Glued magic games self-test maximally entangled states

Laura Mančinska, Thor Gabelgaard Nielsen, and Jitendra Prakash

25th May 2021

Abstract

Self-testing results allow us to infer the underlying quantum mechanical description of states and measurements from classical outputs produced by non-communicating parties. The standard definition of self-testing does not apply in situations when there are two or more inequivalent optimal strategies. To address this, we introduce the notion of self-testing convex combinations of reference strategies, which is a generalisation of self-testing to multiple strategies. We show that the Glued Magic Square game \cite{Cui+20} self-tests a convex combination of two inequivalent strategies. As a corollary, we obtain that the Glued Magic square game self-tests two EPR pairs thus answering an open question from \cite{Cui+20}. Our self-test is robust and extends to natural generalisations of the Glued Magic Square game.

1 Introduction

In this paper, we consider the Glued Magic Square game which was originally constructed in \cite{Cui+20} by building upon the Mermin-Peres Magic Square game \cite{Mer90,Per90}. The authors of \cite{Cui+20} exhibit two inequivalent perfect quantum strategies for the Glued Magic Square game, thus showing that the game does not self-test any quantum strategy. As noted there, the two inequivalent quantum strategies still use equivalent states – which is in fact unavoidable as we show that the Glued Magic Square game self-tests the maximally entangled state of local dimension four (Corollary 3.6). Furthermore we completely characterise the possible optimal strategies, but the usual self-testing definition is clearly insufficient, so we present a generalisation which allows us to self-test a convex combination of strategies. It should be noted that variations in the definition of self-testing has already appeared in the literature.

The Magic Pentagram game introduced by Mermin \cite{Mer90} is very similar to the Magic Square game. It is then natural to consider replacing either one or both Magic Square parts in the Glued Magic Square game by Magic Pentagrams. While a construction similar to that of \cite{Cui+20} still shows that these games do not self-test the measurements in any of their perfect quantum strategies, our arguments for the Glued Magic Square still goes through.

1.1 Organisation of this paper

In this first section we have briefly introduced the motivation for the Glued Magic Square game, and introduce the notation we will use in the rest of this paper. In Section 2, we formally define the nonlocal games we will consider including Glued Magic games, along with the relevant self-testing tools. In Section 3, we build up our some tools for proving self-testing and prove our main result. Furthermore we give examples of possible strategies for the Glued Magic Square game. In Section A.2 we sketch how to translate our results into the robust case.
1.2 Notation

For a natural number $n$, we write $[n] := \{1, \ldots, n\}$. A quantum state (or simply a state) is a unit vector in some Hilbert space. Every state $|\psi\rangle \in \mathcal{H}_A \otimes \mathcal{H}_B$ admits a Schmidt decomposition:

$$|\psi\rangle = \sum_{i} \lambda_i |v_i\rangle |w_i\rangle$$

where $\lambda_i > 0$ for all $i$, and $\{|v_i\rangle\}$ and $\{|w_i\rangle\}$ are orthonormal sets in $\mathcal{H}_A$ and $\mathcal{H}_B$, respectively. We write $\text{supp}_A |\psi\rangle$ for the subspace $\text{span}_i\{|v_i\rangle\} \subseteq \mathcal{H}_A$, and similarly $\text{supp}_B |\psi\rangle := \text{span}_i\{|w_i\rangle\} \subseteq \mathcal{H}_B$. We will also use $\text{supp} |\psi\rangle := \text{span}_i\{|v_i\rangle |w_i\rangle\} \subseteq \mathcal{H}_A \otimes \mathcal{H}_B$. We say that $|\psi\rangle$ is of full Schmidt rank if $\text{supp}_A |\psi\rangle = \mathcal{H}_A$ and $\text{supp}_B |\psi\rangle = \mathcal{H}_B$. For a natural number $k \geq 2$, we will write

$$|\psi_k\rangle := \frac{1}{\sqrt{k}} \sum_{i=0}^{k-1} |ii\rangle$$

for the maximally entangled state of local dimension $k$. By an observable, we mean a self-adjoint unitary operator. Given an observable $A \in \mathcal{B}(\mathcal{H})$ we have the spectral decomposition $A = A^+ - A^-$, where the projection onto the $+1$-eigenspace (resp., $-1$-eigenspace) of $A$ is denoted by $A^+$ (resp., $A^-$). The commutator of two operators $A, B \in \mathcal{B}(\mathcal{H})$ is denoted by $[A, B] := AB - BA$. Let $\mathbb{Z}/d\mathbb{Z} := \{0, 1, \ldots, d-1\}$ denote the ring of integers modulo $d$ for a natural number $d$.

Suppose $\mathcal{H}$ has $n$ mutually orthogonal subspaces $\mathcal{H}_1, \ldots, \mathcal{H}_n$. If for every $|v\rangle \in \mathcal{H}$ there exists a unique $|v_k\rangle \in \mathcal{H}_k$ such that $|v\rangle = \sum_{k=1}^{n} |v_k\rangle$, then $\mathcal{H}$ is a direct sum of the subspaces, and we write $\mathcal{H} = \bigoplus_{k=1}^{n} \mathcal{H}_k$. Unless stated otherwise, any direct sum of Hilbert spaces appearing in this paper will be an internal direct sum. Furthermore, suppose $A_k : \mathcal{H}_k \to \mathcal{K}_k$ is a bounded operator for each $k \in [n]$, and let $\mathcal{K} = \bigoplus_{k=1}^{n} \mathcal{K}_k$ be the external direct sum. By writing $\bigoplus_{k=1}^{n} A_k$, we mean the operator $A : \mathcal{H} \to \mathcal{K}$ acting on a vector $|v\rangle = \sum_{k=1}^{n} |v_k\rangle$, where $|v_k\rangle \in \mathcal{H}_k$ for each $k$, by

$$\left( \bigoplus_{k=1}^{n} A_k \right) |v\rangle = \bigoplus_{k=1}^{n} A_k |v_k\rangle = (A_1 |v_1\rangle, A_2 |v_2\rangle, \ldots, A_n |v_n\rangle). \quad (1.1)$$

We will often identify spaces consisting of tuples of vectors with other isomorphic Hilbert spaces, e.g., $\mathbb{C}^2 \times \mathbb{C}^2 \cong \mathbb{C}^4$.

2 Preliminaries

Definition 2.1 (Nonlocal game). A nonlocal game is a tuple $G = (X, Y, A, B, V, \pi)$, where $X, Y, A$ and $B$ are nonempty finite sets corresponding to the possible questions and answers for each prover, $V : X \times Y \times A \times B \to \{0, 1\}$ is a predicate which we refer to as the verification function, and $\pi$ is a probability distribution over $X \times Y$.

A nonlocal game $G = (X, Y, A, B, V, \pi)$ is played by a referee and two provers (which we will denote by Alice and Bob). It proceeds by the referee choosing at random some pair of questions $(x, y) \in X \times Y$ according to the probability distribution $\pi$ and then sending $x$ to Alice and $y$ to Bob. Alice and Bob, who are not allowed to communicate in any way after they receive the questions, must then each choose an answer to send back, and upon receiving $a \in A$ from Alice and $b \in B$ from Bob, the referee evaluates $V(x, y, a, b)$ to determine whether the provers win. The provers win if $V(x, y, a, b) = 1$, otherwise they lose.

We are interested in a particular subclass of nonlocal games, namely those based upon a system of linear constraints, and aptly called linear constraint system games. Such games have been studied in depth [CM14]. Suppose we have a system of $n$ linear equations over $\mathbb{Z}/d\mathbb{Z}$ in $k$ variables. A natural question in this regard is whether the given system of equations is satisfiable, and this is easy to determine classically. This can also be done by constructing a nonlocal game where Alice is given an equation and has to fill in all the variables, while Bob is given a single variable which he is asked to fill in. The provers then win if and only if Alice’s...
assignment satisfies the equation given to her and Bob’s assignment to his variable is consistent with Alice’s assignment. Formally, a linear constraint system game is defined as follows.

**Definition 2.2** (Linear constraint system game). Let \( n, k, d \in \mathbb{N} \), and consider a system of \( n \) linear equations in \( k \) variables \( e_1, \ldots, e_k \) over \( \mathbb{Z}/d\mathbb{Z} \) given by

\[
\sum_{j=1}^{k} \alpha_{i,j} e_j = \beta_i, \quad i \in [n],
\]  

(2.1)

where \( \alpha_{i,j}, \beta_i \in \mathbb{Z}/d\mathbb{Z} \) for all \( i \in [n] \) and \( j \in [k] \). The linear constraint system game (LCS game) corresponding to the system of linear equations in (2.1) is a nonlocal game with question sets \( X = [n], Y = [k] \), and answer sets \( A = (\mathbb{Z}/d\mathbb{Z})^k, B = \mathbb{Z}/d\mathbb{Z} \). The probability distribution \( \pi \) is the uniform distribution over the set \( \{(x, y) \in X \times Y \mid \alpha_{x,y} \neq 0\} \), and the verification function is

\[
V(x, y, a, b) = \begin{cases} 
1 & \text{if } \sum_{j=1}^{k} \alpha_{x,j} a_j = \beta_x \text{ and } a_y = b, \\
0 & \text{otherwise}.
\end{cases}
\]

Furthermore, if \( d = 2 \), then the game is called a binary linear constraint system game.

Quantum strategies for nonlocal games are usually described by a state shared by Alice and Bob, and sets of measurement operators for both players which may be assumed to be projective. Equivalently, quantum strategies can be described in terms of unitaries which for our purposes will be more convenient. Furthermore, all the LCS games we consider are over \( \mathbb{Z}/2\mathbb{Z} \), so observables will be sufficient.

**Definition 2.3** (Quantum strategy of observables). Suppose \( G = (X, Y, A, B, V, \pi) \) is a binary LCS game. A quantum strategy of observables (or simply a quantum strategy) is a 3-tuple:

\[
S = \left( |\psi\rangle \in \mathcal{H}_A \otimes \mathcal{H}_B, \left\{ A^{(x)}_i : i \in A \right\}_{x \in X}, \left\{ B_j \right\}_{j \in B} \right),
\]

(2.2)

where \( \mathcal{H}_A \) and \( \mathcal{H}_B \) are (possibly infinite dimensional) Hilbert spaces, \( A^{(x)}_i \in \mathcal{B}(\mathcal{H}_A) \) and \( B_j \in \mathcal{B}(\mathcal{H}_B) \) are observables, and \( |\psi\rangle \) is a state. For question \( x \in X \), Alice successively uses \( A^{(x)}_1, \ldots, A^{(x)}_n \) to assign values to each variable, while Bob only uses \( B_j \) to determine his answer. Note that we associate projection onto the +1-eigenspace (resp., -1-eigenspace) with answer 0 (resp., answer 1).

