

One colorful resolution to the neutrino mass generation, three lepton flavor universality anomalies, and the Cabibbo angle anomaly

(Dated: November 2, 2021)

We propose a simple model to simultaneously explain four observed flavor anomalies while generating the neutrino mass at the one-loop level. Specifically, we address the measured anomalous magnetic dipole moments of the muon, Δa_μ , and electron, Δa_e , the observed anomaly of $b \rightarrow sl^+l^-$ in the B -meson decays, and the Cabibbo-angle anomaly. The model consists of four colorful new degrees of freedom: three scalar leptoquarks with the Standard Model quantum numbers $(3, 3, -1/3)$, $(3, 2, 1/6)$, and $(3, 1, 2/3)$, and one pair of down-quark-like vector fermion in $(3, 1, -1/3)$. The baryon number is assumed to be conserved for simplicity.

Phenomenologically viable solutions with the minimal number of real parameters can be found to accommodate all the above-mentioned anomalies and produce the approximate, close to 1σ , neutrino oscillation pattern at the same time. From general consideration, the model robustly predicts: (1) neutrino mass is of the normal hierarchy type, and (2) $\mathcal{M}_{ee}^\nu \lesssim 3 \times 10^{-4} \text{eV}$.

The possible UV origin to explain the flavor pattern of the found viable parameter space is briefly discussed. The parameter space can be well reproduced within a simple split fermion toy model.

I. INTRODUCTION

Despite of the amazing success of the Standard Model (SM) of particle physics, new physics (NP) beyond the SM is ineluctable because compelling evidence showing that at least two active neutrinos are massive[1]. In addition to the nonzero neutrino masses, several recent experimental measurements prominently deviated from the SM predictions are also suggestive to NP. In particular,

- The measured anomalous magnetic moment of muon $(g - 2)_\mu$ [1, 2] differs from the most recent SM prediction[3, 4] by an amount of $\sim 3.7\sigma$:

$$\Delta a_\mu = a_\mu^{exp} - a_\mu^{SM} \simeq (27.4 \pm 7.3) \times 10^{-10}, \quad (1)$$

* wfchang@phys.nthu.edu.tw

where the uncertainty is the quadratic combination of the experimental and theoretical ones. The most recent 0.46ppm measurement conducted at Fermilab[5] gives

$$a_{\mu}^{exp} = 116592040(54) \times 10^{-11}, \quad (2)$$

which agrees with the previous measurements. And the new experimental average of $a_{\mu}^{exp} = 116592061(41) \times 10^{-11}$ drives the deviation to 4.2σ with

$$\Delta a_{\mu} \simeq (25.1 \pm 5.9) \times 10^{-10}. \quad (3)$$

Another new measurement at the J-PARC[6] is also expected to improve the experimental uncertainty in the near future.

- With the determination of the fine-structure constant by using the cesium atom[7], the measured electron $(g-2)_e$ [8] shows a $\sim 2.4\sigma$ discrepancy from the SM prediction[9]:

$$\Delta a_e^{Cs} = a_e^{exp} - a_e^{SM} \simeq (-8.7 \pm 3.6) \times 10^{-13}. \quad (4)$$

Note that Δa_e^{Cs} and Δa_{μ} have opposite signs. New models[10–30] have been constructed to accommodate both Δa_e^{Cs} and Δa_{μ} . Moreover, [31–33] also attempt to incorporate the neutrino mass generation with the observed $\Delta a_{e,\mu}$.

However, the most recent α determination by using the rubidium atom[34] yields a different outcome

$$\Delta a_e^{Rb} \simeq (+4.8 \pm 3.0) \times 10^{-13}, \quad (5)$$

whose sign is different from the one of Δa_e^{Cs} . These two highly precise values of α differ by a tantalizing $\sim 5\sigma$. More independent investigations or measurements are required to resolve this tension. At this moment, we should consider both cases in this work.

- From the global fits[35–46] to various $b \rightarrow sl^+l^-$ data[47–61], the discrepancy is more than 5σ from the SM predictions. The new result[62] further strengthens the lepton flavor universality violation[63, 64]. This anomaly alone convincingly indicates NP, and stimulates many investigations to address this deviation. For example, a new gauge sector was introduced in [65–67], leptoquark has been employed in [68–76], assisted by the 1-loop contributions from exotic particles in [77–81], and more references can be found in [35, 82, 83].

- The so-called Cabibbo angle anomaly refers to the unexpected shortfall in the first row Cabibbo-Kobayashi-Maskawa (CKM) unitarity[1],

$$|V_{ud}|^2 + |V_{us}|^2 + |V_{ub}|^2 = 0.9985 \pm 0.0005. \quad (6)$$

The above value is smaller than one, and the inconsistency is now at the level of $\simeq 2 - 4\sigma$ level[84, 85]. There are tensions among different determinations of the Cabibbo angle from tau decays[86], kaon decays[87], and super-allowed β decay (by using CKM unitarity and the theoretical input[88, 89]). The potential NP involving vector quarks or the origins of lepton flavor universality violation have been discussed in [90–98].

Whether these $2 - 5\sigma$ anomalies will persist is not predictable; the future improvement on the theoretical predictions¹ and the experimental measurements will be the ultimate arbiters. However, at this moment, it is interesting to speculate whether all the above-mentioned anomalies and the neutrino mass can be explained simultaneously. In this paper, we point out one of such resolutions. With the addition of three scalar leptoquarks, $T(3, 3, -1/3)$, $D(3, 2, 1/6)$, and $S(3, 1, 2/3)$, and a pair of vector fermion, $b'_{L,R}(3, 1, -1/3)$, the plethora new parameters (mostly the Yukawa couplings) allow one to reconcile all data contemporarily. Parts of the particle content of this model had been employed in the past to accommodate some of the anomalies. However, to our best knowledge, this model as whole is new to comprehensively interpret all the observed deviations from the SM.

The paper is laid out as follows: in Sec.II we spell out the model and the relevant ingredients. Following that in Sec.III we explain how each anomaly and the neutrino mass generation works in our model. Next we discuss the various phenomenological constraint and provide some model parameter samples in Sec.IV. In Sec.V we discuss some phenomenological consequences, and the UV origin of the flavor pattern of the parameter space. Then comes our conclusion in Sec.VI. Some details of our notation and the low energy effective Hamiltonian are collected in the Appendix.

II. THE MODEL

In this model, three scalar leptoquarks, $T(3, 3, -1/3)$, $D(3, 2, 1/6)$, and $S(3, 1, 2/3)$ ², and a pair of down-quark-like vector fermion, $b'_{L,R}(3, 1, -1/3)$, are augmented on top of the SM. Our notation for the SM particle content and the exotics are listed in Tab.I and Tab.II, respectively.

¹ For example, the recent lattice study[99] suggests the SM prediction used to derive Δa_μ needs to be revised, and there is no significant tension with the recent FNAL experimental determination.

² In the literature[100], the corresponding notations for $D(3, 2, 1/6)$ and $S(3, 1, 2/3)$ are \tilde{R}_2 and $(\tilde{S}_1)^*$, respectively. The one closely related to our $T(3, 3, -1/3)$ is S_3^*

	SM Fermion					SM Scalar

baryon number	$\frac{1}{3}$	$\frac{1}{3}$	$\frac{1}{3}$	$\frac{1}{3}$

TABLE II. New field content and quantum number assignment under the SM gauge symmetries $SU(3)_c \otimes SU(2)_L \otimes U(1)_Y$, and the global lepton/baryon numbers.

Like most models beyond the SM, the complete Lagrangian is lengthy, and not illuminating. In this work, we only focus on the new gauge invariant interactions relevant to addressing the flavor anomalies. For simplicity, we also assume the model Lagrangian respects the global baryon number symmetry, and both T and S carry one third of baryon-number to avoid their possible di-quark couplings. Moreover, we do not consider the possible CP violating signals in this model.

For the scalar couplings, we have³

$$\mathcal{L} \supset \mu_3 \left\{ H, \tilde{D} \right\} \odot T + \mu_1 [H, D] S^{-\frac{2}{3}} + H.c. \quad (7)$$

$$= \mu_3 \left[H^+ D^{\frac{1}{3}} T^{-\frac{4}{3}} - \frac{1}{\sqrt{2}} \left(H^0 D^{\frac{1}{3}} - H^+ D^{-\frac{2}{3}} \right) T^{-\frac{1}{3}} - H^0 D^{-\frac{2}{3}} T^{\frac{2}{3}} \right] \\ - \mu_1 \frac{1}{\sqrt{2}} \left(H^0 D^{\frac{2}{3}} - H^+ D^{-\frac{1}{3}} \right) S^{-\frac{2}{3}} + H.c. \quad (8)$$

The couplings μ_1 and μ_3 are unknown dimensionful parameters. Note that the μ_3 coupling softly breaks the global lepton number by two units, which is crucial for the neutrino mass generation. On the other hand, the lepton-number conserving μ_1 triple scalar interaction is essential for explaining Δa_e and Δa_μ (to be discussed in the following sections). As it will be clear later, to fit all the data, μ_3 turns out to be very small, $\sim \mathcal{O}(0.5\text{keV})$, and $\mu_1 \sim \mathcal{O}(\text{TeV})$.

After electroweak spontaneous symmetry breaking (SSB), $\langle H^0 \rangle = v_0/\sqrt{2}$ and the Goldstone H^\pm are eaten by the W^\pm bosons. Below the electroweak scale, it becomes:

$$- \frac{\mu_3 v_0}{2} D^{\frac{1}{3}} T^{-\frac{1}{3}} - \frac{\mu_3 v_0}{\sqrt{2}} D^{-\frac{2}{3}} T^{\frac{2}{3}} - \frac{\mu_1 v_0}{2} D^{\frac{2}{3}} S^{-\frac{2}{3}} + H.c. \quad (9)$$

Comparing to their tree-level masses, $\widetilde{M}_{T,D,S} \simeq M_{LQ}^4$, we expect the mixings are small and suppressed by the factor of $\mathcal{O}(\mu_{LQ} v_0 / M_{LQ}^2)$. However, these mixings break the isospin multiplet mass degeneracy of T and D . After the mass diagonalization, we have two charge- $\frac{1}{3}$, three charge- $\frac{2}{3}$, and one charge- $\frac{4}{3}$ physical scalar leptoquarks.

In addition to the SM Yukawa interactions in the form of $\bar{Q} d_R H$, $\bar{Q} u_R \tilde{H}$, and $\bar{L} e_R H$, this model has the following new Yukawa couplings (in the interaction basis):

$$\mathcal{L} \supset -\tilde{\lambda}_T T^\dagger \cdot \{ \bar{L}^c, Q \} - \tilde{\lambda}_D \bar{d}_R [L, D] - \tilde{\lambda}'_D \bar{b}'_R [L, D] - \tilde{\lambda}_S \bar{e}_R b'_L S^{-\frac{2}{3}} - \tilde{Y}'_d \bar{Q} b'_R H + H.c. \quad (10)$$

$$= -\tilde{\lambda}_T \left[\bar{\nu}^c u_L T^{-\frac{2}{3}} + (\bar{\nu}^c d_L + \bar{e}^c u_L) \frac{T^{\frac{1}{3}}}{\sqrt{2}} + \bar{e}^c d_L T^{\frac{4}{3}} \right] - \tilde{Y}'_d (\bar{u}_L H^+ + \bar{d}_L H^0) b'_R \\ - \tilde{\lambda}_D \frac{\bar{d}_R}{\sqrt{2}} \left(\nu_L D^{-\frac{1}{3}} - e_L D^{\frac{2}{3}} \right) - \tilde{\lambda}'_D \frac{\bar{b}'_R}{\sqrt{2}} \left(\nu_L D^{-\frac{1}{3}} - e_L D^{\frac{2}{3}} \right) - \tilde{\lambda}_S \bar{e}_R b'_L S^{-\frac{2}{3}} + H.c., \quad (11)$$

where all the generation indices are suppressed to keep the notation simple and it should be understood that all the Yukawa couplings are matrices. Moreover, the model allows two kinds of tree-level Dirac mass term:

$$\mathcal{L} \supset M_1 \bar{b}'_R b'_L + M_2 \bar{d}_R b'_L + H.c. \quad (12)$$

³ To simplify the notation, we use “{,}” and “[,]” to denote the $SU(2)_L$ triplet and singlet constructed from two given $SU(2)_L$ doublets, respectively. Also, “ \odot ” means forming an $SU(2)_L$ singlet from two given triplets; see Appendix for the details.

⁴ Our notation is $\mathcal{L} \supset -\tilde{M}_T^2 T^\dagger T - \tilde{M}_D^2 D^\dagger D - \tilde{M}_S^2 S^\dagger S$. In order to preserve the $SU(3)_c$ symmetry, T, D, S cannot develop nonzero vacuum expectation values.

With the introduction of b' , the mass matrix for down-quark-like fermions after the electroweak SSB becomes:

$$\mathcal{L} \supset -(\bar{d}_R, \bar{b}'_R) \mathcal{M}^d \begin{pmatrix} d_L \\ b'_L \end{pmatrix} + H.c., \quad \mathcal{M}^d = \begin{pmatrix} \frac{\tilde{Y}_d v_0}{\sqrt{2}} & M_2 \\ \frac{\tilde{Y}'_d v_0}{\sqrt{2}} & M_1 \end{pmatrix}, \quad (13)$$

where \tilde{Y}_d is the SM down-quark three-by-three Yukawa coupling matrix in the interaction basis. Note that \mathcal{M}^d is now a four-by-four matrix. This matrix can be diagonalized by the bi-unitary transformation, $\mathcal{M}_{diag}^d = U_R^d \mathcal{M}^d (U_L^d)^\dagger = \text{diag}(m_d, m_s, m_b, M_{b'})$, and

$$U_R^d \mathcal{M}^d (\mathcal{M}^d)^\dagger (U_R^d)^\dagger = U_L^d (\mathcal{M}^d)^\dagger \mathcal{M}^d (U_L^d)^\dagger = (\mathcal{M}_{diag}^d)^2, \quad (14)$$

$$(d_1, d_2, d_3, d_4)_{L/R} = (d, s, b, b')_{L/R} (U_{L/R}^d)^*, \quad (15)$$

where (d_1, d_2, d_3, d_4) and (d, s, b, b') stand for the interaction and mass eigenstates, respectively. The new notation, d_4 , is designated for the interaction basis of the singlet $b'_{L,R}$, and b' is recycled to represent the heaviest mass eigenstate of down-type quark. One will see that the mass and interaction eigenstates of b' are very close to each other from the later phenomenology study.

Similarly, the SM up-type quarks and the charged leptons can be brought to their mass eigenstates by $U_{L/R}^u$ and $U_{L/R}^e$, respectively⁵. Since $\tilde{\lambda}$'s are unknown in the first place, one can focus on the couplings in the charged fermion mass basis, denoted as $\lambda^{T,D,S}$, which are more phenomenologically useful. However, note that the mass diagonalization matrices are in general different for the left-handed (LH) up- and LH down-quark sectors. If we pick the flavor indices of λ^T to label the charged lepton and down quark mass states, the up-type quark in the triplet leptoquark coupling will receive an extra factor to compensate the difference between U_L^d and U_L^u . Explicitly,

$$\begin{aligned} \mathcal{L} \supset & - \sum_{l=e,\mu,\tau} \sum_{p=d,s,b,b'} (\lambda^T)_{lp} \sum_{r=u,c,t} \tilde{A}_{pr}^\dagger \left[\bar{\nu}_l^c T^{-\frac{2}{3}} + \bar{e}_l^c \frac{T^{\frac{1}{3}}}{\sqrt{2}} \right] u_{L,r} \\ & - \sum_{l=e,\mu,\tau} \sum_{p=d,s,b,b'} (\lambda^T)_{lp} \left[\bar{e}_l^c T^{\frac{4}{3}} + \bar{\nu}_l^c \frac{T^{\frac{1}{3}}}{\sqrt{2}} \right] d_{L,p} + H.c. \end{aligned} \quad (16)$$

with the four-by-three matrix

$$\tilde{A}_{pr}^\dagger = \sum_{j=1}^4 (U_L^d)_{pj} (U_L^u)_{jr}^\dagger. \quad (17)$$

As will be discussed in below, \tilde{A} is the extended CKM rotation matrix, \tilde{V} , and $\tilde{A} \rightarrow (V_{CKM})$ if b'_L decouples. Now, all λ^T , λ^D , and λ^S are three-by-four matrices.

⁵ Note that the SM neutrinos are still massless at the tree-level.

In the interaction basis, only the LH doublets participate in the charged-current(CC) interaction. Thus, the SM W^\pm interaction for the quark sector is

$$\mathcal{L} \supset \frac{g_2}{\sqrt{2}} \sum_{i=1}^3 \left(\bar{u}_i \gamma^\alpha \hat{L} d_i \right) W_\alpha^+ + H.c. \quad (18)$$

However, the singlet b'_L mixes with other LH down-type-quarks and change the SM CC interaction.

