DETECTING POSITIVE QUANTUM CAPACITIES OF QUANTUM CHANNELS

SATVIK SINGH AND NILANJANA DATT

Abstract. Using elementary techniques from analytic perturbation theory of Hermitian matrices, we devise a simple strategy to detect positive quantum capacities of quantum channels and their complements. Several noteworthy examples, such as the depolarizing and transpose-depolarizing channels (including the Werner-Holevo channel), dephasing channels, generalized Pauli channels, multi-level amplitude damping channels, and (conjugate) diagonal unitary covariant channels, serve to aptly exhibit the utility of our method. Our main result leads to simplified proofs of certain existing structure theorems for the class of degradable quantum channels, and an extension of their applicability to the larger class of more capable quantum channels.

Dedicated to the thousands of people who have lost their lives to the pandemic – especially in India during the last few weeks – including Raj Datta, a beloved brother who lost his battle on 11.05.21.

1. INTRODUCTION

The capacity of a noisy communication channel quantifies the fundamental physical limit on noiseless communication through it. Shannon proved that every noisy classical channel has a unique capacity which is given in terms of the mutual information between the random variables characterizing the channel’s input and output [Sha48]. In contrast, a quantum channel has many different kinds of capacities. These depend on a variety of factors, for example, on the type of information (classical or quantum) which is being transmitted, whether or not this information is private, the nature of the input states (entangled or not), and whether any auxiliary resource is available to assist the transmission.

The quantum capacity of a quantum channel quantifies the maximum rate of noiseless and coherent quantum communication through it, in the absence of any auxiliary resource. In general,

\[ \text{auxiliary resources like prior shared entanglement between the sender and the receiver can enhance the capacities of a quantum channel. This is in contrast to the case of a classical channel where auxiliary resources, such as shared randomness between the sender and the receiver, fail to enhance the capacity.} \]
it is not possible to explicitly compute the quantum capacity of a given channel. This is because Lloyd [Llo97], Shor [Sho02], and Devetak [Dev05] have shown, with increasing levels of rigour, that the quantum capacity of a channel $\Phi$ is given by the following regularized formula (as opposed to a single letter expression):

$$Q(\Phi) = \lim_{n \to \infty} \frac{Q^{(1)}(\Phi \otimes^n)}{n},$$

(1)

where

$$Q^{(1)}(\Phi) := \max_{\rho} I_c(\rho; \Phi) \quad \text{and} \quad I_c(\rho; \Phi) := S[\Phi(\rho)] - S[\Phi_c(\rho)].$$

(2)

In the above definition, $\Phi_c$ denotes a channel which is complementary to $\Phi$ (see Section 2.1), and for any quantum state $\rho$, $S(\rho) := -\text{Tr}(\rho \log \rho)$ denotes its von Neumann entropy. The quantity $Q^{(1)}(\Phi)$ is called the coherent information of $\Phi$. Usually, it is superadditive: $Q^{(1)}(\Phi \otimes^n) > nQ^{(1)}(\Phi)$, and hence the quantum capacity of $\Phi$ is larger than its coherent information and notoriously difficult to compute. Some exceptional classes of channels which are currently known to have zero capacity (say $\Phi_1$ and $\Phi_2$), each of which has zero quantum capacity, but which can be used in tandem to transmit quantum information, i.e. $Q(\Phi_1 \otimes \Phi_2) > 0$. This startling effect (known as superactivation [SY08]), is a purely quantum phenomenon because classically, if two channels have zero capacity, the capacity of the joint channel must also be zero.

1.1. Summary of main results. In light of the above discussion, it is of utmost importance to determine when a given quantum channel has positive quantum capacity. However, to date, there is no known procedure or algorithm which solves this problem, except in a handful of special cases [SS12]. The main result of this paper makes a significant step forward in this direction by providing a powerful sufficient condition to guarantee positivity of quantum capacities for a wide variety of quantum channels and their complements; see Theorem 3.1 in the main text, which is also stated below for convenience.

**Theorem.** Let $\Phi$ and $\Phi_c$ be complementary quantum channels. For a pure state $|\psi\rangle\langle\psi|$, denote the orthogonal projections onto $\ker \Phi(|\psi\rangle\langle\psi|)$ and $\ker \Phi^c(|\psi\rangle\langle\psi|)$ by $K_\psi$ and $K_\psi^c$, respectively. Then,

- $Q(\Phi) \geq Q^{(1)}(\Phi) > 0$ if there exist states $|\psi\rangle\langle\psi|$ and $\sigma$ such that $\text{Tr}(K_\psi \Phi(\sigma)) > \text{Tr}(K_\psi^c \Phi_c(\sigma))$.
- $Q(\Phi_c) \geq Q^{(1)}(\Phi_c) > 0$ if there exist states $|\psi\rangle\langle\psi|$ and $\sigma$ such that $\text{Tr}(K_\psi \Phi(\sigma)) < \text{Tr}(K_\psi^c \Phi_c(\sigma))$.

An equivalent formulation of the above theorem yields a first-of-its-kind necessary condition for membership in the set of zero capacity quantum channels; see Theorem 3.8. As a sanity check, we prove that some of the few known classes of channels with zero capacity satisfy the necessary condition of Theorem 3.8; see Lemma 3.9. Notably, the main result in [Sid20] arises as an immediate consequence of Theorem 3.1, which can be applied to detect positive quantum capacity of a given channel (or its complement) if the channel’s output and environment dimension are unequal, so that any such channel (or its complement) with unequal output and environment dimension must have positive quantum capacity, irrespective of the specific form of the channel; see Corollary 3.2. Notwithstanding the difficulty in ascertaining the existence of the aforementioned pure state for any given channel, we prove that the desired pure state exists for all channels with sufficiently large input dimensions, so that any such channel (or its complement) with unequal output and environment dimension must have positive quantum capacity, irrespective of the specific form of the channel; see Corollary 3.4. Similar results were obtained in [Sid20] for channels with large output and environment dimensions, which are derived again in Corollary 3.6 with simpler proofs.
Meanwhile, Theorem 3.1 is completely unaffected by the above considerations, and hence can be applied to a much broader spectrum of quantum channels, including the ones which have equal output and environment dimensions and the ones for which no pure state gets mapped to an output state with maximal rank; see Remark 3.3.

Using our main results, we are able to establish positivity of the quantum capacities of numerous important quantum channels and their complements in Section 4. The following is a list of main results in this direction.

- In [LW17], the qubit depolarizing channel $\mathcal{D}_p : \mathcal{M}_2 \to \mathcal{M}_2$ was shown to have positive complementary quantum capacity\(^2\) for all non-zero values of the noise parameter $p > 0$. We extend this result to show that the qubit depolarizing and transpose-depolarizing channels ($\mathcal{D}_p : \mathcal{M}_d \to \mathcal{M}_d$ and $\mathcal{D}_q^\top : \mathcal{M}_d \to \mathcal{M}_d$, respectively) have positive complementary quantum capacities for all $p > 0$ and $q < \frac{d}{d-1}$; see Theorem 4.1. Moreover, the Werner-Holevo channel $\Phi_{\text{WH}} \equiv \mathcal{D}_{\frac{d}{d-1}} : \mathcal{M}_d \to \mathcal{M}_d$ is shown to have positive complementary quantum capacity for all $d \geq 4$; see Theorem 4.3.
- In [LW17], the qubit Pauli channel $\Phi_P : \mathcal{M}_2 \to \mathcal{M}_2$ was also shown to have positive complementary quantum capacity whenever the defining probability matrix $P \in \mathcal{M}_2$ has at least three non-zero entries. An extension of this result for generalized qubit Pauli channels $\Phi_P : \mathcal{M}_d \to \mathcal{M}_d$ with a much simpler proof is presented in Theorem 4.4.
- For a multi-level amplitude damping channel $\Phi_\gamma : \mathcal{M}_d \to \mathcal{M}_d$, we establish simple constraints on the decay rate vector $\gamma \in \mathbb{R}^{(d-1)/2}$ which ensure the positivity of its quantum capacity and its complementary quantum capacity; see Theorem 4.6.
- We show that a generalized dephasing or Hadamard channel $\Phi_B : \mathcal{M}_d \to \mathcal{M}_d$ (parametrized by a correlation matrix $B \in \mathcal{M}_d$) has zero quantum capacity if and only if it is entanglement-breaking; see Theorem 4.12.
- Recently, the family of (conjugate) diagonal unitary covariant (dubbed (C)DUC) quantum channels was introduced in [SN20a]. A rich variety of channels, such as the depolarizing and transpose depolarizing channels, amplitude damping channels, dephasing channels etc. are known to belong in this family. In Proposition 4.10, we completely characterize the class of (C)DUC channels for which there exists a pure input state which gets mapped to a maximal rank output state, so that Corollary 3.2 can be applied to infer positivity of the quantum capacities of these channels and their complements; see Theorem 4.11.

Moreover, Theorem 3.1 has various interesting ramifications, which are studied in Section 5. For instance, it leads to simplified proofs of certain existing structure theorems for the class of degradable quantum channels, and an extension of their applicability to the larger class of more capable quantum channels.

1.2. Mathematical methods. The primary tool employed in the proof of Theorem 3.1 is a seminal result (by Rellich) from the theory of analytic perturbations of Hermitian matrices. Put simply, if a Hermitian matrix $A_0$ with an eigenvalue $\lambda$ of multiplicity $n$ is subjected to a linear (Hermitian) perturbation $A(\epsilon) = A_0 + \epsilon A_1$ in a real parameter $\epsilon$, then the perturbed matrix has exactly $n$ eigenvalues converging to $\lambda$ as $\epsilon \to 0$, all of which, rather remarkably, admit convergent power series expansions in a neighborhood of $\epsilon = 0$; see Theorem A.1. Now, for a given channel $\Phi$, it is trivial to see that $I_c(\rho; \Phi) = 0$ for all pure input states $\rho = |\psi\rangle\langle\psi|$. It turns out that if we choose $\rho(\epsilon) = (1 - \epsilon)|\psi\rangle\langle\psi| + \epsilon\sigma$ as a slight perturbation of an arbitrarily chosen pure state $|\psi\rangle\langle\psi|$ with an arbitrary mixed state $\sigma$, then the first order correction terms in the eigenvalue expansions of the perturbed outputs $\Phi[\rho(\epsilon)]$ and $\Phi_c[\rho(\epsilon)]$ can be analyzed to yield a simple condition which guarantees that $I_c(\rho(\epsilon); \Phi) > 0$ for sufficiently small values of $\epsilon$, so that $Q^{(1)}(\Phi) > 0 \implies \Phi(\Phi) > 0$.\(^2\)

\(^2\)The complementary quantum capacity of a channel refers to the quantum capacity of anyone of its complements.
2. Prerequisites

Let us start our journey by briefly reviewing the basics of quantum channels and their capacities in this section. A more thorough discussion on these topics can be found in [Wat18].

### 2.1. Quantum channels

We denote the set of all $d_1 \times d_2$ complex matrices by $\mathcal{M}_{d_1 \times d_2}$. When $d_1 = d_2 = d$, we denote the corresponding matrix space by $\mathcal{M}_d := \mathcal{M}_{d \times d}$. For $A, B \in \mathcal{M}_d$, $A \leq B$ means that $B - A$ is positive semi-definite. The convex set of quantum states (positive semi-definite matrices with unit trace) in $\mathcal{M}_d$ and $\mathcal{M}_d^{\otimes n}$ (for $n \in \mathbb{N}$) will be denoted by $\mathcal{S}_d$ and $\mathcal{S}_{d^{\otimes n}}$, respectively.

The vectorization map $\text{vec} : \mathcal{M}_{d_1 \times d_2} \to \mathbb{C}^{d_1} \otimes \mathbb{C}^{d_2}$ is a linear bijection defined as

$$\forall X \in \mathcal{M}_{d_1 \times d_2} : \text{vec } X = \sum_{i,j=0}^{d-1} X_{ij} |ij\rangle,$$

where $\{|i\rangle\}_{i \in [d]}$ denotes the standard orthonormal basis of $\mathbb{C}^d$ and $[d] := \{0, 1, \ldots, d-1\}$. For any given $|\psi\rangle \in \mathbb{C}^{d_1} \otimes \mathbb{C}^{d_2}$, one can use the singular value decomposition of $\text{vec}^{-1} |\psi\rangle \in \mathcal{M}_{d_1 \times d_2}$ to obtain the Schmidt decomposition of $|\psi\rangle = \sum_{i=0}^{n-1} \sqrt{s_i} |i\rangle_1 |i\rangle_2$, where $\{|i\rangle_1\}_{i \in [n]} \subseteq \mathbb{C}^{d_1}$ and $\{|i\rangle_2\}_{i \in [n]} \subseteq \mathbb{C}^{d_2}$ are orthonormal sets, $s_i \geq 0$ and $n = \min\{d_1, d_2\}$. The number of non-zero $s_i$ is called the Schmidt rank of $|\psi\rangle$, and is equal to $\text{rank}(\text{vec}^{-1} |\psi\rangle) \leq \min\{d_1, d_2\}$.

A quantum channel is a completely positive and trace preserving linear map $\Phi : \mathcal{M}_{d_1} \to \mathcal{M}_{d_2}$. $\Phi$ is said to be unital if $\Phi(\mathbb{1}_{d_1}) = \mathbb{1}_{d_2}$, where $\mathbb{1}_d \in \mathcal{M}_d$ is the identity matrix. Its adjoint $\Phi^* : \mathcal{M}_{d_2} \to \mathcal{M}_{d_1}$ is a unital completely positive linear map defined uniquely by the following relation:

$$\forall X \in \mathcal{M}_{d_1}, \forall Y \in \mathcal{M}_{d_2} : \text{Tr}[\Phi(X)Y] = \text{Tr}[X\Phi^*(Y)].$$

Two quantum channels $\Phi : \mathcal{M}_d \to \mathcal{M}_{d_{\text{out}}}$ and $\Phi_c : \mathcal{M}_d \to \mathcal{M}_{d_{\text{env}}}$ are complementary to each other if there exists an isometry (often called a Stinespring isometry) $V : \mathbb{C}^d \to \mathbb{C}^{d_{\text{out}}} \otimes \mathbb{C}^{d_{\text{env}}}$ such that

$$\forall X \in \mathcal{M}_d : \Phi(X) = \text{Tr}_{\text{env}}(V XV^\dagger) \quad \text{and} \quad \Phi_c(X) = \text{Tr}_{\text{out}}(V XV^\dagger).$$

In the above scenario, all input states are first isometrically embedded into the combined output-environment space, with the action of $\Phi$ and $\Phi_c$, then retrieved by partially tracing out the environment and the output space, respectively [KMNR07, Hol07]. For a given channel $\Phi : \mathcal{M}_d \to \mathcal{M}_{d_{\text{out}}}$, the collection of all channels that are complementary to $\Phi$ is denoted by $\mathcal{C}_\Phi$.

**Remark 2.1.** To every channel $\Phi : \mathcal{M}_d \to \mathcal{M}_{d_{\text{out}}}$, we can uniquely associate two sets of channels $\mathcal{C}_\Phi$ and $\mathcal{C}_{\Phi_c}$, where $\Phi_c \in \mathcal{C}_{\Phi}$ is complementary to $\Phi$. These sets are non-empty, since the Stinespring dilation theorem guarantees that the given channel $\Phi$ can be expressed as in Eq. (5) for some isometry $V : \mathbb{C}^d \to \mathbb{C}^{d_{\text{out}}} \otimes \mathbb{C}^{d_{\text{env}}}$ [Wat18, Corollary 2.27]. Furthermore, it is easy to see that different choices of $\Phi_c \in \mathcal{C}_\Phi$ yield the same set $\mathcal{C}_\Phi$. Finally, it is straightforward to show that

- any two channels $\Phi_1, \Phi_2 \in \mathcal{C}_\Phi$ (or $\mathcal{C}_{\Phi_c}$) with $\Phi_1 : \mathcal{M}_d \to \mathcal{M}_{d_1}$, $\Phi_2 : \mathcal{M}_d \to \mathcal{M}_{d_2}$, and $d_1 \leq d_2$ are isometrically related, i.e. $\exists$ an isometry $W : \mathbb{C}^{d_1} \to \mathbb{C}^{d_2}$ such that $\Phi_2(X) = W\Phi_1(X)W^\dagger$.
- any two channels $\Phi_1 \in \mathcal{C}_\Phi$ and $\Phi_2 \in \mathcal{C}_{\Phi_c}$ are complementary to each other.