We will be using the term “perfect strategy” for any strategy which wins a nonlocal game with probability 1. Furthermore, we will be using the term “pseudo-telepathic nonlocal game” to refer to a nonlocal game with a perfect quantum strategy but no perfect classical strategies. Observe that it does not refer to the games which do not have any perfect quantum strategy but a limit of quantum strategies wins the game with probability 1.

Observe that for a given quantum strategy as in Expression (2.2), it is not necessarily the case that Alice uses the same observables to assign values to the same variable within different equations she may be asked. That is, \( A^{(x)}_i \neq A^{(x')}_{i'} \) may be possible for \( x \neq x' \). However, as shown in [CM14], if a quantum strategy is perfect for some binary LCS game, then one can show that equality holds in the previous inequality. Moreover, we recall the following theorem.

**Theorem 2.4.** [CM14] Let \( G = (X, Y, A, B, V, \pi) \) be a binary LCS game and let \( S \) as given in Expression (2.2) be a perfect quantum strategy for the game. If \( |\psi\rangle \) is of full Schmidt rank, then

1. \( A^{(x)}_i = A^{(x')}_{i'} \) for all \( x, x' \in X \). By this token, we set \( A_i := A^{(x)}_i = A^{(x')}_{i'} \) for all \( i \in Y \).
2. If variables \( e_i \) and \( e_j \) appear in the same equation, then \( A_i \) and \( A_j \) (resp., \( B_i \) and \( B_j \)) commute.
3. The observables \( \{A_i\}_{i \in Y} \) (resp., \( \{B_j\}_{j \in Y} \)) satisfy the linear equations when written in multiplicative form: 
\[
e_{1}^{α_1} \ldots e_{k}^{α_k} = (-1)^{b_x} \text{ for all } x \in X.
\]

As noted in [CM14], a system of linear constraints is satisfiable if and only if the corresponding nonlocal game can be won perfectly with some classical strategy. Therefore, insatisfiable systems of linear constraints will be of particular importance, as they may have a strictly better quantum strategy. It turns out that some of these even have perfect quantum strategies, a canonical example of which is the Magic Square game.

**Definition 2.5** (Magic Square game). The **Magic Square game** is the LCS game associated with the following system of equations over \( \mathbb{Z}/2\mathbb{Z} \):

\[
\begin{align*}
e_1 + e_2 + e_3 &= 0 \\
e_4 + e_5 + e_6 &= 0 \\
e_7 + e_8 + e_9 &= 0
\end{align*}
\]

It is also possible to visualize the system of equations in (2.3) as a graph – Figure 1a – from which the name derives.

The Magic Pentagram game, which shares many properties with the Magic Square game, can be described by Figure 1b, from which the relevant equations (over \( \mathbb{Z}/2\mathbb{Z} \)) can be readily derived.

This now brings us to the main type of games we will be considering, namely **glued games**, which are straightforward generalisations of the Glued Magic Square game considered in [Cui+20].

**Definition 2.6** (Glued games). Suppose \( G \) is a binary LCS game in the variables \( e_1, \ldots, e_k \) and \( H \) is a binary LCS game in the variables \( e_{k+1}, \ldots, e_{k+\ell} \). Suppose furthermore they each have exactly one equation in which the variables sum to 1. The **glued game** corresponding to these two games is the binary LCS game in the variables \( e_1, \ldots, e_{k+\ell} \) whose equations are the union of all equations in \( G \) and \( H \), except for the two equations having variables sum up to 1 – which we replace by a single equation by adding their left-hand sides and equating it to 1.

The main example of such a game is the Glued Magic Square game which is the gluing of the Magic Square game with itself. The resulting game is illustrated in Figure 2. Gluing the Magic Square together with another Magic Square, or a Magic Pentagram, yields a pseudo-telepathy game, as one possible perfect quantum strategy is to use a perfect quantum strategy for the Magic Square game on the Magic Square part, and use the identity operators on the other part (for example, see Section 9 of [Cui+20]). Similarly, gluing together the Magic Pentagram with itself yields a pseudo-telepathy game.
Figure 2: A visualisation of the Glued Magic Square game, a LCS game with 18 variables. In rows and columns, a solid line indicates that the variables of that row or column multiply to +1, while a dashed line indicates that the product instead should be −1.

We now formally introduce the notion of self-testing. We recall the definition of a local dilation from [MPS21].

**Definition 2.7 (Local dilation).** Suppose $S = (|\psi\rangle \in \mathcal{H}_A \otimes \mathcal{H}_B, \{A_i\}, \{B_j\})$ and $\tilde{S} = (|\tilde{\psi}\rangle \in \tilde{\mathcal{H}}_A \otimes \tilde{\mathcal{H}}_B, \{\tilde{A}_i\}, \{\tilde{B}_j\})$ are two quantum strategies having the same number of observables for each party. We say that $\tilde{S}$ is a local dilation of $S$ if there exist Hilbert spaces $\mathcal{H}_A, \mathcal{H}_B, \mathcal{H}_A, \text{aux}$ and $\mathcal{H}_B, \mathcal{H}_B, \text{aux}$, a state $|\text{aux}\rangle \in \mathcal{H}_A, \text{aux} \otimes \mathcal{H}_B, \text{aux}$ and isometries $U_A : \mathcal{H}_A \to \tilde{\mathcal{H}}_A \otimes \mathcal{H}_A, \text{aux}$ and $U_B : \mathcal{H}_A \to \tilde{\mathcal{H}}_B \otimes \mathcal{H}_B, \text{aux}$ such that with $U := U_A \otimes U_B$ it holds that for all $i$ and $j$,

$$U |\psi\rangle = |\tilde{\psi}\rangle \otimes |\text{aux}\rangle,$$

$$U (A_i \otimes I) |\psi\rangle = (\tilde{A}_i \otimes I) |\tilde{\psi}\rangle \otimes |\text{aux}\rangle,$$

$$U (I \otimes B_j) |\psi\rangle = (I \otimes \tilde{B}_j) |\tilde{\psi}\rangle \otimes |\text{aux}\rangle.$$  \hfill (2.4)

**Definition 2.8 (Self-testing).** A nonlocal game $G = (X, Y, A, B, V, \pi)$ is a self-test for a quantum strategy (which we term ideal or canonical) $\tilde{S}$, if for any quantum strategy $S$ achieving the quantum value of $G$, the strategy $\tilde{S}$ is a local dilation of $S$. If only Equation (2.4) is satisfied, we say that the game $G$ self-tests the state.

We remark that in some cases it is also possible to show that the self-testing is robust, i.e., for all strategies close to optimal, the measurements and state used will also be close to an optimal one in a certain sense, though this is beyond the scope of the main text of this paper.

It turns out that self-testing holds for both the Magic Square and the Magic Pentagram games. We will state a very simplified version of the results – it should be noted that both games in fact robustly self-test their ideal quantum strategies.

**Theorem 2.9 (Self-testing of Magic Square, [WBMS16]).** The Magic Square game self-tests its ideal strategy $S_{MS}$ which consists of nine observables for each party along with the state $|\psi_4\rangle = \frac{1}{2} \sum_{i=0}^3 |ii\rangle$.

**Theorem 2.10 (Self-testing of Magic Pentagram, [KM17]).** The Magic Pentagram game self-tests its ideal strategy $S_{MP}$ which consists of ten observables for each party along with the state $|\psi_8\rangle = \frac{1}{\sqrt{8}} \sum_{i=0}^7 |ii\rangle$.

Later in the paper, we will be working with several different perfect quantum strategies for the same game, and therefore, to be able to completely characterise its perfect quantum strategies, we will need to discuss convex combinations of quantum strategies.
Definition 2.11 (Convex combination of quantum strategies). For each \( k \in [n] \), let

\[
S_k = \left( |\psi^{(k)}\rangle, \{A_i^{(k)}\}_i, \{B_j^{(k)}\}_j \right)
\]

be a quantum strategy for some nonlocal game \( G \), and \( \{\alpha_k\}_{k=1}^n \subseteq [0,1] \) a set of scalars satisfying \( \sum_{k=1}^n \alpha_k^2 = 1 \). The corresponding convex combination is the quantum strategy

\[
S := \sum_{k=1}^n \alpha_k S_k := \left( |\psi\rangle, \{A_i\}_i, \{B_j\}_j \right),
\]

where the state and the observables are given by

\[
|\psi\rangle = \bigoplus_{k=1}^n \alpha_k |\psi^{(k)}\rangle, \quad A_i = \bigoplus_{k=1}^n A_i^{(k)}, \quad B_j = \bigoplus_{k=1}^n B_j^{(k)}.
\]

Observe that the direct sums appearing here can be interpreted in two different ways. Either one can consider the external direct sum, where one forms a new Hilbert space consisting of ordered tuples of elements from each of the original spaces. In this case, we will refer to the convex combination as an external convex combination. Another possible interpretation is that each of the strategies \( S_k \) lives in some subspace of some larger Hilbert space, and the direct sums are therefore the internal direct sum. In this case we refer to the convex combination as an internal convex combination.

Note that the direct sum of states appearing in the definition above is actually a direct sum of tensor product spaces, and for \(|\psi^k\rangle \in \mathcal{H}_A^k \otimes \mathcal{H}_B^k\), the resulting state is thus \(|\psi\rangle \in \bigoplus_{k,\ell=1}^n (\mathcal{H}_A^k \otimes \mathcal{H}_B^\ell)\), which is orthogonal to \( \mathcal{H}_A^k \otimes \mathcal{H}_B^\ell \) for \( k \neq \ell \) (in the sense that projecting the state onto each of these subspaces yields the zero vector). As an example with the external direct sum, it holds that \( \frac{\sqrt{2}}{\sqrt{3}} |\psi_2\rangle + \frac{\sqrt{2}}{\sqrt{3}} |\psi_3\rangle = |\psi_5\rangle \).

At first it might not be clear why we distinguish between internal and external direct sums, as they are isomorphic. However, internal direct sums have a desirable property that they are stable under unitaries, i.e., if one fixes some strategy for some game which decomposes into an internal direct sum, then applying a unitary to that strategy yields a strategy which again decomposes into an internal direct sum. However, that is not the case for external direct sums.

With the notion of a convex combination of quantum strategies in hand, we are ready to generalize the usual definition of self-testing given above by introducing the notion of convex self-testing where we allow multiple inequivalent optimal quantum strategies.

Definition 2.12 (Convex self-testing). A nonlocal game \( G = (X, Y, A, B, V, \pi) \) is a convex self-test for the ideal quantum strategies \( \tilde{S}_1, \ldots, \tilde{S}_n \), if for any quantum strategy \( S \) achieving the quantum value of \( G \), there exist coefficients \( \{\alpha_k\}_{k=1}^n \subseteq [0,1] \) and a decomposition of \( S \) into an internal convex combination \( S = \sum_{k=1}^n \alpha_k \tilde{S}_k \) such that each \( \tilde{S}_k \) is a local dilation of \( S_k \).