In the mass basis, it becomes

$$\mathcal{L} \supset \frac{g_2}{\sqrt{2}} (\bar{u}, \bar{c}, \bar{t}) \gamma^\alpha \hat{L} \tilde{V} \begin{pmatrix} d \\ s \\ b \\ b' \end{pmatrix} W_\alpha^+ + H.c. \quad (19)$$

where

$$\tilde{V} = \begin{pmatrix} \tilde{V}_{ud} & \tilde{V}_{us} & \tilde{V}_{ub} & \tilde{V}_{ub'} \\ \tilde{V}_{cd} & \tilde{V}_{cs} & \tilde{V}_{cb} & \tilde{V}_{cb'} \\ \tilde{V}_{td} & \tilde{V}_{ts} & \tilde{V}_{tb} & \tilde{V}_{tb'} \end{pmatrix}, \text{ and } \tilde{V}_{pq} \equiv \sum_{i=1}^3 (U_L^u)_{pi} (U_L^d)_{iq}^\dagger. \quad (20)$$

Therefore, the SM three-by-three unitary CKM matrix changes into a three-by-four matrix in our model. When the b'_L decouples, the coupling matrix \tilde{V} reduces to the SM V_{CKM} .

Instead of dealing with a three-by-four matrix, it is helpful to consider an auxiliary unitary four-by-four matrix

$$\tilde{V}_4 \equiv \begin{pmatrix} U_L^u & 0 \\ 0 & 1 \end{pmatrix} \cdot (U_L^d)^\dagger = \begin{pmatrix} \tilde{V}_{ud} & \tilde{V}_{us} & \tilde{V}_{ub} & \tilde{V}_{ub'} \\ \tilde{V}_{cd} & \tilde{V}_{cs} & \tilde{V}_{cb} & \tilde{V}_{cb'} \\ \tilde{V}_{td} & \tilde{V}_{ts} & \tilde{V}_{tb} & \tilde{V}_{tb'} \\ (U_L^d)_{d4}^* & (U_L^d)_{s4}^* & (U_L^d)_{b4}^* & (U_L^d)_{b'4}^* \end{pmatrix}. \quad (21)$$

To quantify the NP effect, one can parameterize the four-by-four unitary matrix U_L^d by a unitary three-by-three sub-matrix, U_{L3}^d , and three rotations as:

$$(U_L^d)^\dagger = \begin{pmatrix} (U_{L3}^d)^\dagger & 0 \\ 0 & 1 \end{pmatrix} \cdot R_4, \text{ where } R_4 = \begin{pmatrix} c_1 & 0 & 0 & s_1 \\ -s_1 s_2 & c_2 & 0 & c_1 s_2 \\ -s_1 c_2 s_3 & -s_2 s_3 & c_3 & c_1 c_2 s_3 \\ -s_1 c_2 c_3 & -s_2 c_3 & -s_3 & c_1 c_2 c_3 \end{pmatrix}, \quad (22)$$

where $s_i(c_i)$ stands for $\sin \theta_i(\cos \theta_i)$, and θ_i is the mixing angle between d_{iL} and b'_L . In this work, we assume there is no new CP violation phase beyond the SM CKM phase for simplicity. Now,

Anomaly \ Field	$T(3, 3, -\frac{1}{3})$	$D(3, 2, \frac{1}{6})$	$S(3, 1, \frac{2}{3})$	$b'(3, 1, -\frac{1}{3})$	Remark
Neutrino mass	✓	✓	-	✓	1-loop
Cabibbo angle anomaly	-	-	-	✓	extended CKM
Δa_e	×	✓	✓	✓	1-loop
Δa_μ	✗	✓	✓	✓	1-loop
$b \rightarrow sl^+l^-$	✓	-	-	✓	box diagram

TABLE III. The anomalies and the fields to accommodate them in this model. The meaning of the legends: ✓: essential, ✗: helpful but not important or required, ×: negative effect, -: irrelevant.

Eq.(21) can be parameterized as

$$\tilde{V}_4 = \begin{pmatrix} V_{CKM} & 0 \\ 0 & 1 \end{pmatrix} \cdot R_4. \quad (23)$$

Again, we use d, s, b, b' to denote the mass eigenstates with $m_d \simeq 4.7\text{MeV}$, $m_s \simeq 96\text{MeV}$, $m_b \simeq 4.18\text{GeV}$, and $M_{b'}$, the mass of b' , unknown. The null result of direct searching for the singlet b' at ATLAS sets a limit that $M_{b'} > 1.22\text{TeV}$ [101] (by assuming only three 2-body decays: $b' \rightarrow Wt, bZ, bH$), and similar limits have obtained by CMS[102, 103]. We take $M_{b'} = 1.5\text{TeV}$ as a reference in this paper. Moreover, all the direct searches for the scalar leptoquarks at the colliders strongly depend on the assumption of their decay modes. Depending on the working assumptions, the exclusion limits range from $\sim 0.5\text{TeV}$ to $\sim 1.6\text{TeV}$ [1]. Instead of making simple assumptions, it will be more motivated to associate the leptoquark branching ratios to neutrino mass generation[104] or the b -anomalies [105, 106]. In this paper, we take $m_{T,D,S} \sim M_{LQ} = 1\text{TeV}$ as the reference point. And the constraint we obtained can be easily scaled for a different M_{LQ} or $M_{b'}$.

Since all the new color degrees of freedom are heavier than $\gtrsim \text{TeV}$, it is straightforward to integrate them out and perform the Fierz transformation to get the low energy effective Hamiltonian, see Appendix B.

III. EXPLAINING THE ANOMALIES

A. Neutrino mass

Instead of using the bi-lepton $SU(2)$ singlet and a charged scalar without lepton number as first proposed in Ref.[107], we employ two leptoquarks which carry different lepton numbers to break

FIG. 1. The Feynman diagrams for the neutrino mass generation. (a) General case, where $\phi_{1,2}$ are in their interaction basis, and F is in its mass eigenstate, and (b) for this model, where the fields are in the interaction basis. Here all the flavor indices are omitted.

the lepton number and generate the neutrino mass radiatively. We start with a general discussion on the 1-loop neutrino mass generation. If there are two scalars $\phi_{1,2}$ which interact with fermion F_k and the neutrino via a general Yukawa coupling parameterized as

$$\mathcal{L} \supset \lambda_{ij} \bar{F}_j \nu_{Li} \phi_1 + \kappa_{ij} \bar{F}_j \nu_i^c \phi_2 + H.c., \quad (24)$$

where the fermion F can carry arbitrary lepton number and baryon number (L_F, B_F) . If the two scalars do not mix, ϕ_1/ϕ_2 can be assigned with the lepton-number and baryon number $(L_F - 1, L_B)/(L_F + 1, L_B)$ and the Lagrangian enjoys both the global lepton-number $U(1)_L$ and the global baryon-number $U(1)_B$ symmetries⁶. Without losing the generality, F_k is assumed to be in its mass eigenstate with a mass m_k . If $\phi_{1,2}$ can mix with each other, the lepton number is broken by two units, and the Weinberg operator[113] can be generated radiatively. Let's denote $\phi_{h(l)}$ as the heavier(lighter) mass state with mass $m_h(m_l)$, and parameterize their mixing as $\phi_1 = c_\alpha \phi_l + s_\alpha \phi_h$ and $\phi_2 = -s_\alpha \phi_l + c_\alpha \phi_h$, where $s_\alpha(c_\alpha)$ is the shorthand notation for $\sin \alpha(\cos \alpha)$ and α is the mixing angle. The resultant neutrino mass from Fig.1(a) can be calculated as

$$M_{ij}^\nu = \sum_k \frac{N_c^F m_k}{16\pi^2} s_\alpha c_\alpha (\kappa_{ik} \lambda_{jk} + \kappa_{jk} \lambda_{ik}) \left[\frac{m_h^2}{m_h^2 - m_k^2} \ln \frac{m_h^2}{m_k^2} - \frac{m_l^2}{m_l^2 - m_k^2} \ln \frac{m_l^2}{m_k^2} \right], \quad (25)$$

which is exact and free of divergence. Note that for the diagonal element, the combination in the bracket should be replaced by $2\text{Re}(\kappa_{ik} \lambda_{ik})$. When the mixing is small, this result can also be approximately calculated in the interaction basis of ϕ_1 and ϕ_2 .

In our model, the mass eigenstate F can be the SM down-type quark or the exotic b' , and

⁶ For the discussion of the pure leptonic gauge symmetry $U(1)_L$, see for example [108–112].

$D^{\frac{1}{3}}/T^{\frac{1}{3}}$ plays the role of ϕ_1/ϕ_2 , as depicted in Fig.1(b). Assume the D - T mixing is small, then

$$M_{ij}^\nu \simeq \sum_{k=d,s,b,b'} \frac{3m_k}{32\pi^2} (\lambda_{ik}^T \lambda_{jk}^D + \lambda_{jk}^T \lambda_{ik}^D) \frac{\mu_3 v_0}{M_D^2 - M_T^2} \ln \frac{M_T^2}{M_D^2} \quad (26)$$

for $i \neq j$, and $2\text{Re}(\lambda_{ik}^T \lambda_{ik}^D)$ should be used in the bracket for the diagonal elements. To have sub-eV neutrino masses, we need roughly

$$\mu_3 m_b \lambda^D \lambda^T, \mu_3 M_{b'} \lambda^D \lambda^T \simeq \mathcal{O}(10^{-5}) \times \left(\frac{M_{LQ}}{\text{TeV}} \right)^2 (\text{GeV})^2 \quad (27)$$

if $b^{(\prime)}$ -quark contribution dominates. More comprehensive numerical consideration with other phenomenology will be given in section IV.

B. $(g-2)$ of charged leptons

FIG. 2. The Feynman diagrams in the mass basis for the anomalous magnetic dipole moment of charged lepton in general cases.

We also start with a general discussion on the 1-loop contribution to $(g-2)_\ell$ by adding a fermion, F , and a charged scalar, h . The F - ℓ - h Yukawa interaction can be parameterized as

$$\mathcal{L} \supset \bar{F}(y_R^l \hat{R} + y_L^l \hat{L})\ell h + H.c. \quad (28)$$

where both F and ℓ are in their mass eigenstates. Here, we have suppressed the flavor indices but it should be understood that both y_R and y_L are in general flavor dependent. Then, the resulting 1-loop anomalous magnetic moment depicted in Fig.2(a,b) can be calculated as

$$\Delta a_\ell^h = \frac{-N_c^F (1 + Q_F) m_\ell^2}{8\pi^2} \int_0^1 dx x(1-x) \frac{x \frac{|y_L^l|^2 + |y_R^l|^2}{2} + \frac{m_F}{m_\ell} \Re[(y_R^l)^* y_L^l]}{x^2 m_\ell^2 + x(m_h^2 - m_\ell^2) + (1-x)m_F^2}, \quad (29)$$

$$\Delta a_\ell^F = \frac{-N_c^F Q_F m_\ell^2}{8\pi^2} \int_0^1 dx x^2 \frac{(1-x) \frac{|y_L^l|^2 + |y_R^l|^2}{2} + \frac{m_F}{m_\ell} \Re[(y_R^l)^* y_L^l]}{x^2 m_\ell^2 + x(m_F^2 - m_\ell^2) + (1-x)m_h^2}, \quad (30)$$

where Q_F is the electric charge of F , and $\Delta a_l^F (\Delta a_l^h)$ is the contribution with the external photon attached to the fermion (scalar) inside the loop. We keep $\Delta a_l^F (\Delta a_l^h)$ in the integral form since the analytic expression of resulting integration is not illuminating at all. The physics is also clear from the above expression that one needs $m_F \gg m_l$ also both y_R^l and y_L^l nonzero to make Δa_e and Δa_μ of opposite sign. For $m_F \gg m_l$, we have

$$\Delta a_l^h \simeq \Re[(y_R^l)^* y_L^l] \left(\frac{m_l}{m_F} \right) \frac{-N_c^F (1 + Q_F)}{8\pi^2} \int_0^1 dx \frac{x(1-x)}{x + (1-x) \frac{m_h^2}{m_F^2}}, \quad (31)$$

$$\Delta a_l^F \simeq \Re[(y_R^l)^* y_L^l] \left(\frac{m_l}{m_F} \right) \frac{-N_c^F Q_F}{8\pi^2} \int_0^1 dx \frac{x^2}{x + (1-x) \frac{m_h^2}{m_F^2}}. \quad (32)$$

Namely,

$$\Delta a_l = \Delta a_l^F + \Delta a_l^h \simeq -\frac{N_c^F \Re[(y_R^l)^* y_L^l]}{8\pi^2} \left(\frac{m_l}{m_F} \right) \mathcal{J}_{Q_F} \left(\frac{m_h^2}{m_F^2} \right), \quad (33)$$

where

$$\begin{aligned} \mathcal{J}_Q(\alpha) &= \int_0^1 dx \frac{x(1-x) + xQ}{x + (1-x)\alpha} \\ &= \frac{2Q(1-\alpha)(1-\alpha + \alpha \ln \alpha) + (1-\alpha^2 + 2\alpha \ln \alpha)}{2(1-\alpha)^3}. \end{aligned} \quad (34)$$

From Eq.(34), it is clear that $\mathcal{J}_Q(0) = (1 + 2Q)/2$, $\mathcal{J}_Q(1) = (1 + 3Q)/6$, and $\mathcal{J}_Q(\alpha) \rightarrow (Q \ln \alpha - 1/2)/\alpha$ for $\alpha \gg 1$.

Similar calculation leads to a $l \rightarrow l' \gamma$ transition amplitude:

$$i\mathcal{M} \simeq ie \frac{m_l N_c^F}{16\pi^2 m_F} \mathcal{J}_{Q_F}(\beta_h) \times \overline{u_{l'}}(p-k) \left[\frac{i\sigma^{\alpha\beta} k_\beta \epsilon_\alpha^*}{m_l} \left(A_M^{l'} + A_E^{l'} \gamma^5 \right) \right] u_l(p), \quad (35)$$

where $\beta_h = (m_h/m_F)^2$, ϵ is the polarization of the photon, and

$$A_M^{l'} = \frac{1}{2} \left[(y_R^{l'})^* y_L^l + (y_L^{l'})^* y_R^l \right], \quad A_E^{l'} = \frac{1}{2} \left[(y_R^{l'})^* y_L^l - (y_L^{l'})^* y_R^l \right]. \quad (36)$$

For $l = \mu$ and $l' = e$, the above transition amplitude results in the $\mu \rightarrow e \gamma$ branching ratio[114]

$$Br(\mu \rightarrow e \gamma) = \frac{3\alpha(N_c^F)^2}{8\pi G_F^2 m_F^2 m_\mu^2} \left(|A_M^{\mu e}|^2 + |A_E^{\mu e}|^2 \right), \quad (37)$$

and it must complies with the current experimental limit, $Br(\mu \rightarrow e \gamma) < 4.2 \times 10^{-13}$ [115], or $|A_{E,M}^{\mu e}| \lesssim \mathcal{O}(10^{-8})$. Moreover, if the dipole transition is dominate, then

$$\frac{Br(\mu \rightarrow 3e)}{Br(\mu \rightarrow e \gamma)} = \frac{2\alpha}{3\pi} \left[\ln \frac{m_\mu}{m_e} - \frac{11}{8} \right] \simeq 6.12 \times 10^{-3}, \quad (38)$$

thus can be ignored.

FIG. 3. The Feynman diagrams, in the interaction basis, for the anomalous magnetic dipole moment of charged lepton in this model. Here all the flavor indices are omitted. The external photon (not shown) can be attached to any charged particle in the loop.

