PSL_2(\mathbb{R})[B]\) if \(B = 1/q\).

Proof. Note that \(e^{\pi S} = id\) in \(PSL_2(\mathbb{R})\). Therefore by calculating \(e^{\pi S_B}\), we can compute the degrees of a covering \(p: PSL_2(\mathbb{R}) \rightarrow PSL_2(\mathbb{R})[B]\). Then we perform the integral of eq. (A.44). By using eq. (A.11), we get

\[\int_0^t 2iBy(t')dt' = \int_0^t 2iBy(t')\frac{y'}{y}dt' = \int_C 2iB\frac{dy}{2xy} = \int_C iB\frac{dy}{x},\]

(A.45)

where \(y'\) is a derivative of \(y(t')\) and \(C = \{ e^{t' S}z_0 : 0 \leq t' \leq t \}\). According to Prop. A.2, the curve of C is an arc with a center \(z = ia\) and radius \(b\). Let

\[x = b\cos(\theta), \ y = b\sin(\theta) + a,\]

(A.46)
be functions of $\theta$. We define $\theta_i, \theta_f$ as

$$z(\theta_i) = z_0, \ z(\theta_f) = e^{\imath S}z_0.$$  

So it can be written as an integral by $\theta$:

$$\int_C iB \frac{dy}{x} = \int_{\theta_i}^{\theta_f} iB d\theta = iB(\theta_f - \theta_i).$$  

(A.48)  

Therefore we get

$$j(e^{\imath S}, z) = e^{2\pi B}.$$  

(A.49)  

In particular, $PSL_2(\mathbb{R})$ is a $q$-fold covering of $PSL_2(\mathbb{R})[B]$ if $B = \frac{1}{q}$. \qed  

For simplicity we consider the hyperbolic lattice whose tiling is specified by $\{8, 8\}$. A Fuchsian group corresponding to the $\{8, 8\}$ tiling is defined by eq. (A.20). We define the generators of magnetic Fuchsian group be functions of $\{8, 8\}$ satisfying

$$\gamma_1 \cdot \gamma_2 = \gamma_1 \gamma_2.$$  

(A.20)  

The following theorem relates the magnetic Fuchsian group with the Aharonov–Bohm phase. For a Riemann surface $\Sigma_g$ with genus $g$, the Gauss–Bonnet theorem gives the formula $\text{Area}(\Sigma_g) = 4\pi(g - 1)$.

**Theorem A.10.** Let $\Gamma$ be a Fuchsian group giving the $\{4g, 4g\}$ tiling. The generators $\hat{\gamma}^B_j$ ($j = 1, \cdots, 2g$) of magnetic Fuchsian group corresponding to $\Gamma$ satisfy

$$\hat{\gamma}^B_1 \cdots \hat{\gamma}^B_{2g} = \hat{\gamma}^B_1 \cdots \hat{\gamma}^B_{2g} = e^{4(g - 1)\pi B}.$$  

(A.51)  

Here $4(g - 1)$ is equivalent to the area of the fundamental domain of the $\{4g, 4g\}$ tiling. Therefore $\phi = 4(g - 1)\pi B$ is equal to the magnetic flux through the fundamental domain.

**Proof.** We first show that the left hand side of eq. (A.51) is constant. We define a new path that connect $\gamma_j$ to 1 as

$$\gamma_j(t) = \begin{pmatrix} \cos \left( \frac{t - 1}{4g} \pi \right) & \sin \left( \frac{t - 1}{4g} \pi \right) \\ -\sin \left( \frac{t - 1}{4g} \pi \right) & \cos \left( \frac{t - 1}{4g} \pi \right) \end{pmatrix} \begin{pmatrix} e^t & 0 \\ 0 & e^{-t} \end{pmatrix} \begin{pmatrix} \cos \left( \frac{t - 1}{4g} \pi \right) & -\sin \left( \frac{t - 1}{4g} \pi \right) \\ \sin \left( \frac{t - 1}{4g} \pi \right) & \cos \left( \frac{t - 1}{4g} \pi \right) \end{pmatrix},$$  

