Congruence lattices of SPS lattices

G. Grätzer

Abstract. In this note, I find a new property of the congruence lattice, $\text{Con } L$, of an SPS lattice L (slim, planar, semimodular, where “slim” is the absence of M_3 sublattices) with more than 2 elements: *there are at least two dual atoms in $\text{Con } L$* . So the three-element chain cannot be represented as the congruence lattice of an SPS lattice, supplementing a result of G. Czédli.

Mathematics Subject Classification. 06D05.

Keywords. lattice, congruence, semimodular, planar, slim.

1. Introduction

My paper [6] investigates congruences of fork extensions and in [6, Theorem 5] I prove that the congruence lattice, $\text{Con } L$, of an SPS lattice (a Slim Planar Semimodular lattice, where “slim” means that there is no M_3 sublattice) has the following property:

- (P1) Every join-irreducible congruence has at most two join-irreducible covers (in the order of join-irreducible congruences).

G. Czédli [1, Theorem 1.1] proves that the converse is false by exhibiting an eight-element distributive lattice, D_8 , satisfying (P1), which cannot be represented as the congruence lattice of an SPS lattice; see also my paper [5].

In this note, I observe that the congruence lattice of an SPS lattice L with more than 2 elements has another property:

- (P2) There are at least two dual atoms in $\text{Con } L$.

So the three-element chain C_3 , which satisfies (P1), cannot be represented as the congruence lattice of an SPS lattice, an example of minimal size. Similarly, we can take any distributive lattice of more than two elements with a single dual atom to get a nonrepresentable lattice.

Note that G. Czédli's eight-element example satisfies both (P1) and (P2). To get a condition for representability, we have to go beyond these conditions.

For the basic concepts and notation, see my paper [6] or my books [3] and [4].

2. Verification

In this section, we verify that the three-element chain C_3 cannot be represented as the congruence lattice of an SPS lattice.

Following G. Grätzer and E. Knapp [7], a planar semimodular lattice L is *rectangular*, if the left boundary chain has exactly one doubly-irreducible element, c_l , and the right boundary chain has exactly one doubly-irreducible element, c_r , and these elements are complementary.

Let us assume that L is an SPS lattice with $\text{Con } L \cong C_3$. The following statement is a contradiction.

Proposition. *Let L be an SPS lattice with more than 2 elements. Then (P2) holds.*

Proof. By G. Grätzer and E. Knapp [8, Theorem 7], we can assume that L is rectangular. We prove the following stronger version of the Proposition for slim rectangular lattices:

Let L be a slim rectangular lattice with $c_l, c_t \neq 1$. Then $P_l = [0, c_l]$ and $P_r = [0, c_r]$ are distinct prime ideals of L .

By G. Czédli and E. T. Schmidt [2, Lemma 22], we can obtain L from a grid $D = C_p \times C_q$, where $p, q \geq 2$, with a sequence $D = L_1, L_2, \dots, L_n = L$ of slim rectangular lattices, where we obtain L_{i+1} from L_i by inserting a fork at the covering square $S^i = \{o^i, a_l^i, a_r^i, t^i\}$ for $i = 1, \dots, n - 1$, using the standard notation [6, Section 3, and Figure 5].

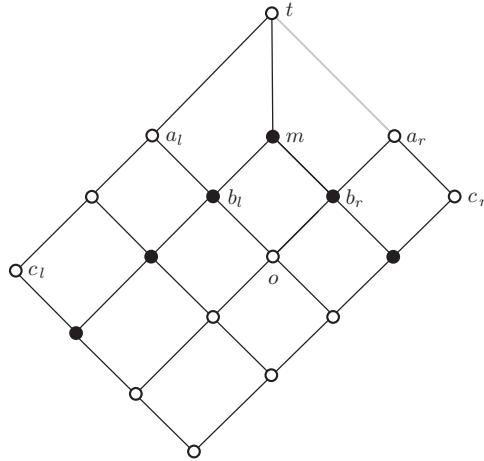

FIGURE 1. Fork insertion

This statement holds for $i = 1$ by inspection, see Figure 1. By induction, assume that the statement holds for $i = n - 1$: $P_l^i = [0, c_l^i]_{L_{n-1}}$ and $P_r^i = [0, c_r^i]_{L_{n-1}}$ are distinct prime ideals of L_{n-1} . The induction step is the same as the induction base, *mutatis mutandis*. \square
