

Torsion of algebraic groups and iterate extensions associated with Lubin-Tate formal groups

Yoshiyasu Ozeki*

January 8, 2022

Abstract

We show finiteness results on torsion points of commutative algebraic groups over a p -adic field K with values in various algebraic extensions L/K of infinite degree. We mainly study the following cases: (1) L is an abelian extension which is a splitting field of a crystalline character (such as a Lubin-Tate extension). (2) L is a certain iterate extension of K associated with Lubin-Tate formal groups, which is familiar with Kummer theory.

1 Introduction

Let p be a prime number. It is known (cf. [Mat], [CL, Theorem 5.2 (a)]) that, for any abelian variety A over a p -adic field K and any finite extension L of K , we have

$$A(L) \simeq \mathbb{Z}_p^{\oplus [L:\mathbb{Q}_p] \cdot \dim A} \oplus (\text{a finite group}).$$

Thus we may say that the free part of the Mordell-Weil group $A(L)$ is well-understood (in contrast to the number field case). Furthermore, some explicit bounds on the size of the torsion part $A(L)_{\text{tor}}$ of $A(L)$ is also studied under certain reduction hypothesis on A (cf. [Si1], [Si2] and [CX]). We are interested in the finiteness of $A(L)_{\text{tor}}$ in the case where L is an algebraic extension of K of infinite degree. Motivated by the Mazur's question [Maz] for the Mordell-Weil group over a cyclotomic field, Imai showed in [Im] that the torsion subgroup of $A(K(\mu_{p^\infty}))$ is finite if A has potential good reduction, which is well-known as a powerful tool in Iwasawa theory. Here, μ_{p^∞} is the set of p -power roots of unity. Some “generalizations” of Imai's theorem are also known. One of generalization is given by Kubo and Taguchi [KT]; they showed that Imai's theorem still holds if we replace $K(\mu_{p^\infty})$ with $K(K^{1/p^\infty})$, where K^{1/p^∞} is the set of p -power roots of all elements of K .

Another generalization is given in [Oz], which shows that Imai's theorem still holds if we replace $K(\mu_{p^\infty})$ with the composite field of K and various Lubin-Tate extensions over p -adic fields.

In this paper, we give further discussions of [Oz] and consider a ‘‘Lubin-Tate theoretic’’ generalization of [KT]. We need some notation to state our main theorems. Let k be a p -adic subfield of K with residue field \mathbb{F}_q , \mathcal{O}_k the integer ring of k and take a uniformizer π of k . We take any $\phi = \phi(X) \in \mathcal{O}_k[[X]]$ with the property that $\phi(X) \equiv X^q \pmod{\pi}$ and $\phi(X) \equiv \pi X \pmod{X^2}$. We set

$$\tilde{K} := K(x \in \mathbf{m}_{\overline{K}} \mid \phi^n(x) \in K \text{ for some } n \geq 1).$$

Here, \overline{K} is a (fixed) algebraic closure of K , $\mathbf{m}_{\overline{K}}$ is its maximal ideal and ϕ^n is the n -th composite of ϕ . The field \tilde{K} has a geometric interpretation as follows: Denote by \mathbf{m}_K the maximal ideal of the integer ring \mathcal{O}_K of K . Let F be the Lubin-Tate formal group over \mathcal{O}_k associated with π . Then \tilde{K} is the extension field of K obtained by adjoining to K all π^n -th roots of all elements of $F(\mathbf{m}_K)$ for all n . If $k = \mathbb{Q}_p$ and $\pi = p > 2$, then we have $\tilde{K} = K((\mathcal{O}_K^\times)^{1/p^\infty})$ where $(\mathcal{O}_K^\times)^{1/p^\infty}$ is the set of p -power roots of all units of \mathcal{O}_K^\times (cf. Example 5.2). Thus, in some sense, the field \tilde{K} is ‘‘closely related’’ to the field studied by Kubo and Taguchi. The field \tilde{K} satisfies the following interesting properties (see Section 5).