(A.52)  

where $e^t$ satisfies

$$1 \leq e^t \leq \frac{\cos \frac{\pi}{4g}}{\sin \frac{\pi}{4g}} + \sqrt{\frac{\cos^2 \frac{\pi}{4g}}{\sin^2 \frac{\pi}{4g}} - 1}.$$  

(A.53)  

By using eq. (A.16), we obtain

$$\gamma_1(t) \gamma_2^{-1}(t) \cdots \gamma_{2g}^{-1}(t) \gamma_1^{-1}(t) \gamma_2(t) \cdots \gamma_{2g}(t) = e^{at(t)U} e^{b(t)T} e^{a(t)S},$$  

(A.54)
where \( a(0) = b(0) = c(0) = 0 \). In particular, if \( e^t = \frac{\cos \frac{t}{a}}{\sin \frac{t}{a}} + \sqrt{\cos^2 \frac{t}{a} - 1} \), they become

\[
a(t) = 2\pi n, \quad b(t) = c(t) = 0 \quad (n \in \mathbb{Z}).
\]

Similarly for the magnetic Fuchsian group, we get

\[
\gamma_1^{B}(t) \cdots \gamma_2^{B}(t)(\gamma_2^{B}(t))^{-1}(\gamma_2^{B})(t)^{-1} \cdots (\gamma_2^{B})^{-1} \gamma_1^{B}(t) = e^{a(t)S_B} e^{b(t)T_B} e^{c(t)U_B}
\]

Therefore when \( e^t = \frac{\cos \frac{t}{a}}{\sin \frac{t}{a}} + \sqrt{\cos^2 \frac{t}{a} - 1} \), we find

\[
\gamma_1^{B} \cdots \gamma_2^{B}(\gamma_1^{B})^{-1}(\gamma_2^{B})^{-1} \cdots (\gamma_2^{B})^{-1} \gamma_1^{B} = e^{2\pi n S_B} = e^{i4\pi B} \tag{A.57}
\]

where \( e^{4\pi B} \) is constant.

We next show \( n = g - 1 \) in rest of the proof. For this purpose we transform the left-hand side of eq. (A.51) in such a way that

\[
\gamma_2^{B} \cdots \gamma_2^{B}(\gamma_1^{B})^{-1}(\gamma_2^{B})^{-1} \cdots (\gamma_2^{B})^{-1} \gamma_1^{B}
\]

be a the change in phase with respect to the vertex \( v_1, \ldots v_{4g} \) defined by eq. (A.19) of \( D \) by acting \( e^{\frac{\pi}{2} S_B} \). Therefore \( \gamma_2^{B} \cdots \gamma_2^{B}(\gamma_1^{B})^{-1}(\gamma_2^{B})^{-1} \cdots (\gamma_2^{B})^{-1} \gamma_1^{B} \) acts on any \( f \in C^\infty(\mathbb{H}) \) at \( z = v_{4g} \) as

\[
\gamma_2^{B} \cdots \gamma_2^{B}(\gamma_1^{B})^{-1}(\gamma_2^{B})^{-1} \cdots (\gamma_2^{B})^{-1} \gamma_1^{B} f(v_{4g})
\]

\[
= \exp(ib((2g - 1)(\theta_1 + \theta_2 + \cdots \theta_2g + 2\theta) - (\theta_2 + \theta_3 + \cdots + \theta_{2g}) - (\theta_{2g+2} + \cdots + \theta_{4g})) f(v_{4g}).
\]

Here \( \theta_2 + \theta_3 + \cdots + \theta_{2g} \) is equal to \( \theta_{2g+2} + \cdots + \theta_{4g} \). So we simply write \( \theta = \theta_2 + \theta_3 + \cdots + \theta_{2g} \).

By using \( \theta_1 + \theta_{2g+1} + 2\theta = 2\pi \), we obtatin

\[
\gamma_2^{B} \cdots \gamma_2^{B}(\gamma_1^{B})^{-1}(\gamma_2^{B})^{-1} \cdots (\gamma_2^{B})^{-1} \gamma_1^{B} f(v_{4g})
\]

\[
= \exp(ib((4g - 2\pi) - 2\theta)) f(v_{4g})
\]

\[
= \exp(ib((4g - 2\pi) - 4\theta)) f(v_{4g}), \tag{A.61}
\]

