# WELL-POSEDNESS FOR HYPERBOLIC EQUATIONS WHOSE COEFFICIENTS LOSE REGULARITY AT ONE POINT 

DANIELE DEL SANTO AND MARTINO PRIZZI

#### Abstract

We prove some $C^{\infty}$ and Gevrey well-posedness results for hyperbolic equations whose coefficients lose regularity at one point.

## 1. Introduction

In this paper we deal with the well-posedness of the Cauchy problem for a linear hyperbolic operator whose coefficients depend only on time. Namely, we consider the equation

$$
\begin{equation*}
u_{t t}-\sum_{i, j=1}^{n} a_{i j}(t) u_{x_{i} x_{j}}=0 \tag{1.1}
\end{equation*}
$$

in $[0, T] \times \mathbb{R}^{n}$, with initial data

$$
\begin{equation*}
u(0, x)=u_{0}(x), \quad u_{t}(0, x)=u_{1}(x) \tag{1.2}
\end{equation*}
$$

in $\mathbb{R}^{n}$. The matrix $\left(a_{i j}\right)_{i, j}$ is supposed to be real and symmetric. Setting

$$
\begin{equation*}
a(t, \xi):=\sum_{i, j=1}^{n} a_{i j}(t) \xi_{i} \xi_{j} /|\xi|^{2}, \quad(t, \xi) \in[0, T] \times\left(\mathbb{R}^{n} \backslash\{0\}\right) \tag{1.3}
\end{equation*}
$$

we assume throughout that $a(\cdot, \xi) \in L^{\infty}(0, T)$ for all $\xi \in \mathbb{R}^{n} \backslash\{0\}$. Moreover, we suppose that the equation (1.1) is strictly hyperbolic, i.e.

$$
\begin{equation*}
\Lambda_{0} \geq a(t, \xi) \geq \lambda_{0}>0 \tag{1.4}
\end{equation*}
$$

for all $(t, \xi) \in[0, T] \times\left(\mathbb{R}^{n} \backslash\{0\}\right)$.
It is a classical result that if the coefficients $a_{i j}(t)$ 's are real integrable functions, then the Cauchy problem (1.1), (1.2) is well posed in $\mathcal{A}^{\prime}\left(\mathbb{R}^{n}\right)$, the space of real analytic functionals; moreover, if the initial data vanish in a ball, then the solution vanishes in a cone, whose slope depends on the coefficients $a_{i j}(t)$ 's (see [1, Theorems 1 and 3.a]). On this basis,

[^0]various well-posedness results can be proved by mean of the PaleyWiener theorem (in the version of [1, p. 517], to which we refer here and throughout) and some energy estimates. If the coefficients $a_{i j}(t)$ 's are Lipschitz-continuous then the Cauchy problem (1.1), (1.2) is well posed in Sobolev spaces. Relaxing this regulatity assumption, one has that if the $a_{i j}(t)$ 's are Log-Lipschitz-continuous or Hölder-continuous of index $\alpha$, then (1.1), (1.2) is well posed in $C^{\infty}$ or in the Gevrey space $\gamma^{(s)}$ for $s<\frac{1}{1-\alpha}$ respectively (see [1, Theorem 3.b,c]). Suitable counterexamples show that in each case the regularity assumption on the $a_{i j}(t)$ 's is sharp for the well posedness of (1.1), (1.2) in the corresponding function space.

It is a remarkable fact that in the above mentioned counterexamples the coefficients $a_{i j}(t)$ 's are in fact $C^{\infty}$ for $t \neq 0$, and each time the specific regularity fails only at $t=0$. In [2] the authors showed that a control on the rate of the loss of Lipschitz regularity of the $a_{i j}(t)$ 's as $t \rightarrow 0$ allows to recover well-posedness of (1.1), (1.2) in suitable function spaces. To be more specific, if the $a_{i j}(t)$ 's are of class $C^{1}$ in $] 0, T]$ and $\left|a_{i j}^{\prime}(t)\right| \leq C t^{-p}$, then (1.1), (1.2) is well posed in $C^{\infty}$ when $p=1$, and in the Gevrey space $\gamma^{(s)}$ for $s<\frac{p}{p-1}$ when $p>1$. Concerning $C^{\infty}$ well-posedness, it was proved in [3] that a control on the second derivative of the $a_{i j}$ 's as $t \rightarrow 0$ allows to relax slightly the growth assumption on the first derivative up to $\left|a_{i j}^{\prime}(t)\right| \leq C t^{-1}|\log t|$. In [5] some of the above results were extended to the case in which the coefficients $a_{i j}$ 's depend also on the $x$ variable in $C^{\infty}$ fashion.

In this paper we consider non Lipschitz coefficients whose regularity is ruled by a modulus of continuity $\mu$, with a constant which blows up as $t \rightarrow 0$. More precisely, we assume that

$$
\begin{equation*}
\left.\left.\left|a_{i j}(t+\tau)-a_{i j}(t)\right| \leq \frac{C}{\nu(t)} \mu(\tau), \quad 0 \leq \tau \leq \tau_{0}, \quad t, t+\tau \in\right] 0, T\right] \tag{1.5}
\end{equation*}
$$

where $\nu(t)^{-1}$ is possibly non integrable at $t=0$ and where $\mu$-continuity is possibly strictly weaker than Lipschitz continuity. We investigate how the interaction between $\nu$ and $\mu$ affects the well-posedness of (1.1), (1.2).