We define the minimal environment and output dimension of $\Phi$ as

$$d^*_{\text{env}}(\Phi) := \min\{d_{\text{env}} : \exists \Phi_c \in \mathcal{C}_\Phi, \Phi_c : \mathcal{M}_d \to \mathcal{M}_{d_{\text{env}}}\} \quad \text{and} \quad d^*_{\text{out}}(\Phi) := d^*_{\text{env}}(\Phi_c),$$

respectively, where $\Phi_c \in \mathcal{C}_\Phi$. Lemma 2.2 tells us that the above definition does not depend on the choice of $\Phi_c$. We say that two complementary channels $\Phi : \mathcal{M}_d \to \mathcal{M}_{d_{\text{out}}}$ and $\Phi_c : \mathcal{M}_d \to \mathcal{M}_{d_{\text{env}}}$ are minimally defined if $d^*_{\text{env}}(\Phi) = d_{\text{env}}$ and $d^*_{\text{out}}(\Phi) = d_{\text{out}}$. It is clear from the definition that if two complementary channels $\Phi$ and $\Phi_c$ are minimally defined, then they are isometrically related to every channel in the sets $\mathcal{C}_{\Phi_c}$ and $\mathcal{C}_\Phi$, respectively, in the sense of Remark 2.1.
The Choi matrix of a quantum channel \( \Phi : \mathcal{M}_d \to \mathcal{M}_{d_{\text{out}}} \) is defined as \([\text{Cho75, Jam72}]\)
\[
J(\Phi) := (\Phi \otimes \text{id}) |\Omega\rangle\langle \Omega|,
\]
where \( |\Omega\rangle := \sum_{i=0}^{d-1} |i\rangle |i\rangle \in \mathbb{C}^d \otimes \mathbb{C}^d \) denotes a maximally entangled state and \( \text{id} : \mathcal{M}_d \to \mathcal{M}_d \) is the identity map. The rank of the Choi matrix of a channel is called the Choi rank of the channel \(^3\). The minimal environment dimension of a channel is related to its Choi rank via the following crucial lemma.

**Lemma 2.2.** For a channel \( \Phi : \mathcal{M}_d \to \mathcal{M}_{d_{\text{out}}} \) and some complementary channel \( \Phi_c \in \mathcal{C}_\Phi \),
\[
d_{\text{env}}(\Phi) = \text{rank} J(\Phi) = \text{rank} \Phi_c(\mathbb{1}_d)
\]
\[
d_{\text{env}}^*(\Phi) = \text{rank} J(\Phi_c) = \text{rank} \Phi(\mathbb{1}_d).
\]

**Proof.** Let us begin with the expression for the minimal environment dimension. For any channel \( \Phi : \mathcal{M}_d \to \mathcal{M}_{d_{\text{out}}} \), the Stinespring dilation theorem tells us that there exists an isometry \( V : \mathbb{C}^d \to \mathbb{C}^{d_{\text{out}}} \otimes \mathbb{C}^{d_{\text{env}}} \) with rank \( J(\Phi) = d_{\text{env}} \) such that \( \Phi(X) = \text{Tr}_{\text{env}}(V XV^\dagger) \) for all \( X \in \mathcal{M}_d \), see \([\text{Wat18, Corollary 2.27}]\). Moreover, any other isometry \( V : \mathbb{C}^d \to \mathbb{C}^{d_{\text{out}}} \otimes \mathbb{C}^{d_{\text{env}}} \) that defines the channel as above must be such that \( \text{rank} J(\Phi) \leq d_{\text{env}} \), so that \( d_{\text{env}}(\Phi) = \text{rank} J(\Phi) \).

Now, let \( r = \text{rank} \Phi_c(\mathbb{1}_d) \) for some \( \Phi_c \in \mathcal{C}_\Phi \). Then, since all complementary channels \( \Phi_c : \mathcal{M}_d \to \mathcal{M}_{d_{\text{env}}} \) are isometrically related (see Remark 2.1), we have \( r = \text{rank} \Phi_c(\mathbb{1}_d) \leq d_{\text{env}} \) for all \( \Phi_c \in \mathcal{C}_\Phi \), so that \( r \leq d_{\text{env}}^*(\Phi) \). To establish the reverse inequality, observe that for any positive semi-definite \( X \in \mathcal{M}_d \) and \( \Phi_c : \mathcal{M}_d \to \mathcal{M}_{d_{\text{out}}} \) complementary to \( \Phi \), there exists a small enough \( \delta > 0 \) such that
\[
\delta X \leq \mathbb{1}_d \implies \delta \Phi_c(X) \leq \Phi_c(\mathbb{1}_d) \implies \text{range} \Phi_c(X) \subseteq \text{range} \Phi_c(\mathbb{1}_d).
\]

If \( W : \text{range} \Phi_c(\mathbb{1}_d) \to \mathbb{C}^{d_{\text{env}}} \) denotes an isometric embedding of range \( \Phi_c(\mathbb{1}_d) \) into \( \mathbb{C}^{d_{\text{env}}} \), then the channel \( \Phi'_c : \mathcal{M}_d \to \mathcal{M}_r \) defined as \( \Phi'_c(X) = W^\dagger \Phi_c(X) W \) is also complementary to \( \Phi \), so that \( d_{\text{env}}^*(\Phi) \leq r \).

Finally, the expression for the minimal output dimension can be derived by applying the formula for the minimal environment dimension to any complementary channel \( \Phi_c \in \mathcal{C}_\Phi \). \( \square \)

**Remark 2.3.** We note some straightforward consequences of Lemma 2.2 below:
- If \( \Phi : \mathcal{M}_d \to \mathcal{M}_{d_{\text{out}}} \) is a unital channel, then \( d_{\text{out}}^*(\Phi) = d_{\text{out}} \).
- If a channel \( \Phi : \mathcal{M}_d \to \mathcal{M}_{d_{\text{out}}} \) admits a Kraus representation \( \Phi(X) = \sum_{i=1}^k A_i X A_i^\dagger \), where \( \{A_i\}_{i=1}^k \) is a linearly independent set of \( d_{\text{out}} \times d_{\text{out}} \) matrices, then \( d_{\text{env}}(\Phi) = k \).
- For a channel \( \Phi : \mathcal{M}_d \to \mathcal{M}_{d_{\text{out}}} \), its adjoint \( \Phi^* \) has \( d_{\text{env}}^*(\Phi^*) = d_{\text{env}}(\Phi) \) and \( d_{\text{out}}^*(\Phi^*) = d \).

### 2.2. Quantum Channel Capacities

The coherent information of a state \( \rho \in \mathcal{S}_d \) with respect to a channel \( \Phi : \mathcal{M}_d \to \mathcal{M}_{d_{\text{out}}} \) is defined as \( I_c(\rho; \Phi) := S[\Phi(\rho)] - S[\Phi_c(\rho)] \), where \( \Phi_c \in \mathcal{C}_\Phi \) is complementary to \( \Phi \) and \( S(\rho) = -\text{Tr}(\rho \log \rho) \) denotes the von Neumann entropy of \( \rho \in \mathcal{S}_d \). The **coherent information** \( \Phi \) is then defined to be
\[
Q^{(1)}(\Phi) := \max_{\rho \in \mathcal{S}_d} I_c(\rho; \Phi)
\]
(8)

Notice that since the entropy \( S \) is continuous over \( \mathcal{S}_d \) which is a compact set (with respect to the standard topology induced by the operator norm, say), the maximum in the above definition is indeed achieved at some \( \rho \in \mathcal{S}_d \). The seminal works of Lloyd \([\text{Llo97}]\), Shor \([\text{Sho02}]\), and Devetak \([\text{Dev05}]\) show that the **quantum capacity** of a channel \( \Phi \) is given by the following regularized expression:
\[
Q(\Phi) = \lim_{n \to \infty} \frac{Q^{(1)}(\Phi^\otimes n)}{n},
\]
(9)
where, for \( n \in \mathbb{N} \), the coherent information of the product channel \( Q^{(1)}(\Phi^\otimes n) \) is called the \( n \)-shot **coherent information** of \( \Phi \). If the maximum in Eq. (8) is attained at \( \rho \in \mathcal{S}_d \), then it is easy to see

\(^3\)Note that it is not equal to the rank of \( \Phi \) as a linear operator from \( \mathcal{M}_d \) to \( \mathcal{M}_{d_{\text{out}}} \).
that \( I_c(\rho^n; \Phi^n) = nQ^{(1)}(\Phi) \), so that \( Q^{(1)}(\Phi^n) \geq nQ^{(1)}(\Phi) \). However, it may happen that the coherent information is superadditive: \( Q^{(1)}(\Phi^n) > nQ^{(1)}(\Phi) \), in which case the task of evaluating \( Q(\Phi) \) becomes intractable [DSS98, CEM+15]. The regularization in Eq. (9) is not required only for certain special channels for which the coherent information is additive: \( Q^{(1)}(\Phi^n) = nQ^{(1)}(\Phi) \), and consequently, the quantum capacities of these channels admit nice single-letter expressions in terms of the channels’ coherent information \( Q(\Phi) = Q^{(1)}(\Phi) \).

**Remark 2.4.** Since for a given channel \( \Phi \), all complementary channels \( \Phi_c \in C(\Phi) \) are isometrically related (in the sense of Remark 2.1), the stated capacity expressions do not depend on the choice of \( \Phi_c \). More generally, the quantum capacities of any two isometrically related channels are identical. Hence, while computing quantum capacities, one can choose to work with channels \( \Phi : M_d \to M_{d_{out}} \) and \( \Phi_c : M_d \to M_{d_{env}} \) that are minimally defined (i.e. \( d_{env} = d^*_{env}(\Phi) \) and \( d_{out} = d^*_{out}(\Phi) \)).

**Degradable, anti-degradable, more capable and PPT channels.**

Degradable channels are the quintessential examples of channels which have additive coherent information [DS05]. A quantum channel \( \Phi : M_d \to M_{d_{out}} \) is said to be *degradable* if there exists a channel \( \mathcal{N} : M_{d_{out}} \to M_{d_{env}} \) such that \( \Phi_c = \mathcal{N} \circ \Phi \) for some complementary channel \( \Phi_c : M_d \to M_{d_{env}} \). Quantum channels that are complementary to degradable channels are known as *anti-degradable*. In other words, a channel \( \Phi : M_d \to M_{d_{out}} \) is said to be *anti-degradable* if there exists a channel \( \mathcal{N} : M_{d_{env}} \to M_{d_{out}} \) such that \( \Phi = \mathcal{N} \circ \Phi_c \) for some complementary channel \( \Phi_c : M_d \to M_{d_{env}} \). If such a channel could be used for reliable quantum communication, then its environment would be able to replicate all the transmitted information by applying the anti-degrading map \( \mathcal{N} \), thus violating the no-cloning theorem [BDS97, SS12]. Hence, anti-degrading channels have zero quantum capacity. More generally, all the currently known classes of channels with additive coherent information lie within the strict superset of *more capable* channels [Wat12], which are defined by the property that their complementary channels have zero quantum capacity.

![Figure 1. SS12 The set of quantum channels with zero quantum capacity: PPT and anti-degradable (ADG) channels are the only kinds of channels which are currently known to belong in this set. Entanglement-breaking (EB) channels form a strict subset of the intersection of the PPT and anti-degradable sets of channels. The question mark indicates that it is not currently known if there exist quantum channels which are neither anti-degradable nor PPT but still have zero quantum capacity.

Apart from anti-degradable channels, only PPT channels [HHH00] are known to have zero capacity. A channel \( \Phi : M_d \to M_{d_{out}} \) is said to be PPT if \( \top \circ \Phi \) is again a quantum channel, where \( \top : M_{d_{out}} \to M_{d_{out}} \) is the transpose map. Equivalently, \( \Phi \) is PPT if and only if its Choi matrix
$J(\Phi) \in M_{d_{\text{out}}} \otimes M_d$ is positive under partial transposition (PPT). Such channels cannot have positive capacity because if they did, one would be able to distill maximally entangled pure states from the PPT Choi matrices of these channels, which is impossible [HHH98]. The well-known family of entanglement-breaking channels [HSR03] – which consists of channels whose Choi matrices are separable – is strictly contained within the the intersection of the anti-degradable and PPT families.

**Transpose degradable and Transpose anti-degradable channels.**

**Remark 2.5.** In [BDHM10], the authors introduced another class of quantum channels with additive coherent information consisting of conjugate degradable channels. According to their definition, a quantum channel is said to be conjugate degradable if its environment can be simulated up to complex conjugation via its output. More precisely, a channel $\Phi : M_d \rightarrow M_{d_{\text{out}}}$ is conjugate degradable if there exists a channel $N : M_{d_{\text{out}}} \rightarrow M_{d_{\text{env}}}$ such that

\[ C \circ \Phi_c = N \circ \Phi, \tag{10} \]

where $C$ denotes (entrywise) complex conjugation on $M_{d_{\text{env}}}$ and $\Phi_c : M_d \rightarrow M_{d_{\text{env}}}$ is complementary to $\Phi$. In an analogous fashion, the class of conjugate anti-degradable channels was defined, and these channels were claimed to have zero quantum capacity. However, there is a fundamental problem with the stated definitions, which stems from the fact that the map $C$ is anti-linear. Therefore, Eq. (10) is invalid, since it is equating an anti-linear map on its left hand side with a linear map on its right hand side. This issue can be easily resolved if we just replace the anti-linear operation of complex conjugation by the linear operation of transposition. Hence, we are led to the following definitions of transpose degradable and transpose anti-degradable channels.

We say that a channel $\Phi : M_d \rightarrow M_{d_{\text{out}}}$ is transpose degradable (resp. transpose anti-degradable) if there exists a channel $N : M_{d_{\text{out}}} \rightarrow M_{d_{\text{env}}}$ (resp. $N : M_{d_{\text{env}}} \rightarrow M_{d_{\text{out}}}$) such that $\mathsf{T} \circ \Phi_c = N \circ \Phi$ (resp. $\mathsf{T} \circ \Phi = N \circ \Phi_c$) for some complementary channel $\Phi_c : M_d \rightarrow M_{d_{\text{env}}}$, where $\mathsf{T}$ denotes the transpose map on the relevant matrix spaces. It is easy to show that transpose degradable channels have additive coherent information, while transpose anti-degradable channels have zero quantum capacity. In this regard, note that all transpose anti-degradable channels are PPT as well. Whether these classes are actually different from their non-transposed counterparts is currently unknown.