where \( \theta \) is defined by \( j(e^{\frac{2\pi}{4g} S_B}, v_1) = e^{iB} \theta \). From eq. (A.44) we get

\[
j(e^{\frac{2\pi}{4g} S_B}, v_1) = \exp\left(2ib\int_0^{\frac{2\pi}{4g}} y(t)dt\right), \tag{A.62}
\]

where \( y(t) = \text{Im}\left\{ e^{iS_B} P_1 \right\} = \text{Im}\left\{ \frac{\cos t P_1 + \sin t}{-\sin t P_1 + \cos t} \right\} \). Therefore this integral is

\[
\int_0^{\frac{2\pi}{4g}} y(t)dt = \int_0^{\frac{2\pi}{4g}} \frac{\cos t P_1 + \sin t}{-\sin t P_1 + \cos t} dt
\]

\[
= -\text{Im}\log\left(\frac{\sin\left(\frac{2g - 1}{4g} \pi\right) P_1 + \cos\left(\frac{2g - 1}{4g} \pi\right)}{P_1 - \tan\left(\frac{1}{4g} \pi\right)}\right)
\]

\[
= -\tan^{-1}\left(\frac{y_1}{x_1 - \tan\left(\frac{1}{4g} \pi\right)}\right), \tag{A.63}
\]
where \( v_1 = x_1 + iy_1 \). From eq. (A.19), the coordinate of \( v_1 \) is

\[
x_1 = -e^\mu + \tan\left(\frac{1}{4g}\pi\right)
\]

\[
y_1 = e^\mu \tan\left(\frac{1}{4g}\pi\right)
\]

\[
e^\mu = \frac{1}{\tan\frac{\pi}{4g}} + \sqrt{\frac{1}{\tan^2\frac{\pi}{4g}} - 1}.
\]  

(A.64)

Then we obtain

\[
j(e^{\frac{2\pi-1}{4g}iS_B}, p_1) = \exp\left(-i2B \tan^{-1}\left(\frac{y_1}{x_1 - \tan\left(\frac{1}{4g}\pi\right)}\right)\right)
\]

\[
= \exp\left(iB \frac{\pi}{2g}\right), \quad \theta = \frac{\pi}{2g}.
\]

(A.65)

Since \( \hat{\gamma}_{2g}^B \cdots \hat{\gamma}_{ij}^B \cdots \hat{\gamma}_{2g}^B \) is a constant, we complete the proof

\[
= \exp(iB((4g - 2)\pi - 2\pi)) = \exp(i4(g - 1)\pi B).
\]

(A.66)

\[\square\]

### A.3 Lattice Hamiltonian on Hyperbolic Tiling

Using the generators (2.3) of \( SL_2(\mathbb{R})[B] \), we write

\[
\hat{J}_1 = \frac{1}{2}(2\hat{T}_B - \hat{S}_B), \quad \hat{J}_2 = \frac{i}{2}\hat{S}_B, \quad \hat{J}_3 = \frac{1}{2}\hat{U}_B,
\]

which satisfies the commutation relation

\[
[\hat{J}_i, \hat{J}_j] = i\epsilon_{ijk}\hat{J}_k.
\]

(A.68)

Using them, we can write the Hamiltonian as

\[
H = \frac{1}{2m}\left(-\sum_{i=1}^{3} \hat{J}_i^2 + B^2\right).
\]

(A.69)

Then by defying the lattice Hamiltonian \( H_{\text{lattice}} \) as

\[
H_{\text{lattice}} = -\sum_{i=1}^{3} \frac{1}{a_i^2} \left(\exp(a_i\hat{J}_i) + \exp(-a_i\hat{J}_i)\right),
\]

(A.70)

we find it converges into \( H (2.6) \) (up to some constant) in the limit of \( a_i \to 0 \).