At first glance, while this appears to be quite different from the usual definition of self-testing, that is not the case, as we can rewrite it with more familiar conditions.

Lemma 2.13. Let \( G \) be a nonlocal game and let \( \tilde{S}_k = \left( |\tilde{\psi}^{(k)}\rangle \in \tilde{\mathcal{H}}_A^k \otimes \tilde{\mathcal{H}}_B^k, \{\tilde{A}_i^{(k)}\}_i, \{\tilde{B}_j^{(k)}\}_j \right) \) be optimal quantum strategies for the game for each \( k \in [n] \). Then the following are equivalent.

1. The game \( G \) is a convex self-test for \( \tilde{S}_1, \ldots, \tilde{S}_n \).

2. Let \( S = (|\psi\rangle \in \mathcal{H}_A \otimes \mathcal{H}_B, \{A_i\}_i, \{B_j\}_j) \) be an optimal quantum strategy of \( G \). Then for each \( k \in [n] \), there exist Hilbert spaces \( \mathcal{H}_{A,aux}^k, \mathcal{H}_{B,aux}^k \), states \( |aux_k\rangle \in \mathcal{H}_{A,aux}^k \otimes \mathcal{H}_{B,aux}^k \),
and isometries \( U_A : \mathcal{H}_A \to \bigoplus_{k=1}^n (\tilde{\mathcal{H}}_A^k \otimes \mathcal{H}_{A,aux}^k) \), \( U_B : \mathcal{H}_B \to \bigoplus_{k=1}^n (\tilde{\mathcal{H}}_B^k \otimes \mathcal{H}_{B,aux}^k) \) such that defining \( U := U_A \otimes U_B \), it holds that:

\[
U |\psi\rangle = \bigoplus_{k=1}^n (\alpha_k |\tilde{\psi}^{(k)}\rangle \otimes |aux_k\rangle), \tag{2.6}
\]

\[
U (A_i \otimes I) |\psi\rangle = \bigoplus_{k=1}^n (\alpha_k (A_i \otimes I) |\tilde{\psi}^{(k)}\rangle \otimes |aux_k\rangle), \tag{2.7}
\]

\[
U (I \otimes B_j) |\psi\rangle = \bigoplus_{k=1}^n (\alpha_k (I \otimes \tilde{B}_j) |\tilde{\psi}^{(k)}\rangle \otimes |aux_k\rangle), \tag{2.8}
\]

**Proof.** First we assume that (1) holds. Let \( S \) be an optimal quantum strategy for the game as in (2). By Definition 2.12 there exist scalars \( \{\alpha_k\}_{k=1}^n \subseteq [0,1] \) such that \( S = \sum_{k=1}^n \alpha_k S_k \), where \( S_k = (|\psi^{(k)}\rangle \in \mathcal{H}_A^k \otimes \mathcal{H}_B^k, \{A_i^{(k)}\}_i, \{B_j^{(k)}\}_j) \), and that for each \( k \in [n] \), \( \tilde{S}_k \) is a local dilation of \( S_k \). By Definition 2.7 there exist isometries \( U_A^{(k)} : \mathcal{H}_A \to \tilde{\mathcal{H}}_A^k \otimes \mathcal{H}_{A,aux}^k \) and \( U_B^{(k)} : \mathcal{H}_B \to \tilde{\mathcal{H}}_B^k \otimes \mathcal{H}_{B,aux}^k \) and an auxiliary state \( |aux_k\rangle \in \mathcal{H}_{A,aux}^k \otimes \mathcal{H}_{B,aux}^k \) such that the equations in Definition 2.7 hold.

Define \( U_A := \bigoplus_{k=1}^n U_A^{(k)} \) and similarly \( U_B := \bigoplus_{k=1}^n U_B^{(k)} \). Observe that while these are defined as the direct sum of operators, this is done as described in Equation (1.1), so assuming all of the operators are finite-dimensional, the matrix representations of \( U_A \) and \( U_B \) are not necessarily block-diagonal.

Now we find that

\[
(U_A \otimes U_B) |\psi\rangle = \bigoplus_{\ell,m=1}^n (U_A^{(\ell)} \otimes U_B^{(m)}) \left( \bigoplus_{k=1}^n (\alpha_k |\psi^{(k)}\rangle) \right)
\]

\[
= \bigoplus_{\ell,m=1}^n (U_A^{(\ell)} \otimes U_B^{(m)}) \left( \bigoplus_{k=1}^n (\alpha_k |\tilde{\psi}^{(k)}\rangle) \right)
\]

\[
= \bigoplus_{k=1}^n (\alpha_k (U_A^{(k)} \otimes U_B^{(k)}) |\psi^{(k)}\rangle)
\]

\[
= \bigoplus_{k=1}^n (\alpha_k |\tilde{\psi}^{(k)}\rangle \otimes |aux_k\rangle), \tag{2.9}
\]

where we in the third equality used that \( |\psi^{(k)}\rangle \in \mathcal{H}_A^k \otimes \mathcal{H}_B^k \) for all \( k \in [n] \).

A similar computation reveals that

\[
(U_A \otimes U_B)(A_i \otimes I) |\psi\rangle = \bigoplus_{k=1}^n (\alpha_k (A_i^{(k)} \otimes I) |\tilde{\psi}^{(k)}\rangle \otimes |aux_k\rangle), \tag{2.10}
\]

\[
(U_A \otimes U_B)(I \otimes B_j) |\psi\rangle = \bigoplus_{k=1}^n (\alpha_k (I \otimes \tilde{B}_j^{(k)}) |\tilde{\psi}^{(k)}\rangle \otimes |aux_k\rangle). \tag{2.11}
\]

While these equations are much closer to those usually found in self-testing statements, there is a crucial difference (apart from the direct sum): In the usual self-testing statements there is a single auxiliary state, but here one appears for each substrategy, and in general they can be different and thus cannot be factored out from the expression above.

We now show the converse; namely that if (2) holds (with the direct sums assumed to be internal direct sums), then so does (1). Note that we need only show that we can decompose the original strategy into \( n \) orthogonal substrategies. For each \( k \in [n] \) define \( \mathcal{H}_A^k := \text{supp}_A \left( U_A \left( |\tilde{\psi}^{(k)}\rangle \otimes |aux_k\rangle \right) \right) \) and similarly \( \mathcal{H}_B^k := \text{supp}_B \left( U_B \left( |\tilde{\psi}^{(k)}\rangle \otimes |aux_k\rangle \right) \right) \). Observe
that we need only show that $\mathcal{H}_A^k \perp \mathcal{H}_A^\ell$ for all $k \neq \ell$ to show that $\mathcal{H}_A = \bigoplus_{k=1}^n \mathcal{H}_A^k$, and from that it follows that Definition 2.12 holds.

Note that $U_A$ is an isometry and obviously $|\tilde{\psi}^{(k)}\rangle \otimes |\text{aux}_k\rangle \in \text{ran}(U_A) \otimes \tilde{\mathcal{H}}_B \otimes \mathcal{H}_{B,\text{aux}}$ for all $k \in [n]$. As $U_A^*$ is an isometry on $\text{ran}(U_A)$, and $\{ |\tilde{\psi}^{(k)}\rangle \otimes |\text{aux}_k\rangle \}_{k=1}^n$ are all mutually orthogonal, this implies that applying $U_A^* \otimes I$ to each of these yield $n$ orthogonal vectors, and furthermore it holds that $|\psi\rangle = \sum_{k=1}^n (U_A^* \otimes I) \left( |\tilde{\psi}^{(k)}\rangle \otimes |\text{aux}_k\rangle \right)$. However, then $\text{supp}_A \left( (U_A^* \otimes I) \left( |\tilde{\psi}^{(k)}\rangle \otimes |\text{aux}_k\rangle \right) \right)$ is orthogonal to $\text{supp}_A \left( (U_A^* \otimes I) \left( |\tilde{\psi}^{(\ell)}\rangle \otimes |\text{aux}_\ell\rangle \right) \right)$ for every $\ell \neq k$, which was what we needed to show.

\section{Convex self-testing of the Glued Magic Square game}

We now show that if two self-tested pseudo-telepathy binary LCS games are glued together to form another pseudo-telepathy game, then the resulting glued game self-tests the common state of the two subgames, as long as the self-tested quantum strategies for each subgame satisfy certain commutation relations. We show that these relations hold for the Magic Square. For the Magic Pentagram such relations also follow similarly and are relegated to Appendix A.1. First, we need a lemma to show that if some operator preserves the state, then it acts like the identity operator.

\textbf{Lemma 3.1.} Suppose $|\psi\rangle \in \mathcal{H}_A \otimes \mathcal{H}_B$ is a state and $G \in \mathcal{B}(\mathcal{H}_A)$ is some operator satisfying $(G \otimes I_B) |\psi\rangle = |\psi\rangle$. Then $G|\text{supp}_A(|\psi\rangle) = I_A|\text{supp}_A(|\psi\rangle)$.

\textbf{Proof.} Let $|\psi\rangle = \sum_i \lambda_i |v_i, w_i\rangle$ be a Schmidt decomposition with $\lambda_i > 0$, and orthonormal sets $\{|v_i\rangle\} \subseteq \mathcal{H}_A$ and $\{|w_i\rangle\} \subseteq \mathcal{H}_B$. Since $(G \otimes I_B) |\psi\rangle = |\psi\rangle$, we get:

$$\sum_i \lambda_i (G |v_i\rangle) |w_i\rangle = \sum_i \lambda_i |v_i\rangle |w_i\rangle,$$

but left-multiplying with $|w_i\rangle$ we get by orthonormality of $\{|w_i\rangle\}$ that $\lambda_i (G |v_i\rangle) = \lambda_i |v_i\rangle$, so $G |v_i\rangle = |v_i\rangle$. Thus, as $\{|v_i\rangle\}_i$ constitutes a basis for $\text{supp}_A(|\psi\rangle)$, we get the desired result. \hfill $\Box$

Before we are able to use this, we will need a result allowing us to restrict observables to the support of the state.

\textbf{Lemma 3.2.} Suppose $A \in \mathcal{B}(\mathcal{H}_A)$ and $B \in \mathcal{B}(\mathcal{H}_B)$ are two observables, and $|\psi\rangle \in \mathcal{H}_A \otimes \mathcal{H}_B$ is a state such that $\langle \psi | (A \otimes B) |\psi\rangle = 1$. Then by defining $\mathcal{H}_A^1 := \text{supp}_A(|\psi\rangle)$ and $\mathcal{H}_A^0 := (\mathcal{H}_A^1)^\perp$, it holds that $\text{ran}(A|_{\mathcal{H}_A^k}) \subseteq \mathcal{H}_A^k$ for $k \in \{0, 1\}$, and furthermore $A = A|_{\mathcal{H}_A^1} \oplus A|_{\mathcal{H}_A^0}$.