In Section 2 we prove a technical regularization result for the coefficients $a_{i j}$ 's.

In Section 3 we consider locally Hölder continuous coefficients satisfying

$$
\begin{equation*}
\left.\left.\left|a_{i j}(t+\tau)-a_{i j}(t)\right| \leq \frac{C}{t^{p}} \tau^{\alpha}, \quad 0 \leq \tau, \quad t, t+\tau \in\right] 0, T\right] \tag{1.6}
\end{equation*}
$$

with $0<\alpha<1$ and $p>1$, and we obtain well-posedness in the Gevrey space $\gamma^{(\sigma)}$ for $\sigma<\frac{p}{p-\alpha}$, a condition which fits perfectly with the ones of [1] and [2].

In Section 4 we consider the problem of $C^{\infty}$ well-posedness and we identify a precise relation between $\mu$ and $\nu$ which guarantees the latter. In particular we obtain well-posedness for coefficients satisfying

$$
\begin{equation*}
\left.\left.\left|a_{i j}(t+\tau)-a_{i j}(t)\right| \leq \frac{C}{t|\log t|} \frac{\tau|\log \tau|}{\log |\log \tau|}, \quad 0 \leq \tau, \quad t, t+\tau \in\right] 0, T\right] \tag{1.7}
\end{equation*}
$$

where one can easily see that $\nu(t)^{-1}$ is non integrable and $\mu$-continuity is strictly weaker than Lipschitz continuity. Also in this situation the results fits with the ones contained in [1] and [2] and contain them as particular cases.

## 2. Approximation

We begin by recalling the notion of modulus of continuity.
Definition 1. Let $\tau_{0}>0$. A function $\mu:\left[0, \tau_{0}\right] \rightarrow[0,+\infty[$ is a modulus of continuity if it is continuous, concave, strictly increasing and $\mu(0)=0$.

Let $\mu$ be a modulus of continuity and let $a:[0, T] \rightarrow \mathbb{R}$ be a bounded function. Without loss of generality we can assume that $\tau_{0} \leq T$. We assume that

$$
\begin{equation*}
\left.\left.|a(t+\tau)-a(t)| \leq \frac{C}{\nu(t)} \mu(\tau), \quad 0 \leq \tau \leq \tau_{0}, \quad t, t+\tau \in\right] 0, T\right] \tag{2.1}
\end{equation*}
$$

where $\nu:] 0, T] \rightarrow] 0,+\infty[$ is a non-decreasing continuous function such that, for some $\kappa>0$,

$$
\begin{equation*}
\nu(t / 2) \geq \kappa \nu(t), \quad t \in] 0, T] . \tag{2.2}
\end{equation*}
$$

Remark 1. Condition (2.2) is satisfied whenever $\nu$ is concave. Moreover, it is satisfied by $\nu(t)=t^{p}$ for every real exponent $p>0$. On the other hand, it is not satisfied if $\nu(t)$ tends to 0 too fast as $t \rightarrow 0$, e.g. by $\nu(t)=e^{-1 / t}$.

Now let $0<\epsilon \leq \tau_{0} \leq T$ and define

$$
\tilde{a}_{\epsilon}(t):= \begin{cases}a(\epsilon) & \text { for } t \leq \epsilon  \tag{2.3}\\ a(t) & \text { for } \epsilon \leq t \leq T \\ a(T) & \text { for } T \leq t\end{cases}
$$

Let $\rho \in C^{\infty}(\mathbb{R})$ with supp $\rho \subset[-1,1], \rho(s) \geq 0, \int_{\mathbb{R}} \rho(s) d s=1$, set $\rho_{\epsilon}(s):=\frac{1}{\epsilon} \rho\left(\frac{s}{\epsilon}\right)$, and define

$$
\begin{equation*}
a_{\epsilon}(t):=\int_{-\epsilon}^{\epsilon} \rho_{\epsilon}(s) \tilde{a}_{\epsilon}(t-s) d s, \quad t \in \mathbb{R} \tag{2.4}
\end{equation*}
$$

We have the following
Proposition 2. Under the above hypotheses, there exist constants $C^{\prime}$ and $C^{\prime \prime}>0$ such that, for $0<\epsilon \leq \tau_{0}$,

$$
\begin{equation*}
\left.\left.\left|a_{\epsilon}(t)-\tilde{a}_{\epsilon}(t)\right| \leq C^{\prime} \min \left\{1, \frac{1}{\nu(t)} \mu(\epsilon)\right\}, \quad t \in\right] 0, T\right] \tag{2.5}
\end{equation*}
$$

and

$$
\begin{equation*}
\left.\left.\left|a_{\epsilon}^{\prime}(t)\right| \leq \frac{C^{\prime \prime}}{\epsilon} \min \left\{1, \frac{1}{\nu(t)} \mu(\epsilon)\right\}, \quad t \in\right] 0, T\right] \tag{2.6}
\end{equation*}
$$