- \tilde{K} is independent of the choice of ϕ ; it depends only on the choice of K, k and π .
- \tilde{K} has a finite residue field and contains k_π . Here, k_π/k is the Lubin-Tate extension associated with π .
- \tilde{K} is a non-abelian p -adic Lie extension of K and the extension \tilde{K}/Kk_π is a $\mathbb{Z}_p^{\oplus [K:\mathbb{Q}_p]}$ -extension. The maximal abelian extension of K contained in \tilde{K} is a finite extension of Kk_π .

For the study of the Galois group $\text{Gal}(\tilde{K}/Kk_\pi)$, we follow the Kummer theory arguments of Ribet [Ri1], [Ri2] and Banaszak-Gajda-Krason [BGK].

Our interest is to study the finiteness of torsion points of abelian varieties, more generally, commutative algebraic groups, with values in (a finite extension of) \tilde{K} . Now, first main result is as follows.

Theorem 1.1. *Assume that the pair (k, π) does not satisfy the condition (W) explained just below. Then, for any finite extension L of \tilde{K} and any abelian variety A over L with potential good reduction, the torsion subgroup $A(L)_{\text{tor}}$ of $A(L)$ is finite.*

The condition (W) appeared in the theorem is as follows. Let k_G be the Galois closure of k/\mathbb{Q}_p and set $d_G := [k_G : \mathbb{Q}_p]$. Fix an embedding $\overline{\mathbb{Q}} \hookrightarrow \overline{\mathbb{Q}_p}$. We say that α is a q -Weil integer of weight w (resp. a q -Weil number of weight w) if α is an algebraic integer (resp. an algebraic number) such that $|\iota(\alpha)| = q^{w/2}$ for any embedding $\iota: \overline{\mathbb{Q}} \hookrightarrow \mathbb{C}$. Then, the condition (W) is;

(W) $\text{Nr}_{k/\mathbb{Q}_p}(\pi)$ is a q -Weil integer of weight d_G/c for some integer c with $1 \leq c \leq d_G$.

Theorem 1.1 is a generalization and also a slight refinement of the main theorem of [Oz]; it shows that, if (W) with a bit stronger assumption on the weight does not hold, then the torsion subgroup of $A(L)$ is finite for any finite extension L of k_π and any abelian variety A over L with potential good reduction. Note that Imai's theorem can be recovered by applying the main theorem of [Oz] (or Theorem 1.1 above) with $k = \mathbb{Q}_p$ and $\pi = p$. We remark that our results should give applications to Iwasawa theory, for example, control theorems of Selmer groups for abelian varieties over certain p -adic Lie extensions of number fields. In fact, arguments of [KT, Section 6] seem to be familiar with our results.

We immediately see that the condition (W) is not enough if we hope to remove the reduction hypothesis from Theorem 1.1 for a finiteness property of torsion points. (In fact, consider the case where A is an elliptic curve with split multiplicative reduction and $(k, \pi) = (\mathbb{Q}_p, p)$. Then the pair (\mathbb{Q}_p, p) does not satisfy (W) but $A(\tilde{K})_{\text{tor}}$ is infinite since \tilde{K} contains $k_\pi = \mathbb{Q}_p(\mu_{p^\infty})$.) To overcome this, we consider the following additional condition.

(μ) $q^{-1}\mathrm{Nr}_{k/\mathbb{Q}_p}(\pi)$ is a root of unity.

Our second result below can be applied to not only abelian varieties with potential good reduction but also all commutative algebraic groups (here, an algebraic group over a field F is a group scheme of finite type over F).

Theorem 1.2. *Assume that the pair (k, π) satisfies neither (W) nor (μ) . Then, for any finite extension L of \tilde{K} and any commutative algebraic group G over L , the torsion subgroup $G(L)_{\mathrm{tor}}$ of $G(L)$ is finite.*

We show this theorem by combining Theorem 1.1, a structure theorem of commutative algebraic groups and a non-archimedean rigid uniformization theorem of abelian varieties ([Ra], [BL] and [BX]).