**Figure 2.** [Wat12] The set of more capable (MC) quantum channels, i.e. channels with zero complementary quantum capacity. Degradable (DG) and transpose degradable (TDG) channels lie strictly within this set. The relationship between the sets of DG and TDG channels is currently unestablished.
3. Main results

We have seen that an explicit computation of the quantum capacity of a quantum channel is usually intractable. So, is it at least possible to determine if a given channel \( \Phi \) has positive quantum capacity or not? The question is clearly of immense significance, as is evident from our discussions in Sections 1 and 2.2. The answer, however, has proved to be quite elusive. The natural first step to tackle this problem would be to show that the coherent information of \( \Phi \) is positive, which, according to our discussion in Section 2.2, trivially provides a lower bound to the quantum capacity. Moreover, for a pure input state \( |\psi\rangle|\psi\rangle \in S_d \) and \( \Phi_c \in C_\phi \), Lemma A.3 informs us that the non-zero eigenvalues of \( \Phi_c(|\psi\rangle|\psi\rangle) \) and \( \Phi_c(|\psi\rangle|\psi\rangle) \) (counted with multiplicities) are identical, and hence \( I_c(|\psi\rangle|\psi\rangle ; \Phi) = 0 \). Now, let’s see if we can slightly perturb our pure input state so as to obtain a positive value of the coherent information. To this end, we define a one-parameter family of input states \( \rho(\epsilon) = (1 - \epsilon)|\psi\rangle|\psi\rangle + \epsilon \sigma \), where \( \sigma \in S_d \) is an arbitrary state and \( \epsilon \in [0, 1] \) is the perturbation parameter. Let us focus on the zero eigenvalue of \( \Phi_c(|\psi\rangle|\psi\rangle) \) and \( \kappa_c = \dim \ker \Phi_c(|\psi\rangle|\psi\rangle) \), respectively. Once we turn on the perturbation,

\[ \Phi_c(\rho(\epsilon); \Phi) = (1 - \epsilon)\Phi_c(|\psi\rangle|\psi\rangle) + \epsilon \Phi_c(\sigma) \quad \text{and} \quad \Phi_c(\rho(\epsilon); \Phi) = (1 - \epsilon)\Phi_c(|\psi\rangle|\psi\rangle) + \epsilon \Phi_c(\sigma) \]  

(11)

will have exactly \( \kappa \) and \( \kappa_c \) eigenvalues, respectively, which converge to zero as \( \epsilon \to 0 \), see Theorem A.1. Remarkably, these eigenvalues admit convergent power series expansions in the perturbation parameter \( \epsilon \) (in a neighborhood of \( \epsilon = 0 \)). Furthermore, if \( K_\psi \) and \( K^c_\psi \) denote the orthogonal projections onto the unperturbed eigenspaces \( \ker \Phi(|\psi\rangle|\psi\rangle) \) and \( \ker \Phi_c(|\psi\rangle|\psi\rangle) \), respectively, then the non-zero eigenvalues of \( K_\psi \Phi_c(\sigma)K_\psi \) and \( K^c_\psi \Phi_c(\sigma)K^c_\psi \) determine the first order correction constants in the aforementioned eigenvalue expansions, thus giving rise to the following crucial term in the derivative of the coherent information\(^4\) (see Appendix A):

\[ I'_c(\rho(\epsilon); \Phi) = \left[ \text{Tr}(K_\psi \Phi(\sigma)) - \text{Tr}(K^c_\psi \Phi_c(\sigma)) \right] \log \left( \frac{1}{\epsilon} \right) + \ldots \]  

(12)

All the higher order corrections above can be shown to be bounded in \( \epsilon \), so that the derivative becomes positive for sufficiently small values of \( \epsilon \) if \( \text{Tr}(K_\psi \Phi(\sigma)) > \text{Tr}(K^c_\psi \Phi_c(\sigma)) \). Hence, \( I_c(\rho(\epsilon); \Phi) \) is strictly increasing when \( 0 < \epsilon < \delta \) (for some small \( \delta > 0 \)), which implies that it has a positive value in the stated range (recall that at \( \epsilon = 0, I_c(\rho(\epsilon); \Phi) = 0 \)).

In order to formulate the above discussion in a mathematically rigorous fashion, a significant number of non-trivial intermediate steps are required, which are presented in Appendix A. The final theorem stated below is the primary result of this paper.

**Theorem 3.1.** Let \( \Phi : M_d \to M_{d_{out}} \) and \( \Phi_c : M_d \to M_{d_{out}} \) be complementary channels. For a pure input state \( |\psi\rangle|\psi\rangle \in S_d \), denote the orthogonal projections onto \( \ker \Phi(|\psi\rangle|\psi\rangle) \) and \( \ker \Phi_c(|\psi\rangle|\psi\rangle) \) by \( K_\psi \) and \( K^c_\psi \), respectively. Then,

- \( Q(\Phi) \geq Q^{(1)}(\Phi) > 0 \) if there exist states \( |\psi\rangle|\psi\rangle, \sigma \in S_d \) such that \( \text{Tr}(K_\psi \Phi(\sigma)) > \text{Tr}(K^c_\psi \Phi_c(\sigma)) \).
- \( Q(\Phi_c) \geq Q^{(1)}(\Phi_c) > 0 \) if there exist states \( |\psi\rangle|\psi\rangle, \sigma \in S_d \) such that \( \text{Tr}(K_\psi \Phi(\sigma)) < \text{Tr}(K^c_\psi \Phi_c(\sigma)) \).

Before proceeding further, let us note that for a given channel \( \Phi : M_d \to M_{d_{out}} \) and an arbitrary pure state \( |\psi\rangle|\psi\rangle \in S_d \), Lemma 2.2 and Lemma A.3 can be exploited to deduce that the maximal possible rank of \( \Phi(|\psi\rangle|\psi\rangle) \) is \( \min\{d^*_{out}(\Phi), d^*_{env}(\Phi)\} \). In other words,

\[ \forall |\psi\rangle|\psi\rangle \in S_d : \quad \text{rank} \Phi(|\psi\rangle|\psi\rangle) \leq \min\{d^*_{out}(\Phi), d^*_{env}(\Phi)\}. \]  

(13)

However, it is not easy to determine if there exists a pure state for which the above bound gets saturated. We will get back to this issue after proving our next result, Corollary 3.2, which is a

---

\(^4\)In [Sid20, Sections III and IV], the first order corrections in the eigenvalues of \( \Phi(\rho(\epsilon)) \) and \( \Phi_c(\rho(\epsilon)) \) which give rise to the trace factor in Eq. (12) are referred to as the rates of the \( \epsilon \)-log singularities of the output entropies \( S[\Phi(\rho(\epsilon))] \) and \( S[\Phi_c(\rho(\epsilon))] \), albeit without any mention of the explicit power series expansions of the relevant eigenvalues.
simple but very useful consequence of Theorem 3.1. We should mention that this result has been derived independently in [Sid20].

Corollary 3.2. Let $\Phi : \mathcal{M}_d \to \mathcal{M}_{d_{\text{out}}}$ be a channel such that there exists a pure state $|\psi\rangle\langle\psi| \in \mathcal{S}_d$ with rank $\Phi(|\psi\rangle\langle\psi|) = \min\{d_{\text{out}}(\Phi), d_{\text{env}}(\Phi)\}$ and $\Phi_{c} \in \mathcal{C}_\Phi$. Then,

$$Q(\Phi) \geq Q^{(1)}(\Phi) > 0 \text{ if } d_{\text{out}}^*(\Phi) > d_{\text{env}}^*(\Phi) \text{ and } Q(\Phi_{c}) \geq Q^{(1)}(\Phi_{c}) > 0 \text{ if } d_{\text{out}}^*(\Phi) < d_{\text{env}}^*(\Phi).$$

Proof. We only prove the second part here and leave a similar proof of the first part to the reader. Firstly, without loss of generality, we can assume that $\Phi : \mathcal{M}_d \to \mathcal{M}_{d_{\text{out}}}$ and $\Phi_c : \mathcal{M}_d \to \mathcal{M}_{d_{\text{env}}}$ are minimally defined, so that $d_{\text{out}}^*(\Phi) = d_{\text{out}}$ and $d_{\text{env}}^*(\Phi) = d_{\text{env}}$ (see Remark 2.4). Now, if there exists $|\psi\rangle\langle\psi| \in \mathcal{S}_d$ with rank $\Phi(|\psi\rangle\langle\psi|) = d_{\text{out}}$, then ker $\Phi(|\psi\rangle\langle\psi|) = \{0\}$. Moreover, since $d_{\text{out}} < d_{\text{env}}$, Lemma A.3 tells us that ker $\Phi_c(|\psi\rangle\langle\psi|) \neq \{0\}$. Hence, in the notation of Theorem 3.1, we have $K_\psi = 0$ but $K_{\psi}^c \neq 0$. Finally, Lemma 2.2 tells us that $\Phi_{c}(1d)$ has full rank in $\mathcal{M}_{d_{\text{env}}}$, so that

$$\text{Tr}(K_\psi^c \Phi_c(1d)) > 0 \Rightarrow \text{Tr}(K_\psi \Phi(1d)) \quad \Longrightarrow \quad Q^{(1)}(\Phi_{c}) > 0.$$

Remark 3.3. Theorem 3.1 is more general than Corollary 3.2, since it can be used to detect positivity of the quantum capacity of channels which lie outside the realm of applicability of Corollary 3.2, especially for channels $\Phi$ with $d_{\text{out}}^*(\Phi) = d_{\text{env}}^*(\Phi)$. In Theorem 4.12, we show that the class of dephasing or Hadamard channels contains such examples; see also Example 4.6. Moreover, there exist channels $\Phi$ for which even though $d_{\text{out}}^*(\Phi) \neq d_{\text{env}}^*(\Phi)$, there is no pure state that gets mapped to an output state with maximal rank, so that Corollary 3.2 cannot be applied. The well-known Werner-Holevo channel provides such an example. Using Theorem 3.1, we obtain positivity of the quantum capacity of its complement for all input dimensions $d \geq 4$ in Theorem 4.3.

Whenever $d_{\text{out}}^*(\Phi) \neq d_{\text{env}}^*(\Phi)$ for some channel $\Phi$, Corollary 3.2 can be applied if the existence of a pure input state that gets mapped to a state with maximal rank in the output space can be guaranteed, see Eq. (13). However, this condition can be difficult to check in practice. In order to see why, let us consider a pair of complementary channels $\Phi : \mathcal{M}_d \to \mathcal{M}_{d_{\text{out}}}$ and $\Phi_c : \mathcal{M}_d \to \mathcal{M}_{d_{\text{env}}}$ with $d_{\text{out}}^*(\Phi) = d_{\text{out}}$ and $d_{\text{env}}^*(\Phi) = d_{\text{env}}$. Then, the associated isometry $V : \mathbb{C}^d \to \mathbb{C}^{d_{\text{out}}} \otimes \mathbb{C}^{d_{\text{env}}}$ which defines these channels (see Eq. (5)) identifies the input space $\mathbb{C}^d$ with a $d$-dimensional subspace range $V \subseteq \mathbb{C}^{d_{\text{out}}} \otimes \mathbb{C}^{d_{\text{env}}}$, which can further be identified with a $d$-dimensional matrix subspace vec$^{-1}(\text{range } V) \subseteq \mathcal{M}_{d_{\text{out}} \times d_{\text{env}}}$ via the inverse of the vectorization map, see Eq. (3). Since

$$\forall |\psi\rangle\langle\psi| \in \mathcal{S}_d : \quad \text{rank } \Phi(|\psi\rangle\langle\psi|) = \text{Schmidt rank}(V |\psi\rangle) = \text{rank}(\text{vec}^{-1}V |\psi\rangle),$$

establishing the existence of a pure state with maximal output rank is equivalent to establishing the existence of a full rank matrix in the subspace vec$^{-1}(\text{range } V) \subseteq \mathcal{M}_{d_{\text{out}} \times d_{\text{env}}}$, which is known to be hard [Lov89, Gur03]. This is why the simple dimensional inequalities given below are so convenient. Put simply, they ensure the existence of the desired pure input state whenever $d_{\text{out}}^*(\Phi)$ or $d_{\text{env}}^*(\Phi)$ is sufficiently large for an arbitrary channel $\Phi$. We should point out that the following inequalities were also derived in [Sid20], albeit in a different way.

Corollary 3.4. Let $\Phi : \mathcal{M}_d \to \mathcal{M}_{d_{\text{out}}}$ and $\Phi_c : \mathcal{M}_d \to \mathcal{M}_{d_{\text{env}}}$ be complementary channels. Then,

- $Q(\Phi) \geq Q^{(1)}(\Phi) > 0$ if $d_{\text{out}}^*(\Phi) > d_{\text{env}}^*(\Phi)$ and $d_{\text{out}}^*(\Phi) > d(d_{\text{env}}^*(\Phi) - 1)$.
- $Q(\Phi_{c}) \geq Q^{(1)}(\Phi_{c}) > 0$ if $d_{\text{env}}^*(\Phi) > d_{\text{out}}^*(\Phi)$ and $d_{\text{env}}^*(\Phi) > d(d_{\text{out}}^*(\Phi) - 1)$.

Proof. Let us begin with the second part. Assume that the channels are minimally defined (i.e. $d_{\text{out}}^*(\Phi) = d_{\text{out}}$ and $d_{\text{env}}^*(\Phi) = d_{\text{env}}$); see Remark 2.3. In view of Corollary 3.2, our goal is to show that if $d_{\text{env}} > d_{\text{out}}$ and $d_{\text{env}} > d(d_{\text{out}} - 1)$, then there exists $|\psi\rangle\langle\psi| \in \mathcal{S}_d$ such that rank $\Phi(|\psi\rangle\langle\psi|) = d_{\text{out}}$. Suppose that this is not the case. Then, for every $|\psi\rangle \in \mathbb{C}^d$, $\Phi(|\psi\rangle) \in \mathcal{M}_{d_{\text{out}}}$ must be singular

$$\Longrightarrow \ker \Phi(|\psi\rangle) \neq \{0\} \quad \Longrightarrow \quad \text{there exists } 0 \neq |\phi\rangle \in \ker \Phi(|\psi\rangle) \text{ such that}$$

$$0 = \text{Tr}(\Phi_{\psi} |\phi\rangle\langle\phi|) = \text{Tr} \left[ (\Phi_{\psi} \otimes |\phi\rangle\langle\phi|) \text{|}\Omega\rangle\langle\Omega| \right] = \text{Tr} \left[ |\psi\phi\rangle\langle\phi\psi| J(\Phi^*) \right],$$

(15)
where $\Phi_\psi = \Phi(|\psi\rangle\langle\psi|)$, $|\Omega\rangle \in \mathbb{C}^{d_{\text{out}}} \otimes \mathbb{C}^{d_{\text{out}}}$ is defined as in Eq. (7), and $J(\Phi^*) = (\Phi^* \otimes \text{id}) |\Omega\rangle\langle\Omega|$. Hence, for every $|\psi\rangle \in \mathbb{C}^d$, there exists $|\phi\rangle \in \mathbb{C}^{d_{\text{out}}}$ such that $|\psi\rangle|\phi\rangle \in \ker J(\Phi^*)$. In particular, there are at least $d$ linearly independent vectors in $\ker J(\Phi^*)$, so that according to the rank-nullity theorem, $d_{\text{env}} = \text{rank} J(\Phi) = \text{rank} J(\Phi^*) \leq d(d_{\text{out}} - 1)$, which contradicts our original assumption. An identical argument can be used to prove the first part as well. $\square$

By exploiting an intriguing matrix-theoretic result (Lemma 3.5), we next derive a new dimensional inequality in Corollary 3.6, which ensure the existence of the sought-after pure state (i.e. the state which gets mapped onto an output state with maximal rank) for any given channel. Unlike Corollary 3.4, the new inequality in Corollary 3.6 implies that all channels with sufficiently large input dimension must either have positive quantum capacity or positive complementary quantum capacity. To see how these two corollaries nicely complement each other, see Remark 3.7.

**Lemma 3.5.** Let $S \subseteq \mathcal{M}_{d_1 \times d_2}$ (with $d_1 \leq d_2$) be a matrix subspace such that $\max_{X \in S} \text{rank } X = r$. Then, $\dim S \leq rd_2$.