\textbf{Proof.} Initially observe that $\|A \otimes B\| \leq 1$, and so Cauchy-Schwarz implies that $A \otimes B |\psi\rangle = |\psi\rangle$. Now Schmidt decompose the state $|\psi\rangle = \sum_i \lambda_i |v_i\rangle |w_i\rangle$, and observe that $\mathcal{H}_A^1 = \text{span}_i \{|v_i\rangle\}$. Suppose for contradiction that $\text{ran}(A|_{\mathcal{H}_A^k}) \cap \mathcal{H}_A^0 \neq \{0\}$. Then for some $j$, as $\{|v_i\rangle\}_i$ constitutes a basis for $\mathcal{H}_A^1$, $A |v_j\rangle = |\varphi_0\rangle + |\varphi_1\rangle$, where $|\varphi_k\rangle \in \mathcal{H}_A^k$, for $k \in \{0, 1\}$, and $|\varphi_0\rangle \neq 0$. However, it therefore holds that

$$\sum_i \lambda_i |v_i\rangle |w_i\rangle = |\psi\rangle = (A \otimes B) |\psi\rangle$$

$$= \sum_i \lambda_i (A |v_i\rangle) \otimes (B |w_i\rangle)$$

$$= \sum_{i\neq j} \lambda_i (A |v_i\rangle) \otimes (B |w_i\rangle) + \lambda_j |\varphi_1\rangle \otimes (B |w_j\rangle) + \lambda_j |\varphi_0\rangle \otimes (B |w_j\rangle)$$

8
But noting that $A$ and $B$ are both observables, they are therefore isometries and thus as $\{ |v_i\rangle \}$ and $\{ |w_i\rangle \}$, are both linearly independent sets, all vectors in the above sum are linearly independent. But as $|\psi_0\rangle \notin H_A^1$, this is a contradiction as $|\psi\rangle \in H_A^1 \otimes H_B^1$. Therefore $\text{ran}(A|\psi_0\rangle) \subseteq H_A^1$, and then by taking $|\phi\rangle \in H_A^1$ we observe that $A^{-1}|\phi\rangle = A|\phi\rangle \in H_A^1$, so it necessarily also holds that $\text{ran}(A|\phi\rangle) \subseteq H_A^1$. \qed

In case of a game with consistent observables, such as the Magic Square game or the Magic Pentagram game, this implies that it is well-defined to restrict Alice’s (resp., Bob’s) operators to $\text{supp}_A(|\psi\rangle)$ (resp., $\text{supp}_B(|\psi\rangle$). Therefore, we can without loss of generality assume the state to have full Schmidt rank.

**Lemma 3.3.** Fix a perfect strategy $|\psi\rangle \in H_A \otimes H_B, \{A_x\}_x, \{B_y\}_y$ for a glued pseudo-telepathy binary LCS game with a Magic Square part, and suppose the observables $A_1, \ldots, A_9$ for Alice (resp., $B_1, \ldots, B_9$ for Bob) correspond to the Magic Square part, as illustrated in Figure 1a. Then with $E := A_3A_6A_9$ and $F := B_3B_6B_9$, it holds that

$$[E, A_i] \otimes I_B |\psi\rangle = 0, \quad \text{and} \quad I_A \otimes [F, B_j] |\psi\rangle = 0$$

for all $i, j \in [9]$.

**Proof.** Note that by symmetry, we need only show $\langle [E, A_i] \otimes I_B |\psi\rangle = 0$ for all $i \in [9]$. Note furthermore that in any perfect strategy, $A_3, A_6$ and $A_9$ commute pairwise (Theorem 2.4(b)), so in particular, they also commute with $E$. Therefore we need only show the statement for $i \in \{1, 2, 4, 5, 7, 8\}$.

Note that we can Schmidt decompose the state as $|\psi\rangle = \sum_i \lambda_i |v_i, w_i\rangle$, for $\lambda_i > 0$ and orthonormal sets $\{ |v_i\rangle \} \subseteq H_A$ and $\{ |w_i\rangle \} \subseteq H_B$. Initially suppose the state has full Schmidt rank, which in particular implies that $\{ |w_i\rangle \}$ constitutes an orthonormal basis for $H_A$. Then, to prove that an operator is the identity operator, it suffices to note that it preserves $|\psi\rangle$ and then use Lemma 3.1.

This implies that any product of operators in a row or column of the Magic Square game (as illustrated in Figure 1a) is identity, except for $E$, as these products applied to the state must preserve the state. We can now use this to prove the required commutation relations. Observe for example that we therefore have $A_1A_2A_3 = I$ and $A_4A_5A_6 = I$, and by using that these are all $\pm 1$-valued observables, commuting within each equation, we get $A_3 = A_2A_1$, $A_6 = A_4A_5$, and thus

$$A_3A_6 = A_2A_1A_4A_5 = A_2A_7A_5,$$

by using that $A_1A_4A_7 = I$, i.e. $A_1A_4 = A_7$. Therefore,

$$A_3A_6A_8 = A_2A_7A_5A_8 = A_2A_7A_2,$$

by using that $A_2A_5A_8 = I$. But this latter fact now implies, using commutation of $A_3$ with $A_6$ and self-adjointness of the observables, that:

Thus, $[A_3A_6, A_8] = 0$. A similar argument gives $[A_3A_6, A_7] = 0$. However, as $A_9$ commutes with $A_3, A_6, A_7$ and $A_8$, we clearly get $[E, A_7] = [A_3A_6A_9, A_7] = 0$, and also $[E, A_8] = 0$. Commutation for $i \in \{1, 2, 4, 5\}$ can be shown similarly.

Now we need only consider the case where $|\psi\rangle$ does not have full Schmidt rank. In this case, note that for $i \in \{1, \ldots, 18\}$, we have $(A_i \otimes B_i) |\psi\rangle = |\psi\rangle$, since $\langle \psi| (A_i \otimes B_i) |\psi\rangle = 1$ and $\| A_i \otimes B_i \| \leq 1$. However this implies $\text{span}\{ |v_i\rangle \}$ is invariant under all $A_j$, and similarly $\text{span}\{ |w_i\rangle \}$ is invariant under all $B_j$. Therefore we can just restrict the operators to these subspaces, and then we from the above part get the desired statement. \qed
This lemma along with Lemma A.1 show that if we glue together the Magic Square or the Magic Pentagram with themselves or each other, then it is well-defined to restrict a perfect strategy for Alice to the quantum strategy for the glued game to one of its constituent parts. For example, if we consider the Glued Magic Square game, then we can restrict a perfect strategy for Alice to the quantum strategy for the glued game to one of its constituent parts. For example, if we consider the Glued Magic Square game, then we can restrict a perfect strategy for Alice to the quantum strategy for the glued game to one of its constituent parts. For example, if we consider the Glued Magic Square game, then we can restrict a perfect strategy for Alice to the quantum strategy for the glued game to one of its constituent parts. For example, if we consider the Glued Magic Square game, then we can restrict a perfect strategy for Alice to the quantum strategy for the glued game to one of its constituent parts. For example, if we consider the Glued Magic Square game, then we can restrict a perfect strategy for Alice to the quantum strategy for the glued game to one of its constituent parts. For example, if we consider the Glued Magic Square game, then we can restrict a perfect strategy for Alice to the quantum strategy for the glued game to one of its constituent parts. For example, if we consider the Glued Magic Square game, then we can restrict a perfect strategy for Alice to the quantum strategy for the glued game to one of its constituent parts. For example, if we consider the Glued Magic Square game, then we can restrict a perfect strategy for Alice to the quantum strategy for the glued game to one of its constituent parts. For example, if we consider the Glued Magic Square game, then we can restrict a perfect strategy for Alice to the quantum strategy for the glued game to one of its constituent parts. For example, if we consider the Glued Magic Square game, then we can restrict a perfect strategy for Alice to the quantum strategy for the glued game to one of its constituent parts. For example, if we consider the Glued Magic Square game, then we can restrict a perfect strategy for Alice to the quantum strategy for the glued game to one of its constituent parts. For example, if we consider the Glued Magic Square game, then we can restrict a perfect strategy for Alice to the quantum strategy for the glued game to one of its constituent parts.

Define \( \mathbb{E} \) to be the two families of possible strategies for the Glued Magic Square game, assuming that \( G_k \) commutes with \( \tilde{A}_i \) for each \( k, \ell \in \{3, 6, 9\} \). This can easily be verified by observing that the first nine observables for each of Alice and Bob constitute a perfect strategy for the Magic Square game, while their remaining observables all commute, square to identity and when taken the product within any row or column of how they are written in (3.1), they multiply to identity.

Symmetrically, one can swap \( A_i \) with \( A_{i+9} \) and \( B_i \) with \( B_{i+9} \) for all \( i \in [9] \) to get another strategy, which we will call \( S_{i+9}^2 \).

We now consider the set of ideal strategies for the Glued Magic Square game.

**Example 3.4.** Let \( \tilde{A}_1, \ldots, \tilde{A}_9 \) denote the optimal operators (for Alice) for the Magic Square game from Theorem 2.9. Let \( \sigma : (\mathbb{Z}/2\mathbb{Z})^4 \to \mathcal{B}(\mathcal{H}) \) be a representation of the abelian group \( (\mathbb{Z}/2\mathbb{Z})^4 = \langle e_1, e_2, e_3, e_4 \mid e_i^2 = [e_i, e_j] = 1 \forall i, j \in [4] \rangle \). Set

\[
\begin{align*}
G_1 &= \sigma(e_1) \\
G_2 &= \sigma(e_2) \\
G_3 &= \sigma(e_3) \\
G_4 &= \sigma(e_4)
\end{align*}
\]

Define \( A_i := B_i := \tilde{A}_i \) and \( A_{19-i} := B_{19-i} := G_i \) for \( i \in [9] \). Then the strategy \( S_i^* := \left( |\psi_4\rangle, \{A_i\}_{i \in [18]}, \{B_j\}_{j \in [18]} \right) \) constitutes a perfect strategy for the Glued Magic Square game, assuming that \( G_k \) commutes with \( \tilde{A}_i \) for each \( k, \ell \in \{3, 6, 9\} \). This can easily be verified by observing that the first nine observables for each of Alice and Bob constitute a perfect strategy for the Magic Square game, while their remaining observables all commute, square to identity and when taken the product within any row or column of how they are written in (3.1), they multiply to identity.

We now state our main theorem which characterises all the possible optimal strategies for the Glued Magic Square game. Note that this is close to being a convex self-test in the sense of Definition 2.12, it is not entirely so, as it in fact self-tests a family of strategies.