The constants $C^{\prime}$ and $C^{\prime \prime}$ depend only on $C, \rho, \kappa$ and $\|a\|_{\infty}$.
Proof. We have

$$
\begin{aligned}
&\left|a_{\epsilon}(t)-\tilde{a}_{\epsilon}(t)\right|=\left|\int_{t-\epsilon}^{t+\epsilon} \rho_{\epsilon}(t-s)\left(\tilde{a}_{\epsilon}(s)-\tilde{a}_{\epsilon}(t)\right) d s\right| \\
& \leq \int_{t-\epsilon}^{t+\epsilon} \rho_{\epsilon}(t-s)\left|\tilde{a}_{\epsilon}(s)-\tilde{a}_{\epsilon}(t)\right| d s
\end{aligned}
$$

If $t \geq 2 \epsilon$, then $t-\epsilon \geq t / 2 \geq \epsilon$, so $\nu(t-\epsilon) \geq \nu(t / 2) \geq \kappa \nu(t)$. Therefore, we have

$$
\begin{aligned}
\left|a_{\epsilon}(t)-\tilde{a}_{\epsilon}(t)\right| \leq & \int_{t-\epsilon}^{t+\epsilon} \rho_{\epsilon}(t-s)|a(s)-a(t)| d s \\
& \leq \int_{t-\epsilon}^{t+\epsilon} \rho_{\epsilon}(t-s) \frac{C}{\nu(t-\epsilon)} \mu(|s-t|) d s \\
& \leq \int_{t-\epsilon}^{t+\epsilon} \rho_{\epsilon}(t-s) \frac{C}{\nu(t / 2)} \mu(|s-t|) d s \\
& \leq \int_{t-\epsilon}^{t+\epsilon} \rho_{\epsilon}(t-s) \frac{C / \kappa}{\nu(t)} \mu(|s-t|) d s \leq \frac{C / \kappa}{\nu(t)} \mu(\epsilon) .
\end{aligned}
$$

If $0<t \leq \epsilon$, then $\tilde{a}_{\epsilon}(s)=\tilde{a}_{\epsilon}(t)=a(\epsilon)$ for $s \leq \epsilon$, and therefore,

$$
\begin{aligned}
\left|a_{\epsilon}(t)-\tilde{a}_{\epsilon}(t)\right| \leq & \int_{\epsilon}^{t+\epsilon} \rho_{\epsilon}(t-s)|a(s)-a(\epsilon)| d s \\
& \leq \int_{\epsilon}^{t+\epsilon} \rho_{\epsilon}(t-s) \frac{C}{\nu(\epsilon)} \mu(|s-\epsilon|) d s \\
& \quad \leq \int_{\epsilon}^{t+\epsilon} \rho_{\epsilon}(t-s) \frac{C}{\nu(t)} \mu(\epsilon) d s \leq \frac{C}{\nu(t)} \mu(\epsilon) .
\end{aligned}
$$

If $\epsilon \leq t \leq 2 \epsilon$, then $0 \leq t-\epsilon \leq \epsilon \leq t$. Therefore, we have

$$
\begin{gathered}
\left|a_{\epsilon}(t)-\tilde{a}_{\epsilon}(t)\right| \leq \int_{t-\epsilon}^{\epsilon} \rho_{\epsilon}(t-s)|a(\epsilon)-a(t)| d s+\int_{\epsilon}^{t+\epsilon} \rho_{\epsilon}(t-s)|a(s)-a(t)| d s \\
\leq \int_{t-\epsilon}^{\epsilon} \rho_{\epsilon}(t-s) \frac{C}{\nu(\epsilon)} \mu(|t-\epsilon|) d s+\int_{\epsilon}^{t+\epsilon} \rho_{\epsilon}(t-s) \frac{C}{\nu(\epsilon)} \mu(|t-s|) d s \\
\leq \frac{C}{\nu(\epsilon)} \mu(\epsilon) \leq \frac{C}{\nu(t / 2)} \mu(\epsilon) \leq \frac{C / \kappa}{\nu(t)} \mu(\epsilon)
\end{gathered}
$$

The thesis follows setting $C^{\prime}:=\max \left\{C, C / \kappa, 2\|a\|_{\infty}\right\}$.
In order to estimate $a_{\epsilon}^{\prime}$, we observe that

$$
\begin{aligned}
\left|a_{\epsilon}^{\prime}(t)\right|=\left|\int_{t-\epsilon}^{t+\epsilon} \rho_{\epsilon}^{\prime}(t-s) \tilde{a}_{\epsilon}(s) d s\right| & =\left|\int_{t-\epsilon}^{t+\epsilon} \rho_{\epsilon}^{\prime}(t-s)\left(\tilde{a}_{\epsilon}(s)-\tilde{a}_{\epsilon}(t)\right) d s\right| \\
& \leq \int_{t-\epsilon}^{t+\epsilon}\left|\rho_{\epsilon}^{\prime}(t-s)\right|\left|\tilde{a}_{\epsilon}(s)-\tilde{a}_{\epsilon}(t)\right| d s
\end{aligned}
$$

Then we procede as above, noticing that $\rho_{\epsilon}^{\prime}(t)=\frac{1}{\epsilon^{2}} \rho^{\prime}\left(\frac{t}{\epsilon}\right)$, and hence

$$
\int_{t-\epsilon}^{t+\epsilon}\left|\rho_{\epsilon}^{\prime}(t-s)\right| d s=\frac{\left\|\rho^{\prime}\right\|_{L^{1}}}{\epsilon}
$$

The thesis follows setting $C^{\prime \prime}:=\left\|\rho^{\prime}\right\|_{L^{1}} \max \left\{C, C / \kappa,\|a\|_{\infty}\right\}$.