**Proof.** This result was first proven in [Fla62] for matrix spaces over fields $F$ with cardinality $|F| \geq r + 1$, and was later generalized to work for arbitrary fields in [Mes85]. We nevertheless provide a simple proof for the case when $F = \mathbb{C}$ is the field of complex numbers. By padding all the matrices in $S$ with extra zero rows, we can assume that $d_1 = d_2 = d$. Now, without loss of generality, we can further assume that the following block matrix is contained in $S$ 

$$I = \begin{bmatrix} 1_r & 0 \\ 0 & 0 \end{bmatrix} \in S,$$

where $1_r \in M_r$ is the identity matrix. If $S$ doesn’t contain such a matrix, then it is easy to find non-singular matrices $P, Q \in M_d$ such that the subspace $PSQ := \{ PXQ : X \in S \}$, which has the same dimension as $S$, contains the aforementioned matrix. Now, let 

$$\tilde{S} := \left\{ \begin{bmatrix} 0 & B^	op \\ B & A \end{bmatrix} : B \in \mathcal{M}_{d-r \times r}, A \in \mathcal{M}_{d-r} \right\}$$

be a matrix subspace with $\dim \tilde{S} = r(d - r) + (d - r)^2 = d(d - r)$. Then, for $0 \neq X \in S \cap \tilde{S}$, 

$$X + cI = \begin{bmatrix} c1_r & B^	op \\ B & A \end{bmatrix} \in S \implies \text{rank}(X + cI) \leq r,$$

where the implication holds for all $c \in \mathbb{C}$. However, another simple application of the Schur complements of block matrices reveals that $\text{rank}(X + cI) = \text{rank} c1_r + \text{rank}(A - \frac{BB^\top}{c}) > r$, where $0 \neq c \in \mathbb{C}$ is such that $A \neq \frac{BB^\top}{c}$. This leads to a contradiction, and hence $S \cap \tilde{S} = \{0\}$. Hence, we arrive at the desired conclusion: $\dim(S + \tilde{S}) = \dim S + \dim \tilde{S} \leq d^2 \implies \dim S \leq d^2 - d(d - r) = dr$. $\square$

**Corollary 3.6.** Let $\Phi : \mathcal{M}_d \rightarrow \mathcal{M}_{d_{\text{out}}}$ and $\Phi_c : \mathcal{M}_d \rightarrow \mathcal{M}_{d_{\text{env}}}$ be complementary channels. Then,

- $Q(\Phi) \geq Q^{(1)}(\Phi) > 0$ if $d_{\text{out}}^*(\Phi) > d_{\text{env}}^*(\Phi)$ and $d > d_{\text{out}}^*(\Phi)(d_{\text{env}}^*(\Phi) - 1)$.

- $Q(\Phi_c) \geq Q^{(1)}(\Phi_c) > 0$ if $d_{\text{env}}^*(\Phi) > d_{\text{out}}^*(\Phi)$ and $d > d_{\text{env}}^*(\Phi)(d_{\text{out}}^*(\Phi) - 1)$.

**Proof.** We only prove the first part here, and leave an analogous proof of the second part to the reader. As usual, we assume that the channels $\Phi : \mathcal{M}_d \rightarrow \mathcal{M}_{d_{\text{out}}}$ and $\Phi_c : \mathcal{M}_d \rightarrow \mathcal{M}_{d_{\text{env}}}$ are minimally defined, so that $d_{\text{out}} = d_{\text{out}}^*(\Phi)$ and $d_{\text{env}} = d_{\text{env}}^*(\Phi)$ (see Remark 2.4). Then, if $V : \mathbb{C}^d \rightarrow \mathbb{C}^{d_{\text{out}}} \otimes \mathbb{C}^{d_{\text{env}}}$ is the associated Stinespring isometry, the matrix subspace $S = \text{vec}^{-1}(\text{range } V) \subseteq \mathcal{M}_{d_{\text{out}} \times d_{\text{env}}}$ has $\dim S = d > d_{\text{out}}(d_{\text{env}} - 1)$. Since $d_{\text{env}} < d_{\text{out}}$, Lemma 3.5 tells us that there exists $X \in S$ with $\text{rank } X = d_{\text{env}}$, so that for $|\psi\rangle \in \mathbb{C}^d$ such that $V|\psi\rangle = \text{vec } X$, we have 

$$\text{rank } \Phi(|\psi\rangle\langle\psi|) = \text{Schmidt rank}(V|\psi\rangle) = \text{rank } X = d_{\text{env}}.$$ 

Hence, Corollary 3.2 can be readily applied to obtain the desired result. $\square$
Remark 3.7. Let us fix two positive integers $d_{\text{out}} > d_{\text{env}}$ and consider the set of all channels $\Phi$ with $d_{\text{out}}^*(\Phi) = d_{\text{out}}$ and $d_{\text{env}}^*(\Phi) = d_{\text{env}}$. Then, the input dimension of these channels can be any positive integer $d \leq d_{\text{out}}^*(\Phi) d_{\text{env}}^*(\Phi)$. Barring the $d = 1$ case, Corollaries 3.4 and 3.6 show that whenever $d$ lies within the two opposite extremes of this range: $d < d_{\text{out}}^*(\Phi)/(d_{\text{env}}^*(\Phi) - 1)$ or $d > d_{\text{out}}^*(\Phi)/(d_{\text{env}}^*(\Phi) - 1)$, the corresponding channel $\Phi$ has positive quantum capacity.

By exploiting Theorem 3.1, we now introduce a powerful necessary condition for a quantum channel to have zero capacity.

**Theorem 3.8.** Let $\Phi : \mathcal{M}_d \to \mathcal{M}_{d_{\text{out}}}$ and $\Phi_c : \mathcal{M}_d \to \mathcal{M}_{d_{\text{env}}}$ be complementary channels. For a pure input state $|\psi\rangle\langle\psi| \in S_{d_{\text{out}}}$, denote the orthogonal projections onto range $\Phi^{\otimes n}(|\psi\rangle\langle\psi|)$ and range $\Phi^{\otimes n}_c(|\psi\rangle\langle\psi|)$ by $R_\psi$ and $R_\psi^c$, respectively. Then, if $Q(\Phi) = 0$, the following relation holds

$$\forall n \in \mathbb{N}, \forall |\psi\rangle\langle\psi| \in S_{d_{\text{out}}} : \quad (\Phi^{\otimes n}_c)^*(R_\psi^c) \leq (\Phi^{\otimes n})^*(R_\psi).$$

**Proof.** Since $Q(\Phi) = 0 \implies Q(\Phi^{\otimes n}) = 0$ for all $n \in \mathbb{N}$, we can apply Theorem 3.1 to $\Phi^{\otimes n}$ for each $n$ to obtain the required implication. Let us spell out the details for the $n = 1$ case. Here, Theorem 3.1 forces $\text{Tr}(K_{\psi}\Phi(\sigma)) \leq \text{Tr}(K_{\psi}^{c}\Phi_c(\sigma))$ for all $|\psi\rangle\langle\sigma|, \sigma \in S_d$, where $K_{\psi}$ and $K_{\psi}^{c}$ are as defined in Theorem 3.1. Hence, the following equivalences hold for each pure state $|\psi\rangle\langle\psi| \in S_d$:

$$\forall \sigma \in S_d : \quad \text{Tr}[(\Phi^{c}_c(K_{\psi}^{c}) - \Phi^*(K_{\psi}))\sigma] \geq 0 \iff \Phi^{c}_c(K_{\psi}^{c}) \geq \Phi^*(K_{\psi}) \iff \Phi^{c}_c(R_\psi^c) \leq \Phi^*(R_\psi).$$

where the equivalence of the latter two operator inequalities in $\mathcal{M}_d$ is a consequence of the fact that both $\Phi^*$ and $\Phi_c^*$ are unital, $R_\psi + K_{\psi} = \mathbb{1}_{d_{\text{out}}}$ and $R_\psi^c + K_{\psi}^{c} = \mathbb{1}_{d_{\text{env}}}$. \hfill $\square$

As a sanity check, the next lemma shows that anti-degradable and transpose anti-degradable channels (which are known to have zero capacity, see Section 2.2) satisfy the necessary condition stated in Theorem 3.8.

**Lemma 3.9.** Let $\Phi : \mathcal{M}_d \to \mathcal{M}_{d_{\text{out}}}$ be an anti-degradable or transpose anti-degradable channel and $\Phi_c : \mathcal{M}_d \to \mathcal{M}_{d_{\text{env}}}$ be complementary to $\Phi$. Then,

$$\forall n \in \mathbb{N}, \forall |\psi\rangle\langle\psi| \in S_{d_{\text{out}}} : \quad (\Phi^{\otimes n}_c)^*(R_\psi^c) \leq (\Phi^{\otimes n})^*(R_\psi),$$

where $R_\psi$ and $R_\psi^c$ are as defined in Corollary 3.8.

**Proof.** We prove the result for anti-degradable channels and leave an almost identical proof of the transposed version to the reader. It suffices to obtain the result for $n = 1$, since if $\Phi$ is anti-degradable, then $\Phi^{\otimes n}$ is also anti-degradable for all $n \in \mathbb{N}$. To begin with, note that the anti-degradability of $\Phi : \mathcal{M}_d \to \mathcal{M}_{d_{\text{out}}}$ implies that there exists a channel $N : \mathcal{M}_{d_{\text{env}}} \to \mathcal{M}_{d_{\text{out}}}$ such that $\Phi = N \circ \Phi_c$ and $\Phi^* = \Phi^*_c \circ N^*$. Hence, for every pure state $|\psi\rangle\langle\psi| \in S_d$, we can exploit Lemma B.1 to obtain the following sequence of implications:

$$\text{range } N(R_\psi^c) = \text{range } R_\psi \implies N(R_\psi)K_{\psi} = 0 \implies \text{Tr}(N(R_\psi^c)K_{\psi}) = 0 = \text{Tr}(R_\psi^cN^*(K_{\psi}))$$

$$\implies R_\psi^cN^*(K_{\psi}) = 0$$

$$\implies \text{range } N^*(K_{\psi}) \subseteq \ker R_\psi^c = \text{range } K_{\psi}^c. \quad (16)$$

Observe that while obtaining the implications above, we used the fact that for $A, B \succeq 0$, $AB = 0 \iff \text{Tr}(AB) = 0$. Now, since $N^*$ is unital and completely positive (being the adjoint of a quantum channel), it is contractive in the operator norm (see [Bha15, Theorem 2.3.7]), which implies that $\|N^*(K_{\psi})\| \leq \|K_{\psi}\| \leq 1$. Combining Eq. (16) with the previous result, we obtain $N^*(K_{\psi}) \leq K_{\psi}^c \implies \Phi^*(K_{\psi}) = \Phi^*_c(N^*(K_{\psi})) \leq \Phi^*_c(K_{\psi}^c) \implies \Phi^*_c(R_\psi^c) \leq \Phi^*(R_\psi).$ \hfill $\square$

**Remark 3.10.** It would be desirable to obtain a result analogous to Lemma 3.9 for PPT channels, which also have zero quantum capacity. Observe that Lemma 3.9 already contains the desired result for transpose anti-degradable channels, which form a subclass of PPT channels. We should
emphasize, however, that the relationship between a (transpose) anti-degradable channel and its complement— which is crucially exploited in the proof of Lemma 3.9— does not hold for PPT channels in general. Hence, the aforementioned proof would not work in this case.

4. Examples

In this section, we apply the results derived in Section 3 to several different families of quantum channels. Before starting with the examples, let us recall from Section 2.2 that a channel \( \Phi \) is said to be more capable if any complementary channel \( \Phi_c \in C_\Phi \) has zero capacity \( Q(\Phi_c) = 0 \). Moreover, all channels which are currently known to have additive coherent information are of the above type. Thus, whenever we show that a channel’s complement has positive quantum capacity, we show that the channel itself is not more capable. In particular, such a channel cannot be degradable or transpose degradable.

4.1. Depolarizing and transpose depolarizing channels. The depolarizing channels \( D_p : \mathcal{M}_d \to \mathcal{M}_d \) and the transpose depolarizing channels \( D_q^\top : \mathcal{M}_d \to \mathcal{M}_d \) form one-parameter families of completely positive and trace-preserving linear maps within their respective parameter ranges \( p \in [0, \frac{d^2}{d^2 - 1}] \) and \( q \in [\frac{d}{d+1}, \frac{d}{d-1}] \), and are defined as follows:

\[
\forall X \in \mathcal{M}_d : \quad D_p(X) = (1 - p)X + p \text{Tr}(X) \frac{1_d}{d} \quad \text{and} \quad D_q^\top(X) = (1 - q)X^\top + q \text{Tr}(X) \frac{1_d}{d}. \tag{17}
\]

These families of channels are arguably two of the most prominent noise models in quantum information theory. While considerable effort has gone into computing the quantum capacity of depolarizing channels [SS08, SSWR17, LDS18], an analysis of their complementary quantum capacities has largely evaded the spotlight. Recently, by carefully scrutinizing the coherent information of the qubit depolarizing channels \( D_p : \mathcal{M}_2 \to \mathcal{M}_2 \), Watrous and Leung have shown that the these channels have positive complementary quantum capacities for all \( p > 0 \) [LW17, Theorem 1]. A similar analysis has also been performed for the qubit \( D_q^\top : \mathcal{M}_2 \to \mathcal{M}_2 \) and qutrit \( D_q^\top : \mathcal{M}_3 \to \mathcal{M}_3 \) transpose-depolarizing channels to establish positivity of their complementary quantum capacities for certain values of the parameter \( q \), see [Brá15, Section 3.1]. We now substantially generalize the above results to obtain positivity of the complementary quantum capacities of depolarizing and transpose-depolarizing channels in arbitrary dimensions while also providing much simpler proofs.

**Theorem 4.1.** Let \( D_p : \mathcal{M}_d \to \mathcal{M}_d \) and \( D_q^\top : \mathcal{M}_d \to \mathcal{M}_d \) be the qudit depolarizing and transpose-depolarizing channels with \( p \in [0, \frac{d^2}{d^2 - 1}] \) and \( q \in [\frac{d}{d+1}, \frac{d}{d-1}] \). Then,

- if \( p > 0 \), any complementary channel \( D_p^c \in C_{D_p} \) has positive quantum capacity.
- if \( q < \frac{d}{d-1} \), any complementary channel \( (D_q^\top)^c \in C_{D_q^\top} \) has positive quantum capacity.

**Proof.** Firstly, observe that for all allowed \( p, q \), both \( D_p \) and \( D_q^\top \) are unital so that \( d_{\text{out}}^*(D_p) = d_{\text{out}}^*(D_q^\top) = d \), see Remark 2.3. Moreover, the Choi matrices of these channels can be written as

\[
J(D_p) = \frac{p}{d}(1_d \otimes 1_d) + (1 - p) \sum_{i,j=0}^{d-1} |ii\rangle\langle jj| \quad \text{and} \quad J(D_q^\top) = \frac{q}{d}(1_d \otimes 1_d) + (1 - q) \sum_{i,j=0}^{d-1} |ij\rangle\langle ji|. \tag{18}
\]

These are, respectively, the well-known Isotropic [HH99] and Werner [Wer89] matrices, which admit nice block diagonal decompositions so that their ranks can be easily computed (see [SN20a, Example
The smaller group of diagonal unitary matrices.