In our model, the vector fermion $b'_{L,R}(3, 1, -1/3)$, Fig.3(a), and/or the SM b-quark, Fig.3(b), can play the role of F both carrying an electric charge $-\frac{1}{3}$. The function $\mathcal{J}_{-\frac{1}{3}}(\alpha)$ takes a value in the range from -0.022 to 0.087 for $\alpha \in [0.1, 10.0]$. In the interaction basis, $T(3, 3, -1/3)$ does not couple to b' , $D(3, 2, 1/6)$ only couples to left-handed charged lepton, and $S(3, 1, 2/3)$ only couples to the right-handed charged lepton. Due to the D - S and D - T mixings, the three charge-2/3 physical mass states acquire both the LH and RH Yukawa couplings as shown in Eq.(28). However, the physical state dominated by the T component gets double suppression from D - T and d - b' mixings, thus not important here. Assuming small D - S mixing in our model, the anomalous magnetic moment of charged lepton becomes

$$\begin{aligned} \Delta a_l \simeq & (\lambda_{lb'}^D \lambda_{lb'}^S) \frac{3\mu_1 v_0}{16\sqrt{2}\pi^2} \frac{m_l}{M_{b'}^3} \times \mathcal{K} \left(\frac{M_D^2}{M_{b'}^2}, \frac{M_S^2}{M_{b'}^2} \right) \\ & + (\lambda_{lb}^D \lambda_{lb}^S) \frac{3\mu_1 v_0}{16\sqrt{2}\pi^2} \frac{m_l}{m_b^3} \times \mathcal{K} \left(\frac{M_D^2}{m_b^2}, \frac{M_S^2}{m_b^2} \right), \end{aligned} \quad (39)$$

where

$$\mathcal{K}(a, b) \equiv \frac{\mathcal{J}_{-\frac{1}{3}}(a) - \mathcal{J}_{-\frac{1}{3}}(b)}{b - a}. \quad (40)$$

When $a \simeq b$, the function \mathcal{K} takes a limit

$$\mathcal{K}(a, b) \xrightarrow{b \rightarrow a} - \frac{d}{d\alpha} \mathcal{J}_{-\frac{1}{3}}(\alpha) \Big|_{\alpha=a} = - \frac{11 - 4a - 7a^2 + 2[2 + a(6 + a)] \ln a}{6(1 - a)^4}. \quad (41)$$

For $a \simeq b \simeq 1$, it can be approximated by $\mathcal{K}(a, b) \simeq 1/36 - (a+b-2)/45$, and $\mathcal{K}(a, b) \simeq -\ln a/(3a^2)$ for $a \simeq b \gg 1$.

If factoring out the $M_F = M_{b'}$, the dipole transition coefficients in Eq.(37) are given by

$$A_{M/E}^{\mu e} \simeq - \frac{\mu_1 v_0}{4\sqrt{2}M_{b'}^2} \left\{ [(\lambda_{eb'}^S)^* \lambda_{\mu b'}^D \pm (\lambda_{eb'}^D)^* \lambda_{\mu b'}^S] \mathcal{K}(\beta_D, \beta_S) + \frac{M_{b'}^3}{m_b^3} [(\lambda_{eb}^S)^* \lambda_{\mu b}^D \pm (\lambda_{eb}^D)^* \lambda_{\mu b}^S] \mathcal{K}(b_D, b_S) \right\}, \quad (42)$$

where $b_{D,S} \equiv (M_{D,S}/m_b)^2$, and $\beta_{D,S} = (M_{D,S}/M_{b'})^2$. The current upper bound of $Br(\mu \rightarrow e\gamma)$ amounts to a stringent limit that the relevant $|\lambda^S \lambda^D| \lesssim 10^{-5}$. Instead of making the product of Yukawa couplings small, the $\mu \rightarrow e\gamma$ transition from D - S mixing, Fig.3, can be simply arranged to vanish if muon/electron only couples to b'/b or the other way around.

Modulating by the leptoquark masses, numerically we have either

Sol-1 :

$$\begin{aligned}\Delta a_e &\simeq 2.28 \times 10^{-5} \times [\lambda_{eb}^D \lambda_{eb}^S] \times \left(\frac{\mu_1}{\text{GeV}}\right) \times \mathcal{K}(b_D, b_S), \\ \Delta a_\mu &\simeq 1.03 \times 10^{-10} \times [\lambda_{\mu b'}^D \lambda_{\mu b'}^S] \times \left(\frac{\mu_1}{\text{GeV}}\right) \left(\frac{1.5\text{TeV}}{M_{b'}}\right)^3 \times \mathcal{K}(\beta_D, \beta_S),\end{aligned}\quad (43)$$

or

Sol-2 :

$$\begin{aligned}\Delta a_e &\simeq 5.00 \times 10^{-13} \times [\lambda_{eb'}^D \lambda_{eb'}^S] \times \left(\frac{\mu_1}{\text{GeV}}\right) \left(\frac{1.5\text{TeV}}{M_{b'}}\right)^3 \times \mathcal{K}(\beta_D, \beta_S), \\ \Delta a_\mu &\simeq 4.71 \times 10^{-3} \times [\lambda_{\mu b}^D \lambda_{\mu b}^S] \times \left(\frac{\mu_1}{\text{GeV}}\right) \times \mathcal{K}(b_D, b_S).\end{aligned}\quad (44)$$

For $M_{b'} = 1.5\text{TeV}$ and $M_{LQ} \simeq 1\text{TeV}$, then either $\{\mu_1 \lambda_{eb}^D \lambda_{eb}^S, \mu_1 \lambda_{\mu b'}^D \lambda_{\mu b'}^S\} \simeq \{49.4[-27.3], 279.9\}\text{GeV}$ for (Sol-1), or $\{\mu_1 \lambda_{eb'}^D \lambda_{eb'}^S, \mu_1 \lambda_{\mu b}^D \lambda_{\mu b}^S\} \simeq \{-20.1[11.1], -689.5\}\text{GeV}$ for (Sol-2) can accommodate the observed central values of $\Delta a_e^{Cs}[\Delta a_e^{Rb}]$ and Δa_μ simultaneously with vanishing $Br(\mu \rightarrow e\gamma)$. However, as will be discussed later, only Sol-2 is viable to simultaneously accommodate the neutrino data.

C. $b \rightarrow sl^+l^-$

The $b \rightarrow s\mu\bar{\mu}$ transition can be generated by tree-level diagrams mediated by $T^{\frac{4}{3}}, D^{\frac{2}{3}}, S^{\frac{2}{3}}$, and the one from D - S mixing, see Fig.4. In Fig.4(c), the crosses represent the mixing between the b'_L and the physical b and s quarks, because S only couples to b'_L in the interaction basis. From Eq.(B3), we see that this model can yield $b \rightarrow s\mu\bar{\mu}$ operators in the vector, scalar, and tensor forms. However, we failed to find a viable parameter space to explain the $b \rightarrow sl^+l^-$ anomaly and simultaneously comply with other experimental constraints⁷, see Sec.IV A.

Instead, to bypass the stringent experimental bounds and the fine-tuning of the parameters, we go for the 1-loop box diagram contribution, as shown in Fig.5, which requires only four nonzero triplet Yukawa couplings $\lambda_{\tau s}^T, \lambda_{\tau b}^T, \lambda_{\mu b}^T, \lambda_{\mu b'}^T$.

⁷ On the other hand, we cannot rule out the possibility of finding such a solution with fine-tuning.

FIG. 4. The potential tree-level Feynman diagrams for $b \rightarrow s\mu\bar{\mu}$ transition.FIG. 5. The Feynman diagram for $b \rightarrow s\mu\bar{\mu}$ transition.

In the usual convention, the transition is described by a low energy effective Hamiltonian

$$\mathcal{H}_{eff}^{b \rightarrow s\mu\mu} = -\frac{G_F}{\sqrt{2}} \tilde{V}_{tb} \tilde{V}_{ts}^* \frac{\alpha}{\pi} \sum_i \mathcal{C}_i \mathcal{O}_i + H.c. \quad (45)$$

with

$$\mathcal{O}_9 = (\bar{s}\gamma^\alpha \hat{L}b) (\bar{\mu}\gamma_\alpha \mu), \quad \mathcal{O}_{10} = (\bar{s}\gamma^\alpha \hat{L}b) (\bar{\mu}\gamma_\alpha \gamma^5 \mu), \quad (46)$$

$$\mathcal{O}'_9 = (\bar{s}\gamma^\alpha \hat{R}b) (\bar{\mu}\gamma_\alpha \mu), \quad \mathcal{O}'_{10} = (\bar{s}\gamma^\alpha \hat{R}b) (\bar{\mu}\gamma_\alpha \gamma^5 \mu). \quad (47)$$

Ignoring the tau mass in the loop, Fig.5(a), the effective Hamiltonian generated by the box-diagram can be easily calculated as

$$\mathcal{H}_{eff(a)}^{b \rightarrow s\mu\mu} \simeq -\frac{\lambda_{\tau b}^T (\lambda_{\tau s}^T)^*}{64\pi^2} \left(\frac{|\lambda_{\mu b'}^T|^2}{M_{b'}^2} \mathcal{G}(\beta_T') + \frac{|\lambda_{\mu b}^T|^2}{m_b^2} \mathcal{G}(\beta_T) \right) (\bar{s}\gamma^\alpha \hat{L}b) (\bar{\mu}\gamma_\alpha \hat{L}\mu) + H.c., \quad (48)$$

where $\beta_T' \equiv (M_T/M_{b'})^2$, $\beta_T \equiv (M_T/m_b)^2$, and

$$\mathcal{G}(x) = \left[\frac{1}{1-x} + \frac{\ln x}{(1-x)^2} \right]. \quad (49)$$

The function has a limit $\mathcal{G}(x=1) = -1/2$, and $\mathcal{G} \rightarrow -1/x$ when $x \gg 1$.

The second contribution from the box diagram with $T^{\pm\frac{1}{3}}$ and up-type quark running in the loop yields

$$\mathcal{H}_{eff(b)}^{b \rightarrow s \mu \mu} \simeq \frac{\lambda_{\tau b}^T (\lambda_{\tau s}^T)^*}{64\pi^2} \frac{1}{4M_T^2} [|\lambda_{\mu b'}^T|^2 (s_1^2 + s_2^2 + s_3^2) + |\lambda_{\mu b}^T|^2] \left(\bar{s} \gamma^\alpha \hat{L} b \right) \left(\bar{\mu} \gamma_\alpha \hat{L} \mu \right) + H.c.. \quad (50)$$

In arriving the above expression, we have made use of the unitarity of \tilde{V} , namely,

$$|\tilde{V}_{ub'}|^2 + |\tilde{V}_{cb'}|^2 + |\tilde{V}_{tb'}|^2 = 1 - c_1^2 c_2^2 c_3^2 \simeq s_1^2 + s_2^2 + s_3^2 \ll 1, \quad (51)$$

and

$$|\tilde{V}_{ub}|^2 + |\tilde{V}_{cb}|^2 + |\tilde{V}_{tb}|^2 \simeq 1. \quad (52)$$

It is clear that the contribution from Fig.5(b) is dominated by $\lambda_{\mu b}^T$.

And the relevant Wilson coefficients are determined to be

$$\begin{aligned} \mathcal{C}_9 = -\mathcal{C}_{10} &\simeq \frac{\sqrt{2}}{128\pi\alpha} \frac{\lambda_{\tau b}^T (\lambda_{\tau s}^T)^*}{V_{tb} V_{ts}^* G_F M_T^2} \left[|\lambda_{\mu b'}^T|^2 \beta'_T \mathcal{G}(\beta'_T) - \frac{5}{4} |\lambda_{\mu b}^T|^2 \right], \\ \mathcal{C}'_9 = -\mathcal{C}'_{10} &= 0. \end{aligned} \quad (53)$$

For a typical value of $\beta'_T = (1.0\text{TeV}/1.5\text{TeV})^2$, $\beta'_T \mathcal{G}(\beta'_T) = -0.3677$.

We use the following values,

$$(\mathcal{C}_9)^\mu = -(\mathcal{C}_{10})^\mu \simeq -0.41 \pm 0.07, \quad (54)$$

for muon, and

$$(\mathcal{C}_9)^e \simeq (\mathcal{C}_{10})^e \simeq (\mathcal{C}'_9)^e \simeq (\mathcal{C}'_{10})^e \simeq 0 \quad (55)$$

for the electron counter part, from the global fit to the $b \rightarrow sl^+ l^-$ data [63]⁸.

If we take $\tilde{V}_{tb} \tilde{V}_{ts}^* = -0.03975$, then it amounts to

$$\lambda_{\tau b}^T (\lambda_{\tau s}^T)^* \left[-|\lambda_{\mu b'}^T|^2 \beta'_T \mathcal{G}(\beta'_T) + \frac{5}{4} |\lambda_{\mu b}^T|^2 \right] \simeq -(0.394 \pm 0.067) \left(\frac{M_T}{\text{TeV}} \right)^2. \quad (56)$$

Since the combination in the squared bracket is positive, the product $\lambda_{\tau b}^T (\lambda_{\tau s}^T)^*$ has to be negative.

The constraints from B_s - \bar{B}_s mixing and $b \rightarrow s \gamma$ will be carefully discussed in Sec.IV.

⁸ Similar result is also yielded by [64]. There are other suggestion by the recent studys of [63, 64]. However, to only produce $C_9^{\mu\mu}$ in our model requires large both b - b' and b' - s mixings and the tree-level processes, which we discard.

D. Cabibbo-angle anomaly

From the unitarity of \tilde{V}_4 , it is clear that

$$|\tilde{V}_{ud}|^2 + |\tilde{V}_{us}|^2 + |\tilde{V}_{ub}|^2 = 1 - |\tilde{V}_{ub'}|^2 \leq 1, \quad (57)$$

and the Cabibbo-angle anomaly(CAA) is naturally embedded in this model. Moreover, the most commonly discussed unitarity triangle becomes

$$\tilde{V}_{ud}\tilde{V}_{ub}^* + \tilde{V}_{cd}\tilde{V}_{cb}^* + \tilde{V}_{td}\tilde{V}_{tb}^* = -(U_L^d)_{d4}^*(U_L^d)_{b4}. \quad (58)$$

Similarly, this model also predicts that

$$|\tilde{V}_{cd}|^2 + |\tilde{V}_{cs}|^2 + |\tilde{V}_{cb}|^2 = 1 - |\tilde{V}_{cb'}|^2, \quad (59)$$

$$|\tilde{V}_{td}|^2 + |\tilde{V}_{ts}|^2 + |\tilde{V}_{tb}|^2 = 1 - |\tilde{V}_{tb'}|^2, \quad (60)$$

$$|\tilde{V}_{ud}|^2 + |\tilde{V}_{cd}|^2 + |\tilde{V}_{td}|^2 = 1 - |(U_L^d)_{d4}|^2, \quad (61)$$

$$|\tilde{V}_{us}|^2 + |\tilde{V}_{cs}|^2 + |\tilde{V}_{ts}|^2 = 1 - |(U_L^d)_{s4}|^2, \quad (62)$$

$$|\tilde{V}_{ub}|^2 + |\tilde{V}_{cb}|^2 + |\tilde{V}_{tb}|^2 = 1 - |(U_L^d)_{b4}|^2, \quad (63)$$

and all the other SM CKM unitary triangles are no more closed in general.

The matrix elements are easy to read. For example, we have

$$\tilde{V}_{us} = c_2 V_{us} - s_2 s_3 V_{ub}, \quad \tilde{V}_{ub'} = s_1 V_{ud} + c_1 s_2 V_{us} + c_1 c_2 s_3 V_{ub}, \quad (64)$$

$$\left\{ (U_L^d)_{d4}, (U_L^d)_{s4}, (U_L^d)_{b4}, (U_L^d)_{b'4} \right\} = \{ -s_1 c_2 c_3, -s_2 c_3, -s_3, c_1 c_2 c_3 \}. \quad (65)$$

The mixing θ_i is expected to be small, so a smaller universal

$$|\tilde{V}_{us}| \simeq |V_{us}| \left(1 - \frac{\theta_2^2}{2} \right) \quad (66)$$

to leading order is expected as well. By using the Wolfenstein parameterization and the central values from global fit[1], we have

$$\tilde{V}_{ub'} \simeq 0.9740 s_1 + 0.2265 c_1 s_2 + 0.0036 c_1 c_2 s_3 e^{1.196i}. \quad (67)$$

Therefore, to accommodate the deficit of 1st row CKM unitarity (Eq.(6) and Eq.(57)) we have

$$|s_1 + 0.233 s_2| \simeq 0.039(7). \quad (68)$$

Anomaly	Requirement	Remark
m_ν	$\mu_3 m_{b'} \lambda^D \lambda^T \simeq \mathcal{O}(10^{-5})(\text{GeV})^2$	Eq.(26)
$\Delta a_e^{Cs[Rb]}, \Delta a_\mu$ (Sol-1)	$\left\{ \mu_1 \lambda_{eb}^D \lambda_{eb}^S, \mu_1 \lambda_{\mu b'}^D \lambda_{\mu b'}^S \right\} \simeq \{(49 \pm 20)[-27 \pm 17], (280 \pm 66)\} \text{GeV}$	Eq.(43)
$\Delta a_e^{Cs[Rb]}, \Delta a_\mu$ (Sol-2)	$\left\{ \mu_1 \lambda_{eb'}^D \lambda_{eb'}^S, \mu_1 \lambda_{\mu b}^D \lambda_{\mu b}^S \right\} \simeq \{-(20.1 \pm 8.3)[+11.1 \pm 6.9], -(689 \pm 162)\} \text{GeV}$	Eq.(44)
$b \rightarrow sl^+l^-$	$\lambda_{\tau b}^T (\lambda_{\tau s}^T)^* (\lambda_{\mu b'}^T ^2 + 3.39 \lambda_{\mu b}^T ^2) \simeq -(1.07 \pm 0.18)$	Eq.(53)
Cabibbo angle anomaly	$ s_1 + 0.233s_2 \simeq 0.039(7)$	Eq.(57)

TABLE IV. The requirement for explaining each mechanism/anomaly. For illustration, we take the following values: $\tilde{V}_{tb}\tilde{V}_{ts}^* = -0.03975$, $M_{LQ} = 1.0$ TeV, and $M_{b'} = 1.5$ TeV.