Furthermore, we show that, for given p -adic fields $k \subset K$, there are only finitely many possibilities of the absolute norm $\mathrm{Nr}_{k/\mathbb{Q}_p}(\pi)$ which might admit infiniteness of $G(\tilde{K})_{\mathrm{tor}}$ for some algebraic group G over K . Moreover, we show “uniform” version of this phenomenon. We denote by f_K the extension degree of the residue field extension of K/\mathbb{Q}_p .

Theorem 1.3. *Let $f, g > 0$ be positive integers. There exists a finite set $\mathcal{W} = \mathcal{W}(f, g; k)$ of q -Weil integers depending only on f, g and k which satisfies the following property: If $\mathrm{Nr}_{k/\mathbb{Q}_p}(\pi) \notin \mathcal{W}$, then for any finite extension K/k with $f_K \leq f$, any commutative algebraic group G over K of dimension at most g and any finite extension L/\tilde{K} , it holds that $G(L)_{\mathrm{tor}}$ is finite.*

In Section 4, we also give finiteness results, such as Theorems 1.1 and 1.2, on torsion of commutative algebraic groups with values in abelian extensions which are splitting fields of some crystalline characters (such as Lubin-Tate extensions). The results seem to be conceptual and theoretical but they covers main results of [Im] and [Oz].

Acknowledgments. The author would like to express his sincere gratitude to T. Hiranouchi and Y. Taguchi for useful discussions. This work is supported by JSPS KAKENHI Grant Number JP19K03433.

Notation : For any algebraic extension F of \mathbb{Q}_p , we denote by G_F the absolute Galois group of F . We also denote by \mathcal{O}_F and \mathfrak{m}_F the ring of integers of F and its maximal ideal, respectively. For an algebraic extension F'/F , we denote by $f_{F'/F}$ the extension degree of the residue field extension of F'/F . We set $f_F := f_{F/\mathbb{Q}_p}$ to simplify notation. We denote by $\mu_n(F)$ the set of n -th roots of unity in F , $\mu_n := \mu_n(\overline{\mathbb{Q}_p})$, $\mu_{\ell^\infty}(F) := \cup_{m \geq 0} \mu_{\ell^m}(F)$ for any prime number ℓ and $\mu_\infty(F) := \cup_{n \geq 0} \mu_n(F)$. Finally, any representation over a field in this paper is of finite dimension.

2 Finiteness criteria of torsion of algebraic groups

The aim of this section is to show that we may reduce arguments of finiteness of torsion points of commutative algebraic groups to the cases of tori and abelian varieties with potential good reduction. Let K be a p -adic field and L an algebraic extension of K . Let $0 < g \leq \infty$ and let ℓ be any prime number (including the case $\ell = p$). We consider the following conditions for a fixed data $(L/K, g, \ell)$:

(μ_{ℓ^∞}) The set $\mu_{\ell^\infty}(L')$ is finite for any finite extension L' of L .

$(\mathrm{AV}_{\ell^\infty})$ For any abelian variety A over K with potential good reduction of dimension $\leq g$, the set $A(L)[\ell^\infty]$ is finite.

We also consider the following conditions for a fixed data $(L/K, g)$:

(μ_∞) The set $\mu_\infty(L')$ is finite for any finite extension L' of L .

(AV $_{\infty}$) For any abelian variety A over K with potential good reduction of dimension $\leq g$, the set $A(L)_{\text{tor}}$ is finite.

Remark 2.1. Suppose that L is a Galois extension of K . We check that the condition $(\mu_{\ell^{\infty}})$ (resp. (μ_{∞})) holds if and only if the set $T(L)[\ell^{\infty}]$ (resp. $T(L)_{\text{tor}}$) is finite for any torus T over K .