## 3. Well posedness in Gevrey spaces

In this section we shall prove that if the coefficients $a_{i j}$ 's are locally Hölder continuous of exponent $\alpha$, with a Hölder constant which grows like $t^{-p}$ as $t \rightarrow 0$, then the Cauchy problem (1.1), (1.2) is well posed in a suitable Gevrey space $\gamma^{(\sigma)}$, where $\sigma$ depends on $\alpha$ and $p$.

As we pointed out in the Introduction, since the coefficients $a_{i j}$ 's are real integrable functions, the Cauchy problem (1.1), (1.2) is well posed in $\mathcal{A}^{\prime}\left(\mathbb{R}^{n}\right)$, the space of real analytic functionals (which have by definition compact support). Moreover, if the initial data vanish in a ball, then the solution vanishes in a cone, whose basis is the same ball
and whose slope depends on the coefficients $a_{i j}$ 's. Therefore, it will be sufficient to show that if $u_{0}$ and $u_{1}$ belong to a a suitable Gevrey space $\gamma^{(\sigma)}$ and have compact support, then the corresponding solution $u$ is not only in $W^{2,1}\left([0, T], \mathcal{A}^{\prime}\left(\mathbb{R}^{n}\right)\right)$, but it belongs to the same Gevrey space in the $x$ variable for all $t \in[0, T]$. The result for initial data which do not have compact support follows by an exhaustion argument. Our main tools in the proof will be the Paley-Wiener theorem and energy estimates.

Theorem 3. Let $p>1$ and $0<\alpha<1$, and assume that there exists a constant $C>0$ such that the function $a=a(t, \xi)$ defined by (1.3) satisfies

$$
\begin{equation*}
\left.\left.|a(t+\tau, \xi)-a(t, \xi)| \leq \frac{C}{t^{p}} \tau^{\alpha}, \quad 0 \leq \tau, \quad t, t+\tau \in\right] 0, T\right] \tag{3.1}
\end{equation*}
$$

for all $\xi \in \mathbb{R}^{n} \backslash\{0\}$. Then the Cauchy problem (1.1), (1.2) is $\gamma^{(\sigma)}$-wellposed for $1 \leq \sigma<\frac{p}{p-\alpha}$.

Remark 2. For a fixed $p>1$, passing to the limit as $\alpha \rightarrow 1$ we regain the result of [2]. In the same way, for a fixed $\alpha<1$, passing to the limit as $p \rightarrow 1$ we extend to $p=1$ the result of [1] which was valid only for $p<1$. The case $\alpha=1, p=1$ was considered in [2] and will be reconsidered here in a more general context: in this case one has well posedness in $C^{\infty}$.

Remark 3. The result in Theorem 3 can be considered sharp in the following sense. Let $p_{0}>1$ and $0<\alpha_{0}<1$. It is possible to construct a positive function $\left.\left.a \in C^{\infty}(] 0, T\right]\right) \cap C([0, T])$ such that

$$
\left.\left.|a(t+\tau)-a(t)| \leq \frac{C}{t^{p_{0}}} \tau^{\alpha_{0}}, \quad 0 \leq \tau, \quad t, t+\tau \in\right] 0, T\right]
$$

and it is possible to construct two functions $u_{0}, u_{1} \in \gamma^{(s)}(\mathbb{R})$, for all $s>\frac{p_{0}}{p_{0}-\alpha_{0}}$ such that the Cauchy problem

$$
\left\{\begin{array}{l}
u_{t t}-a(t) u_{x x}=0 \\
u(0, x)=u_{0}(x), u_{t}(0, x)=u_{1}(x)
\end{array}\right.
$$

has no solution in $C^{1}\left(\left[0, r\left[; D^{\prime(s)}\right)\right.\right.$, for all $s>\frac{p_{0}}{p_{0}-\alpha_{0}}$ and for all $r>$ 0 (here $D^{\prime(s)}$ denotes the set of Gevrey-ultradistributions of index s). The construction of such a counterexample is exactly the same as that contained in Theorem 5 in [2].

Remark 4. A result analogous to that of Theorem 3 can be proved if the singularity of the $a_{i j}$ 's is located at $t=T$, with only minor obvious changes in the proof. As a consequence, the result is still valid
if the coefficients have a finite number of singularities, where the loss of regularity is controlled as in (3.1).

Proof of Theorem [3. We take the Fourier transform of $u$ with respect to $x$, and we denote it by $\hat{u}$. Equation (1.1) then transforms to

$$
\begin{equation*}
\hat{u}_{t t}(t, \xi)+a(t, \xi)|\xi|^{2} \hat{u}(t, \xi)=0 \tag{3.2}
\end{equation*}
$$

Let $\epsilon$ be a positive parameter and for each $\epsilon$ let $a_{\varepsilon}:[0, T] \times\left(\mathbb{R}^{n} \backslash\{0\}\right) \rightarrow$ $\mathbb{R}$ be defined according to (2.3)-(2.4).