IV. CONSTRAINTS AND PARAMETER SPACE

As discussed in the previous section, this model is capable to address neutrino mass generation, $\Delta a_{e,\mu}$, $b \rightarrow s\mu\mu$, and the CAA. For readers' convenience, all the requirements are collected and displayed in Table IV.

In this section, we should carefully scrutinize all the existing experimental limits and try to identify the viable model parameter at the end.

A. Low energy $2q2l$ effective Hamiltonian

In this model, the minimal set (MinS_T) of λ^T parameters for addressing all the anomalies and neutrino mass consists of five elements:

$$\text{MinS}_T = \{\lambda_{\tau b}^T, \lambda_{\tau s}^T, \lambda_{\tau b'}^T, \lambda_{\mu b'}^T, \lambda_{\mu b}^T\}. \quad (69)$$

The following are the consequences of adding other Triplet Yukawa couplings outside the MinS_T :

- (1) At tree-level, λ_{ed}^T leads to $B^+ \rightarrow \pi^+ e\mu$, $B^0 \rightarrow \bar{e}\tau$, $\tau \rightarrow eK$, and μ - e conversion. Then $\lambda_{ed}^T \lesssim 10^{-2}$ must be satisfied if all other λ^T 's are around $\mathcal{O}(1)$.
- (2) At tree-level, λ_{es}^T leads to $B^+ \rightarrow K^+ e\mu$ and μ - e conversion. Then $\lambda_{es}^T \lesssim 10^{-2}$ is also required if all other λ^T 's are around $\mathcal{O}(1)$.
- (3) At tree-level λ_{eb}^T also leads to μ - e conversion, but the constraint is weak due to the $|\tilde{V}_{ub}|^2$ suppression. On the other hand, at 1-loop level, it generates the unfavored $b \rightarrow see$ transition. Also, note that $\lambda_{eb}^T \neq 0$ is not helpful for generating M_{ee}^ν , which is crucial for the neutrinoless double beta decay.
- (4) Together with $\lambda_{\tau s}^T$, required for $b \rightarrow s\mu\mu$, any nonzero $\lambda_{\ell id}^T (i = e, \mu, \tau)$ gives rise to $K^+ \rightarrow \pi^+ \nu\nu$ at the tree-level, and thus strongly constrained. Moreover, $\lambda_{\tau s}^T$ and $\lambda_{\tau d}^T$ generate the K - \bar{K} mixing via the 1-loop box diagram, and thus stringently limited.
- (5) Together with MinS_T, the presence of any of $\lambda_{ed_i}^T (i = d, s, b, b')$ leads to $l \rightarrow l'\gamma$ transition at the one-loop level.
- (6) On the other

$\frac{(\bar{q}_k \gamma^\mu \hat{L} q_l)(\bar{e}_i \gamma_\mu \hat{L} e_j)}{4M_T^2}$	Wilson Coef.	Constraint	Model

^a There is no such effective operator at tree-level.

^b We update this value by using the new data $\mathcal{B}(B^+ \rightarrow K^+ \mu^+ \tau^-) < 4.5 \times 10^{-5}$ [1].

^c We update this value by using the new data $\mathcal{B}(D^+ \rightarrow \pi^+ \mu^+ \mu^-) < 7.3 \times 10^{-8}$ [1].

^d We obtain the limit by using the top quark decay width, $\Gamma_t = 1.42\text{GeV}$, and $\mathcal{B}(t \rightarrow ql'') < 1.86 \times 10^{-5}$ [117].

TABLE V. The tree-level NC operators and their Wilson coefficients. We take $M_T = 1\text{TeV}$ for illustration, and the values in last two columns scale as $(M_T/1\text{TeV})^2$. By using the parameter set example of Eq.(109), the model predictions, with the signs kept, are displayed in the last column. In the table, 0* stems from choosing $\tilde{V}_{cb}^* \lambda_{\mu b}^T + \tilde{V}_{cb'}^* \lambda_{\mu b'}^T = 0$ to retain the μ - e universality in $b \rightarrow cl\nu$ transition as discussed in the text.

hand, the introduction of $\lambda_{\tau d}^T$ generates $s \rightarrow d\mu\mu$ transition via the box-diagram which is severely constraint by the $K_L \rightarrow \mu\mu$ data. So it has to be small too. (7) In general, adding $\lambda_{\mu s}^T$ will cause conflict with the precision Kaon data.

From the above discussion, adding any $\lambda^T \notin \text{MinS}_T$ requires fine tuning the parameters. For simplicity, we set any triplet Yukawa couplings outside the MinS_T to zero. However, we still need to scrutinize all the phenomenological constraint on the minimal set of parameters. All the potential

^a This is the effective operator to address the $R(D^{(*)})$ anomaly.

TABLE VI. The tree-level CC operators and their Wilson coefficients. All the constraints are taken and derived from[116]. By using the parameter set example of Eq.(109), the model predictions, with the signs kept, are displayed in the last column. We take $M_T = 1\text{TeV}$ for illustration, and the values in last two columns scale as $(M_T/1\text{TeV})^2$. Note that the coefficients for $su(c)\nu_\mu\tau$ and $su(c)\nu_\mu\mu$ are zero at tree-level. In the table, 0* stems from choosing $\tilde{V}_{cb}^* \lambda_{\mu b}^T + \tilde{V}_{cb'}^* \lambda_{\mu b'}^T = 0$ to retain the μ - e universality in $b \rightarrow cl\nu$ transition as discussed in the text.

detectable effective operators from tree-level contribution of MinS_T are listed in Table V and Table VI. And one has to make sure all the constraints have to be met.

In addition to the limits considered in Ref[116], one needs to take into account the constraint from the lepton universality tests in B decays[83]. In particular, the μ - e universality in the $b \rightarrow cl_i\nu(i = e, \mu)$ transition has been tested to $\simeq 1\%$ level[118]. The MinS_T of λ^T introduces two operators, $(\bar{b}\gamma^\alpha \hat{L} c)(\bar{\nu}_\mu \gamma_\alpha \hat{L} \mu)$ and $(\bar{b}\gamma^\alpha \hat{L} c)(\bar{\nu}_\tau \gamma_\alpha \hat{L} \mu)$, where the first one interferes with the SM CC interaction while the second one does not. On the other hand, there are no electron counter parts. Therefore, it is required that the modification to the $b \rightarrow c\mu\nu_j$ transition rate due to the two

new operators is less than $\sim 2\%$. Their Wilson coefficients, the third and the fourth entities from the end in Table VI, are both proportional to $(\tilde{V}_{cb}^* \lambda_{\mu b}^T + \tilde{V}_{cb'}^* \lambda_{\mu b'}^T)$. For simplicity, we artificially set this combination to zero to make sure the perfect μ - e universality in $b \rightarrow cl\nu$ at tree level, such that the ratio of $\lambda_{\mu b}^T/\lambda_{\mu b'}^T$ is fixed as well. However, if more parameter space is wanted, this strict relationship can be relaxed as long as the amount of μ - e universality violation is below the experimental precision.

Finally, due to the QCD corrections, the semi-leptonic effective vector operator for addressing the $b \rightarrow s\mu\mu$ anomaly gets about $\sim +10\%$ enhancement at low energy[119]. However, all the tree-level $2q2l$ vectors operators listed in Table V and Table VI, as the constraint, also get roughly the same enhancement factor. Therefore, we do not consider this RGE running factor at this moment.

Next, we move on to consider the tree-level effects from the doublet leptoquark. The non-zero $\lambda_{\tau b}^D$ and $\lambda_{\mu b}^D$, required for addressing $\Delta a_{e,\mu}$ and neutrino data, lead to the following relevant low energy effective Hamiltonian,

$$\mathcal{H}_{eff}^D \supset \frac{[\bar{b}\gamma^\alpha \hat{R}b]}{4M_D^2} \left[|\lambda_{\tau b}^D|^2 (\bar{\tau}\gamma_\alpha \hat{L}\tau) + |\lambda_{\mu b}^D|^2 (\bar{\mu}\gamma_\alpha \hat{L}\mu) + \lambda_{\mu b}^D (\lambda_{\tau b}^D)^* (\bar{\tau}\gamma_\alpha \hat{L}\mu) + \lambda_{\tau b}^D (\lambda_{\mu b}^D)^* (\bar{\mu}\gamma_\alpha \hat{L}\tau) \right], \quad (70)$$

and its neutrino counter part as well, see Eq.(B3). However, the constraint on these operators are rather weak[116] and can be ignored.

B. SM Z^0 couplings

Because $b'_{L,R}$ are charged under $U(1)_Y$ hypercharge, they interact with the Z^0 boson. In the interaction basis⁹, the SM Z^0 interaction for the down quark sector is

$$\mathcal{L} \supset \frac{g_2}{c_W} \left[g_L^{SM} \sum_{i=1}^3 \bar{d}_{Li} \gamma^\alpha d_{Li} + g_R^{SM} \sum_{i=1}^3 \bar{d}_{Ri} \gamma^\alpha d_{Ri} + g_R^{SM} (\bar{b}'_L \gamma^\alpha b'_L + \bar{b}'_R \gamma^\alpha b'_R) \right] Z_\alpha, \quad (71)$$

where $g_R^{SM} = \frac{s_W^2}{3} \simeq 0.077$, $g_L^{SM} = (-\frac{1}{2} + \frac{s_W^2}{3}) \simeq -0.423$, $s_W = \sin \theta_W$, and θ_W is the Weinberg angle. If we denote b' as d_4 , then the above expression can be neatly written as

$$\frac{g_2}{c_W} \left[g_L^{SM} \sum_{i=1}^4 \bar{d}_{Li} \gamma^\alpha d_{Li} + g_R^{SM} \sum_{i=1}^4 \bar{d}_{Ri} \gamma^\alpha d_{Ri} + \frac{1}{2} (\bar{b}'_L \gamma^\alpha b'_L) \right] Z_\alpha. \quad (72)$$

When rotating into the mass basis, due to the unitarity of the four-by-four $U_{L,R}^d$, it becomes

$$\frac{g_2}{c_W} \left[\sum_{\alpha=s,d,b,b'} \bar{d}_\alpha \gamma^\alpha (g_L^{SM} \hat{L} + g_R^{SM} \hat{R}) d_\alpha \right] Z_\mu + \frac{g_2}{2c_W} \sum_{\alpha,\beta=s,d,b,b'} \kappa_{\alpha\beta} \left[(\bar{d}_\alpha \gamma^\alpha \hat{L} d_\beta) \right] Z_\alpha, \quad (73)$$

⁹ Here we temporarily switch back to earlier notation that $b'_{L,R}$ represent the interaction basis.

where $\hat{L} = (1 - \gamma^5)/2$, $\hat{R} = (1 + \gamma^5)/2$, and

$$\kappa_{\alpha\beta} \equiv (U_L^d)_{\alpha 4} [(U_L^d)_{\beta 4}]^* . \quad (74)$$

Using the CP-conserving parametrization introduced in Eq.(22), we have

$$\kappa_{sd} = \kappa_{ds} = s_1 s_2 c_2 c_3^2, \quad \kappa_{sb} = \kappa_{bs} = s_2 s_3 c_3, \quad \kappa_{bd} = \kappa_{db} = s_1 s_3 c_2 c_3 . \quad (75)$$

It is clear that, with the presence of b'_L , the tree-level Flavor-Changing-Neutral-Current (FCNC) in the down sector is inevitable unless at most one of $\theta_{1,2,3}$ being sizable. For simplicity, we assume one nonvanishing $(U_L^d)_{4d_F}$, where F could be one of d, s, b , and all the others are zero.

Let's focus on that specific non-zero flavor diagonal Z - d_F - \bar{d}_F coupling. The mixing with b' leads to

$$g_{d_F,R}^{SM} \Rightarrow g_{d_i,R}^{SM}, \quad g_{d_F,L}^{SM} \Rightarrow g_{d_i,L}^{SM} + \frac{1}{2} \left| (U_L^d)_{4d_F} \right|^2, \quad (76)$$

The introduction of $b'_{L,R}$ leads to a robust prediction that $(g_{d_F L})^2 < (g_{d_F L}^{SM})^2$ and $(g_{d_F R})^2 = (g_{d_F R}^{SM})^2$ for that down-type quark at the tree-level. Namely, in this model, A_F and A_F^{FB} (both $\propto [(g_{d_F L})^2 - (g_{d_F R})^2]$), and Γ_{d_F} ($\propto [(g_{d_F L})^2 + (g_{d_F R})^2]$) are smaller than the SM prediction. This remind us the long standing puzzle of the bottom-quark forward-backward asymmetry, A_{FB}^b , which is 2.3σ below the SM value[1]. However, if we pick θ_3 to be nonzero, then the CAA cannot be addressed, see Eq.(68). Moreover, from our numerical study, only $\theta_1 \neq 0$ is viable to satisfy all experimental limits. Thus we set $\theta_2 = \theta_3 = 0$. From Eq.(68), we have

$$|s_1| \simeq 0.039(7), \quad (77)$$

and

$$\tilde{V}_{ub'} = s_1 \tilde{V}_{ud} \simeq 0.03798, \quad \tilde{V}_{cb'} = s_1 \tilde{V}_{cd} \simeq -0.00883, \quad \tilde{V}_{tb'} = s_1 \tilde{V}_{td} \simeq 0.00033, \quad (78)$$

if we take θ_1 to be positive. This predicts $g_{dL} = g_{dL}^{SM} + s_1^2/2$ at tree-level, but with negligible effect.

On the other hand, one may wonder whether the introduction of $\lambda_{\tau b}^T, \lambda_{\mu b}^T$ and $\lambda_{\tau b}^D$ can lead to sizable non-oblique radiative Z - b - \bar{b} vertex corrections and address both the A_{FB}^b anomaly and R_b with the later one agrees with the SM prediction. To address the A_b^{FB} anomaly and R_b simultaneously, one needs to increase g_{bR}^2 and decrease g_{bL}^2 at the same time. We perform the 1-loop calculation in the \overline{MS} scheme and the on-shell renormalization, and obtain the UV-finite result:

$$\begin{aligned} \delta g_L^b &\simeq \frac{|\lambda_{\tau b}^T|^2 + |\lambda_{\mu b}^T|^2}{64\pi^2} \left[\left(-1 + \frac{5}{3} s_W^2 \right) \frac{1}{9\beta_Z} - s_W^2 \frac{2 \ln \beta_Z + \frac{1}{3} + i\pi/2}{3\beta_Z} \right], \\ \delta g_R^b &\simeq \frac{|\lambda_{\tau b}^D|^2}{64\pi^2} \left[\left(-\frac{1}{3} s_W^2 \right) \frac{1}{9\beta_Z} + s_W^2 \frac{2 \ln \beta_Z + \frac{1}{3} + i\pi/2}{3\beta_Z} \right], \end{aligned} \quad (79)$$

where $\beta_Z = (M_{LQ}/m_Z)^2$. Note the diagrams with Z attached to the lepton in the loop have imaginary parts, and this is due to that the lepton pair can go on-shell. Unfortunately, these loop corrections are too small, $|\delta g_{L,R}^b| \sim \mathcal{O}(10^{-5}) \times |\lambda^{T,D}|^2$, to be detectable. From the above, we conclude that, barring the tree-level FCNC Z coupling, both A_{FB}^b and R_b receive no significant modification in this model. Of course, future Z -pole electroweak precision measurements[120–122] will remain the ultimate judge. If the A_{FB}^b deviation endures, one must go beyond this model. We note by passing that more complicated model constructions are possible to address the A_{FB}^b anomaly. For example, this anomaly can be addressed by adding an anomaly-free set of chiral exotic quarks and leptons[123, 124], or the vector-like quarks[91, 92, 125] to the SM.