Now let us tune the parameter \( a_i \) so that the Hamiltonian preserves the original \( \{4g, 4g\} \) tiling structure. For this purpose we use the formula

\[
e^{-\theta\hat{S}_B}e^{\mu\hat{U}_B}e^{\theta\hat{S}_B} = \exp\left(\mu \left(\cos(2\theta)\hat{U}_B - \sin(2\theta)(2\hat{T}_B - \hat{S}_B)\right)\right)
\]

(A.71)

and find

\[
\exp\left(2\mu\hat{J}_1\right) = \exp\left(\mu(2\hat{T}_B - \hat{S}_B)\right) = e^{-\frac{\pi}{4}\hat{S}_B}e^{-\mu\hat{U}_B}e^{\frac{\pi}{4}\hat{S}_B} = (\hat{\gamma}_1^B)^{-1}
\]

\[
\exp\left(-i\frac{\pi}{4}\hat{J}_2\right) = \exp\left(i\frac{\pi}{8}\hat{S}_B\right)
\]

\[
\exp\left(2\mu\hat{J}_3\right) = \hat{\gamma}_1^B.
\]

(A.72)
where $e^k = (1 + \sqrt{2})(1 + \sqrt{2}\sqrt{2} - 1)$. The Hamiltonian transformed in this way respects the original $\{8,8\}$ tiling:

$$H_{\text{lattice}} = -\frac{1}{4\mu^2}(\tilde{\gamma}_1^B + (\tilde{\gamma}_1^B)^{-1} + \tilde{\gamma}_3^B + (\tilde{\gamma}_3^B)^{-1} + \frac{4^2}{\pi^2}(\exp(\frac{\pi}{8}\hat{S}^B) + \exp(-\frac{\pi}{8}\hat{S}^B)))$$

(A.73)

Alternatively one can use the Hamiltonian that converges into the same limit

$$H_{\text{lattice}} = -\frac{1}{8\mu^2}\sum_{i=1}^4(\tilde{\gamma}_i^B + (\tilde{\gamma}_i^B)^{-1}) + \frac{4^2}{\pi^2}(e^{\hat{S}^B} + e^{-\hat{S}^B}),$$

(A.74)

whose first term has a resemble form of the traditional tight-binding Hamiltonian on a torus ($g = 1$). However, due to the negative curvature of the hyperbolic space, the energy spectrum has a different structure in general. In what follows, we solve the characteristic equation of those Hamiltonian and plot the spectrum as a function of a magnetic flux. The spectra of the Hamiltonian (A.73) and that of the Hamiltonian (A.74) and shown in Fig. 3 and Fig. 5, respectively.

We call $\psi_{n,k}$ magnetic hyperbolic Bloch state obeying the conditions (A.75).

**Theorem A.11.** Let $\phi = 4(g-1)\pi B = 4\pi B$ be a magnetic flux through a regular 8-gon, where $B = p/2q$ with co-primes $p, q$. Then there exists functions $\psi_{n,k}$ $(n = 0, \ldots, q - 1, k = (k_1, k_2, k_3, k_4))$ satisfying

$$\tilde{\gamma}_1^B \psi_{n,k}(z) = j(\tilde{\gamma}_1^B, z)\psi_{n,k}(\gamma_1 z) = e^{ik_1}\psi_{n+1,k}(z)$$

$$(\tilde{\gamma}_1^B)^q \psi_{n,k}(z) = e^{ik_1q}\psi_{n+q,k}(z) = e^{ik_1}\psi_{n,k}(z)$$

$$(\tilde{\gamma}_2^B) \psi_{n,k}(z) = j(\tilde{\gamma}_2^B, z)\psi_{n,k}(\gamma_2 z) = e^{ik_2-\im\phi}\psi_{n,k}(z)$$

$$(\tilde{\gamma}_3^B \psi_{n,k}(z) = j(\tilde{\gamma}_3^B, z)\psi_{n,k}(\gamma_3 z) = e^{ik_3}\psi_{n,k}(z)$$

(A.75)

**Proof.** According to Prop. A.3, $\Gamma$ gives the $\{8,8\}$ tiling as $\mathbb{H} = \bigcup_{\gamma \in \Gamma} \gamma D$. Therefore it suffices to show that there exist functions $\psi_{n,k}$ in $D$ satisfying eq. (A.75) and are consistent with eq. (A.51). Let $C_j$ $(j = 1, \ldots, 8)$ be the edges of $D$. They are transformed by $\gamma_i$ in such a way that $\gamma_i C_{j+4} = C_j$.