**Theorem 3.5.** Let \( \hat{S}_k = \{S_k^\sigma \mid \sigma \text{ is a representation of } (\mathbb{Z}/2\mathbb{Z})^4\} \) be the two families of possible strategies for the Glued Magic Square game as given in Example 3.4. The Glued Magic Square game is a convex self-test of the families \( \hat{S}_1 \) and \( \hat{S}_2 \) in the sense that for any perfect strategy \( S \) for the Glued Magic Square game, there exists representations \( \sigma_1, \sigma_2 \) of \( (\mathbb{Z}/2\mathbb{Z})^4 \), strategies \( S_1, S_2 \) and constants \( \alpha_1, \alpha_2 \in [0, 1] \), such that \( S \) is an internal convex combination of \( S_1 \) and \( S_2 \), i.e. \( S = \alpha_1 S_1 + \alpha_2 S_2 \), and \( S_k^\sigma \in \hat{S}_k \) is a local dilation of \( S_k \) for each \( k \in [2] \).

**Proof.** Let \( S = (|\psi\rangle) \in \mathcal{H}_A \otimes \mathcal{H}_B, \{A_i\}_{i \in [18]}, \{B_j\}_{j \in [18]} \) be a perfect quantum strategy for the Glued Magic Square game. Set

\[
\begin{align*}
E &= A_3 A_6 A_9, & F &= A_{10} A_{13} A_{16}, & G &= B_3 B_6 B_9, & H &= B_{10} B_{13} B_{16}.
\end{align*}
\]
We begin by decomposing the spaces $\mathcal{H}_A$ and $\mathcal{H}_B$. Consider the eigendecomposition: $E = E^+ - E^-$ and $F = F^+ - F^-$. As the quantum strategy $S$ is assumed to be perfect, we have $(EF \otimes I_B) |\psi\rangle = -|\psi\rangle$, which implies

$$-1 = \langle \psi | (EF \otimes I_B) |\psi\rangle = \langle \psi | ((EF)^+ \otimes I_B) |\psi\rangle - \langle \psi | ((EF)^- \otimes I_B) |\psi\rangle,$$

and since $(EF)^+$ and $(EF)^-$ are projections, we necessarily have $0 \leq \langle \psi | ((EF)^+ \otimes I_B) |\psi\rangle \leq 1$ and $0 \leq \langle \psi | ((EF)^- \otimes I_B) |\psi\rangle \leq 1$. Therefore, the only possible way in which Equation (3.2) can hold is if $\langle \psi | (EF)^+ \otimes I_B |\psi\rangle = 0$ and $\langle \psi | (EF)^- \otimes I_B |\psi\rangle = 1$, the latter of which implies $((EF)^- \otimes I_B) |\psi\rangle = |\psi\rangle$. By using $I_A = E^+ + E^-$ and $I_B = F^+ + F^-$, we get:

$$(EF)^- = E^+ F^- + E^- F^+ = (I_A - E^-) F^- + E^-(I_A - F^-) = E^- + F^- - 2E^- F^-$$

However, as $(EF)^+ = E^+ F^+ + E^- F^-$, Equation (3.2) implies that

$$|\psi\rangle = ((EF)^- \otimes I_B) |\psi\rangle = ((E^- + F^-) \otimes I_B) |\psi\rangle.$$

(3.3)

Let $|\psi\rangle = \sum_i \lambda_i |v_i\rangle |w_i\rangle$ be a Schmidt decomposition with $\lambda_i > 0$ and orthonormal sets $\{|v_i\rangle\} \subseteq \mathcal{H}_A$ and $\{|w_i\rangle\} \subseteq \mathcal{H}_B$. By defining $\mathcal{H}_0^A := \text{supp}_A(|\psi\rangle)$ we now get the decomposition $\mathcal{H}_A = \mathcal{H}_0^A \oplus \text{supp}_A(|\psi\rangle)$. However, now note that as $((EF)^+ \otimes I_B) |\psi\rangle = 0$, in particular we have $(E^- F^- \otimes I_B) |\psi\rangle = 0$. But as $((E^- + F^-) \otimes I_B) |\psi\rangle = |\psi\rangle$, this implies by Lemma [3.1] that on $\text{supp}_A(|\psi\rangle)$, $E^- + F^-$ is the identity operator, and therefore, as they are projections, they partition $\text{supp}_A(|\psi\rangle)$ into two subspaces, $\mathcal{H}_1^A := \text{ran}(E^-) \cap \text{supp}_A(|\psi\rangle)$ and $\mathcal{H}_2^A := \text{ran}(F^-) \cap \text{supp}_A(|\psi\rangle)$. Thus, we now have the desired decomposition $\mathcal{H}_A = \mathcal{H}_0^A \oplus \mathcal{H}_1^A \oplus \mathcal{H}_2^A$ of Bob’s space using the operators $G$ and $H$.

We now wish to show that we can split the state $|\psi\rangle$ into a direct sum, but to do so requires us to show that $|\psi\rangle$ is orthogonal to both $\mathcal{H}_1^A \otimes \mathcal{H}_2^B$ and $\mathcal{H}_2^A \otimes \mathcal{H}_2^B$, which we proceed to do now.

As the strategy is perfect, it is in particular consistent, i.e., $\langle \psi | A_i \otimes B_i |\psi\rangle = 1$ for all $i \in [18]$. Hence, we have $A_i \otimes B_i |\psi\rangle = |\psi\rangle$. Also, as noted in the second paragraph of this proof, $E(-F) \otimes I_B |\psi\rangle = |\psi\rangle$. Thus we find:

$$1 = \langle \psi | (A_6 \otimes B_6)(A_6 \otimes B_6)(E(-F) \otimes I_B) |\psi\rangle = \langle \psi | (E^2 \otimes G) |\psi\rangle = -\langle \psi | F \otimes G |\psi\rangle,$$

where we used $E^2 = I_A$. But this implies $(F \otimes G) |\psi\rangle = -|\psi\rangle$, and then as $\|F \otimes G\| \leq 1$, we find $(F \otimes G)^+ |\psi\rangle = 0$, and in particular, $(F^- \otimes G^-) |\psi\rangle = 0$. Similarly we find $(E^- \otimes H^-) |\psi\rangle = 0$, and in total we therefore have

$$|\psi\rangle = ((E^- + F^-) \otimes (G^- + H^-)) |\psi\rangle = (E^- \otimes G^-) |\psi\rangle + (E^- \otimes H^-) |\psi\rangle + (F^- \otimes G^-) |\psi\rangle + (F^- \otimes H^-) |\psi\rangle$$

(3.4)

By definition of the subspaces, we therefore have $\text{supp} |\psi\rangle \perp \mathcal{H}_1^A \otimes \mathcal{H}_2^B$ and $\text{supp} |\psi\rangle \perp \mathcal{H}_2^A \otimes \mathcal{H}_2^B$.

Therefore we can define $|\varphi_1\rangle := (E^- \otimes G^-) |\psi\rangle$ and $|\varphi_2\rangle := (F^- \otimes H^-) |\psi\rangle$; then we have $|\psi\rangle = |\varphi_1\rangle \oplus |\varphi_2\rangle$. Now we can define two sub-strategies $S_k$, for $k \in \{1, 2\}$ under the assumption that $|\varphi_k\rangle \neq 0$:

$$S_k = \left( \frac{|\varphi_k\rangle}{\|\varphi_k\|} \right) \in \mathcal{H}_A^k \otimes \mathcal{H}_B^k, \left\{ A_i |h_k^A \rangle \right\}_{i \in [18]} \left\{ B_j |h_k^B \rangle \right\}_{j \in [18]}$$

However, we must be careful and verify that this strategy is well-defined – in particular to use it we need to apply several operators in succession, so we need to verify that $\text{ran} A_i |h_k^A \rangle \subseteq \mathcal{H}_A^k$ (and
similarly for $H_B^i$). However, as $\langle \psi | (A_i \otimes B_i) | \psi \rangle = 1$, we have ran $((A_i \otimes B_i) |_{\text{supp}_A(\langle \psi \rangle) \otimes H_B}) \subseteq \text{supp}_A(\langle \psi \rangle) \otimes H_B$. This implies that ran $A_i|_{H_A^1 \oplus H_A^2} \subseteq H_A^1 \oplus H_A^2$, and so it is well-defined to restrict observables to this space. Now, further restricting to $H_A^1$, we note that this can be accomplished by first applying $E^-|_{H_A^1 \oplus H_A^2}$, i.e.:

$$A_i|_{H_A^1} = A_i|_{H_A^1 \oplus H_A^2} E^-|_{H_A^1 \oplus H_A^2} A_i|_{H_A^1 \oplus H_A^2} E^-|_{H_A^1 \oplus H_A^2}$$

Here we have used that $[E^-, H_A^1 \oplus H_A^2, A_i|_{H_A^1 \oplus H_A^2}] = 0$, and thus we can commute $E^-|_{H_A^1 \oplus H_A^2}$ to the beginning of the equation. Observe that while Lemma 3.3 only gives $[E^-, H_A^1 \oplus H_A^2, A_i|_{H_A^1 \oplus H_A^2}] = 0$ for $i \in [9]$, it also gives $[E^-, H_A^1 \oplus H_A^2, A_i|_{H_A^1 \oplus H_A^2}] = 0$ for $i \in \{10, \ldots, 18\}$, and Equation 3.3 implies that $E^-|_{H_A^1 \oplus H_A^2} + F^-|_{H_A^1 \oplus H_A^2} = I|_{H_A^1 \oplus H_A^2}$, so $[E^-, H_A^1 \oplus H_A^2, A_i|_{H_A^1 \oplus H_A^2}] = 0$ as well. However, this now implies ran $(A_i|_{H_A^1}) \subseteq H_A^1$, and similar arguments show that the range of the rest of the operators is also contained within the space they are restricted to. This implies that the strategy is indeed well-defined.

However, it is now easy to verify that $S_1$ and $S_2$ both are perfect strategies for the Magic Square game, and therefore by self-testing of the Magic Square game, Theorem 2.9, for each $k \in \{1, 2\}$, there exists isometries $V_{k,A} : H_A^k \to \mathbb{C}^4 \otimes H_{A,aux}^k$ and $V_{k,B} : H_B^k \to \mathbb{C}^4 \otimes H_{B,aux}^k$ and normalised states $|aux_k\rangle$ such that

$$\begin{align*}
(V_{k,A} \otimes V_{k,B}) |\varphi_k\rangle = |\psi_4\rangle \otimes |aux_k\rangle & \quad k \in \{1, 2\} \\
(V_{1,A} \otimes V_{1,B}) (A_i|_{H_A^1} \otimes B_j|_{H_B^1}) |\varphi_1\rangle = (\tilde{A}_i \otimes \tilde{B}_j) |\psi_4\rangle \otimes |aux_1\rangle, & \quad i, j \in [9] \\
(V_{2,A} \otimes V_{2,B}) (A_i|_{H_A^1} \otimes B_j|_{H_B^1}) |\varphi_2\rangle = (\tilde{A}_{i-9} \otimes \tilde{B}_{j-9}) |\psi_4\rangle \otimes |aux_2\rangle, & \quad i, j \in \{10, \ldots, 18\},
\end{align*}$$

where the operators $\tilde{A}_i, \tilde{B}_j, i, j \in [9]$ are the ideal operators for the Magic Square game.