C. $B_s - \bar{B}_s$ mixing

One important constraint on the parameters related to $b \rightarrow s\mu\mu$ transition comes from the $B_s - \bar{B}_s$ mixing. In our model, the box diagrams with leptoquark T and lepton running in the loop give a sole effective Hamiltonian

$$\mathcal{H}_{eff}^{B\bar{B}} = \mathcal{C}_{B\bar{B}} \left(\bar{s}\gamma^\alpha \hat{L}b \right) \left(\bar{s}\gamma_\alpha \hat{L}b \right) + H.c. \quad (80)$$

The Wilson coefficient can be easily calculated to be

$$\mathcal{C}_{B\bar{B}} \simeq \frac{|\lambda_{Tb}^T|^2 |\lambda_{Ts}^T|^2}{128\pi^2 M_T^2} \left(1 + \frac{1}{4} \right), \quad (81)$$

where the one-fourth in the parenthesis is the contribution from $T^{\pm\frac{1}{3}}$. Note that this $\mathcal{C}_{B\bar{B}}$ and the SM one are of the same sign, and it increases ΔM_s , the mass difference between B_s and \bar{B}_s . But, the central value of the precisely measured $\Delta M_s = 17.757(21)\text{ps}^{-1}$ [86] is smaller than the SM one. On the other hand, the SM prediction has relatively large, $\sim 10\%$ [126, 127], uncertainties arising from the hadronic matrix elements. If putting aside the hadronic uncertainty, this tension could be alleviated in this model by the extended CKM, $V_{ts}^* V_{tb} \Rightarrow \tilde{V}_{ts}^* \tilde{V}_{tb} = (V_{ts}^* c_2 - V_{tb}^* s_2 s_3) V_{tb} c_3$, which reduces the SM prediction. However, it does not work because we set $\theta_3 = \theta_2 = 0$ as discussed in Sec.IV B. Instead, we use the 2σ range to constraint the model parameters. Following Refs.[81, 128], the NP contribution can be constrained to be

$$\left| 1 + \frac{0.8\mathcal{C}_{B\bar{B}}(\mu_{LQ})}{\mathcal{C}_{B\bar{B}}^{SM}(\mu_b)} \right| - 1 = -0.09 \pm 0.08, \text{ at } 1 \sigma \text{ C.L.}, \quad (82)$$

where the factor 0.8 is the RGE running effect from $\mu_{LQ} \simeq 1\text{TeV}$ to μ_b , and $\mathcal{C}_{B\bar{B}}^{SM}(\mu_b) \simeq 7.2 \times 10^{-11}\text{GeV}^{-2}$ is the SM value at the scale μ_b . From the above, we obtain

$$|\lambda_{\tau b}^T(\lambda_{\tau s}^T)^*| < 0.0798 \left(\frac{M_T}{\text{TeV}} \right), \quad (83)$$

so that Eq.(82) can be inside the 2σ confidence interval.

Together with Eq.(56) and assuming that $(\tilde{V}_{cb}^* \lambda_{\mu b}^T + \tilde{V}_{cb'}^* \lambda_{\mu b'}^T) = 0$, the requirement of the tree-level μ - e universality in $b \rightarrow cl\nu$, one sees that

$$|\lambda_{\mu b'}^T| > 3.401 \left[\frac{C_{10}^\mu (= -C_9^\mu)}{0.41} \right]^{\frac{1}{2}} \left(\frac{M_T}{\text{TeV}} \right). \quad (84)$$

From this inequality, M_T must be around or smaller than TeV for this model parameter to stay in the perturbative region. However, this statement strongly relies on the SM prediction of ΔM_s and the values of $C_{9,10}^\mu$.

D. $B \rightarrow K^{(*)}\nu\bar{\nu}$

In this model, the $B \rightarrow K^{(*)}\nu\bar{\nu}$ transition can be mediated by T at tree-level and described by an effective Hamiltonian

$$\mathcal{H}_{eff}^{NP} \supset -\frac{\alpha G_F}{\sqrt{2}\pi} \tilde{V}_{tb} \tilde{V}_{ts}^* C_{ij}^\nu \left[\bar{s} \gamma^\alpha \hat{L} b \right] \left[\bar{\nu}_i \gamma_\alpha (1 - \gamma^5) \nu_j \right] + H.c., \quad (85)$$

where

$$C_{\tau\mu}^\nu = \frac{\pi}{\alpha G_F \tilde{V}_{tb} \tilde{V}_{ts}^*} \frac{\lambda_{\mu b}^T (\lambda_{\tau s}^T)^*}{4\sqrt{2}M_T^2}, \quad C_{\tau\tau}^\nu = \frac{\pi}{\alpha G_F \tilde{V}_{tb} \tilde{V}_{ts}^*} \frac{\lambda_{\tau b}^T (\lambda_{\tau s}^T)^*}{4\sqrt{2}M_T^2}, \quad (86)$$

and all other Wilson coefficients are zero. Following [129], the normalized branching ratio for $B \rightarrow K^{(*)}\nu\bar{\nu}$ is given by

$$R_{K^{(*)}}^\nu = \frac{|C_{SM}^\nu + C_{\tau\tau}^\nu|^2 + 2|C_{SM}^\nu|^2 + |C_{\tau\mu}^\nu|^2}{3|C_{SM}^\nu|^2}, \quad (87)$$

where the SM contribution $C_{SM}^\nu \simeq -6.35$ and it is dominated by the Z-penguin. Using $\tilde{V}_{tb} \tilde{V}_{ts}^* = -0.03975$ and the current 90%C.L. limits $R_K^\nu < 3.9$ and $R_{K^*}^\nu < 2.7$ given by [130], we obtain a constraint

$$|\lambda_{\tau b}^T (\lambda_{\tau s}^T)^* + 0.03868|^2 + |\lambda_{\mu b}^T (\lambda_{\tau s}^T)^*|^2 < 9.127 \times 10^{-3} \times \left(\frac{M_T}{\text{TeV}} \right)^2. \quad (88)$$

This inequality alone implies $|\lambda_{\mu b}^T (\lambda_{\tau s}^T)^*| < 0.0955$, which is slightly stronger than the constraint derived from $\mathcal{B}(B^+ \rightarrow K^+ \mu^+ \tau^-) < 4.5 \times 10^{-5}$, see Table V.

E. $\tau \rightarrow \mu(e)\gamma$

Since we also set $\lambda_{ed_i}^T = 0 (d_i = d, s, b, b')$, there is no $\mu \rightarrow e\gamma$ transition at 1-loop level by default. Therefore, we only focus on the constraint from $\tau \rightarrow \mu\gamma$ and $\tau \rightarrow e\gamma$.

FIG. 6. The Feynman diagram for (a) $\tau \rightarrow \mu\gamma$, and (b,c) $b \rightarrow s\gamma(g)$ transition. The external photon (gluon), which is not shown in the illustration, can attach to any charged(color) line in the loop.

The rare $\tau \rightarrow \mu\gamma$ transition can be induced when both $\lambda_{\tau b'}^T$ and $\lambda_{\mu b'}^T$ are nonzero. The 1-loop diagram are shown in Fig.6(a).

The dipole $\tau \rightarrow \mu\gamma$ amplitude can be parameterized as

$$i\mathcal{M}^\mu = i \left[\bar{\mu} (i\sigma^{\mu\nu} k_\nu) (d_R^{\tau\mu} \hat{R} + d_L^{\tau\mu} \hat{L}) \tau \right], \quad (89)$$

where k is the photon momentum transfer. If ignoring the muon mass, the partial decay width is given as[114]

$$\Gamma(\tau \rightarrow \mu\gamma) \simeq \frac{m_\tau^3}{16\pi} (|d_R^{\tau\mu}|^2 + |d_L^{\tau\mu}|^2). \quad (90)$$

Since the leptoquark $T(D)$ only couples to the LH(RH) charged leptons, it contributes solely to $d_{R(L)}^{\tau\mu}$.

If ignoring the charged lepton masses in the loop, the dipole transition coefficient can be easily calculated to be

$$d_R^{\tau\mu} = \frac{eN_c m_\tau}{16\pi^2 M_T^2} \{ \lambda_{\tau b'}^T (\lambda_{\mu b'}^T)^* \beta_T' [-Q_T R_S(\beta_T') + Q_{(b')^c} R_F(\beta_T')] \\ + \lambda_{\tau b}^T (\lambda_{\mu b}^T)^* \beta_T [-Q_T R_S(\beta_T) + Q_{(b)^c} R_F(\beta_T)] \}. \quad (91)$$

In the above, $\beta_T' \equiv (M_T/M_{b'})^2$, $\beta_T \equiv (M_T/m_b)^2$, $Q_T(Q_{(b')^c})$ is the electric charge of the scalar(fermion) in the loop, and the loop functions,

$$R_S(x) = \frac{2 + 3x - 6x^2 + x^3 + 6x \ln x}{12(1-x)^4}, \text{ and} \\ R_F(x) = \frac{R_S(1/x)}{x} = \frac{1 - 6x + 3x^2 + 2x^3 - 6x^2 \ln x}{12(1-x)^4}, \quad (92)$$

correspond to the contributions where the external photon attached to the scalar and fermion line in the loop, respectively. Both functions have the same limit $1/24$ when $x \rightarrow 1$. When $x \gg 1$, $R_S(x) \rightarrow 1/12x$ and $R_F(x) \rightarrow 1/6x$. Note the fermionic and bosonic contributions have opposite signs, and the charged fermion in the loop is the anti- $b^{(\prime)}$.

Similarly, the contribution from the diagram with leptoquark $D^{-\frac{2}{3}}$ and $b^{(\prime)}$ running in the loop yields

$$d_L^{\tau\mu} = \frac{eN_c m_\tau}{32\pi^2 M_D^2} \left\{ \lambda_{\tau b'}^D (\lambda_{\mu b'}^D)^* \beta_D' \left[+\frac{2}{3}R_S(\beta_D') - \frac{1}{3}R_F(\beta_D') \right] + \lambda_{\tau b}^D (\lambda_{\mu b}^D)^* \beta_D \left[+\frac{2}{3}R_S(\beta_D) - \frac{1}{3}R_F(\beta_D) \right] \right\}. \quad (93)$$

As discussed in Sec.III B, we set $\lambda_{\mu b'}^D = 0$ in (Sol-2) to avoid the dangerous $\mu \rightarrow e\gamma$ transition¹⁰. Then, we obtain

$$d_L^{\tau\mu} \simeq \frac{eN_c m_\tau}{32\pi^2 M_D^2} \lambda_{\tau b}^D (\lambda_{\mu b}^D)^* \beta_D \left[\frac{2}{3}R_S(\beta_D) - \frac{1}{3}R_F(\beta_D) \right] \simeq 0, \quad (94)$$

and due to the accidental cancellation in the squared bracket, it vanishes in the limit of $m_b \ll m_D$ in this case. Therefore, only $d_R^{\tau\mu}$ needs to be taken into account. From $\tau_\tau = (290.3 \pm 0.5) \times 10^{-15} s$ [1], the branching ratio of this rare process is

$$\begin{aligned} \mathcal{B}(\tau \rightarrow \mu\gamma) &= \Gamma(\tau \rightarrow \mu\gamma) / \Gamma_\tau \\ &\simeq 5.14 \times 10^{-6} \left| \lambda_{\tau b'}^T (\lambda_{\mu b'}^T)^* \frac{\beta_T'}{3} [4R_S(\beta_T') + R_F(\beta_T')] + \frac{\lambda_{\tau b}^T (\lambda_{\mu b}^T)^*}{6} \right|^2 \times \left(\frac{\text{TeV}}{M_T} \right)^4. \end{aligned} \quad (95)$$

The current experimental bound, $\mathcal{B}(\tau \rightarrow \mu\gamma) < 4.4 \times 10^{-8}$ [131], sets an upper bound

$$\left| \lambda_{\tau b'}^T (\lambda_{\mu b'}^T)^* \frac{4\beta_T'}{3} [R_S(\beta_T') + R_F(\beta_T')] + \frac{\lambda_{\tau b}^T (\lambda_{\mu b}^T)^*}{6} \right| < 0.092 \times \left(\frac{M_T}{\text{TeV}} \right)^2. \quad (96)$$

On the other hand, if both $\lambda_{\tau b'}^D$ and $\lambda_{eb'}^D$ present, we have

$$d_L^{\tau e} \simeq \frac{eN_c m_\tau}{16\pi^2 M_D^2} \frac{\lambda_{\tau b'}^D (\lambda_{\mu b'}^D)^* \beta_D'}{6} [2R_S(\beta_D') - R_F(\beta_D')] \quad (97)$$

for $\tau \rightarrow e\gamma$ transition. From $\mathcal{B}(\tau \rightarrow e\gamma) < 3.3 \times 10^{-8}$ [131], it gives a weak bound

$$|\lambda_{\tau b'}^D (\lambda_{eb'}^D)^*| < 16.93 \times \left(\frac{M_D}{\text{TeV}} \right)^2 \quad (98)$$

for $\beta_D' = (1.0/1.5)^2$.

¹⁰ It will be clear that this is the case for fitting neutrino oscillation data successfully.

F. $b \rightarrow s\gamma$

Similar to the previous discussion on $\tau \rightarrow \mu\gamma$, the $b \rightarrow s\gamma(g)$ transition can be induced when both $\lambda_{\tau b}^T$ and $\lambda_{\tau s}^T$ are nonzero, see Fig.6(b,c). Moreover, the fermion masses, m_τ or m_{ν_τ} , can be ignored, which corresponds to the $\beta_T \gg 1$ limit. From Eq.(92), it is easy to see that $R_S(x) \rightarrow 1/(12x)$ and $R_F(x) \rightarrow 1/(6x)$ when $x \gg 1$. Therefore, by plugging in the electric charges in the loop, the $b \rightarrow s\gamma$ transition amplitude can readily read as

$$i\mathcal{M}^\mu(b \rightarrow s\gamma) \simeq i\frac{em_b}{16\pi^2} \frac{\lambda_{\tau b}^T(\lambda_{\tau s}^T)^*}{12m_T^2} \left[-\frac{1}{2} \left(-\frac{1}{3} \right) - \left(-\frac{1}{4} \right) + 2(1) \right] \left[\bar{s} (i\sigma^{\mu\nu} k_\nu) \hat{R} b \right]. \quad (99)$$

The first one-half factor comes from the $T^{-\frac{1}{3}}$ Yukawa couplings which associate with the $(1/\sqrt{2})$ normalization, see Eq.(11), and the factor 2 in the last term comes from the anti-tau contribution. We also need to consider $b \rightarrow sg$ transition because the RGE running will generate the $b \rightarrow s\gamma$ operator at the low energy. Because the gluon can only couple to the leptoquark, the amplitude reads

$$i\mathcal{M}^\mu(b \rightarrow sg) \simeq i\frac{g_s m_b}{16\pi^2} \frac{\lambda_{\tau b}^T(\lambda_{\tau s}^T)^*}{12m_T^2} \left[-\frac{1}{2} - (1) \right] \left[\bar{s} \left(iT^{(a)} \sigma^{\mu\nu} k_\nu \right) \hat{R} b \right]. \quad (100)$$

where $T^{(a)}$ is the $SU(3)_c$ generator.

Conventionally, the relevant effective Hamiltonian is given as

$$\mathcal{H}_{eff}^{b \rightarrow s\gamma} = -\frac{4G_F}{\sqrt{2}} V_{tb} V_{ts}^* (\mathcal{C}_7 \mathcal{O}_7 + \mathcal{C}_8 \mathcal{O}_8), \quad (101)$$

with

$$\begin{aligned} \mathcal{O}_7 &= \frac{e}{16\pi^2} m_b \bar{s} \sigma^{\mu\nu} \hat{R} b F_{\mu\nu}, \\ \mathcal{O}_8 &= \frac{g_s}{16\pi^2} m_b \bar{s}_\alpha \sigma^{\mu\nu} \hat{R} T_{\alpha\beta}^{(a)} b_\beta G_{\mu\nu}^{(a)}, \end{aligned} \quad (102)$$

In our model, the Wilson coefficients for \mathcal{O}_7 and \mathcal{O}_8 can be identified as

$$\begin{aligned} \mathcal{C}_7 &\simeq \frac{1}{2\sqrt{2}G_F V_{tb} V_{ts}^*} \frac{7\lambda_{\tau b}^T(\lambda_{\tau s}^T)^*}{48M_T^2}, \\ \mathcal{C}_8 &\simeq -\frac{1}{2\sqrt{2}G_F V_{tb} V_{ts}^*} \frac{\lambda_{\tau b}^T(\lambda_{\tau s}^T)^*}{8M_T^2}. \end{aligned} \quad (103)$$

The current experimental measurement, $Br^{Exp}(b \rightarrow s\gamma) = (3.32 \pm 0.15) \times 10^{-4}$ [132], and the SM prediction, $Br^{SM}(b \rightarrow s\gamma) = (3.36 \pm 0.23) \times 10^{-4}$ [133, 134], agree with each other and set constraints on the NP contribution. Following Refs.[78, 81, 128], we adopt the 2σ bound for the NP that $|\mathcal{C}_7 + 0.19\mathcal{C}_8| \lesssim 0.06$, which leads to $|\lambda_{\tau b}^T(\lambda_{\tau s}^T)^*| < 0.55$. This limit is much weaker than the one obtained from ΔM_s .