(A.76)

Therefore we find that functions $\psi_{n,k}$ in $D$ satisfy

$$j(\tilde{\gamma}_1^B, z)\psi_{n,k}(C_1) = e^{ik_1}\psi_{n+1,k}(C_5)$$

$$(\tilde{\gamma}_1^B)^q \psi_{n,k}(C_2) = e^{ik_2-\im\phi}\psi_{n,k}(C_6)$$

$$(\tilde{\gamma}_1^B)^{q} \psi_{n,k}(C_3) = e^{ik_3}\psi_{n,k}(C_4) (a = 3, 4).$$

(A.77)

It follows that $\psi_{n,k}$ is consistent with (A.51):

$$\gamma_4^B \gamma_{1/2}^B \gamma_{1/3}^B \gamma_{2/3}^B \gamma_{1/4}^B \gamma_{3/4}^B \gamma_{1/5}^B \gamma_{1/6}^B \gamma_{1/7}^B \gamma_{1/8}^B \psi_{n,k}$$

$$= e^{ik_1-ik_2+ik_3-ik_4+i(n+1)\phi}\psi_{n,k}$$

(A.78)

In order to diagonalize the Hamiltonian (A.74), we compute with the basis

$$\left(\psi_{0,k} e^{\hat{S}_B} \psi_{0,k}, \psi_{1,k} e^{\hat{S}_B} \psi_{1,k}, \psi_{1,k} e^{\hat{S}_B} \psi_{1,k}, e^{\hat{S}_B} \psi_{1,k}, e^{\hat{S}_B} \psi_{1,k}, \psi_{q-1,k} e^{\hat{S}_B} \psi_{q-1,k}, \psi_{q-1,k} e^{\hat{S}_B} \psi_{q-1,k}\right)$$

(A.79)
It is important to recall that $R(\theta)$ acts on $\psi(x) = \exp(\imath n x)$, $n \in \mathbb{Z}$, in such a way that $R(\theta) \exp(\imath n x) = \exp(\imath n(2\theta + x))$. Then the Hamiltonian can be represented as

$$H_{\text{lattice}} = \begin{pmatrix} A_0 & B^\dagger & & \cdots & & B \\ B & A_1 & B^\dagger & & & \\ & B & A_2 & & & \\ & & \ddots & \ddots & \ddots \\ B^\dagger & & & \cdots & \cdots & A_{q-2} \end{pmatrix} \begin{pmatrix} \cdots & 0 & 1 & 0 & 1 \\ 1 & 0 & 1 & 0 & 1 \\ 0 & 1 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ \cdots & \cdots & \cdots & \cdots & \cdots \end{pmatrix} \begin{pmatrix} B \\ B^\dagger \\ \ddots \\ \ddots \\ A_{q-2} \end{pmatrix},$$

(A.80)

where $A_n, B$ ($n = 1, \cdots, q - 1$) are the following 8 by 8 matrices

$$A_n = -\frac{2}{8\mu^2} \left( \cos(k_2 - n\phi) + \cos(k_3) + \cos(k_4) \right) \mathbf{I}_{8 \times 8} + \frac{4^2}{\pi^2} \begin{pmatrix} 0 & 1 & e^{i2\pi B} \\ 1 & 0 & 1 \\ 1 & 0 & 1 \\ 1 & 0 & 1 \\ e^{-i2\pi B} & 1 & 0 \end{pmatrix},$$

(A.81)

$$B = -\frac{\imath k_1}{8\mu^2} \mathbf{I}_{8 \times 8}$$

(A.82)

Since $H_{\text{lattice}}$ and $e^{\frac{\pi}{8} \hat{S}_B} + e^{-\frac{\pi}{8} \hat{S}_B}$ are commutative, there exists simultaneous eigenstates. $e^{\frac{\pi}{8} \hat{S}_B}$ satisfies

$$(e^{\frac{\pi}{8} \hat{S}_B})^8 = e^{2\pi B},$$

(A.83)

so $e^{\frac{\pi}{8} \hat{S}_B}$ has eight eigenvalues $\exp\left(\frac{i2\pi B}{8} + \frac{i2\pi m}{8}\right)$ ($m = 0, \cdots, 7$). We obtain the eigenvalues of $e^{\frac{\pi}{8} \hat{S}_B} + e^{-\frac{\pi}{8} \hat{S}_B}$ as

$$2 \cos\left(\frac{\pi B}{4} + \frac{m\pi}{4}\right) (m = 0, \cdots, 7)$$

(A.84)