Now, it was shown in [Hol07] that

admits a complementary channel

\( Φ_c : Md \to Md \ominus Md \) of the following form:

∀X ∈ Md : \( Φ_c(X) = \frac{1}{2(d-1)}(1_d \otimes 1_d - F)(X \otimes 1_d)(1_d \otimes 1_d - F) \) (22)
where \( F : \mathbb{C}^d \otimes \mathbb{C}^d \to \mathbb{C}^d \otimes \mathbb{C}^d \) is the flip operator whose action on the canonical basis \( \{|i\rangle \otimes |j\rangle\}_{i,j=0}^{d-1} \) of \( \mathbb{C}^d \otimes \mathbb{C}^d \) is defined as \( F |i\rangle \otimes |j\rangle = |j\rangle \otimes |i\rangle \). Let us now see how \( \Phi_c \) acts on \( |0\rangle\langle 0| \):

\[
\Phi_c(|0\rangle\langle 0|) = \frac{1}{2(d-1)} \left[ |0\rangle\langle 0| \otimes \mathbb{1}_d - (|0\rangle\langle 0| \otimes \mathbb{1}_d)F - F(|0\rangle\langle 0| \otimes \mathbb{1}_d) + F(|0\rangle\langle 0| \otimes \mathbb{1}_d)F \right]
\]

\[
= \frac{1}{2(d-1)} \sum_{i=0}^{d-1} \left[ |0i\rangle\langle 0i| - |0i\rangle\langle 0i| - |0i\rangle\langle 0i| + |0i\rangle\langle 0i| \right]
\]

\[
= \frac{1}{2(d-1)} \sum_{i=0}^{d-1} (|0i\rangle - |i0\rangle)(\langle 0i| - \langle i0|) . \tag{23}
\]

Clearly, range \( \Phi_c(|0\rangle\langle 0|) \) lies within the anti-symmetric subspace of \( \mathbb{C}^d \otimes \mathbb{C}^d \). If

\[
|\psi_{ij}^+\rangle = \begin{cases} 
|ij\rangle + |ji\rangle)/\sqrt{2}, & \text{if } i < j \\
|ii\rangle, & \text{if } i = j
\end{cases}
\]

then the orthogonal projections onto the symmetric and anti-symmetric subspaces of \( \mathbb{C}^d \otimes \mathbb{C}^d \) can be written as \( P_s = \sum_{i<j} |\psi_{ij}^+\rangle \langle \psi_{ij}^+| \) and \( P_a = \sum_{i<j} |\psi_{ij}^-\rangle \langle \psi_{ij}^-| \), respectively. Using Eq. (23), we can express the orthogonal projection onto \( \ker \Phi_c(|0\rangle\langle 0|) \) as follows

\[
K_0^c = P_s + \sum_{i \neq 0; i < j} |\psi_{ij}^-\rangle \langle \psi_{ij}^-|.
\]

Finally, since \( \Phi(\mathbb{1}_d) = \mathbb{1}_d \) and \( \Phi_c(\mathbb{1}_d) = \frac{1}{d-1}(\mathbb{1}_d \otimes \mathbb{1}_d - F) \), the required trace expressions can be easily calculated. We have \( \text{Tr}(K_0^c \Phi(\mathbb{1}_d)) = 1 \) and for all \( d \geq 4, \)

\[
\text{Tr}(K_0^c \Phi_c(\mathbb{1}_d)) = \frac{1}{d-1} \text{Tr} \left[ P_s + \sum_{i \neq 0; i < j} |\psi_{ij}^-\rangle \langle \psi_{ij}^-| (\mathbb{1}_d \otimes \mathbb{1}_d - P_s + P_a) \right]
\]

\[
= \frac{2}{d-1} \text{Tr} \left[ \sum_{i \neq 0; i < j} |\psi_{ij}^-\rangle \langle \psi_{ij}^-| \right] = \frac{2}{d-1} \left[ \frac{d(d-1)}{2} - (d-1) \right] = d - 2 > 1.
\]

A direct application of Theorem 3.1 suffices to conclude that \( Q^{(1)}(\Phi_c) > 0. \)

\[ \square \]

4.2. Generalized Pauli (or Weyl Covariant) Channels. For an entrywise non-negative matrix \( P \in \mathcal{M}_d \) satisfying \( \sum_{ij} P_{ij} = 1 \), the generalized Pauli channel \( \Phi_P : \mathcal{M}_d \to \mathcal{M}_d \) associated with \( P \) is a mixed unitary channel defined as follows:

\[
\forall X \in \mathcal{M}_d : \quad \Phi_P(X) = \sum_{0 \leq i,j \leq d-1} p_{ij} U_{ij} X U_{ij}^\dagger, \tag{25}
\]

where \( \{U_{ij}\}_{i,j=0}^{d-1} \) is the unitary orthogonal basis of \( \mathcal{M}_d \) formed by the discrete Heisenberg–Weyl operators:

\[
U_{ij} = X^i Z^j, \quad \text{where } X = \sum_{k=0}^{d-1} |k+1\rangle \langle k| \quad \text{and} \quad Z = \sum_{k=0}^{d-1} \omega^k |k\rangle \langle k| \tag{26}
\]

are the so-called shift and clock matrices, respectively. Note that in the above definition, addition inside kets happens modulo \( d \) and \( \omega = e^{2\pi i/d} \) is the \( d^{th} \) root of unity. The orthogonality of the unitary basis \( \{U_{ij}\}_{i,j=0}^{d-1} \) can be easily verified by showing that \( \text{Tr}(U_{ij}^\dagger U_{kl}) = d \delta_{ik} \delta_{jl} \). When \( d = 2 \), these unitary matrices are identical to the familiar \( 2 \times 2 \) pauli matrices. In this case, a sophisticated analysis of the coherent information of the qubit Pauli channels reveals that these channels have positive complementary quantum capacity whenever the associated matrix \( P \in \mathcal{M}_2 \) has at least 3
are used to parameterize the decay rates of the particle from a higher so that the MAD channel output:

\[ \vec{\gamma} \]

is an eigenvector of the shift matrix \( X \). Complete positivity and trace preserving property of the associated Hilbert space are employed to model the decay dynamics of a particle in a Multi-level amplitude damping channels.

4.3. Multi-level amplitude damping channels. Multi-level amplitude damping (MAD) channels are employed to model the decay dynamics of a particle in a \( d \)-level quantum system with the associated Hilbert space \( \mathbb{C}^d = \text{span}\{\{|i\rangle\}_i \}. \) A total of \( d(d-1)/2 \) real numbers \( \{\gamma_{j\rightarrow i}\}_{0 \leq i < j \leq d-1} \) are used to parameterize the decay rates of the particle from a higher \( j \)th level to a lower \( i \)th level, so that the MAD channel \( \Phi_{\vec{\gamma}} : \mathcal{M}_d \rightarrow \mathcal{M}_d \) admits the following Kraus representation

\[ \forall X \in \mathcal{M}_d : \quad \Phi_{\vec{\gamma}}(X) = A_0 X A_0^\dagger + \sum_{0 \leq i < j \leq d-1} A_{ij} X A_{ij}^\dagger, \quad (27) \]

where \( \vec{\gamma} \in \mathbb{R}^{d(d-1)/2} \), \( A_0 = |0\rangle\langle 0| + \sum_{j=1}^{d-1} \sqrt{1 - \sum_{i<j} \gamma_{j\rightarrow i}} |j\rangle\langle j| \) and \( A_{ij} = \sqrt{\gamma_{j\rightarrow i}} |i\rangle\langle j| \) for all \( i < j \).

Complete positivity and trace preserving property of \( \Phi_{\vec{\gamma}} \) implies that

\[ \forall i < j : \quad \gamma_{j\rightarrow i} \geq 0 \quad \text{and} \quad \forall j \in [d] : \quad \sum_{i<j} \gamma_{j\rightarrow i} \leq 1. \quad (28) \]

We say that a level \( j \in \{1, \ldots, d-1\} \) gets totally depleted under the channel \( \Phi_{\vec{\gamma}} \) if for all \( k > j \), \( \gamma_{k\rightarrow j} = 0 \) (i.e., no higher level has a positive rate of decaying to the \( j \)th level) and \( \sum_{i<j} \gamma_{j\rightarrow i} = 1 \) (i.e., the sum of decay rates from the \( j \)th level to all the lower levels equals one). Since there are no levels below the ground level \( j = 0 \), it can never get totally depleted. Given \( \Phi_{\vec{\gamma}} \), we denote the number of levels which do not get totally depleted (including the ground level) by \( n_1(\vec{\gamma}) \). We denote the total number of non-zero decay rates in \( \vec{\gamma} \) by \( n_2(\vec{\gamma}) \). The following lemma relates these newly defined parameters with the minimal output and environment dimensions of \( \Phi_{\vec{\gamma}} \).

**Lemma 4.5.** Let \( \Phi_{\vec{\gamma}} : \mathcal{M}_d \rightarrow \mathcal{M}_d \) be a MAD channel parameterized by \( \vec{\gamma} \in \mathbb{R}^{d(d-1)/2} \). Then,

\[ d_{\text{out}}^*(\Phi_{\vec{\gamma}}) = n_1(\vec{\gamma}) \quad \text{and} \quad d_{\text{env}}^*(\Phi_{\vec{\gamma}}) = 1 + n_2(\vec{\gamma}). \]

**Proof.** Apply the channel \( \Phi_{\vec{\gamma}} \) on the identity matrix \( \mathbb{I}_d \in \mathcal{M}_d \) to deduce that rank \( \Phi_{\vec{\gamma}}(\mathbb{I}_d) = d_{\text{out}}^*(\Phi_{\vec{\gamma}}) = n_1(\vec{\gamma}) \). To obtain the expression for \( d_{\text{env}}^*(\Phi_{\vec{\gamma}}) \), observe that the number of linearly independent Kraus operators in the Kraus representation of \( \Phi_{\vec{\gamma}} \) (see Eq. (27)) is \( 1 + n_2(\vec{\gamma}) \), so that rank \( J(\Phi_{\vec{\gamma}}) = d_{\text{env}}^*(\Phi_{\vec{\gamma}}) = 1 + n_2(\vec{\gamma}) \), see Remark 2.3. \( \square \)

The quantum capacity of the 2-level (or qubit) amplitude damping channels is quite well understood [GF05]. This is because any such channel is completely determined by a single decay rate \( \gamma \in \mathbb{R} \), so that \( d_{\text{env}}^*(\Phi_{\vec{\gamma}}) \leq 2 \) and these types of channels are known to be either degradable or anti-degradable [WPG07]. Unfortunately, the same cannot be said for MAD channels in higher dimensions. Hence, their capacity analysis has recently started attracting significant interest from the community, see [CG21] and references therein. However, to the best of our knowledge, virtually

non-zero entries [LW17, Theorem 2]. Our next theorem extends this result for generalized Pauli channels acting in arbitrary dimensions.

**Theorem 4.4.** Let \( \Phi_P : \mathcal{M}_d \rightarrow \mathcal{M}_d \) be a generalized Pauli channel associated with \( P \in \mathcal{M}_d \). If \( P \) has at least \( d+1 \) non-zeros entries distributed in such a way that either every row or every column of \( P \) is non-zero, then any complementary channel \( \Phi_P^* \in \mathcal{C}_P \) has positive quantum capacity.

**Proof.** Firstly, since \( \Phi_P \) is unital, we have \( d_{\text{env}}^*(\Phi_P) = d \). In addition, if \( P \) has at least \( d+1 \) non-zero entries, then \( d_{\text{env}}^*(\Phi_P) \geq d+1 \) (see Remark 2.3), so that Corollary 3.2 can be applied to obtain the desired result if there exists a pure state \( |\psi\rangle\langle \psi| \in \mathcal{S}_d \) such that \( \Phi_P(|\psi\rangle\langle \psi|) \in \mathcal{S}_d \) has full rank. Now, if \( P \) has a non-zero entry \( p_{ik} \neq 0 \) for each \( i \in \{0, 1, \ldots, d-1\} \), then every power of the shift matrix \( X \) is present in the Kraus decomposition of \( \Phi_P \) (see Eq. (25)). Hence, by choosing \( |\psi\rangle \) to be an eigenvector of the clock matrix \( Z \) (say \( |\psi\rangle = |0\rangle \)), we get a full rank state on the output: \( \Phi_P(|0\rangle\langle 0|) \geq \sum_{i=0}^{d-1} p_{ik} |i\rangle\langle i| \). Similarly, if every column of \( P \) has a non-zero entry, then an eigenvector of the shift matrix \( X \), say \( |\psi\rangle = \frac{1}{\sqrt{d}} \sum_{i=0}^{d-1} |i\rangle \), would result in a full rank output. \( \square \)
nothing is known about the complementary quantum capacities of these channels. In the following
theorem, we obtain the first results in this direction by deriving simple sufficient conditions on the
decay rate vector $\vec{\gamma} \in \mathbb{R}^{d(d-1)/2}$ which ensure that the associated MAD channel $\Phi_{\vec{\gamma}}$ has positive
(complementary) capacity.

**Theorem 4.6.** Let $\Phi_{\vec{\gamma}} : \mathcal{M}_d \to \mathcal{M}_d$ be a MAD channel parameterized by $\vec{\gamma} \in \mathbb{R}^{d(d-1)/2}$.

- If $1 + n_2(\vec{\gamma}) > n_1(\vec{\gamma})$ and for every $j \in \{0, 1, \ldots, d - 2\}$ which does not get totally depleted,
  there exists a non-zero decay rate $\gamma_{k \to j}$ for some $k > j$, then any complementary channel $\Phi_{\vec{\gamma}}^c \in \mathcal{C}_{\Phi_{\vec{\gamma}}}$ has positive quantum capacity.
- If $1 + n_2(\vec{\gamma}) < n_1(\vec{\gamma})$ and every $j \in \{0, 1, \ldots, d - 2\}$ which does not get totally depleted
  receives a decay contribution from not more than one higher level, then the channel $\Phi_{\vec{\gamma}}$ has positive quantum capacity.

**Proof.** Let $|e\rangle = \sum_{i=0}^{d-1} |i\rangle$ and $|\Gamma\rangle = |0\rangle + \sum_{i=1}^{d-1} \sqrt{1 - \sum_{j<i} \gamma_{j \to i}} |j\rangle$, so that

$$\Phi_{\vec{\gamma}}(|e\rangle\langle e|) = \sum_j \sum_{k>j} \gamma_{k \to j} |j\rangle\langle j| + |\Gamma\rangle\langle \Gamma|$$

and the conditions stated in the theorem ensure that

$$\text{rank } \Phi_{\vec{\gamma}}(|e\rangle\langle e|) = \begin{cases} n_1(\vec{\gamma}) & \text{if } 1 + n_2(\vec{\gamma}) > n_1(\vec{\gamma}) \\ 1 + n_2(\vec{\gamma}) & \text{if } 1 + n_2(\vec{\gamma}) < n_1(\vec{\gamma}) \end{cases}.$$ 

Then Lemma 4.5 and Corollary 3.2 can be readily applied to obtain the required results. \hfill \square

**Remark 4.7.** Theorem 4.6 can be considered as a special case of a more general result which holds for the class of (conjugate) diagonal unitary covariant channels, see Proposition 4.10 and Theorem 4.11.

4.4. (Conjugate) diagonal unitary covariant channels. Let us denote the group of diagonal unitary matrices in $\mathcal{M}_d$ by $\mathcal{DU}_d$. A channel $\Phi : \mathcal{M}_d \to \mathcal{M}_d$ is said to be diagonal unitary covariant (DUC) (resp. conjugate diagonal unitary covariant (CDUC)) if for all $U \in \mathcal{DU}_d$ and $X \in \mathcal{M}_d$,

$$\Phi(UXU^\dagger) = U^\dagger \Phi(X)U \quad \text{resp.} \quad \Phi(UXU^\dagger) = U \Phi(X)U^\dagger. \quad (29)$$

It is easy to see that if $\Phi$ is DUC (resp. CDUC), then for all $U \in \mathcal{DU}_d$,

$$(U \otimes U)J(\Phi)(U^\dagger \otimes U^\dagger) = J(\Phi) \quad \text{resp.} \quad (U \otimes U^\dagger)J(\Phi)(U^\dagger \otimes U) = J(\Phi). \quad (30)$$

These channels and their corresponding Choi matrices have recently been examined quite thoroughly
in [JM19, SN20a, SN20b, Sin21]. In particular, it has been shown that the action of a DUC (resp. CDUC) channel can be parameterized by two matrices $A, B \in \mathcal{M}_d$ with equal diagonals:

$$\Psi_{A,B}(X) = \text{diag}(A \mid \text{diag } X) + \bar{B} \odot X^\top \equiv \sum_{i,j} A_{ij} X_{ij} |i\rangle \langle i| + \sum_{i \neq j} B_{ij} X_{ji} |i\rangle \langle j| \quad (31)$$

resp. $\Phi_{A,B}(X) = \text{diag}(A \mid \text{diag } X) + \bar{B} \odot X \equiv \sum_{i,j} A_{ij} X_{ij} |i\rangle \langle i| + \sum_{i \neq j} B_{ij} X_{ji} |i\rangle \langle j| \quad (32)$

where $\bar{B} = B - \text{diag } B$ and $\odot$ denotes the entrywise or Hadamard matrix product.