G. Neutrino oscillation data

As discussed before, the vanishing $\lambda_{ed_i}^T$ are preferred by phenomenological consideration. It is then followed by a robust prediction that $\mathcal{M}_{ee} = 0$, and the neutrinoless double beta decay mediated by \mathcal{M}_{ee} vanishes as well. Therefore, the neutrino mass is predicted to be the normal hierarchical(NH). Later we should discuss the consequence if this vanishing- $\lambda_{ed_i}^T$ assumption is relaxed.

A comprehensive numerical fit to the neutrino data is unnecessary to understand the physics, and it is beyond the scope of this paper as well. For simplicity, we assume all the Yukawa couplings are real, and thus all the CP phases in the neutrino mixings vanish. However, this model has no problem to fit the CP violation phases of any values once the requirement of all the Yukawa couplings being real is lifted. Moreover, to adhere to the philosophy of using the least number of real parameters, only two more Yukawa couplings, $\lambda_{\tau b'}^D$ and $\lambda_{\tau b}^D$, are introduced to fit the neutrino data¹¹. Together with MinS_T, we make use of eleven Yukawa couplings, and the complete minimal set of parameter is

$$\text{MinS} = \text{MinS}_T \cup \{ \lambda_{eb'}^D, \lambda_{\tau b'}^D, \lambda_{\mu b}^D, \lambda_{\tau b}^D, \lambda_{eb'}^S, \lambda_{\mu b}^S \}. \quad (104)$$

Assuming that $M_D \simeq M_T \simeq M_{LQ}$, the neutrino mass matrix takes the form

$$\mathcal{M}^\nu \simeq N^\nu \begin{pmatrix} 0 & \lambda_{eb'}^D \lambda_{\mu b'}^T & \lambda_{eb'}^D \lambda_{\tau b'}^T \\ \lambda_{eb'}^D \lambda_{\mu b'}^T & 2\rho_b \lambda_{\mu b}^D \lambda_{\mu b}^T & \rho_b (\lambda_{\mu b}^D \lambda_{\tau b}^T + \lambda_{\tau b}^D \lambda_{\mu b}^T) + \lambda_{\mu b'}^D \lambda_{\tau b'}^T \\ \lambda_{eb'}^D \lambda_{\tau b'}^T & \rho_b (\lambda_{\mu b}^D \lambda_{\tau b}^T + \lambda_{\tau b}^D \lambda_{\mu b}^T) + \lambda_{\mu b'}^D \lambda_{\tau b'}^T & 2\rho_b \lambda_{\tau b}^D \lambda_{\tau b}^T + 2\lambda_{\tau b'}^D \lambda_{\tau b'}^T \end{pmatrix}, \quad (105)$$

where $\rho_b = m_b/M_{b'}$ and $N^\nu = \frac{3\mu_3 v_0 M_{b'}}{32\pi^2 M_{LQ}^2}$. Note that the leptoquark Yukawa couplings are tightly entangled with the neutrino mass matrix. For instance, $\lambda_{\tau b'}^T/\lambda_{\mu b'}^T = \mathcal{M}_{e\tau}^\nu/\mathcal{M}_{e\mu}^\nu$ is required by this minimal assumption.

For illustration, we consider an approximate neutrino mass matrix¹²

$$\mathcal{M}^\nu \simeq \begin{pmatrix} 0 & 0.90792 & 0.13812 \\ 0.90792 & -2.4923 & -2.7643 \\ 0.13812 & -2.7643 & -1.9353 \end{pmatrix} \times 10^{-2} \text{eV}, \quad (106)$$

with all elements being real. It leads to the following mixing angles and mass squared differences

$$\begin{aligned} \theta_{12} &\simeq 33.0^\circ, \quad \theta_{23} \simeq 48.7^\circ, \quad \theta_{13} \simeq 8.6^\circ, \quad \delta_{CP} = 0^\circ, \\ \Delta m_{21}^2 &\sim 7.47 \times 10^{-5} \text{eV}^2, \quad \Delta m_{31}^2 \sim 2.53 \times 10^{-3} \text{eV}^2. \end{aligned} \quad (107)$$

¹¹ Note that we have not employed $\lambda_{\tau s}^T$ in the neutrino data fitting yet.

¹² It is just a randomly generated example for illustration. There are infinite ones with the similar structure.

Note all of the above values, except δ_{CP} , are inside the 1σ best fit (with SK atmospheric data) range for the normal ordering given by [135],

$$\begin{aligned} \theta_{12} &\in (32.7 - 34.21)^\circ, \theta_{23} \in (48.0 - 50.1)^\circ, \theta_{13} \in (8.45 - 8.69)^\circ, \delta_{CP} \in (173 - 224)^\circ, \\ \Delta m_{21}^2 &\in (7.22 - 7.63) \times 10^{-5} \text{eV}^2, \Delta m_{31}^2 \in (2.489 - 2.543) \times 10^{-3} \text{eV}^2. \end{aligned} \quad (108)$$

This example neutrino mass matrix captures the essential features of the current neutrino data. A better fitting to the neutrino oscillation data, including the phase, by using more (complex) model parameters is expected.

In order to reproduce the neutrino mass matrix, the second solution to $\Delta a_{e,\mu}$, Eq.(44), must be adopted. Because the first solution $\Delta a_{e,\mu}$, Eq.(43), requires $\mu_1 \gg M_{LQ}$ to render mass matrix elements of about the same order, as shown in Eq.(106). All the best fit central values for $b \rightarrow s\mu\mu$, $\Delta a_{e,\mu}$, CAA, and the approximate neutrino mass matrix shown in Eq.(106) can be easily accommodated with the specified non-vanishing parameters in the model. Since $(M_{b'}/m_b) \gg 1$, $\lambda_{\mu b}^D, \lambda_{eb'}^S > \sqrt{4\pi}$ are required if aiming for explaining the central values of $\Delta a_{e,\mu}$. However, reliable nonperturbative treatment is beyond the scope of this paper. Instead, we consider the 1σ ranges of best fit for $b \rightarrow s\mu\bar{\mu}$ and Δa_e . As an example, below is one of the viable sets of model parameters for $\Delta a_e = -5.1[1.8] \times 10^{-13}$ and $C_9 = -C_{10} = -0.351^{13}$,

$$\begin{aligned} M_{LQ} &= 1.0 \text{ TeV}, M_{b'} = 1.5 \text{ TeV}, \mu_1 = 2.298[-0.818] \text{ TeV}, \mu_3 = 0.513 \text{ keV}, s_1 = 0.039 \\ \lambda_{\mu b'}^T &= -3.34514, \lambda_{\tau b'}^T = -0.508902, \lambda_{\mu b}^T = -0.728492, \\ \lambda_{\tau b}^T &= 0.929742, \lambda_{\tau s}^T = -0.076018, \\ \lambda_{eb'}^D &= -0.00151, \lambda_{\mu b}^D = 3.4, \lambda_{\tau b'}^D = 0.00760, \lambda_{\tau b}^D = -0.58293, \\ \lambda_{eb'}^S &= 3.4, \lambda_{\mu b}^S = -0.088264[0.24798], \end{aligned} \quad (109)$$

and all the other Yukawa couplings are set to zero. This specific set of model parameters also predicts $\Delta M_s \simeq 1.06 \Delta M_s^{SM}$, $R_{K^{(*)}}^\nu = 1.21$,

$$\mathcal{B}(\tau \rightarrow \mu\gamma) = 6.0 \times 10^{-9}, \mathcal{B}(\tau \rightarrow e\gamma) = 1.5 \times 10^{-20}, \mathcal{B}(B^+ \rightarrow K^+\mu^+\tau^-) = 1.4 \times 10^{-5}, \quad (110)$$

and pass all experimental limits we have considered, the last column in Tables V and VI.

Note that $\lambda_{\mu b'}^T$, $\lambda_{\mu b}^D$, and $\lambda_{eb'}^S$ in Eq.(109) are close to but below the nonperturbative limit $\sqrt{4\pi}$. However, this is because we want to use the minimal number of model parameters. For instance, if

¹³ The values of Δa_e correspond to the 1σ boundaries of $\Delta a_e^{Cs}[\Delta a_e^{Rb}]$, and the $C_{9(10)}$ is close to the fitted value by only using the theoretically clean modes in [63]. All others are taken to be their central values.

FIG. 7. The Feynman diagrams for $0\nu\beta\beta$ decay (a) mediated by the T - D mixing, and (b) mediated by the neutrino Majorana mass.

the complex Yukawa is allowed, the degrees of freedom are doubled. Lowering $M_{b'}$ and increasing μ_1 can both make $\lambda_{\mu b}^D$ and $\lambda_{eb'}^S$ smaller as well. We have no doubt that a better fitting can be achieved in this model by using more (complex) free parameters. But we are content with the demonstration about the ability of this model to accommodate all the observed anomalies and explain the pattern of the observed neutrino data with minimal number of real parameters.

H. $0\nu\beta\beta$ decay

The mixing between T and D breaks the global lepton number, see Appendix B. Here, we consider whether the neutrinoless double beta decay can be generated beyond the contribution from the neutrino Majorana mass. From the low energy effective Hamiltonian, together with the SM CC interaction, the lepton number violating charged current operators can induce the $0\nu\beta\beta$ process via the diagram, see Fig.7(a). By order of magnitude estimation, the absolute value of the amplitude strength relative to the usual one mediated by the neutrino Majorana mass, Fig.7(b), is given by

$$\left| \frac{\mathcal{M}_{TD}}{\mathcal{M}_{m_\nu}} \right| \simeq \frac{\lambda_T \lambda_D \mu_3 v_0}{M_T^2 M_D^2} \frac{M_W^2 \langle p \rangle}{g_2^2 \mathcal{M}_{ee}^\nu} \simeq 10^{-5} \left(\frac{1 \text{ TeV}}{M_{LQ}} \right)^4 \ll 1. \quad (111)$$

In arriving the above value, we take $\mu_3 = 0.5 \text{ keV}$, $\langle p \rangle \sim 1 \text{ MeV}$ for the typical average momentum transfer in the $0\nu\beta\beta$ process and assume $\mathcal{M}_{ee}^\nu \sim 0.01 \text{ eV}$ for comparison. Thus, this tree-level process mediated by T and D can be ignored.

I. A recap

After taking into account all the phenomenological limits, we found the following simple assignment with minimal number of real parameters,

$$\begin{aligned}
M_{LQ} &\simeq 1.0 \text{ TeV}, \quad M_{b'} = 1.5 \text{ TeV}, \quad \mu_1 = 2.3[-0.82] \text{ TeV}, \quad \mu_3 \simeq 0.5 \text{ keV}, \\
\mu_1 \lambda_{eb'}^S \lambda_{eb'}^D &= -12[4] \text{ GeV}, \quad \mu_1 \lambda_{\mu b}^S \lambda_{\mu b}^D = -690 \text{ GeV}, \\
\theta_2 = \theta_3 &= 0, \quad \sin \theta_1 = 0.039, \\
\lambda_{\mu b'}^T &\simeq -3.3, \quad \lambda_{\tau b'}^T \simeq -0.51, \quad \lambda_{\mu b}^T \simeq -0.72, \quad \lambda_{\tau b}^T \simeq 0.93, \quad \lambda_{\tau s}^T \simeq -0.08, \\
\lambda_{eb'}^D &\simeq -0.002, \quad \lambda_{\mu b}^D \simeq 3.4, \quad \lambda_{\tau b'}^D \simeq 0.008, \quad \lambda_{\tau b}^D \simeq -0.58,
\end{aligned} \tag{112}$$

is able to accommodate $\Delta a_e^{Cs}[\Delta a_e^{Rb}]$, Δa_μ , the Cabibbo angle, and $b \rightarrow s\mu\mu$ anomalies simultaneously. Moreover, the resulting neutrino mass pattern is very close to the observed one.

V. DISCUSSION

A. Neutrino mass hierarchy and neutrinoless double beta decay

Because we set $\lambda_{edi}^T = 0 (i = d, s, b, b')$, the neutrino mass element M_{ee}^ν vanishes and the neutrino mass is of the NH type. Since we have used $\lambda_{eb'}^S$ to explain the observed Δa_e , adding $\lambda_{eb'}^T$ is the minimal extension to yield a non-zero M_{ee}^ν . Together with $\lambda_{\mu b}^T$ and $\lambda_{\mu b'}^T$, the augmentation of $\lambda_{eb'}^T$ leads to an effective Hamiltonian,

$$H \supset \frac{\mathcal{C}_{\mu e}}{4M_T^2} (\bar{u}\gamma^\mu \hat{L}u)(\bar{\mu}\gamma_\mu \hat{L}e) + H.c., \tag{113}$$

where

$$\mathcal{C}_{\mu e} = \lambda_{eb'}^T (\tilde{V}_{ub'})^* \left[\tilde{V}_{ub} (\lambda_{\mu b}^T)^* + \tilde{V}_{ub'} (\lambda_{\mu b'}^T)^* \right]. \tag{114}$$

Numerically,

$$\mathcal{C}_{\mu e} \simeq 1.44 \times 10^{-3} \lambda_{eb'}^T (\lambda_{\mu b'}^T)^* + 1.37 \times 10^{-4} \lambda_{eb'}^T (\lambda_{\mu b}^T)^*, \tag{115}$$

if we set $s_1 = 0.039$ and $\tilde{V}_{ub} = 0.00361$.

The Wilson coefficient is severely constrained, $\mathcal{C}_{\mu e} < 9.61 \times 10^{-5}$, from the experimental limit of μ - e conversion rate[116, 136]. Namely, $\lambda_{eb'}^T (\lambda_{\mu b'}^T)^* \lesssim 0.07$ unless the cancellation is arranged in Eq.(115). Moreover, in this model, the ratio of neutrino mass element M_{ee}^ν to $M_{e\mu}^\nu$, see Eq.(105),

$$\frac{M_{ee}^\nu}{M_{e\mu}^\nu} = \frac{2M_{b'} \lambda_{eb'}^D \lambda_{eb'}^T}{M_{b'} \lambda_{eb'}^D \lambda_{\mu b'}^T} = \frac{2\lambda_{eb'}^T}{\lambda_{\mu b'}^T}, \tag{116}$$

should be around $\sim \mathcal{O}(1)$ and $\sim \mathcal{O}(10)$ for the NH and Inverted Hierarchy (IH) type, respectively. Since we need $\lambda_{\mu b'}^T \sim \mathcal{O}(1)$ to accommodate the b-anomalies, that implies $\frac{M_{ee}^\nu}{M_{e\mu}^\nu} \lesssim 0.07$. Thus, even if we include a non-zero $\lambda_{eb'}^T$ to generate the ee -component of M_ν , the neutrino mass is still of the NH type, and roughly $|M_{ee}^\nu| \lesssim 3 \times 10^{-4} \text{eV}$. The precision required is beyond the capabilities of the near future experiments[137].

B. Some phenomenological consequences at the colliders

The smoking gun signature of this model will be the discovery of b' and the three scalar leptoquarks. Once their quantum numbers are identified, the gauge invariant allowed Yukawa couplings and the mechanisms to address the anomalies discussed in the paper follow automatically. The collider physics of leptoquarks have been extensively studied before, and thus we do not have much to add. The readers interested in this topic are referred to the comprehensive review [138] and the references therein. In the paper, we should concentrate on the flavor physics at around or below the Z pole.