We now need only show that the remaining operators constitute a representation of $(\mathbb{Z}/2\mathbb{Z})^4$. Therefore we consider how $A_1, \ldots, A_9$ acts on $H_A^2$; note that how $A_{10}, \ldots, A_{18}$ acts on $H_A^1$ follows symmetrically. Recall that $A_3 A_6 A_9 A_{10} A_{13} A_{16} = -I$ when restricted to $H_A^1 \oplus H_A^2$, which in particular implies it holds on $H_A^2$. However, that space is characterised by $A_{10} A_{13} A_{16} = -I$, which implies $A_3 A_6 A_9 = I$ on $H_A^2$. However, then we see (note that this is restricted to $H_A^2$ – we temporarily suppress the notation indicating restriction):

$$A_2 A_4 A_2 A_4 = A_3 A_1 A_1 A_7 A_8 A_5 A_6 = A_3 A_7 A_8 A_6 = A_3 A_9 A_6 = I$$

Thus, $[A_2, A_4] = 0$, and symmetrically, $[A_1, A_5] = 0$. We note that we can write $(\mathbb{Z}/2\mathbb{Z})^4 = \langle x_1, x_2, x_3, x_4 \mid x_i^2, [x_i, x_j] \rangle, i, j \in [4]$,

so define the function $f : G \to B(H_A^2)$ by

$$f(x_1) = A_1|_{H_A^2} \quad f(x_2) = A_2|_{H_A^2}$$
$$f(x_3) = A_4|_{H_A^2} \quad f(x_4) = A_5|_{H_A^2},$$

we find that the images of the generators satisfy the constraints of the group, and therefore it is well-defined to merely extend $f$ by multiplication (in any way) to cover the entire group. But this then shows that $A_1, \ldots, A_9$ restricted to $H_A^2$ gives a representation of $(\mathbb{Z}/2\mathbb{Z})^4$. 

Now define $\sigma_2(g) := V_{2,A} f(g) V_{2,A}^*$, and observe that since \(3.5\) holds, we therefore have:

\[
(V_{2,A} \otimes V_{2,B}) (f(g) \otimes I) \frac{|\varphi_2\rangle}{||\varphi_2||} = (V_{2,A} \otimes V_{2,B}) (f(g) \otimes I) (V_{2,A} \otimes V_{2,B})^* (V_{2,A} \otimes V_{2,B}) \frac{|\varphi_2\rangle}{||\varphi_2||} \\
= (V_{2,A} f(g) V_{2,A}^*) (V_{2,A} \otimes V_{2,B}) \frac{|\varphi_2\rangle}{||\varphi_2||} \\
= \sigma_2(g) (|\psi_4\rangle \otimes |aux_2\rangle),
\]

and thus we find that the strategy restricted to $\mathcal{H}_A^2$ is a local dilation of $\mathcal{S}_A^2$. Similarly we find that there is a representation $\sigma_1$ of $(\mathbb{Z}/2\mathbb{Z})^4$ such that the strategy restricted to $\mathcal{H}_A^1$ is a local dilation of $\mathcal{S}_A^1$.

Finally note that we can remove the assumption that $|\varphi_k\rangle \neq 0$, as in that case, we must have $|\varphi_{3-k}\rangle = |\psi\rangle$, implying that $\mathcal{S}$ is then equal to $\mathcal{S}_{3-k}$ while $\mathcal{S}_k$ will then be zero. The above then implies that either $\mathcal{S}_A^1$ or $\mathcal{S}_A^2$ is a local dilation of the nonzero strategy.

\[\square\]

**Corollary 3.6.** The Glued Magic Square game self-tests the state $|\psi_4\rangle$.

**Proof.** Fix a perfect strategy $\mathcal{S}$ for the Glued Magic Square, and use Theorem 3.5 to decompose this into $\alpha_1 \mathcal{S}_A^1 + \alpha_2 \mathcal{S}_A^2$. Let $|\varphi_k\rangle$ denote the state used in $\mathcal{S}_k$, $k \in \{2\}$, and note that these are both local dilations of $\mathcal{S}_{MS}$ whose state is $|\psi_4\rangle$. This implies that there exists isometries $V_{k,A}$ and $V_{k,B}$, for $k \in \{2\}$ such that $(V_{k,A} \otimes V_{k,B}) |\varphi_k\rangle = |\psi_4\rangle \otimes |aux_k\rangle$ for some auxiliary states $|aux_k\rangle$.

By defining $V_A := V_{1,A} \otimes V_{2,A}$ and $V_B := V_{1,B} \otimes V_{2,B}$ and extending these to $\mathcal{H}_A$ and $\mathcal{H}_B$, respectively, we find, by observing $|\psi\rangle = \alpha_1 |\varphi_1\rangle + \alpha_2 |\varphi_2\rangle$, that

\[
(V_A \otimes V_B) |\psi\rangle = ((V_{1,A} \otimes V_{2,A}) \otimes (V_{1,B} \otimes V_{2,B})) (\alpha_1 |\varphi_1\rangle \otimes \alpha_2 |\varphi_2\rangle) \\
= \bigoplus_{k=1}^2 \alpha_k (V_{k,A} \otimes V_{k,B}) |\varphi_k\rangle \\
= \bigoplus_{k=1}^2 |\psi_4\rangle \otimes (\alpha_k |aux_k\rangle) \\
= |\psi_4\rangle \otimes (\alpha_1 |aux_1\rangle \otimes \alpha_2 |aux_2\rangle),
\]

and by defining $|aux\rangle := \alpha_1 |aux_1\rangle \otimes \alpha_2 |aux_2\rangle$ and noting that $||aux_1||^2 + ||aux_2||^2 = 1$, we get the desired result. \[\square\]

While it may seem trivial at first to extend this proof to the robust case by using robustness of the constituent games, this is a little more difficult, as our result also relies on the restriction to the eigenspaces of some operators being well-defined. As our proofs of this in Lemma 3.3 and Lemma A.1 relied on all constraints being satisfied exactly, they cannot immediately be translated into the robust case, however in Section A.2 we sketch the required arguments.

**Example 3.7.** We have fully characterised all (pure) strategies for the Glued Magic Square game in Theorem 3.5, so it is worth considering an example of such a strategy. Let $\alpha, \beta > 0$ be two real numbers which satisfy $\alpha^2 + \beta^2 = 1$, and let $|\xi\rangle \in \mathbb{C}^6 \otimes \mathbb{C}^5$ be some state, . Then, the following state and observables constitute a perfect strategy for the Glued Magic Square game:

\[
|\psi\rangle := \alpha |\psi_4\rangle \oplus \beta (|\psi_4\rangle \otimes |\xi\rangle) \\
A_i = B_i := \tilde{A}_i \oplus \left( (I_1 \oplus (\bar{I}_1) \oplus I_2) \otimes I_3 \right) \quad i \in [9] \\
A_{19-i} = B_{19-i} := \left( (-I_2) \oplus I_1 \oplus (\bar{I}_1) \right) \oplus \left( \tilde{A}_i \otimes I_5 \right) \quad i \in [9],
\]

where $\tilde{A}_i \in \mathcal{B}(\mathbb{C}^4)$ are the optimal operators for the Magic Square game. Note the structure of this strategy: it is composed of two perfect strategies for the Magic Square game – one for each
constituent part of the Glued Magic Square game. However, while the operators $A_1, \ldots, A_9$ have to constitute a perfect strategy for the Magic Square game on one part, they don’t have to be identity on the other part, as we can take them to be any representation of $\left(\mathbb{Z}/2\mathbb{Z}\right)^4$ (where $A_1, A_2, A_4$ and $A_5$ corresponds to the natural generators of this group). Therefore it is in particular possible to use the direct sum of several different irreducible representations, which we have done here.

A Appendix

A.1 Magic Pentagram

It should be noted that while we have only considered the Glued Magic Square in the main text, the proof of self-testing can easily be extended to the case where either one or both parts are the Magic Pentagram. However, for that, we need to show that gluing the Magic Pentagram with some binary LCS game, the observables used for the Magic Pentagram part will also satisfy some particular commutation relations. Note then that gluing two copies of Magic Pentagram together yields a self-test for the state $|\psi_8\rangle$, while one can only extract $|\psi_4\rangle$ if any part is Magic Square. Of course it should be noted that this self-testing result also requires an application of Theorem 2.10 which states that the Magic Pentagram game self-tests $|\psi_8\rangle$ along with some ideal observables.

Lemma A.1. Fix a perfect strategy $(|\psi\rangle) \in \mathcal{H}_A \otimes \mathcal{H}_B, \{A_x\}_x, \{B_y\}_y$ for a glued pseudo-telepathic LCS with a Magic Pentagram part, and suppose the observables $A_1, \ldots, A_{10}$ for Alice (resp.,
$B_1, \ldots, B_{10}$ for Bob) correspond to the Magic Pentagram part as illustrated in Figure 1b. Then with $E := A_2A_3A_4A_5$ and $F := B_2B_3B_4B_5$, it holds that

$$[E, A_i] \otimes I_B |\psi\rangle = 0, \quad \text{and} \quad I_A \otimes [F, B_j] |\psi\rangle = 0$$

for all $i, j \in \{0, 1, \ldots, 10\}$.

Proof. We proceed as in Lemma 3.3 and assume that the state has full Schmidt rank; therefore the initial observations of Lemma 3.3 also hold here. In particular, every product of operators along a straight line in Figure 1b is identity, and we will make use of this fact repeatedly. Observe initially that $A_2, A_3, A_4$ and $A_5$ each commute with $E$ (otherwise the strategy wouldn’t be well-defined), and therefore we need only prove the statement for $i \in \{1, 6, 7, 8, 9, 10\}$. We initially find that

$$A_2A_5 = A_6A_8A_{10}A_7A_3A_9$$

where we in the second equality have used that $A_8$ commutes with all operators present in the expression, and otherwise the relations forcing certain products to be identity (i.e. $A_1A_4A_7A_{10} = I$ and the factors pairwisely commute, so $A_{10}A_7 = A_1A_4$). Now, we therefore have

$$E = A_2A_3A_4A_5 = A_3A_4A_2A_5$$

so in particular, as $A_1$ commutes with $A_4$ and $A_9$, $[E, A_1] = 0$. But the same holds true for $A_7$, so $[E, A_7] = 0$. Symmetrically, we can show $E = A_3A_{10}A_3A_{10}$, and since $A_3$ and $A_{10}$ each commute with $A_6$ (as they share a constraint), $[E, A_6] = 0$.