Therefore the explicit representation of the Hamiltonian (A.80) is

$$H_{\text{lattice}} = -\frac{1}{8\mu^2} \begin{pmatrix} 2 \cos(k_2) & e^{-i k_1} & e^{i k_1} \\ e^{i k_1} & 2 \cos(k_2 - \phi) & \cdots \\ \cdot & \cdots & \cdots \\ e^{-i k_1} & e^{i k_1} & 2 \cos(k_2 - (q-2)\phi) \\ \cdots & \cdots & \cdots \\ -\frac{2}{8\mu^2} (\cos(k_3) + \cos(k_4)) \mathbf{I}_{q \times q} + 2 \cos\left(\frac{\pi B}{4} + \frac{m\pi}{4}\right) \mathbf{I}_{q \times q} \end{pmatrix}.$$

(A.85)

The eigenvalues of $e^{\frac{\pi}{8} \hat{S}_B} + e^{-\frac{\pi}{8} \hat{S}_B}$ makes eight bunches of bands, and two standard butterflies appear on the bands. So we can see 16 large butterflies (see Fig. 5). With a generic $\{4g, 4g\}$ tiling, $e^{\frac{\pi}{8} \hat{S}_B} + e^{-\frac{\pi}{8} \hat{S}_B}$ makes 4g bunches of bands, and 2($g-1$) large butterflies appear on the bands. Therefore a total of $8g(g-1)$ large butterflies can be found.
Figure 5: [Left] Spectrum of (A.74), plotted as a function of a rational flux and [Right] its zoomed picture between between $-3.7 \leq E \leq -3.0$.

In addition the Hamiltonian (A.73) can be represented as (A.80), where $A_n, B(n = 0, \cdots q - 1)$ are determined by

$$A_n = - \frac{2}{4\mu^2} \begin{pmatrix} 
\cos(k_3) & \cos(k_2 - n\phi) + \cos(k_4) \\
\cos(k_2 - n\phi) + \cos(k_4) & \cos(k_3) 
\end{pmatrix} + \frac{\epsilon^2}{\pi^2} \begin{pmatrix} 
1 & 0 & 1 & 1 & 0 & 1 & 1 & 0 & 1 \\
0 & 1 & 0 & 1 & 0 & 1 \\
\cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots 
\end{pmatrix} \begin{pmatrix} 
e^{2\pi B} 
\end{pmatrix} + \frac{4^2}{\pi^2} \begin{pmatrix} 
1 & 0 & 1 & 1 & 0 & 1 & 1 & 0 & 1 \\
0 & 1 & 0 & 1 & 1 & 0 & 1 & 1 & 0 \\
\cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots 
\end{pmatrix} e^{-2\pi B} + \frac{4^2}{\pi^2} \begin{pmatrix} 
1 & 0 & 1 & 1 & 0 & 1 & 1 & 0 & 1 \\
0 & 1 & 0 & 1 & 1 & 0 & 1 & 1 & 0 \\
\cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots 
\end{pmatrix} e^{-2\pi B}$$

$$B = - \frac{e^{ik_1}}{4\mu^2} \begin{pmatrix} 
1 & 0 & 1 & 1 & 0 & 1 & 1 & 0 & 1 \\
0 & 1 & 0 & 1 & 1 & 0 & 1 & 1 & 0 \\
\cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots 
\end{pmatrix} \begin{pmatrix} 
e^{2\pi B} 
\end{pmatrix} + \frac{4^2}{\pi^2} \begin{pmatrix} 
1 & 0 & 1 & 1 & 0 & 1 & 1 & 0 & 1 \\
0 & 1 & 0 & 1 & 1 & 0 & 1 & 1 & 0 \\
\cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots 
\end{pmatrix} e^{-2\pi B} + \frac{4^2}{\pi^2} \begin{pmatrix} 
1 & 0 & 1 & 1 & 0 & 1 & 1 & 0 & 1 \\
0 & 1 & 0 & 1 & 1 & 0 & 1 & 1 & 0 \\
\cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots 
\end{pmatrix} e^{-2\pi B}$$

The spectrum of this Hamiltonian is as shown in the main text.