**Remark 4.8.** $\Phi_{A,B}$ (resp. $\Psi_{A,B}$) is completely positive and trace preserving if and only if

- $A$ is entrywise non-negative (denoted $A \succ 0$) and $B \succeq 0$, see [SN20a, Lemma 6.11].
- resp. $A \succ 0$, $B = B^\dagger$, and $A_{ij} A_{ji} \geq |B_{ij}|^2$ for all $i, j \in [d]$, see [SN20a, Lemma 6.10].

A plethora of different classes of quantum channels can be shown to belong to the families of DUC and CDUC channels; see [SN20a, Section 7]. In particular, the previously considered classes of depolarizing- and MAD channels are CDUC, while the transpose-depolarizing channels are DUC.
In this section, we derive very general sufficient conditions on the matrices \(A, B \in \mathcal{M}_d\) which ensure that the associated DUC and CDUC channels have positive complementary quantum capacity. Theorems 4.1 and 4.6 would then pop out as special cases of these more general results. To this end, let us first see how the minimal output and environment dimensions of these channels can be obtained from the associated matrices \(A, B \in \mathcal{M}_d\).

**Lemma 4.9.** For a DUC channel \(\Psi_{A,B} : \mathcal{M}_d \rightarrow \mathcal{M}_d\) and a CDUC channel \(\Phi_{A,B} : \mathcal{M}_d \rightarrow \mathcal{M}_d\),
\[
\begin{align*}
d_{\text{out}}^* (\Psi_{A,B}) &= |\{ i \in [d] : \exists j \in [d], A_{ij} \neq 0 \}| = d_{\text{out}}^* (\Phi_{A,B}) \\
d_{\text{env}}^* (\Psi_{A,B}) &= |\{ i \in [d] : A_{ii} \neq 0 \}| + \sum_{i<j} \text{rank} \begin{bmatrix} A_{ij} & B_{ij} \\ B_{ji} & A_{jj} \end{bmatrix} \\
d_{\text{env}}^* (\Phi_{A,B}) &= \text{rank} B + |\{ (i,j) \in [d] \times [d] : i \neq j \text{ and } A_{ij} \neq 0 \}| 
\end{align*}
\]

**Proof.** Apply the channels \(\Phi_{A,B}\) and \(\Psi_{A,B}\) on the identity matrix \(\mathbb{1}_d \in \mathcal{M}_d\) to conclude that their minimal output dimensions are both equal to the number of non-zero rows present in \(A\), see Lemma 2.2. The expressions of the minimal environment dimensions can be derived by computing the relevant Choi ranks, see [SN20a, Theorem 6.4 and Corollary 4.2] and Lemma 2.2. \(\square\)

Equipped with the necessary background, we are now ready to characterize the class of (C)DUC channels \(\Phi\) for which there exist a pure state \(|\psi\rangle\langle\psi|\) such that \(\text{rank } \Phi(|\psi\rangle\langle\psi|) = \min\{d_{\text{out}}^*(\Phi), d_{\text{env}}^*(\Phi)\}\), so that Corollary 3.2 can be invoked to obtain positivity of the (complementary) capacities of these channels whenever \(d_{\text{out}}^*(\Phi) \neq d_{\text{env}}^*(\Phi)\). Recall the discussion following Remark 3.3, where the difficulty in obtaining such a characterization for arbitrary channels is clearly highlighted. More often than not, one can only hope to obtain some sufficient conditions on the channel under consideration (like the one presented in Theorem 4.4) to guarantee that the required pure state exists. This fact makes the following Proposition all the more important, since it contains a simple necessary and sufficient condition to ensure the existence of the desired pure state for arbitrary (C)DUC channels.

**Proposition 4.10.** Let \(\Phi : \mathcal{M}_d \rightarrow \mathcal{M}_d\) be a DUC or a CDUC channel and \(|e\rangle = \sum_i |i\rangle \in \mathbb{C}^d\). Then,
\[
\max_{|\psi\rangle\langle\psi| \in \mathcal{S}_d} \text{rank } \Phi(|\psi\rangle\langle\psi|) = \text{rank } \Phi(|e\rangle\langle e|).
\]

**Proof.** In order to prove the proposition, it suffices to show that for a DUC or a CDUC channel \(\Phi\), if \(\text{rank } \Phi(|e\rangle\langle e|) < r\), then for all \(|\psi\rangle\langle\psi| \in \mathcal{S}_d\), \(\text{rank } \Phi(|\psi\rangle\langle\psi|) < r\) as well. Moreover, since a positive semi-definite matrix \(X \in \mathcal{M}_d\) has rank \(X < r\) if and only if all its \(r \times r\) principal submatrices are singular, we can choose to work with \(r \times r\) principal submatrices corresponding to an arbitrary selection of \(r\) rows and columns indexed by some \(I \subseteq [d]\) with \(|I| = r\). Hence, we only need to prove that (see Appendix C for the relevant notation):
\[
\Phi(|e\rangle\langle e|)[I] \text{ is singular } \implies \Phi(|\psi\rangle\langle\psi|)[I] \text{ is singular for all } |\psi\rangle\langle\psi| \in \mathcal{S}_d.
\]
The following proof is split into two cases, and can be found in Appendix C. \(\square\)

**Theorem 4.11.** Let \(|e\rangle = \sum_i |i\rangle \in \mathbb{C}^d\) and \(\Phi : \mathcal{M}_d \rightarrow \mathcal{M}_d\) be a DUC or a CDUC channel such that
\[
\max_{|\psi\rangle\langle\psi| \in \mathcal{S}_d} \text{rank } \Phi(|\psi\rangle\langle\psi|) = \text{rank } \Phi(|e\rangle\langle e|) = \min\{d_{\text{out}}^*(\Phi), d_{\text{env}}^*(\Phi)\}.
\]

Then,
\begin{itemize}
  \item if \(d_{\text{out}}^*(\Phi) > d_{\text{env}}^*(\Phi)\), the channel \(\Phi\) has positive quantum capacity.
  \item if \(d_{\text{out}}^*(\Phi) < d_{\text{env}}^*(\Phi)\), any complementary channel \(\Phi_c \in \mathcal{C}_\Phi\) has positive quantum capacity.
\end{itemize}

**Proof.** The proof is a straightforward consequence of Proposition 4.10 and Corollary 3.2. \(\square\)
4.5. Generalized dephasing or Hadamard channels. Generalized dephasing or Hadamard channels (also known as Schur multipliers) $\Phi_B: \mathcal{M}_d \to \mathcal{M}_d$ have the effect of diminishing the magnitude of the off-diagonal entries of the input states while perfectly preserving their diagonal elements. These channels are parameterized by a correlation matrix $B \in \mathcal{M}_d$ (i.e., $B \geq 0$ and all its diagonal entries are equal to one):

$$\forall X \in \mathcal{M}_d : \quad \Phi_B(X) = B \odot X. \quad (33)$$

Note that $\odot$ above denotes the Hadamard or entrywise matrix product. It is clear that a dephasing channel $\Phi_B = \Phi_{A,B}$ is CDUC (see Eq. (32)) with $A = \mathds{1}_d$. Complementary channels to the dephasing channels are known to be entanglement-breaking (and hence also antidegradable); so they have zero quantum capacity. This, in particular, implies that the dephasing channels themselves are all degradable and hence their quantum capacities admit a single-letter expression in terms of the channels’ coherent information $Q(\Phi_B) = Q^{(1)}(\Phi_B)$. In the following theorem, we obtain a complete characterization of the set of zero capacity dephasing channels.

**Theorem 4.12.** Let $\Phi_B : \mathcal{M}_d \to \mathcal{M}_d$ be a dephasing channel associated with $B \in \mathcal{M}_d$. Then,

$$Q(\Phi_B) = 0 \iff \Phi_B \text{ is entanglement-breaking} \iff \Phi_B \text{ is PPT} \iff B = \mathds{1}_d$$

**Proof.** It is well-known that the final three equivalences hold, see [SN20a, Example 7.3] for instance. Moreover, if $\Phi_B$ is entanglement-breaking, then it clearly has zero capacity. Hence, to prove the theorem, it suffices to show that if $\Phi_B$ is not entanglement-breaking, then $Q(\Phi_B) > 0$. Now, since $\Phi_B$ is unital, $d^{\text{out}}(\Phi_B) = d$ (see Remark 2.3). Moreover, it is easy to see that the Choi matrix $J(\Phi_B) = \sum_{i,j=0}^{d-1} B_{ij} |ii\rangle\langle jj|$ has the same rank as $B$, so that according to Lemma 2.2, $d^{\text{env}}(\Phi_B) = \text{rank } B$. Let us split the remaining proof into two cases.

**Case 1.** rank $B < d$.

Since $d^{\text{env}}(\Phi_B) < d^{\text{out}}(\Phi_B)$, the result follows by noting that $\Phi_B(|e\rangle\langle e|) = B$, see Theorem 4.11.

**Case 2.** rank $B = d$.

In this case, we have $d^{\text{env}}(\Phi_B) = d^{\text{out}}(\Phi_B) = d$, so Corollary 3.2 can no longer be applied. Let $\{ |\phi_i\rangle \}_{i=0}^{d-1} \subseteq \mathbb{C}^d$ be a set of $d$ linearly independent unit vectors such that $B^\dagger = \text{gram} \{ |\phi_i\rangle \}_{i=0}^{d-1}$, i.e., $\forall i,j : B_{ij} = \langle \phi_j | \phi_i \rangle$. Then, we can define an isometry $V : \mathbb{C}^d \to \mathbb{C}^d \otimes \mathbb{C}^d$ by setting $V |i\rangle = |i\rangle \otimes |\phi_i\rangle$ as its action on the standard basis of $\mathbb{C}^d$, so that

$$\forall X \in \mathcal{M}_d : \quad \Phi_B(X) = \text{Tr}_2(V XV^\dagger) \quad \text{and} \quad \Phi_B^c(X) = \text{Tr}_1(V XV^\dagger),$$

where $\text{Tr}_1(2)$ denote the partial trace over the first (second) system and $\Phi_B \in \mathcal{C}_B$. Now, since $\Phi$ is not entanglement breaking and hence $B \neq \mathds{1}_d$, there exist indices $i \neq j$ such that $B_{ij} \neq 0$. Choose $|\psi\rangle = |i\rangle$, so that in the notation of Theorem 3.8, $R_\psi = |i\rangle\langle i|$ and $R^c_\psi = |\phi_i\rangle\langle \phi_i|$. Let us now analyse the action of the adjoint maps $\Phi_B^*$ and $(\Phi_B^c)^*$ on the projectors $R_\psi$ and $R^c_\psi$: \[
\begin{align*}
V \Phi_B^*(R_\psi)V^\dagger &= VV^\dagger(R_\psi \otimes \mathds{1}_d)VV^\dagger \\
&= \sum_{k=0}^{d-1} VV^\dagger |ik\rangle\langle ik| VV^\dagger \\
&= |i\phi_i\rangle\langle i\phi_i| \sum_{k=0}^{d-1} |\phi_i|\langle k| |\phi_i\rangle\langle k|=0 \Rightarrow \sum_{k=0}^{d-1} |\phi_i|\langle k| |\phi_i\rangle\langle k|=0 \Rightarrow \sum_{k=0}^{d-1} |\phi_i|\langle k| |\phi_i\rangle\langle k|=0 \Rightarrow \sum_{k=0}^{d-1} |\phi_i|\langle k| |\phi_i\rangle\langle k|=0 \Rightarrow \sum_{k=0}^{d-1} |\phi_i|\langle k| |\phi_i\rangle\langle k|=0 \Rightarrow \sum_{k=0}^{d-1} |\phi_i|\langle k| |\phi_i\rangle\langle k| \end{align*}\]

In the above calculation, we have used the fact that $VV^\dagger = \sum_{l=0}^{d-1} |l\phi_l\rangle\langle l\phi_l|$ acts as the orthogonal projection onto range $V \subseteq \mathbb{C}^d \otimes \mathbb{C}^d$. As $\langle \phi_j | \phi_i \rangle \neq 0$, the number of terms in the second sum above is at least two, so that $V (\Phi_B^c)^*(R^c_\psi)V^\dagger$ has rank at least two. Therefore, $V (\Phi_B^c)^*(R^c_\psi)V^\dagger \aleq
leads to a contradiction (see Section 4.6). Thus, we must have $d_{\text{out}}^*(\Phi) \leq \Phi\left(\left|\psi\right\rangle\right) \leq d_{\text{out}}^*(\Phi)$, since $V \Phi^*(\Phi_{\psi}) V^\dagger$ is of unit rank. Theorem 3.8 then tells us that $Q^{(1)}(\Phi_{B}) > 0$, and the proof is complete. □

4.6. A family of channels with equal output and environment dimensions. Consider a unitary operator $V : \mathbb{C}^4 \rightarrow \mathbb{C}^2 \otimes \mathbb{C}^2$, and a pure state $|\psi\rangle \in \mathbb{C}^4$ such that $V |\psi\rangle = |0\rangle \otimes |1\rangle$, where $\{0\}, \{1\}$ denotes the computational basis of $\mathbb{C}^2$. Then, for the quantum channel $\Phi : \mathcal{M}_4 \rightarrow \mathcal{M}_2$ and its complement $\Phi_c : \mathcal{M}_4 \rightarrow \mathcal{M}_2$, defined as follows, $d_{\text{out}}^*(\Phi) = d_{\text{env}}^*(\Phi) = 2$:

$$\Phi(X) = \text{Tr}_2(VXV^\dagger) ; \quad \Phi_c(X) = \text{Tr}_1(VXV^\dagger).$$

The orthogonal projections onto range $\Phi(|\psi\rangle\langle\psi|)$ and range $\Phi_c(|\psi\rangle\langle\psi|)$ are given by $R_{\psi} = |0\rangle|0\rangle$ and $R_{\psi} = |1\rangle|1\rangle$, respectively. It is clear that the adjoints of $\Phi$ and $\Phi_c$ act on these projectors as follows:

$$\Phi^*(R_{\psi}) = V^\dagger(R_{\psi} \otimes \mathbb{1}_2) V ; \quad \Phi^*_c(R_{\psi}) = V^\dagger(\mathbb{1}_2 \otimes R_{\psi}^\dagger) V.$$ 

Now, by using the fact that $VV^\dagger = \mathbb{1}_4$ (since $V$ is unitary), we obtain

$$V \Phi^*(R_{\psi}) V^\dagger = VV^\dagger(R_{\psi} \otimes \mathbb{1}_2) VV^\dagger = (R_{\psi} \otimes \mathbb{1}_2) = |0\rangle|0\rangle \otimes (|0\rangle|0\rangle + |1\rangle|1\rangle);$$

$$V \Phi^*_c(R_{\psi}) V^\dagger = VV^\dagger(\mathbb{1}_2 \otimes R_{\psi}^\dagger) VV^\dagger = (\mathbb{1}_2 \otimes R_{\psi}^\dagger) = (|0\rangle|0\rangle + |1\rangle|1\rangle) \otimes |1\rangle|1\rangle.$$

Hence, $V \Phi^*(R_{\psi}) V^\dagger \ngeq V \Phi^*_c(R_{\psi}) V^\dagger$, and therefore $\Phi^*_c(R_{\psi}) \nleq \Phi^*(R_{\psi})$. By Theorem 3.8, we then conclude that such a channel $\Phi$ has $Q^{(1)}(\Phi) > 0$. The same argument applied to the complementary channel shows that $Q^{(1)}(\Phi_c) > 0$ as well.

By considering unitary mappings $V : \mathbb{C}^{d^2} \rightarrow \mathbb{C}^2 \otimes \mathbb{C}^d$ and following the same steps as above, it is easy to infer that for any channel $\Phi : \mathcal{M}_d \rightarrow \mathcal{M}_{\text{dout}}$ with $d = d_{\text{out}}^*(\Phi) = d_{\text{env}}^*(\Phi)$, both $Q^{(1)}(\Phi)$ and $Q^{(1)}(\Phi_c)$ are positive. In particular, such a channel can neither be degradable nor anti-degradable.