Now, as $A_9 = A_1A_3A_6$, and each factor has been found to commute with $E$, $[E, A_9] = 0$. Symmetrically, $[E, A_{10}] = 0$. Finally, $A_8 = A_5A_7A_9$, each of which commute with $E$, so $[E, A_8] = 0$.

## A.2 Robustness

In this appendix we sketch the arguments required to show that the Glued Magic Square in fact robustly self-tests the state $|\psi_4\rangle$. In particular, while we do not define robust self-testing explicitly, we show that just as in Theorem 3.5 one can from a strategy winning the Glued Magic Square game with probability $1 - \varepsilon$ extract strategies winning the Magic Square game with probability $1 - O(\varepsilon)$ (note, though, that one of these strategies can be zero just as in the perfect case). By using robustness of the Magic Square one can then approximately extract $|\psi_4\rangle$ from each of the two substrategies.

We start out by proving a few lemmas that will enable us to show this result. Note that these are not necessarily novel – a result similar to Lemma A.3 appears in [CS17].
Lemma A.2. Suppose \( |\psi\rangle \in \mathcal{H} \) is a state, and \( A, B \in \mathcal{B}(\mathcal{H}) \) are unitary operators satisfying 
\[ \Re \langle \psi | AB | \psi \rangle \geq 1 - \varepsilon \] and \( \Re \langle \psi | B | \psi \rangle \geq 1 - \delta \) for some \( \varepsilon, \delta \geq 0 \). Then,
\[ \Re \langle \psi | AB | \psi \rangle \geq 1 - \left( \sqrt{\varepsilon} + \sqrt{\delta} \right)^2. \]

Moreover, if \( \langle \psi | A | \psi \rangle \) and \( \langle \psi | B | \psi \rangle \) are real, then so is \( \langle \psi | AB | \psi \rangle \).

Proof. Observe that \( \| (A - I) | \psi \rangle \|^2 = 2 - 2\Re \langle \psi | A | \psi \rangle \leq 2\varepsilon \), and similarly \( \| (B - I) | \psi \rangle \|^2 \leq 2\delta \). Thus, using Cauchy-Schwarz inequality,
\[ |\Re \langle \psi | (A - I)(B - I) | \psi \rangle | \leq |\langle \psi | (A - I)(B - I) | \psi \rangle| \leq \| (A - I) | \psi \rangle \| \cdot \| (B - I) | \psi \rangle \| \leq 2\sqrt{\varepsilon \delta} \]

Since, \( \langle \psi | (A - I)(B - I) | \psi \rangle = \langle \psi | AB | \psi \rangle + \langle \psi | I | \psi \rangle - \langle \psi | A | \psi \rangle - \langle \psi | B | \psi \rangle \), upon rearranging and taking the real value yields
\[ \Re \langle \psi | AB | \psi \rangle = \Re \langle \psi | A | \psi \rangle + \Re \langle \psi | B | \psi \rangle - 1 + \Re \langle \psi | (A - I)(B - I) | \psi \rangle \]
\[ \geq 1 - \varepsilon + 1 - \delta - 2\sqrt{\varepsilon \delta} = 1 - \left( \sqrt{\varepsilon} + \sqrt{\delta} \right)^2, \]
as required. \( \square \)

Observe that if \( U_1, \ldots, U_n \) are all unitaries satisfying \( \Re \langle \psi | U_i | \psi \rangle \geq 1 - \varepsilon \), then repeatedly applying Lemma A.2 we obtain \( \Re \langle \psi | U_1 U_2 \cdots U_n | \psi \rangle \geq 1 - n^2 \varepsilon \). In general, one can also note that if \( \Re \langle \psi | U_i | \psi \rangle \geq 1 - C_i \varepsilon \) for some constants \( C_i \geq 0 \), then there is a constant \( C \geq 0 \) such that \( \Re \langle \psi | U_1 U_2 \cdots U_n | \psi \rangle \geq 1 - C \varepsilon \).

Lemma A.3. Suppose \( |\psi\rangle \in \mathcal{H}_A \otimes \mathcal{H}_B \) is a state and \( A, U \in \mathcal{B}(\mathcal{H}_A) \) and \( B \in \mathcal{B}(\mathcal{H}_B) \) are all unitary operators. Furthermore suppose there exists some \( \varepsilon \geq 0 \) such that \( \langle \psi | (U \otimes I) | \psi \rangle \geq 1 - \varepsilon \) and \( \langle \psi | (A \otimes B) | \psi \rangle \geq 1 - \varepsilon \). Then it holds that \( \langle \psi | (UA^* \otimes I) | \psi \rangle \geq 1 - 9\varepsilon \).

Proof. Observe that \( \langle \psi | (A \otimes B) | \psi \rangle = \langle \psi | (A \otimes B)^* | \psi \rangle \) and \( \langle \psi | (UA^* \otimes I) | \psi \rangle = \langle \psi | (A \otimes B)(U \otimes I)(A \otimes B)^* | \psi \rangle \), so applying Lemma A.2 twice yields the desired conclusion. \( \square \)

Note that as before, if \( \langle \psi | (U \otimes I) | \psi \rangle \geq 1 - O(\varepsilon) \) and \( \langle \psi | (A \otimes B) | \psi \rangle \geq 1 - O(\varepsilon) \), then this lemma implies \( \langle \psi | (UA^* \otimes I) | \psi \rangle \geq 1 - O(\varepsilon) \).

These two results forms the main ingredients in proving robustness. In the ideal case, we were able to prove that restricting operators to certain eigenspaces was well-defined, but that is somewhat more difficult to do robustly. We will need a way to translate approximate commutation for our entire quantum strategy into an approximate commutation on some eigenspace. However, to do this we first need to show that if we restrict to some space then approximate relations are still conserved.

Lemma A.4. Suppose \( |\psi\rangle \in \mathcal{H}_A \otimes \mathcal{H}_B \) is a unit vector, \( A \in \mathcal{B}(\mathcal{H}_A) \) is a self-adjoint operator of norm at most 1, and \( \langle \psi | (A \otimes I) | \psi \rangle \geq 1 - \varepsilon \). Then for any decomposition \( |\psi\rangle = |\varphi \rangle \oplus |\phi \rangle \) there exists a constant \( C > 0 \) such that \( \langle \varphi | (A \otimes I) | \varphi \rangle \geq \| |\varphi \rangle \|^2 - C \varepsilon \).

Proof. Schmidt decompose \( |\psi\rangle = \sum_{i=1}^k \lambda_i |v_i\rangle |w_i\rangle \) with \( \lambda_i > 0 \) for all \( i \in [k] \). Observe that then \( \langle v_i | A | v_i \rangle \geq 1 - \frac{\lambda_i}{\lambda_i^2} \) for all \( i \in [k] \); since otherwise, if this failed for some \( \ell \in [k] \), then
\[ \langle \psi | (A \otimes I) | \psi \rangle = \sum_{i=1}^k \lambda_i^2 \langle v_i | A | v_i \rangle = \lambda_i^2 \sum_{i=1}^k \langle v_i | A | v_i \rangle \]
\[ < \lambda_i^2 \left( 1 - \frac{\varepsilon}{\lambda_i^2} \right) + 1 - \lambda_i^2 = 1 - \varepsilon, \]
for some \( \lambda_i > 0 \).
which is a contradiction. Note that we used the assumption \( \|A\| \leq 1 \) to bound the sum in the third line by \( 1 - \lambda_i^2 \).

Now as \(|\psi\rangle = |\phi\rangle \otimes |\phi\rangle\), there exists coefficients \( \{\alpha_i\}_{i=1}^k \subseteq [0, 1] \) such that \(|\varphi\rangle = \sum_{i=1}^k \alpha_i \lambda_i |v_i\rangle |v_i\rangle\) (these can be obtained by projecting \( \lambda_i |v_i\rangle |v_i\rangle \) onto the direct summand in which \(|\varphi\rangle\) lies). By orthonormality one has \( \| |\varphi\rangle\| = \sum_{i=1}^k \alpha_i^2 \lambda_i^2 \), using which we find

\[
\langle \varphi | A | \varphi \rangle = \sum_{i=1}^k \alpha_i^2 \lambda_i^2 (\langle v_i | A | v_i \rangle) \geq \sum_{i=1}^k \alpha_i^2 \lambda_i^2 \left(1 - \frac{\varepsilon}{\lambda_i^2}\right) = \| |\varphi\rangle\|^2 - \sum_{i=1}^k \alpha_i^2 \varepsilon,
\]

which finishes the proof.

Now recall that our proof of self-testing in the exact case relied upon restriction to certain eigenspaces being well-defined. That is not true in the approximate case, but we can now show that if all observables approximately commute with some specific observable, then so do they do with its \(-1\)-eigenprojector.

**Lemma A.5.** Suppose \(|\psi\rangle \in \mathcal{H}_A \otimes \mathcal{H}_B\) is a unit vector, \(A, E \in \mathcal{B}(\mathcal{H}_A)\) are operators of norm at most 1, and \(E\)'s only eigenvalues are \(\pm 1\). Suppose that \(A\) and \(E\) approximately commute on \(|\psi\rangle\) in the sense that \(\langle \psi | (AEA^*E^* \otimes I) | \psi \rangle \geq 1 - \varepsilon\) for some \(\varepsilon \geq 0\). Then there exists some \(C > 0\) such that \(\langle \varphi | (AE - A^*E^*)(E^- \otimes I) | \varphi \rangle \geq 1 - C\varepsilon\), where \(|\varphi\rangle = \frac{(E^- \otimes I)|\psi\rangle}{\| (E^- \otimes I) | \psi \rangle \|}

**Proof.** Note that by Lemma A.4 there is some constant \(C > 0\) such that \(\langle \varphi | (AEA^*E^* \otimes I) | \varphi \rangle \geq 1 - C\varepsilon\). By using that \(E = E^+ - E^-\) and that \(E^+ + E^- = I\), we find that \(E = I - 2E^-\), and therefore we get

\[
1 - C\varepsilon \leq \langle \varphi | (AEA^*E^* \otimes I) | \varphi \rangle = \langle \varphi | (AIA^*E^* \otimes I) | \varphi \rangle - 2 \langle \varphi | (AE - A^*E^*) (E^- \otimes I) | \varphi \rangle = 1 - 2 \langle \varphi | ((E^-)^* \otimes I) | \varphi \rangle - 2 \langle \varphi | (AE - A^*E^*) (E^- \otimes I) | \varphi \rangle + 2 \langle \varphi | (AE - A^*E^*) (E^- \otimes I) | \varphi \rangle,
\]

and noting that \(E^-\) is a projector, we find that \(\langle \varphi | (AE - A^*E^*) (E^- \otimes I) | \varphi \rangle \geq 0\), so rearranging the above, we get that

\[
\langle \varphi | (AE - A^*E^*) (E^- \otimes I) | \varphi \rangle \geq \langle \varphi | (E^- \otimes I) | \varphi \rangle + \langle \varphi | (AE - A^*E^*) (E^- \otimes I) | \varphi \rangle - C\varepsilon = \langle \varphi | (E^- \otimes I) | \varphi \rangle - C\varepsilon = 0 - \frac{C\varepsilon}{2},
\]

as required.