We define the approximate energy of $\hat{u}$ by
$E_{\varepsilon}(t, \xi):=a_{\varepsilon}(t, \xi)|\xi|^{2}|\hat{u}(t, \xi)|^{2}+\left|\hat{u}_{t}(t, \xi)\right|^{2}, \quad(t, \xi) \in[0, T] \times\left(\mathbb{R}^{n} \backslash\{0\}\right)$.
Differentiating $E_{\varepsilon}$ with respect to $t$ and using (3.2) we get

$$
\begin{aligned}
& E_{\varepsilon}^{\prime}(t, \xi)=a_{\varepsilon}^{\prime}(t, \xi)|\xi|^{2}|\hat{u}(t, \xi)|^{2}+2 a_{\varepsilon}(t, \xi)|\xi|^{2} \operatorname{Re}\left(\hat{u}_{t}(t, \xi) \overline{\hat{u}}(t, \xi)\right) \\
&+2 \operatorname{Re}\left(\hat{u}_{t t}(t, \xi) \overline{\hat{u}}_{t}(t, \xi)\right) \\
& \leq\left(\frac{\mid a_{\varepsilon}^{\prime}(t, \xi \mid}{a_{\varepsilon}(t, \xi)}+\frac{\left|a_{\varepsilon}(t, \xi)-a(t, \xi)\right|}{a_{\varepsilon}(t, \xi)^{1 / 2}}|\xi|\right) E_{\varepsilon}(t, \xi) .
\end{aligned}
$$

By Gronwall's lemma we obtain

$$
\begin{equation*}
E_{\varepsilon}(t, \xi) \leq E_{\varepsilon}(0, \xi) \exp \left(\int_{0}^{T} \frac{\mid a_{\varepsilon}^{\prime}(t, \xi \mid}{a_{\varepsilon}(t, \xi)} d t+|\xi| \int_{0}^{T} \frac{\left|a_{\varepsilon}(t, \xi)-a(t, \xi)\right|}{a_{\varepsilon}(t, \xi)^{1 / 2}} d t\right) \tag{3.4}
\end{equation*}
$$

for all $t \in[0, T]$ and for all $\xi \in \mathbb{R}^{n},|\xi| \geq 1$.
By Proposition 2 with $\mu(\tau)=\tau^{\alpha}$ and $\nu(t)=t^{p}$ we have

$$
\begin{aligned}
& \int_{0}^{T} \frac{\mid a_{\varepsilon}^{\prime}(t, \xi \mid}{a_{\varepsilon}(t, \xi)} d t+|\xi| \int_{0}^{T} \frac{\left|a_{\varepsilon}(t, \xi)-a(t, \xi)\right|}{a_{\varepsilon}(t, \xi)^{1 / 2}} d t \\
& \leq \int_{0}^{T} \frac{\mid a_{\varepsilon}^{\prime}(t, \xi \mid}{a_{\varepsilon}(t, \xi)} d t+|\xi| \int_{0}^{T}\left(\frac{\left|a(t, \xi)-\tilde{a}_{\epsilon}(t, \xi)\right|}{a_{\varepsilon}(t, \xi)^{1 / 2}}+\frac{\left|a_{\varepsilon}(t, \xi)-\tilde{a}_{\epsilon}(t, \xi)\right|}{a_{\varepsilon}(t, \xi)^{1 / 2}}\right) d t \\
& \leq \int_{0}^{\epsilon^{\epsilon^{\alpha / p}}} \frac{C^{\prime \prime}}{\lambda_{0} \epsilon} d t+\int_{\epsilon^{\alpha / p}}^{T} \frac{C^{\prime \prime}}{\lambda_{0} \epsilon} t^{-p} \epsilon^{\alpha} d t+\frac{2 \Lambda_{0}}{\lambda_{0}^{1 / 2}|\xi| \epsilon} \\
& \quad+|\xi|\left(\int_{0}^{\epsilon^{\alpha / p}} \frac{C^{\prime}}{\lambda_{0}^{1 / 2}} d t+\int_{\epsilon^{\alpha / p}}^{T} \frac{C^{\prime}}{\lambda_{0}^{1 / 2}} t^{-p} \epsilon^{\alpha} d t\right) \\
& \leq M|\xi| \epsilon+M\left(|\xi|+\frac{1}{\epsilon}\right)\left(\epsilon^{\alpha / p}+\left(\epsilon^{\alpha / p}\right)^{1-p} \epsilon^{\alpha}\right) \\
& \quad=M|\xi| \epsilon+2 M\left(|\xi|+\frac{1}{\epsilon}\right) \epsilon^{\alpha / p}
\end{aligned}
$$

where $M$ depends on $C^{\prime}, C^{\prime \prime}, \lambda_{0}, \Lambda_{0}, \alpha$ and $p$. Choosing $\epsilon=|\xi|^{-1}$ we get

$$
\begin{equation*}
\left[\int_{0}^{T} \frac{\mid a_{\varepsilon}^{\prime}(t, \xi \mid}{a_{\varepsilon}(t, \xi)} d t+|\xi| \int_{0}^{T} \frac{\left|a_{\varepsilon}(t, \xi)-a(t, \xi)\right|}{a_{\varepsilon}(t, \xi)^{1 / 2}} d t\right]_{\epsilon=|\xi|^{-1}} \leq M+4 M|\xi|^{\frac{p-\alpha}{p}} \tag{3.5}
\end{equation*}
$$