5. Structure theorems for more capable quantum channels

Cubitt et al proved two structure theorems for degradable channels (see [CRS08, Theorem 3 and 4]), which we extend in this section to the strictly larger class of more capable quantum channels. Their proofs follow simply from our results in Section 3.

**Theorem 5.1.** Let $\Phi : \mathcal{M}_d \rightarrow \mathcal{M}_{\text{dout}}$ be a more capable quantum channel. If there exists a pure state $|\psi\rangle\langle\psi| \in \mathcal{S}_d$ such that $\text{rank} \Phi(|\psi\rangle\langle\psi|) = d_{\text{out}}^*(\Phi)$, then $d_{\text{out}}^*(\Phi) = d_{\text{env}}^*(\Phi)$.

**Proof.** By Lemma A.3, we know that for all $|\psi\rangle\langle\psi| \in \mathcal{S}_d$, $\text{rank} \Phi(|\psi\rangle\langle\psi|) = \text{rank} \Phi_c(|\psi\rangle\langle\psi|)$. Hence, we must have $d_{\text{env}}^*(\Phi) \geq d_{\text{out}}^*(\Phi)$. However, if $d_{\text{env}}^*(\Phi) > d_{\text{out}}^*(\Phi)$, then according to Corollary 3.2, $Q(\Phi_c) > 0$, which leads to a contradiction. Hence, $d_{\text{env}}^*(\Phi) = d_{\text{out}}^*(\Phi)$. □

**Theorem 5.2.** Let $\Phi : \mathcal{M}_d \rightarrow \mathcal{M}_{\text{dout}}$ be a more capable quantum channel with $d_{\text{out}}^*(\Phi) = 2$. Then $d_{\text{env}}^*(\Phi) \leq 2$ and $d \leq 3$.

**Proof.** If there exists a pure state $|\psi\rangle\langle\psi| \in \mathcal{M}_d$ such that $\text{rank} \Phi(|\psi\rangle\langle\psi|) = 2$, then Theorem 5.1 implies that $d_{\text{env}}^*(\Phi) = 2$. If no such pure state exists, then it must be the case that $\Phi$ always maps pure states to pure states. Then by [CRS08, Theorem 1], either (i) $\Phi(X) = UXU^\dagger$, where $U : \mathbb{C}^d \rightarrow \mathbb{C}^{d_{\text{out}}}$ is an isometry, in which case Lemma 2.2 tells us that $d_{\text{env}}^*(\Phi) = 1$, or (ii) $\Phi$ is the completely noisy channel which maps everything to a single fixed pure state: $\Phi(X) = \text{Tr}(X) \left|\phi\right\rangle\left\langle\phi\right|$, which cannot be true since $d_{\text{out}}^*(\Phi) = 2$. Hence, we always have $d_{\text{env}}^*(\Phi) \leq 2$. Now, let $V : \mathbb{C}^d \rightarrow \mathbb{C}^2 \otimes \mathbb{C}^{d_{\text{env}}}$ be the Stinespring isometry which defines the minimally defined complementary pair $\Phi : \mathcal{M}_d \rightarrow \mathcal{M}_2$ and $\Phi_c : \mathcal{M}_d \rightarrow \mathcal{M}_{\text{denv}}$ (i.e. $d_{\text{env}} = d_{\text{env}}(\Phi_c)$), see Eq. (5). Then,

$$d \leq 2d_{\text{env}}^*(\Phi) \quad \Rightarrow \quad d \leq \begin{cases} 2 & \text{if} \ d_{\text{env}}^*(\Phi) = 1 \\ 4 & \text{if} \ d_{\text{env}}^*(\Phi) = 2 \end{cases}.$$ 

If $d = 4$, $V : \mathbb{C}^4 \rightarrow \mathbb{C}^2 \otimes \mathbb{C}^2$ becomes a unitary map, which implies that $Q^{(1)}(\Phi_c) > 0$ and hence leads to a contradiction (see Section 4.6). Thus, $d \leq 3$ and the proof is complete. □
6. Conclusion and open problems

In this paper, we have employed some basic techniques from analytic perturbation theory of Hermitian matrices (Theorem A.1) to derive a powerful sufficient condition for a quantum channel (or its complement) to have positive quantum capacity (Theorem 3.1). An equivalent formulation of this condition equips us with a first-of-its-kind necessary condition for membership in the set of zero capacity quantum channels (Theorem 3.8). These are significant results because to date, no systematic procedure is known to check if a given quantum channel can be used to reliably transmit quantum information, and this is precisely because of our limited understanding of the set of zero capacity quantum channels. Notably, the main result in [Sid20] pops out as an immediate consequence of Theorem 3.1, which can be used to detect positive quantum capacities of channels (or their complements) with unequal output and environment dimensions for which there exists a pure input state which gets mapped to a maximal rank output state (Corollary 3.2). Obtaining a complete characterization of channels for which such a pure state exists is a rather formidable task. Nevertheless, we have derived simple inequalities between the input, output and environment dimensions of a given channel that suffice to ensure the existence of the sought-after pure state, irrespective of the specific structure of the channel (Corollaries 3.4 and 3.6). By exploiting our main results, we have shown that a variety of interesting examples of quantum channels have positive quantum capacity (Section 4). Moreover, our results lead to simplified proofs of certain existing structure theorems for the class of degradable quantum channels, and an extension of their applicability to the larger class of more capable quantum channels.

Listed below are some of the open problems that stem from our research.

- Show that PPT channels satisfy the necessary condition of Theorem 3.8 for membership in the set of zero capacity quantum channels.
- Look for other quantum channels which satisfy the condition stated in Theorem 3.8. This could potentially lead to new examples of channels which are neither anti-degradable nor PPT, but still have zero quantum capacity.
- Obtain examples of channels which satisfy the condition stated in Theorem 3.8 for all positive integers \( n \leq m \) for some fixed \( m \in \mathbb{N} \), but not for \( n > m \). Such channels, if they exist, would have positive \( n \)-shot coherent information for all \( n > m \) but at the same time, would satisfy the necessary condition for having zero \( n \)-shot coherent information for all \( n \leq m \), and hence could potentially shed new light on the superadditivity of coherent information.
- Investigate whether Theorem 3.1 can be used to detect positive quantum capacity of a (C)DUC channel when Theorem 4.11 is inapplicable.

Further work on applying the techniques developed in this paper to random quantum channels and quantum channels acting on infinite dimensional Hilbert spaces is currently in progress.

Appendix A. Proof of Theorem 3.1

**Theorem A.1.** [Bau85, Introduction, Theorem 1] or [RB69, Chapter 1, Theorem 1]

Let \( A(\epsilon) = A_0 + \epsilon A_1 \), where \( A_0, A_1 \in \mathcal{M}_d \) are Hermitian matrices and \( \epsilon \in \mathbb{R} \). Let \( \lambda_0 \) be an eigenvalue of \( A_0 \) of multiplicity \( n \) and let \( P_0 \) be the orthogonal projection onto the corresponding \( n \)-dimensional eigenspace. Then, for sufficiently small \( |\epsilon| \), \( A(\epsilon) \) has exactly \( n \) analytic eigenvalues (counted with multiplicities) in the neighborhood of \( \lambda_0 \) with convergent power series expansions:

\[
\lambda_i(\epsilon) = \lambda_0 + \lambda_{i1}\epsilon + \lambda_{i2}\epsilon^2 + \ldots, \quad i = 1, 2, \ldots, n.
\]

Further, the non-zero first order correction terms \( \lambda_{i1} \) are the non-zero eigenvalues of \( P_0A_1P_0 \).

**Lemma A.2.** Let \( R > 0 \) and \( f \in C^\infty([0, R]) \) be a non-negative real analytic function (not identically equal to zero) with the following power series expansion:

\[
f(\epsilon) = f_0 + f_1\epsilon + f_2\epsilon^2 + \ldots, \quad \epsilon \in [0, R]
\]
Then, there exists \( r \in (0, R) \) such that \( g(\epsilon) = f(\epsilon) \log f(\epsilon) \) is real analytic on the interval \((0, r)\), i.e. \( g \in C^\infty(0, r) \). Moreover, the derivative \( g' \in C^\infty(0, r) \) is unbounded if and only if \( f_0 = 0 \) and \( f_1 \neq 0 \).

Proof. This proof exploits some basic properties of real analytic functions, see [KP02, Chapter 1]. Firstly, recall that since the Taylor series of \( f \) converges in the interval \([0, R]\), the derived series \( f' \) also converges in the same interval. Hence, for every \( r \in (0, R) \) we can uniformly bound both \( f \) and \( f' \) on the domain \([0, r]\). Moreover, since the zeros of analytic functions are isolated, it is easy to find an \( r \in (0, R) \) such that no zeros of \( f \) lie within the range \([0, r]\), i.e. \( \forall \epsilon \in (0, r] : f(\epsilon) > 0 \). Hence, there exist constants \( c_1, c_2 > 0 \) such that \( \forall \epsilon \in (0, r] : c_1 \leq f(\epsilon) \leq c_2 \), except possibly when \( f_0 = f(0) = 0 \), in which case \( f \) is still strictly positive and bounded on \((0, r)\) but \( f(\epsilon) \to 0 \) as \( \epsilon \to 0 \).

Now, since \( \log \) is real analytic on \((0, \infty)\) and \( f \) maps \((0, r)\) within \((0, \infty)\), it is clear that \( g \) is real analytic on \((0, r)\). Then, \( g' \) is also analytic on \((0, r)\) and admits an expression of the form

\[
g'(\epsilon) = f'(\epsilon) \log f(\epsilon) + f(\epsilon)
\]

where we have used the symbol \( O(\epsilon^k) \) as a placeholder for functions \( h \) for which there exists \( 0 < r_0 \leq r \) and \( C > 0 \) such that \( \forall \epsilon \in [0, r_0] : |h(\epsilon)| \leq C\epsilon^k \). It is then straightforward to infer from our previous discussion that the terms in the square brackets above are always bounded in the interval \((0, r)\). Now, if either \( f_0 \neq 0 \) or \( f_1 = 0 \), the first term is also bounded. However, if \( f_0 = 0 \) and \( f_1 \neq 0 \), the first term splits up into \( f_1 \log \epsilon + f_1 \log(f_1 + O(\epsilon)) \), which blows up as \( \epsilon \to 0 \). Hence, we can write the derivative as follows

\[
g'(\epsilon) = \begin{cases} f_1 \log \epsilon + K_1(\epsilon), & \text{if } f_0 = 0, f_1 \neq 0 \\ K_2(\epsilon), & \text{otherwise} \end{cases}
\]

where both \( K_1 \) and \( K_2 \) are bounded on \((0, r)\).

Lemma A.3. Let \( \Phi : \mathcal{M}_d \to \mathcal{M}_{d_{\text{out}}} \) be a channel and \( \Phi_c \in \mathcal{C}_d \). Then, for a pure state \( |\psi\rangle\langle\psi| \in \mathcal{S}_d \), the non-zero eigenvalues (counted with multiplicity) of \( \Phi(|\psi\rangle\langle\psi|) \) and \( \Phi_c(|\psi\rangle\langle\psi|) \) are identical.

Proof. Let \( V : \mathbb{C}^d \to \mathbb{C}^d_{\text{out}} \otimes \mathbb{C}^d_{\text{env}} \) be the isometry that defines the complementary channels \( \Phi \) and \( \Phi_c \) as in Eq (5). Using Schmidt decomposition, we can express \( V |\psi\rangle = \sum_{i=1}^n \sqrt{s_i} |i\rangle_{\text{out}} \langle i|_{\text{env}} \), where \( \{|i\rangle_{\text{out}}\}_{i=1}^n \subseteq \mathbb{C}^d_{\text{out}} \) and \( \{|i\rangle_{\text{env}}\}_{i=1}^n \subseteq \mathbb{C}^d_{\text{env}} \) are orthonormal sets, \( s_i \geq 0 \) and \( n \leq \min\{d_{\text{out}}, d_{\text{env}}\} \). Then, the desired result follows by noting that

\[
\Phi(|\psi\rangle\langle\psi|) = \sum_i s_i |i\rangle_{\text{out}} \langle i| \quad \text{and} \quad \Phi_c(|\psi\rangle\langle\psi|) = \sum_i s_i |i\rangle_{\text{env}} \langle i|.
\]

Proof of Theorem 3.1. We consider the one-parameter family of states \( \rho(\epsilon) = (1 - \epsilon) |\psi\rangle\langle\psi| + \epsilon |\sigma\rangle\langle\sigma| \) within the range \( 0 \leq \epsilon \leq 1 \), and analyse the outputs under the given channels

\[
\Phi[\rho(\epsilon)] = (1 - \epsilon) \Phi(|\psi\rangle\langle\psi|) + \epsilon \Phi(|\sigma\rangle\langle\sigma|), \quad \Phi_c[\rho(\epsilon)] = (1 - \epsilon) \Phi_c(|\psi\rangle\langle\psi|) + \epsilon \Phi_c(|\sigma\rangle\langle\sigma|).
\]

At \( \epsilon = 0 \), both \( \Phi(|\psi\rangle\langle\psi|) \) and \( \Phi_c(|\psi\rangle\langle\psi|) \) have the same non-zero spectrum (Lemma A.3):

\[
\text{spec } \Phi(|\psi\rangle\langle\psi|) = \{s_{10}, \ldots, s_{n0}, 0, \ldots, 0\} \quad \text{and} \quad \text{spec } \Phi_c(|\psi\rangle\langle\psi|) = \{s_{10}, \ldots, s_{n0}, 0, \ldots, 0\},
\]

where \( n \in \mathbb{N} \) is the number of non-zero eigenvalues counted with multiplicities, so that \( K_\psi \) and \( K_\psi^c \) are projectors onto the respective null spaces of dimensions \( \kappa = d_{\text{out}} - n \) and \( \kappa_c = d_{\text{env}} - n \). Observe that for our purposes, the spectrum of a \( d \times d \) matrix is just the (unordered) sequence of all its
eigenvalues counted with multiplicities. Now, once we turn on the perturbation and $\epsilon$ is sufficiently small (say $0 \leq \epsilon < R$), we get the following analytic eigenvalue functions (see Theorem A.1):

\[
s_i(\epsilon) = s_{i0} + s_{i1}\epsilon + s_{i2}\epsilon^2 \ldots \quad \lambda_j(\epsilon) = 0 + \lambda_{j1}\epsilon + \lambda_{j2}\epsilon^2 \ldots
\]

\[
s_i^c(\epsilon) = s_{i0} + s_{i1}^c\epsilon + s_{i2}^c\epsilon^2 \ldots \quad \lambda_k^c(\epsilon) = 0 + \lambda_{k1}^c\epsilon + \lambda_{k2}^c\epsilon^2 \ldots
\]

such that

\[
\text{spec } \Phi(\rho(\epsilon)) = \{ s_i(\epsilon), \lambda_j(\epsilon) \} \quad \text{and} \quad \text{spec } \Phi_c(\rho(\epsilon)) = \{ s_i^c(\epsilon), \lambda_k^c(\epsilon) \},
\]

where $i = 1, 2, \ldots, n$, $j = 1, 2, \ldots, d_{\text{out}} - n$, and $k = 1, 2, \ldots, d_{\text{env}} - n$. Assume, without loss of generality, that all the above functions are not identically zero (otherwise, we can just restrict ourselves to those which are non-zero). We are interested in analyzing the coherent information of $\rho(\epsilon)$ with respect to $\Phi$, which has the following form (see Section 2.2)

\[
I(\epsilon) := I_c(\rho(\epsilon); \Phi) = S[\Phi(\rho(\epsilon))] - S[\Phi_c(\rho(\epsilon))]
\]

\[
= \sum_i s_i^c(\epsilon) \log s_i^c(\epsilon) + \sum_k \lambda_k^c(\epsilon) \log \lambda_k^c(\epsilon) - \sum_i s_i(\epsilon) \log s_i(\epsilon) - \sum_j \lambda_j(\epsilon) \log \lambda_j(\epsilon).
\]

Observe that we can immediately apply Lemma A.2 to each term in the above sum, so that we obtain $0 < r < R$ such that $I(\epsilon)$ is analytic on $(0, r)$ and its derivative can be written as

\[
I'(\epsilon) = \left[ \sum_{j: \lambda_{j1} \neq 0} \lambda_{j1} - \sum_{k: \lambda_{k1}^c \neq 0} \lambda_{k1}^c \right] \log(1/\epsilon) + K(\epsilon),
\]

where $K$ is bounded on $(0, r)$, see Eq (36). Now, Theorem A.1 tells us that the term in the brackets above is nothing but $\text{Tr}(K\psi\Phi(\sigma)) - \text{Tr}(K\psi\Phi_c(\sigma))$. Hence, if $\text{Tr}(K\psi\Phi(\sigma)) > \text{Tr}(K\psi\Phi_c(\sigma))$, we can find a small enough $0 < \delta < r$ such that the first term above dominates the other when $\epsilon < \delta$ and consequently, $\forall \epsilon \in (0, \delta) : I'(\epsilon) > 0$. A simple application of the mean value theorem then tells us that $I(\epsilon)$ is strictly increasing on the interval $[0, \delta]$. Moreover, since $I(0) = 0$, we obtain $\forall \epsilon \in (0, \delta) : I(\epsilon) > 0 \implies \mathcal{Q}^{(1)}(\Phi) > 0$. The other case can be tackled similarly. 