The necessity is clear and so we show the sufficiency. Assume that the set $T(L)[\ell^{\infty}]$ (resp. $T(L)_{\text{tor}}$) is finite for any torus T over K . Let L' be a finite extension of L . Let $T_L := \text{Res}_{L'/L}(\mathbb{G}_m)$ be the Weil restriction of \mathbb{G}_m . We have $T_L(L) = \mathbb{G}_m(L')$ by definition. The torus T_L descends to a torus T_{K_0} over a finite subextension K_0/K of L/K . We set $H := \text{Res}_{K_0/K}(T_{K_0})$, which is a torus over K . Since L is a Galois extension of K , we have isomorphisms

$$H(L) = T_{K_0}(L \otimes_K K_0) \simeq \prod_{\sigma} T_{K_0}(L) \simeq \prod_{\sigma} \mathbb{G}_m(L')$$

where σ runs through all K -algebra embeddings $K_0 \hookrightarrow L$. Now the finiteness of $\mu_{\ell^{\infty}}(L')$ (resp. $\mu_{\infty}(L')$) follows by the assumption.

Proposition 2.2. *Assume that L is a Galois extension of K .*

- (1) *If both $(\mu_{\ell^{\infty}})$ and $(\text{AV}_{\ell^{\infty}})$ hold for $(L/K, g, \ell)$, then $G(L)[\ell^{\infty}]$ is finite for any commutative algebraic group G over K of dimension $\leq g$.*
- (2) *If both (μ_{∞}) and (AV_{∞}) hold for $(L/K, g)$, then $G(L)_{\text{tor}}$ is finite for any commutative algebraic group G over K of dimension $\leq g$.*

Proof. At first, we reduce a proof to the case where G is an abelian variety. By a structure theorem of commutative algebraic groups (cf. [Br, Theorem 2.9]), the commutative algebraic group G lies in an exact sequence

$$0 \rightarrow M \times U \rightarrow G \rightarrow A \rightarrow 0$$

of group schemes over K . Here, M is a subgroup scheme of a torus, U is unipotent and A is an abelian variety. Since $U(L)$ is torsion free, we have exact sequences

$$0 \rightarrow M(L)[\ell^{\infty}] \rightarrow G(L)[\ell^{\infty}] \rightarrow A(L)[\ell^{\infty}] \quad \text{and} \quad 0 \rightarrow M(L)_{\text{tor}} \rightarrow G(L)_{\text{tor}} \rightarrow A(L)_{\text{tor}} \quad (2.1)$$

of G_K -modules. The finiteness of $M(L)[\ell^{\infty}]$ (resp. $M(L)_{\text{tor}}$) follows from $(\mu_{\ell^{\infty}})$ (resp. (μ_{∞})). Thus, to show the proposition, we may assume that G is an abelian variety.

In the rest of the proof, we assume that G is an abelian variety of dimension $\leq g$ and denote G by A . We denote by g_A the dimension of A . We use a non-archimedean rigid uniformization theorem of abelian varieties ([Ra], [BL] and [BX]); there exist the following data, which is called a *rigid uniformization* of A (cf. [BX, Definition 1.1 and Theorem 1.2]):

- (i) S is a semi-abelian variety of dimension g_A fits into an exact sequence of K -group schemes $0 \rightarrow T \rightarrow S \rightarrow B \rightarrow 0$ where T is a torus of rank m and B is an abelian variety which has potential good reduction,
- (ii) a closed immersion of rigid K -groups $N^{\text{an}} \hookrightarrow S^{\text{an}}$ where N is a group scheme which is isomorphic to $\mathbb{Z}^{\oplus m}$ after a finite base extension. Here, the subscript “an” is the GAGA functor, and
- (iii) a faithfully flat morphism $S^{\text{an}} \rightarrow A^{\text{an}}$ of rigid K -groups with kernel N^{an} .

It holds that $\dim B \leq g_A \leq g$ and we have exact sequences

$$0 \rightarrow N(\overline{K}) \rightarrow S(\overline{K}) \rightarrow A(\overline{K}) \rightarrow 0 \quad \text{and} \quad 0 \rightarrow T(\overline{K}) \rightarrow S(\overline{K}) \rightarrow B(\overline{K}) \rightarrow 0$$

of G_K -modules (since “ $N \rightarrow S \rightarrow A$ ” are rigid analytic morphisms, the exactness of the former sequence might not be well-known; see the proof of [CX, Theorem 2.3] for this).