We are now ready to prove approximate commutation of \(A_1, \ldots, A_9\) with \(E = A_3A_6A_9\) for a \((1 - \varepsilon)\)-optimal strategy for the Glued Magic Square game, where we will then later use Lemma A.4 to show that it does in fact restrict to a \((1 - O(\varepsilon))\)-optimal strategy for the Magic Square game.

**Lemma A.6.** Fix a strategy \(|\psi\rangle \in \mathcal{H}_A \otimes \mathcal{H}_B, \{A_x\}_x, \{B_j\}_j\) for a glued pseudo-telepathy LCS with a Magic Square part achieving a winning probability of \(1 - \varepsilon\) for some \(\varepsilon > 0\), and suppose the observables \(A_1, \ldots, A_9\) for Alice and \(B_1, \ldots, B_9\) correspond to the Magic Square part, as illustrated in Figure 1a. Then it holds that for \(E := A_3A_6A_9\) and \(F := B_3B_6B_9\), we have

\[
\langle \psi | (E_{ij}E_i^* \otimes I_B) | \psi \rangle = 1 - O(\varepsilon), \quad \text{and} \quad \langle \psi | (I_A \otimes FB_jF^*B_j^*) | \psi \rangle = 1 - O(\varepsilon)
\]

for all \(i, j \in [9]\).
Similarly, by defining $F = A_2 A_3 \otimes I$ we get 11 possible questions and wins using her strategy along with Bob with probability $1 - \varepsilon$, she correctly answers every question with probability at least $1 - 11\varepsilon$. This implies, for example, that $\langle \psi \rangle (A_1 A_2 A_3 \otimes I) |\psi\rangle = 1 - O(\varepsilon)$, and similarly for other products of operators along rows and columns, except for the column corresponding to the odd constraint. We therefore find:

$$1 = \langle \psi | I |\psi\rangle = \langle \psi | (A_2 A_2 \otimes I) |\psi\rangle$$

$$= \langle \psi | ((A_2 A_7 A_7 A_2) \otimes I) |\psi\rangle$$

$$= \langle \psi | ((A_2 A_7 A_2 A_7 A_2) \otimes I) |\psi\rangle$$

$$= \langle \psi | ((A_2 (A_1 A_4)(A_5 A_8)) A_2 (A_1 A_4) (A_5 A_8) \otimes I) |\psi\rangle - O(\varepsilon)$$

$$= \langle \psi | ((A_3 A_6 A_8 A_3 A_6 A_8) \otimes I) |\psi\rangle - O(\varepsilon)$$

$$= \langle \psi | ((A_2 A_1 A_4 A_5 A_4 A_5 A_4 A_3 A_6 A_8) \otimes I) |\psi\rangle - O(\varepsilon)$$

$$= \langle \psi | ((E A_8 E A_8) \otimes I) |\psi\rangle - O(\varepsilon)$$

Note that in the first three lines we have merely used that $A_2$ and $A_7$ are observables, while we have inserted several relations using Lemma A.2 between the third and fourth line. As Lemma A.2 does not directly allow insertion inside a product but only at the two ends, we have used Lemma A.3 to cyclically shift the expression such that the place we want to insert a relation is at the beginning or end.

Now note that the above expression is indeed what we want, as both $E$ and $A_8$ are self-adjoint. The proof of approximate commutation for $A_i$ with $E$ for $i \in \{1, 2, 4, 5, 7\}$ follow in a similar way (for $i \in \{3, 6, 9\}$ it holds exactly as this is required for the strategy to be well-defined), and so does the approximate commutation between $B_j$ and $F$, for $j \in [9]$.

**Theorem A.7.** Suppose $S = (\{\psi\} \in H_A \otimes H_B, \{A_2\}_{x \in [18]}, \{B_j\}_{y \in [18]})$ is a strategy winning the Glued Magic Square game with probability $1 - \varepsilon$ for some $\varepsilon \geq 0$. Then by defining $E = A_3 A_6 A_9$, $G = B_3 B_6 B_9$ and $|\varphi_1\rangle := \frac{(E - G^+)|\psi\rangle}{\|(E - G^+)|\psi\rangle}$, there exists a constant $C \geq 0$ such that the strategy $S_1 = (|\varphi_1\rangle, \{E_A^1 E_{A^1}\}_{x \in [9]}, \{G_B^1 G_{B^1}\}_{y \in [9]})$ wins the Magic Square game with probability $1 - C\varepsilon$.

Similarly, by defining $F = A_{10} A_{13} A_{16}$ and $H = B_{10} B_{13} B_{16}$ and $|\varphi_2\rangle := \frac{(F - H^+)|\psi\rangle}{\|(F - H^+)|\psi\rangle}$, there is some constant $C' \geq 0$ such that $S_2 = (|\varphi_2\rangle, \{F_A^1 F_{A^1}\}_{x \in [9]}, \{H_B^1 H_{B^1}\}_{y \in [9]})$ wins the Magic Square game with probability $1 - C'\varepsilon$.

**Proof.** Initially consider the state $|\eta\rangle = (E^\perp \otimes I) |\psi\rangle$, which is in general not normalised, and consider

$$\langle \eta | (E^\perp \otimes G^+) |\eta\rangle = \langle \eta | (E^\perp \otimes I) |\eta\rangle - \langle \eta | (E^\perp \otimes G^+) |\eta\rangle$$

$$= \langle \psi | (E^\perp \otimes I)^3 |\psi\rangle - \langle \psi | (E^\perp \otimes I)(E^\perp \otimes G^+)(E^\perp \otimes I) |\psi\rangle$$

$$= \langle \psi | (E^\perp \otimes I) |\psi\rangle - \langle \psi | (E^\perp \otimes G^+) |\psi\rangle$$

$$= \| (E^\perp \otimes I) |\psi\rangle \|^2 - \langle \psi | (E^\perp \otimes G^+) |\psi\rangle .$$

Now note that $\langle \psi | (E^\perp \otimes G^+) |\psi\rangle$ gives the probability that Alice’s and Bob’s are not consistent when Alice is asked for the odd constraint and Bob is asked to assign values to either of the topmost three variables. However, they are consistent with probability $1 - O(\varepsilon)$, so we find $\langle \psi | (E^\perp \otimes G^+) |\psi\rangle = O(\varepsilon)$. Therefore, by defining the normalised state $|\phi\rangle = \frac{|\eta\rangle}{\| |\eta\rangle \|}$ we find by the above that

$$\langle \phi | (E^\perp \otimes G^+) |\phi\rangle = \frac{1}{\| |\eta\rangle \|^2} \left( \| (E^\perp \otimes I) |\eta\rangle \|^2 - \langle \psi | (E^\perp \otimes G^+) |\psi\rangle \right) = 1 - O(\varepsilon), \quad (A.1)$$
which shows that $E^- \otimes G^-$ approximately acts like the identity operator on $(E^- \otimes I) |\psi\rangle$.

Note that for any $i \in [9]$ it holds by Lemma [A.6] that $\langle \phi | (A_i E A_i^\dagger E^*) \otimes I | \phi \rangle = 1 - O(\epsilon)$. We can use this to show that $\mathcal{S}_1$ approximately satisfies the relations required by the Magic Square by initially using Lemma [A.4] to conclude that the relation approximately holding on $|\phi\rangle$ also does so on $|\phi\rangle$ (note that here $|\phi\rangle$ is normalised, while the lemma is formulated without that assumption).

\[
1 - O(\epsilon) = \langle \psi | ((A_1 A_2 A_3) \otimes I) | \psi \rangle = \langle \phi | ((A_1 A_2 A_3) \otimes I) | \phi \rangle - O(\epsilon) = \langle \phi | ((E^- \otimes I)^6 (A_1 A_2 A_3) \otimes I) | \phi \rangle - O(\epsilon) = \langle \phi | ((E^- A_1 E^- A_2 E^- A_3 E^-) \otimes I) | \phi \rangle - O(\epsilon)
\]

Note that in the third equality we have merely used that $E^- \otimes I$ is idempotent, and that it preserves $|\phi\rangle$. In the fourth equality we have used Lemma [A.2] and [A.3] to insert the commutation relations between $A_i$ and $E^-$ which we get from Lemma [A.6] and use Lemma [A.5] to restrict to $|\phi\rangle$.

Similarly one can show that the operators $E^- A_i E^- \forall O(\epsilon)$-approximately satisfy the relations required of the Magic Square game, when applying them to the state $|\phi\rangle$. However $\mathcal{S}_1$ uses another state, so we need to translate between those two. Therefore, suppose $R$ is a relation which is approximately satisfied for $|\phi\rangle$, i.e. that $\langle \phi | R | \phi \rangle = 1 - O(\epsilon)$. Then by using Lemma [A.2] we find that as $\langle \phi | E^- \otimes G^- | \phi \rangle = 1 - O(\epsilon)$,

\[
1 - O(\epsilon) = \langle \phi | (E^- \otimes G^-) R (E^- \otimes G^-) | \phi \rangle = \| |\phi\| |^2 \cdot \langle \psi | (E^- \otimes I) R (E^- \otimes G^-) | \psi \rangle = \langle \psi | (E^- \otimes I) | \psi \rangle \cdot \langle \psi | (E^- \otimes G^-) R (E^- \otimes G^-) | \psi \rangle = \frac{\langle \psi | (E^- \otimes I) | \psi \rangle}{\langle \psi | (E^- \otimes G^-) | \psi \rangle} \cdot \langle \psi | (E^- \otimes G^-) R (E^- \otimes G^-) | \psi \rangle ,
\]

and by using [A.1], we find that $\frac{\langle \psi | (E^- \otimes I) | \psi \rangle}{\langle \psi | (E^- \otimes G^-) | \psi \rangle} = 1 - O(\epsilon)$. This now implies that $\mathcal{S}_1$ is a $(1-O(\epsilon))$-optimal strategy for the Glued Magic Square game, since we can perform similar proofs for Bob’s strategy. Furthermore, the same proofs go through for $\mathcal{S}_2$, as long as $(F^- \otimes H^-) | \psi \rangle \neq 0$. \qed