\section*{Appendix B: Lemma B.1}

\textbf{Lemma B.1.} Let $\rho \in S_d$ and $P_\rho$ denote the orthogonal projection onto range $\rho$. Then, for an arbitrary channel $\Phi : \mathcal{M}_d \rightarrow \mathcal{M}_{d_{\text{out}}}$, the following equality holds: range $\Phi(\rho) = \text{range } \Phi(\rho)$.

Spectrally decompose $\rho = \sum_{i=1}^n \lambda_i P_i$, where $\lambda_i > 0$ are the distinct non-zero eigenvalues of $\rho$ and $P_i$ are the orthogonal projections onto the corresponding eigenspaces, so that $\Phi(\rho) = \sum_i \Phi(P_i)$ and $\Phi(\rho) = \sum_i \lambda_i \Phi(P_i)$. Now, the conclusion follows by noting that

\[
\ker \sum_i \Phi(P_i) = \bigcap_i \ker \Phi(P_i) = \bigcap_i \ker \lambda_i \Phi(P_i) = \ker \sum_i \lambda_i \Phi(P_i). \quad \square
\]

\section*{Appendix C: Proof of Proposition 4.10}

Before proving the main result, it is essential to introduce some notation. Given a $d_1 \times d_2$ matrix $X$ and $I \subseteq [d_1]$, $J \subseteq [d_2]$, the $|I| \times |J|$ submatrix containing the rows and columns of $X$ corresponding to the indices $i \in I$ and $j \in J$, respectively, is denoted by $X[I,J]$. The basis vectors $\{|i\rangle\}_{i \in I}$ and $\{|j\rangle\}_{j \in J}$ are then thought to lie in $\mathbb{C}^{|I|}$ and $\mathbb{C}^{|J|}$, respectively, so that $X[I,J] = \sum_{i \in I, j \in J} X_{ij} |i\rangle \langle j|$. If $I = [d_1]$ (or $J = [d_2]$), the associated submatrix is denoted by $X[d_1|J]$ (or $X[I|d_2]$). If $I = J$, we use $X[I] := X[I,I]$ to denote the associated $|I| \times |I|$ principal submatrix. Let us also recall the definition of the determinant function $\det : \mathcal{M}_d \rightarrow \mathbb{C}$:

\[
\det(X) = \sum_{\pi \in S_d} X_{\pi}, \quad \text{(37)}
\]
where $S_d$ denotes the permutation group of the set $[d]$ and $X_\pi = \prod_{i \in [d]} X_{i\pi_i}$.

Finally, let us prove a lemma regarding an intriguing matrix determinant.

**Lemma C.1.** Let $X \in \mathcal{M}_d$ ($d \geq 2$) be such that it has exactly two non-zero entries in each row, i.e., $\forall i \in [d]$, there exist unique $i_1, i_2 \in [d]$ such that $X_{ij} \neq 0 \iff j \in \{i_1, i_2\}$. For $|\psi\rangle \in \mathbb{C}^d$, define
\[
\psi(X)_{ij} = \begin{cases} 
0 & \text{if } j \notin \{i_1, i_2\} \\
X_{i_1i_j} \psi_{i_2} & \text{if } j = i_1 \\
X_{i_2i_j} \psi_{i_1} & \text{if } j = i_2
\end{cases}
\]

Then,
\[
\det \psi(X) = \left( \prod_{i \in [d]} \psi_{i}^{n_i-1} \right) \det X,
\]
where $n_i$ denotes the number of non-zero entries in the $i^{th}$ column of $X$.

**Proof.** Let us begin by observing that for every $\pi \in S_d$, we must have $\psi(X)_\pi = (\prod_{i \in [d]} \psi_i^{k_i(\pi)}) X_\pi$, where $\{k_i(\pi)\}_{i \in [d]}$ is a set of positive integers. This is because the matrix $\psi(X)$ has the same entries as $X$ up to multiplication by the entries of $|\psi\rangle$. Hence, our task is to show that
\[
\forall i \in [d], \forall \pi \in S_d : \quad k_i(\pi) = n_i - 1,
\]
where $n_i$ denotes the number of non-zero entries in the $i^{th}$ column. Firstly, note that if $\pi$ is such that $X_\pi = 0$, then $\psi(X)_\pi = 0$ as well, so there’s nothing to prove here. Hence, let $\pi \in S_d$ be an arbitrary permutation with $X_\pi \neq 0$. Now, suppose on the contrary that the desired claim does not hold and there exists $j \in [d]$ such that $k_j(\pi) \neq n_j - 1$. Let us collect all the rows $i \in [d]$ with $X_{ij} \neq 0$ in the set $R_j$, so that $n_j = |R_j|$. Then, for each row $i \in R_j$, one of the two non-zero entries is present in the column $i_1 = j$. Since $X_\pi \neq 0$, it must be the case that $\pi_i = i_2$ for all $i \in R_j$ such that $\pi_i \neq j = i_1$, which implies that
\[
\prod_{i \in R_j, \pi_i \neq j} \psi(X)_{i\pi_i} = \prod_{i \in R_j, \pi_i \neq j} X_{i_1i_j} \psi_{i_2} = \psi_j^{n_j-1} \prod_{i \in R_j, \pi_i \neq j} X_{i\pi_i}.
\]
Since $\psi_j$ cannot arise from any other term in the product $\prod_{i \in [d]} \psi(X)_{i\pi_i}$, we arrive at a contradiction. 

**Proof of Proposition 4.10** Recall that in order to prove the proposition, it suffices to show that
\[
\Phi(|e\rangle\langle e|)[I] \text{ is singular } \implies \Phi(|\psi\rangle\langle \psi|)[I] \text{ is singular for all } |\psi\rangle \in S_d,
\]
where $I \subseteq [d]$ is an arbitrary index set of size $|I| = r$.

**Case 1.** $\Phi = \Phi_{A,B}$ is a CDUC channel with $A \succ 0$ and $B \succeq 0$.

Let us express $\Phi_{A,B}(|e\rangle\langle e|)[I] = \sum_{i \in I} \sum_{k \neq i} A_{ik} |i\rangle\langle i| + [B[I]]$ as a sum of two $r \times r$ positive semi-definite matrices, so that $\Phi_{A,B}(|e\rangle\langle e|)[I]$ is singular if and only if the two matrices in the above sum have a non-trivial common kernel. Since $\ker \sum_{i \in I} \sum_{k \neq i} A_{ik} |i\rangle\langle i| = \text{span}\{|j\rangle\}_{j \in I \setminus J} \subseteq \mathbb{C}^r$ with $J = \{j \in I : \exists k \in [d], k \neq j, A_{jk} \neq 0\}$, we obtain
\[
\Phi_{A,B}(|e\rangle\langle e|)[I] \text{ is singular } \iff \{B[I,j]\}_{j \in I \setminus J} \subseteq \mathbb{C}^r \text{ is linearly dependent},
\]
where $|B[I,j]\rangle := B[I]|j\rangle$ is the $j^{th}$ column of $B[I]$. Now, for $|\psi\rangle \in \mathbb{C}^d$, we have
\[
\Phi_{A,B}(|\psi\rangle\langle \psi|)[I] = \sum_{i \in I} \sum_{k \neq i} A_{ik} |\psi_k|^2 |i\rangle\langle i| + (B \odot |\psi\rangle\langle \psi|)[I].
\]
Note that $\text{span}\{|j\rangle\}_{j \in I \setminus J} \subseteq \text{ker} \sum_{i \in I} \sum_{k \neq i} A_{ik} |\psi_k|^2 |i\rangle\langle i|$ and equality holds whenever $\psi_i \neq 0$ for all $i \in [d]$. Clearly, since the $j^{th}$ column of $(B \odot |\psi\rangle\langle \psi|)[I]$ is nothing but $\sum_j |\psi_j|^2 |B[I,j]\rangle \odot |\psi[I]\rangle$, the column
set \{ (B \otimes |\psi)(\psi|)[I]_{j} \}_{j \in I \setminus J} \subseteq \mathbb{C}^r \} is linearly dependent as well, so that the two matrices in the sum in Eq. (39) again have a non-trivial common kernel. Hence, \( \Phi_{A,B}(|\psi)(\psi|)[I] \) is singular.

**Case 2.** \( \Phi = \Psi_{A,B} \) is a DUC channel with \( A \succ 0, B = B^\dagger \) and \( A_{ij}A_{ji} \geq |B_{ij}|^2 \).

In this case, since \( B \) is not positive semi-definite, the previous approach would not work. Even so, let us still try to express \( \Psi_{A,B}(|\psi)(\psi|)[I] \) as a sum of positive semi-definite matrices:

\[
\Psi_{A,B}(|\psi)(\psi|)[I] = \sum_{i \in I} \left( A_{ii} + \sum_{j \neq i, j \notin I} A_{ij} \right) |i\rangle\langle i| + \sum_{i < j} (A_{ij} |i\rangle\langle j| + B_{ij} |j\rangle\langle i| + A_{ji} |j\rangle\langle j|) \\
= \sum_{i \in I} |\lambda_i\rangle\langle \lambda_i| + \sum_{i < j} (|\lambda_{ij}^1\rangle\langle \lambda_{ij}^1| + |\lambda_{ij}^2\rangle\langle \lambda_{ij}^2|) \\
= \Lambda^\dagger \Lambda,
\]

where the vectors \( |\lambda_i\rangle \in \text{span}\{ |i\rangle \} \subseteq \mathbb{C}^r \) (for \( i \in I \)) and \( |\lambda_{ij}^k\rangle \in \text{span}\{ |i\rangle, |j\rangle \} \subseteq \mathbb{C}^r \) (for \( i < j, i, j \in I, \) and \( k \in \{1, 2\} \)) form the rank one decompositions of the corresponding positive semi-definite matrices from the previous sum, and \( \Lambda \in M_{n \times r} \) stores these vectors in its rows. Notice that the conditions \( A \succ 0, B = B^\dagger \) and \( A_{ij}A_{ji} \geq |B_{ij}|^2 \) ensure that all the matrices in the two sums above are indeed positive semi-definite. Similar decomposition can be obtained for an arbitrary pure input state \( |\psi\rangle\langle \psi| \in \mathcal{S}_d \):

\[
\Phi_{A,B}(|\psi)(\psi|)[I] = \sum_{i \in I} \left( A_{ii} |\psi_i\rangle\langle \psi_i| + \sum_{j \neq i, j \notin I} A_{ij} |\psi_j\rangle\langle \psi_j| + A_{ji} |\psi_j\rangle\langle \psi_i| \right) \\
= \sum_{i \in I} |\psi(\lambda_i)\rangle\langle \psi(\lambda_i)| + \sum_{i < j} |\psi(\lambda_{ij}^1)\rangle\langle \psi(\lambda_{ij}^1)| + |\psi(\lambda_{ij}^2)\rangle\langle \psi(\lambda_{ij}^2)| \\
= |\psi(\Lambda)^\dagger\rangle\langle \psi(\Lambda)|,
\]

where the vectors \( |\psi(\lambda_i)\rangle \in \text{span}\{ |i\rangle \} \subseteq \mathbb{C}^r \) (for \( i \in I \)), \( |\psi(\lambda_{ij}^k)\rangle \in \text{span}\{ |i\rangle, |j\rangle \} \subseteq \mathbb{C}^r \) (for \( i < j, i, j \in I, \) and \( k \in \{1, 2\} \)) and the matrix \( \psi(\Lambda) \in M_{n \times r} \) are defined as before. Notice that for all \( i, j, k \):

\[
|\psi(\lambda_{ij})\rangle = |\lambda_{ij}^k\rangle \otimes (\psi_i |i\rangle + \psi_j |j\rangle),
\]

where \( \otimes \) denotes the entrywise vector product with respect to the standard basis in \( \mathbb{C}^r \). Now, if \( n < r \), we have rank \( \Phi_{A,B}(|\psi)(\psi|)[I] = \text{rank} \Lambda < r \) and rank \( \Phi_{A,B}(|\psi)(\psi|)[I] = \text{rank} \psi(\Lambda) < r \), so that both \( \Phi_{A,B}(|\psi)(\psi|)[I] \) and \( \Phi_{A,B}(|\psi)(\psi|)[I] \) are always singular. Otherwise, if \( n \geq r \), we need to show that for \( r \times r \) submatrices \( \Lambda_{[J]} := \Lambda^{(r)} \) and \( \psi(\Lambda)_{[J]} := \psi^{(r)}(\Lambda) \) constructed by arbitrarily choosing \( r \) rows according to a random index set \( J \subseteq [n] \) with \( |J| = r \),

\[
\det \Lambda^{(r)} = 0 \implies \det \psi^{(r)}(\Lambda) = 0.
\]

If \( \det \Lambda^{(r)} = 0 \) because \( \forall \pi \in S_r : \Lambda^{(r)}_{\pi \pi} = 0 \), then since \( \Lambda^{(r)}_{ij} = 0 \implies \psi^{(r)}(\Lambda)_{ij} = 0 \) for all \( i, j \), the desired claim is trivial to prove. Otherwise, there must exist at least two distinct permutations \( \pi_1, \pi_2 \in S_r \) such that \( \Lambda^{(r)}_{\pi_1} \) and \( \Lambda^{(r)}_{\pi_2} \) are non-zero. In this case, after suitable elementary row and column operations, \( \Lambda^{(r)} \) and \( \psi^{(r)}(\Lambda) \) can be brought, respectively, into the block diagonal forms

\[
\begin{pmatrix}
X & 0 \\
0 & Y
\end{pmatrix}
\quad \text{and} \quad
\begin{pmatrix}
\psi(X) & 0 \\
0 & \psi(Y)
\end{pmatrix},
\]

(41)
where \( X, \tilde{\psi}(X) \in M_k \) are such that \( \det X = X_\pi \neq 0 \) and \( \det \tilde{\psi}(X) = \tilde{\psi}(X)_\pi \) for a unique \( \pi \in S_k \) and \( Y, \tilde{\psi}(Y) \in M_{r-k} \) are of the form described in Lemma C.1, see Eq. (40). In the notation of Lemma C.1, the vector \( \tilde{\psi} \in \mathbb{C}^{r-k} \) which implements the transformation \( Y \mapsto \tilde{\psi}(Y) \) can be obtained by choosing some \( r-k \) entries from \( \psi \in \mathbb{C}^d \). Its exact form is irrelevant for our purposes. When written in the above form, it should be evident that \( \det \Lambda^{(r)} = 0 \iff \det Y = 0 \), in which case Lemma C.1 informs us that \( \det \tilde{\psi}(Y) = 0 \implies \det \psi^{(r)}(\Lambda) = 0 \), and the proof is complete.