However, it is worthy to point out the nontrivial decay branching ratios of the exotic color states. If we assume the mixings among the leptoquarks are small, their isospin members should be approximately degenerate in mass. Then, the decays are dominated by 2-body decay with two SM fermions in the final states. From the Yukawa couplings shown in Eq.(109), the decay branching ratio of leptoquarks can be easily read. For $T^{-\frac{1}{3}}$, its decay branching ratios are

$$\begin{aligned} \mathcal{B}(T^{-\frac{1}{3}} \rightarrow b\nu_\mu) &\simeq 18.9\%, \mathcal{B}(T^{-\frac{1}{3}} \rightarrow b\nu_\tau) \simeq 30.9\%, \mathcal{B}(T^{-\frac{1}{3}} \rightarrow s\nu_\tau) \simeq 2.1 \times 10^{-3}, \\ \mathcal{B}(T^{-\frac{1}{3}} \rightarrow \tau t) &\simeq 30.8\%, \mathcal{B}(T^{-\frac{1}{3}} \rightarrow \mu t) \simeq 18.9\%, \mathcal{B}(T^{-\frac{1}{3}} \rightarrow \tau c) \simeq 2.0 \times 10^{-3}. \end{aligned} \quad (117)$$

For $T^{\frac{2}{3}}$ and $T^{\frac{4}{3}}$, the corresponding decay branching ratios are

$$\begin{aligned} \mathcal{B}(T^{\frac{2}{3}} \rightarrow t\nu_\mu) &\simeq 37.9\%, \mathcal{B}(T^{\frac{2}{3}} \rightarrow t\nu_\tau) \simeq 61.7\%, \mathcal{B}(T^{\frac{2}{3}} \rightarrow c\nu_\tau) \simeq 0.4\%, \\ \mathcal{B}(T^{-\frac{4}{3}} \rightarrow b\mu^-) &\simeq 37.9\%, \mathcal{B}(T^{-\frac{4}{3}} \rightarrow b\tau^-) \simeq 61.7\%, \mathcal{B}(T^{-\frac{4}{3}} \rightarrow s\tau^-) \simeq 0.4\%. \end{aligned} \quad (118)$$

Finally, we have

$$\begin{aligned} \mathcal{B}(D^{-\frac{1}{3}} \rightarrow b\bar{\nu}_\mu) &\simeq 97.1\%, \mathcal{B}(D^{-\frac{1}{3}} \rightarrow b\bar{\nu}_\tau) \simeq 2.9\%, \\ \mathcal{B}(D^{\frac{2}{3}} \rightarrow b\mu^+) &\simeq 97.1\%, \mathcal{B}(D^{\frac{2}{3}} \rightarrow b\tau^+) \simeq 2.9\%, \\ \mathcal{B}(S^{\frac{2}{3}} \rightarrow b\mu^+) &\simeq 100\%, \end{aligned} \quad (119)$$

for D and S leptoquarks.

The dominate decay modes of b' are $b' \rightarrow LQ + l$, and $b' \rightarrow W^- u_i (u_i = u, c, t)$ through the mixing of $\tilde{V}_{u_i b'}$. Comparing to $M_{b'}$, the masses of final state particles can be ignored. The width for $b' \rightarrow W u_i$ is simply given by

$$\Gamma(b' \rightarrow u_i W^-) \simeq \frac{G_F |\tilde{V}_{u_i b'}|^2 M_{b'}^3}{8\sqrt{2}\pi}, \quad (120)$$

and

$$\begin{aligned} \Gamma(b' \rightarrow \bar{\nu}_i T^{-\frac{1}{3}}) &\simeq \frac{|\lambda_{l_i b'}^T|^2}{64\pi} M_{b'} \left(1 - \frac{M_T^2}{M_{b'}^2}\right)^2, \quad \Gamma(b' \rightarrow \ell_i^+ T^{-\frac{4}{3}}) \simeq \frac{|\lambda_{l_i b'}^T|^2}{32\pi} M_{b'} \left(1 - \frac{M_T^2}{M_{b'}^2}\right)^2, \\ \Gamma(b' \rightarrow \nu_i D^{-\frac{1}{3}}) &\simeq \Gamma(b' \rightarrow \ell_i^- D^{\frac{2}{3}}) \simeq \frac{|\lambda_{l_i b'}^D|^2}{64\pi} M_{b'} \left(1 - \frac{M_D^2}{M_{b'}^2}\right)^2, \\ \Gamma(b' \rightarrow \ell_i S^{\frac{2}{3}}) &\simeq \frac{|\lambda_{l_i b'}^S|^2}{32\pi} M_{b'} \left(1 - \frac{M_S^2}{M_{b'}^2}\right)^2. \end{aligned} \quad (121)$$

The Yukawa coupling between b' and the SM Higgs is through the b' - d mixing. So the resulting Yukawa coupling gets double suppression from the small θ_1 and the ratio of m_d/v_0 , and so the $b' \rightarrow Hd$ decay can be ignored. Similarly the decays of $b' \rightarrow Z^0 d_i$ can be ignored as well. By plugging in the parameters we found, the total decay width of b' is $\Gamma_{b'} \simeq 134.0\text{GeV}$, and the branching ratios are

$$\begin{aligned} \mathcal{B}(b' \rightarrow uW^-) &\simeq 1.2\%, \quad \mathcal{B}(b' \rightarrow cW^-) \simeq 6 \times 10^{-4}, \quad \mathcal{B}(b' \rightarrow tW^-) \simeq 9 \times 10^{-7}, \\ \mathcal{B}(b' \rightarrow \bar{\nu} T^{-\frac{1}{3}}) &\simeq 19.7\%, \quad \mathcal{B}(b' \rightarrow \mu^+ T^{-\frac{4}{3}}) \simeq 38.5\%, \\ \mathcal{B}(b' \rightarrow \tau^+ T^{-\frac{4}{3}}) &\simeq 0.9\%, \quad \mathcal{B}(b' \rightarrow e S^{\frac{2}{3}}) \simeq 39.7\%, \end{aligned} \quad (122)$$

for $M_{LQ} = 1\text{TeV}$ and $M_{b'} = 1.5\text{TeV}$.

We stress that the above decay branching ratios are the result of using the example parameter set given in Eq.(109). The decay branching ratios depend strongly on the model parameters, and the branching ratio pattern varies dramatically from one neutrino mass matrix to another¹⁴. However, one can see that the decay pattern of the heavy exotic color states in this example solution is very different from the working assumption of 100% $b' \rightarrow tW, Zb, Hb$ used for singlet b' and other assumption used for the leptoquark searches at the colliders.

Before closing this section, we want to point out some potentially interesting FCNC top 3-body decays in this framework. From the example solution, we have

$$\mathcal{B}(t \rightarrow u\tau^+\mu^-) \simeq \mathcal{B}(t \rightarrow u\mu^+\mu^-) \simeq 2 \times 10^{-9}. \quad (123)$$

¹⁴ In particular, in the minimal setup one has $\lambda_{\tau b'}^T/\lambda_{\mu b'}^T = \mathcal{M}_{e\tau}^\nu/\mathcal{M}_{e\mu}^\nu$.

With an integrated luminosity of 3ab^{-1} and CM energy at 13TeV , about 2.5×10^9 top quark pair events will be produced at the LHC. Therefore, only ~ 5 events which include at least one top decaying in these 3-body FCNC are expected. However, the 3-body FCNC $t \rightarrow cl_i l_j$ branching ratios change if adopting a different solution. During our numerical study, we observe that in some cases there are one or two of them at the $\mathcal{O}(10^{-7})$ level, which might be detectable at the LHC. See [139] for the prospect of studying these potentially interesting 3-body top decay modes at the LHC.

C. Flavor violating neutral current processes

A few comments on the data fitting are in order: From Table V, one sees that the fit almost saturates, $\sim 80\%$, of the current limit on decay branching ratio $B^+ \rightarrow K^+ \mu^+ \tau^-$. Moreover, the fit is very close to the 2σ limit from $B_s - \bar{B}_s$ mixing. The solution seems to be stretched to the limit, and the discovery of lepton flavor violating signals are around the corners. However, this is the trade-off of using minimal number of parameters to reproduce all the central values. If instead aiming for the 1σ values, both can be reduced by half. In addition, the Yukawa couplings are tightly connected with the neutrino mass matrix. During our numerical study, we observe that $D^+ \rightarrow \pi^+ \mu^+ \mu^-$ and $B^+ \rightarrow K^+ \mu^+ \tau^-$ can be far below their experimental upper bounds while $\tau \rightarrow \mu \gamma$ close to the current experimental limit if using some different neutrino mass matrix or relaxing the strict relationship that $\tilde{V}_{cb}^* \lambda_{\mu b}^T + \tilde{V}_{cb'}^* \lambda_{\mu b'}^T = 0$. Therefore, the model has vast parameter space to accommodate the anomalies with diversified predictions, and we cannot conclusively predict the pattern of the rare process rates at the moment.

However, because we need $\lambda_{\tau b}^T \lambda_{\tau s}^T \neq 0$ to explain the $b \rightarrow s \mu \mu$ anomaly, the $b \rightarrow s \tau \tau$ transition will be always generated at the tree-level. From the example solution, we have

$$\begin{aligned} \mathcal{H}_{eff}^{b \rightarrow s \tau \tau} &\simeq -\frac{G_F}{\sqrt{2}} \tilde{V}_{tb} \tilde{V}_{ts}^* \frac{\alpha}{\pi} \mathcal{C}^{bs\tau\tau} \left[\bar{s} \gamma^\alpha \hat{L} b \right] \left[\bar{\tau} \gamma_\alpha (1 - \gamma^5) \tau \right] + H.c., \\ \mathcal{C}^{bs\tau\tau} &\simeq \frac{\sqrt{2}\pi}{4\alpha} \frac{\lambda_{\tau b}^T (\lambda_{\tau s}^T)^*}{\tilde{V}_{tb} \tilde{V}_{ts}^* G_F M_T^2} = 23.2 \times \left(\frac{\text{TeV}}{M_T} \right)^2, \end{aligned} \quad (124)$$

if taking $\tilde{V}_{tb} \tilde{V}_{ts}^* = -0.03975$. The additional 1-loop contribution via the box diagram similar to that of $b \rightarrow s \mu \mu$ can be ignored. This Wilson coefficient is roughly six times larger than the SM prediction that $\mathcal{C}_{SM}^{bs\tau\tau} \sim -4.3$ [140–142], and push the decay branching ratio to $Br(B_s \rightarrow \tau^+ \tau^-) \simeq 1.6 \times 10^{-5}$. Although the above value is still two orders below the relevant experimental upper limit, $\sim \mathcal{O}(10^{-3})$, for $B_s \rightarrow \tau^+ \tau^-$ at LHCb[143] and $B^+ \rightarrow K^+ \tau^+ \tau^-$ at BaBar[144], this interesting $b \rightarrow s \tau \tau$ transition could be potentially studied at the LHCb and Belle II[145], or at the Z-pole[146].

FIG. 8. The Feynman diagram for $b \rightarrow c\tau\nu$ transition.

D. $B \rightarrow D^{(*)}\tau\bar{\nu}$

Alongside the $b \rightarrow sl^+l^-$ anomaly, the global analysis[132, 147–150] of the $R(D^{(*)}) = \mathcal{B}(B \rightarrow D^{(*)}\tau\nu)/\mathcal{B}(B \rightarrow D^{(*)}\mu\nu)$ data [151–156] also point to the τ - μ lepton flavor universality violation with a significance of $\geq 3\sigma$. In this mode, the MinS_T of λ^T contains the needed tree-level $b \rightarrow c\tau\nu$ operator, Fig.8, to address the $R(D^{(*)})$ problem, and

$$\mathcal{H}_{eff}^{CC} \supset - \left[\frac{\lambda_{\tau s}^T (\lambda_{\tau b}^T)^* \tilde{V}_{cs} + \lambda_{\tau b}^T (\lambda_{\tau b'}^T)^* \tilde{V}_{cb'} + |\lambda_{\tau b}^T|^2 \tilde{V}_{cb}}{4M_T^2} \right] (\bar{c}\gamma^\alpha \hat{L}b) (\bar{\tau}\gamma_\alpha \hat{L}\nu_\tau) + H.c. \quad (125)$$

This is to compare with the standard effective Hamiltonian

$$\mathcal{H}_{eff}^{b \rightarrow cl\nu} = \frac{4G_F}{\sqrt{2}} V_{cb} [(1 + \mathcal{C}_{V_L}) \mathcal{O}_{V_L} + \mathcal{C}_{V_R} \mathcal{O}_{V_R} + \mathcal{C}_{S_L} \mathcal{O}_{S_L} + \mathcal{C}_{S_R} \mathcal{O}_{S_R} + \mathcal{C}_T \mathcal{O}_T] + H.c. \quad (126)$$

where

$$\begin{aligned} \mathcal{O}_{V_{L,R}} &= (\bar{c}\gamma^\mu b_{L,R})(\bar{l}_L\gamma_\mu \nu_{lL}), \\ \mathcal{O}_{S_{L,R}} &= (\bar{c}b_{L,R})(\bar{l}_R\nu_{lL}), \quad \mathcal{O}_T = (\bar{c}\sigma^{\mu\nu}b_L)(\bar{l}_R\sigma_{\mu\nu}\nu_{lL}). \end{aligned} \quad (127)$$

In this model, the only CC operator can be generated at tree-level is \mathcal{O}_{V_L} , thus $\mathcal{C}_{V_R} = 0$, $\mathcal{C}_{S_{R,L}} = 0$, and $\mathcal{C}_T = 0$. From the global fit with single operator[147], the $R(D^{(*)})$ anomaly can be well addressed if $\mathcal{C}_{V_L} \simeq 0.08$. However, the requirement to retain the μ - e universality in $b \rightarrow cl\nu$ strictly limits the parameter space. By using the real MinS of parameters, we found the model can render at most $\mathcal{C}_{V_L}^{NP} \lesssim 0.01$. On the other hand, we cannot rule out the possibility that the model has the viable complex number parameter space to accommodate this anomaly with others simultaneously.

On the other hand, this model predicts the lepton universality violation in the $b \rightarrow ul_i\nu_j$ ($i, j = \mu, \tau$) transition, see the relevant Wilson coefficients in Table VI. Again, there is no electron counter parts if we use the MinS_T. From our example solution, the rate of $b \rightarrow u\mu\nu$ could deviate from the SM one by $\sim 40\%$ due to the smallness of \tilde{V}_{ub} and the interference between the NP and the SM weak interaction. More insights of the intriguing flavor problem are expected if the better experimental measurements on the $b \rightarrow ul\nu$ transitions are available[157].

E. Origin of the flavor structure

Not only the subset of parameters are required to explain the anomalies, the nearly vanishing entities in the Yukawa matrices play vital roles to bypass the strong flavor-changing experimental constraints. The next question is how to understand the origin of this staggering flavor pattern. Usually, the flavor pattern is considered within the framework of flavor symmetries. It is highly nontrivial to embed the flavor pattern we found into a flavor symmetry, and it is beyond the scope of this paper. Alternatively, we discuss the possible geometric origin of the flavor pattern in the extra-dimensional theories[158–161].

A comprehensive fitting, including all the SM fermion masses and mixings, like [162–165] is also beyond the scope of this paper. Instead, here we only consider how to generate the required flavor pattern of the leptoquark Yukawa coupling shown in Eq.(112). To illustrate, we consider a simple split fermion toy model[161]. We assume all the chiral fermion wave functions are Gaussian locating in a small region, but at different positions, in the fifth dimension. Moreover, all the 5-dim Gaussian distributions are assumed to share a universal width, σ_{SF} . As for the three leptoquarks, we assume they do not have the zero mode such that their first Kaluza-Klein(KK) mode are naturally heavy. More importantly, this setup forbids the leptoquark to develop VEV and break the $SU(3)_c$ symmetry. In addition, the wavefunctions of the first leptoquark KK mode are assumed to be slowly varying in the vicinity of the fermion cluster, and can be approximated as constants. On the other hand, the SM Higgs must acquires the zero mode so that it can develop v_0 and breaks the SM electroweak symmetry. Then, the 4-dim effective theory is obtained after integrating out the fifth dimension. The effective $\lambda_{ij}^s (s = T, D, S)$ Yukawa couplings is determined by the overlapping of two chiral fermions' 5-dim wave functions times the product of the scalar-specific 5-dim Yukawa coupling and the scalar's 5-dim wavefunction, denoted as N_s , in the vicinity where the fermions locate. The 4-dim Yukawa coupling is given by

$$\lambda_{ij}^s = N_s \text{Exp} \left[-\frac{(z_i - z_j)^2}{2\sigma_{SF}^2} \right], \quad (s = T, D, S), \quad (128)$$

where z_i is the center location in the fifth dimension of the Gaussian wave function of particle- i . It is clear that only the relative distances matter, so we arbitrarily set $z_{\tau_L} = 0$ for the LH tau. Note that different fermion chiralities are involved for different scalar leptoquark Yukawa couplings. For example, λ_{ij}^T is determined by the separation between the corresponding LH down-quark($z_{d_{jL}}$) and the LH lepton($z_{\ell_{iL}}$), but $z_{\ell_{iR}}$ and $z_{d_{jL}}$ are involved for λ_{ij}^S .