Putting together (3.4) and (3.5) we get

$$
\begin{equation*}
E_{1 /|\xi|}(t, \xi) \leq e^{M} e^{4 M|\xi| \frac{p-\alpha}{p}} E_{1 /|\xi|}(0, \xi) \tag{3.6}
\end{equation*}
$$

and, finally,

$$
\begin{equation*}
\left|\hat{u}_{t}(t, \xi)\right|^{2}+|\xi|^{2}|\hat{u}(t, \xi)|^{2} \leq \frac{e^{M} \Lambda_{o}}{\lambda_{0}} e^{4 M|\xi|^{\frac{p-\alpha}{p}}}\left(\left|\hat{u}_{t}(0, \xi)\right|^{2}+|\xi|^{2}|\hat{u}(0, \xi)|^{2}\right) \tag{3.7}
\end{equation*}
$$

Now if $u_{0}, u_{1} \in \gamma^{(\sigma)} \cap C_{0}^{\infty}$, the Paley-Wiener theorem ensures that there exist $K, \delta>0$ such that

$$
\begin{equation*}
|\hat{u}(0, \xi)|^{2}+\left|\hat{u}_{t}(0, \xi)\right|^{2} \leq K \exp \left(-\delta|\xi|^{1 / \sigma}\right) \tag{3.8}
\end{equation*}
$$

for all $\xi \in \mathbb{R}^{n},|\xi| \geq 1$. It follows from (3.7) that if $\sigma<p /(p-\alpha)$, then there exist $K^{\prime}, \delta^{\prime}>0$ such that

$$
\begin{equation*}
|\hat{u}(t, \xi)|^{2}+\left|\hat{u}_{t}(t, \xi)\right|^{2} \leq K^{\prime} \exp \left(-\delta^{\prime}|\xi|^{1 / \sigma}\right) \tag{3.9}
\end{equation*}
$$

for all $t \in[0, T]$ and for all $\xi \in \mathbb{R}^{n},|\xi| \geq 1$ and, therefore, $u \in$ $W^{2,1}\left([0, T], \gamma^{(\sigma)}\right)$. The proof is complete.

## 4. Well posedness in $C^{\infty}$

Let $\psi:[1,+\infty[\rightarrow] 0,+\infty[$ be a strictly increasing continuous function, such that $\psi^{\prime}$ is non-increasing and $e^{r} \psi^{\prime}(r)$ is non-decreasing. Moreover, we assume that
(1) $\lim _{r \rightarrow \infty} \psi(r)=\chi, 0<\chi \leq+\infty$;
(2) $\lim _{r \rightarrow \infty} \psi^{\prime}(r)=\eta, 0 \leq \eta<+\infty$;

We set

$$
\nu(t):= \begin{cases}\frac{t}{\psi^{\prime}(|\log t|)} & \text { for } 0<t \leq e^{-1}  \tag{4.1}\\ \frac{e^{-1}}{\psi^{\prime}(1)} & \text { for } e^{-1} \leq t\end{cases}
$$

A direct computation shows that $\nu$ is a non-decreasing continuous function and that $\nu(t / 2) \geq(1 / 2) \nu(t)$ for $t \in] 0, T]$. We define

$$
\begin{equation*}
\mu(\tau):=\frac{\tau|\log \tau|}{\psi(|\log \tau|)} \tag{4.2}
\end{equation*}
$$

and we assume that $\mu$ is strictly increasing and concave in $\left.] 0, \tau_{0}\right]$ for a suitable $\tau_{0}>0$, so it is a modulus of continuity.

Theorem 4. Let $\nu=\nu(t)$ and $\mu=\mu(\tau)$ be as above, and assume that there exists a constant $C>0$ such that the function $a=a(t, \xi)$ defined by (1.3) satisfies

$$
\begin{equation*}
\left.\left.|a(t+\tau, \xi)-a(t, \xi)| \leq \frac{C}{\nu(t)} \mu(\tau), \quad 0 \leq \tau \leq \tau_{0}, \quad t, t+\tau \in\right] 0, T\right] \tag{4.3}
\end{equation*}
$$

for all $\xi \in \mathbb{R}^{n} \backslash\{0\}$. Then the Cauchy problem (1.1), (1.2) is well-posed in $C^{\infty}$.

Remark 5. Examples of functions satisfying all the above properties are $\psi(r)=1-e^{-\alpha r}$ with $0<\alpha \leq 1, \psi(r)=1+\log r$ and $\psi(r)=r^{\beta}$ with $0<\beta \leq 1$. In particular, we have:

- if $\psi(r)=r$ we have $\eta=1$ and $\chi=+\infty$ and we get $\mu(\tau)=\tau$ and $\nu(t)=t$, that is the situation considered in [2];
- if $\psi(r)=1-e^{-\alpha r}$ we have $\eta=0$ and $\chi=1$ and we get $\mu(\tau)=\tau|\log \tau| /\left(1-\tau^{\alpha}\right)$, which is equivalent to $\mu(\tau)=\tau|\log \tau|$, and $\nu(t)=\alpha t^{1-\alpha}$, that is a situation covered by the result of [1], since $\nu(t)^{-1}$ is integrable;
- if $\psi(r)=1+\log r$ or $\psi(r)=r^{\beta}$ with $0<\beta<1$, we have $\eta=0$ and $\chi=+\infty$, and we get $\mu(\tau)=\tau|\log \tau| /(1+\log |\log \tau|)$ or $\mu(\tau)=\tau|\log \tau|^{1-\beta}$. In both cases $\mu$-continuity is weaker than Lipschitz continuity. Moreover we have $\nu(t)=t|\log t|$ or $\nu(t)=t|\log t|^{1-\beta}$, so in both cases $\nu(t)^{-1}$ is not integrable.
The case in which $\mu(\tau)=\tau|\log \tau|$ and $\nu(t)^{-1}$ is not integrable is not covered by Theorem 4, and we were not able to find a counterexample to $C^{\infty}$ well posedness either, so the question remains open. On the other hand, when $\mu(\tau)=\tau|\log \tau|$ and $\nu(t)=t$ by Theorem 3 we get authomatically $\gamma^{(\infty)}$ well posedness.

Remark 6. A result analogous to that of Theorem 4 can be proved if the singularity of the $a_{i j}$ 's is located at $t=T$, with only minor obvious changes in the proof. As a consequence, the result is still valid if the coefficients have a finite number of singularities, where the loss of regularity is controlled as in (4.3).

Proof of Theorem 4. Like in the proof of Theorem 3, we take the Fourier transform $\hat{u}$ of $u$. Equation (1.1) then transforms to

$$
\begin{equation*}
\hat{u}_{t t}(t, \xi)+a(t, \xi)|\xi|^{2} \hat{u}(t, \xi)=0 \tag{4.4}
\end{equation*}
$$

For $0<\epsilon \leq \tau_{1}:=\min \left\{\tau_{0}, T, e^{-1}\right\}$ we define $a_{\varepsilon}:[0, T] \times\left(\mathbb{R}^{n} \backslash\{0\}\right) \rightarrow \mathbb{R}$ according to (2.3)-(2.4). Again, we define an approximate energy of $\hat{u}$
by
$E_{\varepsilon}(t, \xi):=a_{\varepsilon}(t, \xi)|\xi|^{2}|\hat{u}(t, \xi)|^{2}+\left|\hat{u}_{t}(t, \xi)\right|^{2}, \quad(t, \xi) \in[0, T] \times\left(\mathbb{R}^{n} \backslash\{0\}\right)$.
Differentiating $E_{\varepsilon}$ with respect to $t$ and using (4.4) we get

$$
\begin{aligned}
E_{\varepsilon}^{\prime}(t, \xi)=a_{\varepsilon}^{\prime}(t, \xi)|\xi|^{2} \mid & \left.\hat{u}(t, \xi)\right|^{2}+2 a_{\varepsilon}(t, \xi)|\xi|^{2} \operatorname{Re}\left(\hat{u}_{t}(t, \xi) \overline{\hat{u}}(t, \xi)\right) \\
& +2 \operatorname{Re}\left(\hat{u}_{t t}(t, \xi) \overline{\hat{u}}_{t}(t, \xi)\right) \\
& \leq\left(\frac{\mid a_{\varepsilon}^{\prime}(t, \xi \mid}{a_{\varepsilon}(t, \xi)}+\frac{\left|a_{\varepsilon}(t, \xi)-a(t, \xi)\right|}{a_{\varepsilon}(t, \xi)^{1 / 2}}|\xi|\right) E_{\varepsilon}(t, \xi) .
\end{aligned}
$$

By Gronwall's lemma we obtain

$$
\begin{equation*}
E_{\varepsilon}(t, \xi) \leq E_{\varepsilon}(0, \xi) \exp \left(\int_{0}^{T} \frac{\mid a_{\varepsilon}^{\prime}(t, \xi \mid}{a_{\varepsilon}(t, \xi)} d t+|\xi| \int_{0}^{T} \frac{\left|a_{\varepsilon}(t, \xi)-a(t, \xi)\right|}{a_{\varepsilon}(t, \xi)^{1 / 2}} d t\right) \tag{4.6}
\end{equation*}
$$

for all $t \in[0, T]$ and for all $\xi \in \mathbb{R}^{n},|\xi| \geq 1$. By Proposition 2 with $\mu(\tau)$ and $\nu(t)$ given by (4.2) and (4.1), we have

$$
\begin{aligned}
& \int_{0}^{T} \frac{\mid a_{\varepsilon}^{\prime}(t, \xi \mid}{a_{\varepsilon}(t, \xi)} d t=\int_{0}^{\epsilon} \frac{\mid a_{\varepsilon}^{\prime}(t, \xi \mid}{a_{\varepsilon}(t, \xi)} d t+\int_{\epsilon}^{e^{-1}} \frac{\mid a_{\varepsilon}^{\prime}(t, \xi \mid}{a_{\varepsilon}(t, \xi)} d t+\int_{e^{-1}}^{T} \frac{\mid a_{\varepsilon}^{\prime}(t, \xi \mid}{a_{\varepsilon}(t, \xi)} d t \\
\leq & \frac{C^{\prime \prime}}{\lambda_{0} \epsilon}\left(\epsilon+\int_{\epsilon}^{e^{-1}} \frac{\psi^{\prime}(|\log t|)}{t} \frac{\epsilon|\log \epsilon|}{\psi(|\log \epsilon|)} d t+\int_{e^{-1}}^{T} \frac{\psi^{\prime}(1)}{e^{-1}} \frac{\epsilon|\log \epsilon|}{\psi(|\log \epsilon|)} d t\right) .
\end{aligned}
$$