For simplicity, we assume the mass and interaction eigenstates coincide for the down-type quarks

and the SM charged leptons. We found the flavor structure can be excellently reproduced if the chiral fermion locations in the fifth dimension are

$$\begin{aligned} \{z_{\tau_L}, z_{\mu_L}, z_{e_L}, z_{\mu_R}, z_{e_R}\} &= \{0, -0.49, 7.75[7.80], -4.99[-4.72], -0.89[-0.97]\}, \\ \{z_{d_L}, z_{s_L}, z_{b_L}, z_{b'_L}, z_{b_R}, z_{b'_R}\} &= \{-5.27[-5.53], 2.86[2.90], -2.14[-2.13], \\ &\quad -1.90[-1.95], -2.06[-2.09], 3.66[3.74]\}, \end{aligned} \quad (129)$$

in the unit of σ_{SF} , and $\{N_T, N_D, N_S\} = \{4.5, 6.2, 5.5\}$. The above configuration of split fermion locations results in

$$\begin{aligned} |\lambda_{\mu b'}^T| &= 1.66[1.56], |\lambda_{\tau b'}^T| = 0.74[0.68], |\lambda_{\mu b}^T| = 1.15[1.17], |\lambda_{\tau b}^T| = 0.46[0.46], |\lambda_{\tau s}^T| = 7.5[6.8] \times 10^{-2}, \\ |\lambda_{eb'}^D| &= 1.5[1.6] \times 10^{-3}, |\lambda_{\mu b}^D| = 1.78[1.71], |\lambda_{\tau b'}^D| = 7.5[5.8] \times 10^{-3}, |\lambda_{\tau b}^D| = 0.74[0.69], \\ |\lambda_{eb'}^S| &= 3.31[3.42], |\lambda_{\mu b}^S| = 9.4[19.2] \times 10^{-2}. \end{aligned}$$

Comparing to Eq.(109), one can see that all the Yukawa coupling magnitudes agree with the fitted values within $\lesssim 60\%$. Moreover, the parameters we set to zero to evade the stringent constraints from Koan and muon data are indeed very small,

$$\begin{aligned} |\lambda_{eb}^D| &= 7.5[3.6] \times 10^{-21}, |\lambda_{\mu b'}^D| = 1.1[0.8] \times 10^{-3}, \\ |\lambda_{ed}^T| &= 7.0[0.13] \times 10^{-37}, |\lambda_{es}^T| = 2.9[2.8] \times 10^{-5}, |\lambda_{eb}^T| = 2.6[1.8] \times 10^{-21}, \\ |\lambda_{eb'}^T| &= 2.7[1.1] \times 10^{-20}, |\lambda_{\mu d}^T| = 4.8[1.4] \times 10^{-5}, |\lambda_{\tau d}^T| = 4.2[1.0] \times 10^{-6}, \end{aligned} \quad (130)$$

in this given split fermion location configuration.

Finally, the lepton number symmetry is broken if $\mu_3 \neq 0$. The phenomenological solution we found only calls for a very tiny $\mu_3 \sim \mathcal{O}(0.5)\text{keV}$. The smallness of μ_3 can be arranged by assigning different orbifolding parities to T and D such that their 5-D wave functions are almost orthogonal to each other and leads to the tiny 4D effective mixing¹⁵. Contrarily, S and D should share the same orbifolding parities such that the maximal mixing yields a large effective 4D mixing $\mu_1 \sim \mathcal{O}(\text{TeV})$. On the other hand, in terms of flavor symmetry, the smallness of μ_3 seems to indicate the global/gauged lepton number symmetry is well preserved and only broken very softly or radiatively.

VI. CONCLUSION

We proposed a simple scenario with the addition of three scalar leptoquarks $T(3, 3, -1/3)$, $D(3, 2, 1/6)$, $S(3, 1, 2/3)$, and one pair of down-quark-like vector fermion $b'_{L,R}(3, 1, -1/3)$ to the

¹⁵ For instance, one takes $(+-)$ and the other takes $(-+)$ Kaluza-Klein parity on the $S_1/(Z_2 \times Z_2)$ orbifold.

SM particle content. The global baryon number $U(1)_B$ is assumed for simplicity. This model is able to accommodate the observed $\Delta a_e^{Cs[Rb]}$, a_μ , $R(K)$, Cabibbo angle anomalies, and pass all experimental limits simultaneously. Moreover, the right pattern of neutrino oscillation data can be reproduced as well. We have shown the existence of phenomenologically viable model parameter set by furnishing one example configuration with the minimal number of real Yukawa couplings. For the possible UV origin, we provided a split fermion toy model to explain the flavor structure embedded in the viable model parameter set. It will be interesting to reproduce the flavor pattern by nontrivial flavor symmetry. However, the tiny lepton number violating parameter, $\mu_3 \sim \mathcal{O}(0.5)\text{keV}$, seems to indicate the possible link of global/gauged lepton number and the unknown underlying flavor symmetry.

In addition to the smoking gun signatures, the discovery of these new color states, this model robustly predicts the neutrino mass is of the normal hierarchy type with $\mathcal{M}_{ee}^\nu \lesssim 3 \times 10^{-4}\text{eV}$. The $R(D^{(*)})$ anomaly can only be partially addressed in this model if one employs the minimal number of real Yukawa couplings. However, we cannot rule out the possibility that could be achieved by using more (complex) parameters. From the parameter set example, more motivated heavy color state decay branching ratios should be taken into account in their collider searches.

Appendix A: some properties of the $SU(2)$ triplet

It is well-known that the Pauli matrices can serve as the generators for the 2-dimensional $SU(2)$ representations. Namely, $t_i^{(2)} = \frac{\sigma_i}{2}$, ($i = 1, 2, 3$), and they satisfy the relationship $[t_i^{(2)}, t_j^{(2)}] = i\epsilon_{ijk}t_k^{(2)}$ ($i, j, k = 1, 2, 3$). Any $SU(2)$ doublet $R^{(2)}$ transforms as $R^{(2)} \rightarrow U^{(2)}(\vec{\theta})R^{(2)}$, where $U^{(2)}(\vec{\theta}) = \exp(i\vec{\theta} \cdot t^{(2)})$ and $\vec{\theta} = (\theta_1, \theta_2, \theta_3)$ is the transformation angle vector. It is popular to represent the triplet by a bi-doublet, and the 3-dimensional representation is less discussed in the literature. Equivalently, one can also construct the $SU(2)$ invariants intuitively using the 3-dimensional representation. This is the notation adopted in this paper, and we think it might be useful to collect some facts here for the reader.

It can be checked the following 3-dimensional representation,

$$t_1^{(3)} = \frac{1}{\sqrt{2}} \begin{pmatrix} 0 & 1 & 0 \\ 1 & 0 & 1 \\ 0 & 1 & 0 \end{pmatrix}, \quad t_2^{(3)} = \frac{1}{\sqrt{2}} \begin{pmatrix} 0 & -i & 0 \\ i & 0 & -i \\ 0 & i & 0 \end{pmatrix}, \quad t_3^{(3)} = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & -1 \end{pmatrix}, \quad (\text{A1})$$

also satisfy the algebra $[t_i^{(3)}, t_j^{(3)}] = i\epsilon_{ijk}t_k^{(3)}$, and serve as the group generators. Therefore, any $SU(2)$ triplet $R^{(3)}$ transforms as $R^{(3)} \rightarrow U^{(3)}(\vec{\theta})R^{(3)}$, where $U^{(3)}(\vec{\theta}) = \exp(i\vec{\theta} \cdot t^{(3)})$. Because $U^{(3)}(\vec{\theta})$ is unitary, $(R^{(3)})^\dagger \cdot R^{(3)}$ is $SU(2)$ invariant. For two given $SU(2)$ doublet $R_1^{(2)} = \begin{pmatrix} u_1 \\ d_1 \end{pmatrix}$ and $R_2^{(2)} = \begin{pmatrix} u_2 \\ d_2 \end{pmatrix}$, it can be shown that $\{R_1^{(2)}, R_2^{(2)}\} \equiv (u_1u_2, (u_1d_2 + u_2d_1)/\sqrt{2}, d_1d_2)^T$ is a triplet which transforms according to $U^{(3)}(\vec{\theta})$, and $[R_1^{(2)}, R_2^{(2)}] \equiv (u_1d_2 - u_2d_1)/\sqrt{2}$ is a singlet.

In order to construct an $SU(2)$ singlet from any two $SU(2)$ triplets, $R_1^{(3)}$ and $R_2^{(3)}$, we define

$$t_4^{(3)} = \begin{pmatrix} 0 & 0 & 1 \\ 0 & -1 & 0 \\ 1 & 0 & 0 \end{pmatrix}, \quad \text{and} \quad (t_4^{(3)})^2 = 1. \quad (\text{A2})$$

It is easy to verify that

$$t_4^{(3)}t_j^{(3)} = (-)^j t_j^{(3)}t_4^{(3)} \quad (j = 1, 2, 3). \quad (\text{A3})$$

Therefore,

$$t_4^{(3)} (t_i^{(3)})^* t_4^{(3)} = -t_i^{(3)}, \quad t_4^{(3)} (t_i^{(3)})^T t_4^{(3)} = -t_i^{(3)}. \quad (\text{A4})$$

One can prove that

$$R_1^{(3)} \odot R_2^{(3)} \equiv (R_1^{(3)})^T \cdot t_4^{(3)} \cdot R_2^{(3)} \quad (\text{A5})$$

is an $SU(2)$ singlet.

Finally, similar to $\widetilde{R^{(2)}} \equiv i\sigma_2(R^{(2)})^*$ in the doublet cases, the object

$$\widetilde{R^{(3)}} \equiv t_4^{(3)}(R^{(3)})^* \quad (\text{A6})$$

transforms as a triplet but it carries the opposite $U(1)$ charge(s) of $R^{(3)}$.

Appendix B: low energy effective Hamiltonian

After the electroweak SSB and the mass diagonalization, see Sec., the leptoquark coupling matrix λ 's are in the charged fermion mass basis. The relevant lagrangian is:

$$\begin{aligned} \mathcal{L} \supset & -\lambda_T \left[\bar{\nu}^c u_L T^{-\frac{2}{3}} + (\bar{\nu}^c d_L + \bar{e}^c u_L) \frac{T^{\frac{1}{3}}}{\sqrt{2}} + \bar{e}^c d_L T^{\frac{4}{3}} \right] - \lambda_D \frac{\bar{d}_R}{\sqrt{2}} \left(\nu_L D^{-\frac{1}{3}} - e_L D^{\frac{2}{3}} \right) \\ & - \lambda_S \bar{e}_R d_L S^{-\frac{2}{3}} - \frac{\mu_3 v_0}{2} D^{\frac{1}{3}} T^{-\frac{1}{3}} - \frac{\mu_3 v_0}{\sqrt{2}} D^{-\frac{2}{3}} T^{\frac{2}{3}} - \frac{\mu_1 v_0}{2} D^{\frac{2}{3}} S^{-\frac{2}{3}} + H.c. \end{aligned} \quad (B1)$$

In the above expression, the fields should be understood as the vectors in the flavor space: $u = \tilde{V}^\dagger \cdot (u, c, t)^T$, $d = (d, s, b, b')^T$, $e = (e, \mu, \tau)^T$, and $\nu = (\nu_e, \nu_\mu, \nu_\tau)^T$.

If the mixings among the leptoquarks are small, it can be treated by the triple scalar interaction vertices to the leading approximation. Moreover, masses are nearly degenerated within the leptoquark $SU(2)$ multiplets. After integrating out the heavy leptoquarks, we arrive the following low energy effective Hamiltonian:

$$\begin{aligned} \mathcal{H}_{eff} \simeq & -\frac{1}{M_T^2} \lambda_T \lambda_T^\dagger \left[(\bar{\nu}^c u_L)(\bar{u}_L \nu^c) + \frac{1}{2} (\bar{\nu}^c d_L + \bar{e}^c u_L)(\bar{d}_L \nu^c + \bar{u}_L e^c) + (\bar{e}^c d_L)(\bar{d}_L e^c) \right] \\ & - \frac{1}{2M_D^2} \lambda_D \lambda_D^\dagger \left[(\bar{d}_R \nu_L)(\bar{\nu}_L d_R) + (\bar{d}_R e_L)(\bar{e}_L d_R) \right] - \frac{1}{M_S^2} \lambda_S \lambda_S^\dagger (\bar{e}_R d_L)(\bar{d}_L e_R) \\ & - \left\{ \frac{\mu_1 v_0}{2\sqrt{2}M_S^2 M_D^2} \lambda_S \lambda_D (\bar{e}_R d_L)(\bar{d}_R e_L) + H.c. \right\} \\ & - \left\{ \frac{\mu_3 v_0}{2M_T^2 M_D^2} \lambda_T \lambda_D \left[(\bar{\nu}^c u_L)(\bar{d}_R e_L) - \frac{1}{2} (\bar{\nu}^c d_L + \bar{e}^c u_L)(\bar{d}_R \nu_L) \right] + H.c. \right\} \end{aligned} \quad (B2)$$

After performing the Fierz transformation and applying the identities associated with charge conjugation, the effective Hamiltonian takes a more familiar form:

$$\begin{aligned} \mathcal{H}_{eff} \simeq & -\frac{1}{2M_T^2} \lambda_T \lambda_T^\dagger \left[(\bar{u} \gamma^\alpha \hat{L} u) \left(\bar{\nu} \gamma_\alpha \hat{L} \nu + \frac{1}{2} \bar{e} \gamma_\alpha \hat{L} e \right) + (\bar{d} \gamma^\alpha \hat{L} d) \left(\bar{e} \gamma_\alpha \hat{L} e + \frac{1}{2} \bar{\nu} \gamma_\alpha \hat{L} \nu \right) \right] \\ & - \frac{1}{4M_T^2} \lambda_T \lambda_T^\dagger \left[(\bar{u} \gamma^\alpha \hat{L} d)(\bar{e} \gamma_\alpha \hat{L} \nu) + (\bar{d} \gamma^\alpha \hat{L} u)(\bar{\nu} \gamma_\alpha \hat{L} e) \right] \\ & + \frac{1}{4M_D^2} \lambda_D \lambda_D^\dagger \left[(\bar{d} \gamma^\alpha \hat{R} d)(\bar{\nu} \gamma_\alpha \hat{L} \nu + \bar{e} \gamma_\alpha \hat{L} e) \right] + \frac{1}{2M_S^2} \lambda_S \lambda_S^\dagger (\bar{d} \gamma^\alpha \hat{L} d)(\bar{e} \gamma_\alpha \hat{R} e) \\ & + \left\{ \frac{\mu_1 v_0}{4\sqrt{2}M_S^2 M_D^2} \lambda_S \lambda_D \left[(\bar{d} \hat{L} d)(\bar{e} \hat{L} e) + \frac{1}{4} (\bar{d} \sigma^{\alpha\beta} \hat{L} d)(\bar{e} \sigma_{\alpha\beta} \hat{L} e) \right] + H.c. \right\} \\ & + \left\{ \frac{\mu_3 v_0}{4M_T^2 M_D^2} \lambda_T \lambda_D \left[(\bar{d} \hat{L} u)(\bar{\nu}^c \hat{L} e) - (\bar{d} \hat{L} d)(\bar{\nu}^c \hat{L} \nu) \right] + H.c. \right\} \\ & + \left\{ \frac{\mu_3 v_0}{32M_T^2 M_D^2} \lambda_T \lambda_D \left[3(\bar{d} \sigma^{\alpha\beta} \hat{L} u)(\bar{\nu}^c \sigma_{\alpha\beta} \hat{L} e) - (\bar{d} \sigma^{\alpha\beta} \hat{L} d)(\bar{\nu}^c \sigma_{\alpha\beta} \hat{L} \nu) \right] + H.c. \right\} \end{aligned} \quad (B3)$$

where $\hat{L} = (1 - \gamma^5)/2$ and $\hat{R} = (1 + \gamma^5)/2$. From the last three terms in the above, it is clear that: (1) the $SU(2)$ symmetry is broken after the electroweak SSB, (2) the mixing of leptoquarks with different lepton number breaks the global lepton number, as has been discussed in Sec.II.

So far, we have suppressed the flavor indices to avoid the unnecessary notational burden, but it is easy to trace and put them back in when needed. For example, the effective Hamiltonian generated by the pair of triplet Yukawa couplings, λ_{id}^T and λ_{jD}^T , is given by

$$\begin{aligned} \mathcal{H}_{eff} \supset & -\frac{\lambda_{id}^T(\lambda_{jD}^T)^*}{2M_T^2} \sum_{u,U=u,c,t} \left[\left(\bar{D}\gamma^\alpha \hat{L}d \right) \left(\bar{e}_j\gamma_\alpha \hat{L}e_i + \frac{1}{2}\bar{\nu}_j\gamma_\alpha \hat{L}\nu_i \right) \right. \\ & + \frac{1}{2}\tilde{V}_{UD} \left(\bar{U}\gamma^\alpha \hat{L}d \right) \left(\bar{e}_j\gamma_\alpha \hat{L}\nu_i \right) + \frac{1}{2}\tilde{V}_{ud}^* \left(\bar{D}\gamma^\alpha \hat{L}u \right) \left(\bar{\nu}_j\gamma_\alpha \hat{L}e_i \right) \\ & \left. + \tilde{V}_{ud}^*\tilde{V}_{UD} \left(\bar{U}\gamma^\alpha \hat{L}u \right) \left(\bar{\nu}_j\gamma_\alpha \hat{L}\nu_i + \frac{1}{2}\bar{e}_j\gamma_\alpha \hat{L}e_i \right) \right] + H.c. \end{aligned} \quad (B4)$$