Since

$$
\frac{\psi^{\prime}(|\log t|)}{t}=-\frac{d}{d t} \psi(|\log t|)
$$

and $\psi(|\log \epsilon|) \geq \psi\left(\left|\log \tau_{1}\right|\right)$, we obtain

$$
\begin{equation*}
\int_{0}^{T} \frac{\mid a_{\varepsilon}^{\prime}(t, \xi \mid}{a_{\varepsilon}(t, \xi)} d t \leq M^{\prime \prime}(1+|\log \epsilon|) \tag{4.7}
\end{equation*}
$$

On the other hand

$$
\begin{aligned}
& \int_{0}^{T} \frac{\left|a_{\varepsilon}(t, \xi)-a(t, \xi)\right|}{a_{\varepsilon}(t, \xi)^{1 / 2}} d t=\int_{0}^{T}\left(\frac{\left|a(t, \xi)-\tilde{a}_{\epsilon}(t, \xi)\right|}{a_{\varepsilon}(t, \xi)^{1 / 2}}+\frac{\left|a_{\varepsilon}(t, \xi)-\tilde{a}_{\epsilon}(t, \xi)\right|}{a_{\varepsilon}(t, \xi)^{1 / 2}}\right) d t \\
\leq & \frac{2 \Lambda_{0}}{\lambda_{0}^{1 / 2}} \epsilon+\frac{C^{\prime}}{\lambda_{0}^{1 / 2}}\left(\epsilon+\int_{\epsilon}^{e^{-1}} \frac{\psi^{\prime}(|\log t|)}{t} \frac{\epsilon|\log \epsilon|}{\psi(|\log \epsilon|)} d t+\int_{e^{-1}}^{T} \frac{\psi^{\prime}(1)}{e^{-1}} \frac{\epsilon|\log \epsilon|}{\psi(|\log \epsilon|)} d t\right) .
\end{aligned}
$$

Arguing as above we, get

$$
\begin{equation*}
\int_{0}^{T} \frac{\left|a_{\varepsilon}(t, \xi)-a(t, \xi)\right|}{a_{\varepsilon}(t, \xi)^{1 / 2}} d t \leq M^{\prime} \epsilon(1+|\log \epsilon|) . \tag{4.8}
\end{equation*}
$$

Choosing $\epsilon=|\xi|^{-1}$ we get

$$
\begin{equation*}
\left[\int_{0}^{T} \frac{\mid a_{\varepsilon}^{\prime}(t, \xi \mid}{a_{\varepsilon}(t, \xi)} d t+|\xi| \int_{0}^{T} \frac{\left|a_{\varepsilon}(t, \xi)-a(t, \xi)\right|}{a_{\varepsilon}(t, \xi)^{1 / 2}} d t\right]_{\epsilon=|\xi|^{-1}} \leq M((1+\log |\xi|) \tag{4.9}
\end{equation*}
$$

for $|\xi| \geq \tau_{1}^{-1}$.
Putting together (4.6) and (4.9) we get

$$
\begin{equation*}
E_{1 /|\xi|}(t, \xi) \leq e^{M}|\xi|^{M} E_{1 /|\xi|}(0, \xi) \tag{4.10}
\end{equation*}
$$

and, finally,

$$
\begin{equation*}
\left|\hat{u}_{t}(t, \xi)\right|^{2}+|\xi|^{2}|\hat{u}(t, \xi)|^{2} \leq \frac{e^{M} \Lambda_{o}}{\lambda_{0}}|\xi|^{M}\left(\left|\hat{u}_{t}(0, \xi)\right|^{2}+|\xi|^{2}|\hat{u}(0, \xi)|^{2}\right) \tag{4.11}
\end{equation*}
$$

Now if $u_{0}, u_{1} \in C_{0}^{\infty}$, the Paley-Wiener theorem ensures that for all $\zeta>0$ there exists $K_{\zeta}>0$ such that

$$
\begin{equation*}
|\hat{u}(0, \xi)|^{2}+\left|\hat{u}_{t}(0, \xi)\right|^{2} \leq K_{\zeta}|\xi|^{-\zeta} \tag{4.12}
\end{equation*}
$$

for all $\xi \in \mathbb{R}^{n},|\xi| \geq \tau_{1}^{-1}$. It follows from (4.11) that for all $\theta>0$ there exist $K_{\theta}^{\prime}>0$ such that

$$
\begin{equation*}
|\hat{u}(t, \xi)|^{2}+\left|\hat{u}_{t}(t, \xi)\right|^{2} \leq K_{\theta}^{\prime}|\xi|^{-\theta} \tag{4.13}
\end{equation*}
$$

for all $t \in[0, T]$ and for all $\xi \in \mathbb{R}^{n},|\xi| \geq \tau_{1}^{-1}$, and therefore, $u \in$ $W^{2,1}\left([0, T], C_{0}^{\infty}\right)$. The proof is complete.