Proof of (1). Assume (μ_{ℓ^∞}) and (AV_{ℓ^∞}) for $(L/K, g, \ell)$. We have exact sequences

$$0 \rightarrow V_\ell(S)^{G_L} \rightarrow V_\ell(A)^{G_L} \rightarrow \mathbb{Q}_\ell \otimes_{\mathbb{Z}} N(\overline{K}) \quad \text{and} \quad 0 \rightarrow V_\ell(T)^{G_L} \rightarrow V_\ell(S)^{G_L} \rightarrow V_\ell(B)^{G_L}$$

of G_K -modules (here we recall that L is a Galois extension of K), where $V_\ell(*)$ stands for the rational ℓ -adic Tate module. By (μ_{ℓ^∞}) and (AV_{ℓ^∞}) for $(L/K, g, \ell)$, we know that $V_\ell(T)^{G_L}$ and $V_\ell(B)^{G_L}$ are zero, respectively (here, we recall that the dimension of B is at most g). This gives the fact that $V_\ell(S)^{G_L}$ is also zero. Hence we have an injection $V_\ell(A)^{G_L} \hookrightarrow \mathbb{Q}_\ell \otimes_{\mathbb{Z}} N(\overline{K})$ of G_K -modules. This shows that the G_K -action on $V_\ell(A)^{G_L}$ factors through a finite quotient. Hence there exists a p -adic subfield K' of L such that $V_\ell(A)^{G_L} = V_\ell(A)^{G_{K'}}$. Since $V_\ell(A)^{G_{K'}}$ is zero by the main theorem of [Mat], we conclude that $A(L)[\ell^\infty]$ is finite.

Proof of (2). Assume (μ_∞) and (AV_∞) for $(L/K, g)$. It follows from (1) that $A(L)[\ell^\infty]$ is finite for all prime numbers ℓ . Hence it suffices to show that $A(L)[\ell] = 0$ for almost all prime numbers $\ell \neq p$. Consider exact sequences

$$0 \rightarrow S(L)[\ell] \rightarrow A(L)[\ell] \rightarrow N(\overline{K})/\ell N(\overline{K}) \quad \text{and} \quad 0 \rightarrow T(L)[\ell] \rightarrow S(L)[\ell] \rightarrow B(L)[\ell]$$

of G_K -modules (again we recall that L is a Galois extension of K). It follows from (μ_∞) and (AV_∞) for $(L/K, g)$ that $T(L)[\ell]$ and $B(L)[\ell]$ are zero for any ℓ large enough, respectively (again, we recall that the dimension of B is at most g), which implies $S(L)[\ell] = 0$. For such ℓ , we have an injection $A(L)[\ell] \hookrightarrow N(\overline{K})/\ell N(\overline{K})$ of G_K -modules. Now we take a finite extension K'/K so that N is isomorphic to a constant group $\mathbb{Z}^{\oplus m}$ over K' . Then the existence of an injection $A(L)[\ell] \hookrightarrow N(\overline{K})/\ell N(\overline{K})$ of G_K -modules shows $A(L)[\ell] = A(L \cap K')[\ell]$, which must be zero for any ℓ large enough by the main theorem of [Mat]. \square

Remark 2.3. In Proposition 2.2, the condition that L is a *Galois* extension of K is necessarily. Let ϖ be a uniformizer of K and ϖ_n a p^n -th power root of ϖ such that $\varpi_0 = \varpi$ and $\varpi_{n+1}^p = \varpi_n$ for all $n \geq 0$. We set $L := K(\varpi_n; n \geq 0)$, which is not a Galois extension of K . We see that (μ_∞) is satisfied for $(L/K, g)$. It is a result of [KT] that (AV_∞) also hold for $(L/K, g)$. However, if we denote by E_ϖ the Tate curve over K associated with ϖ , then $E_\varpi(L)[p^\infty]$ is infinite.

By considering Weil restrictions, we obtain a slight generalization of Proposition 2.2 in the case $g = \infty$.

Corollary 2.4. *Assume that L is a Galois extension of K .*

- (1) *If both (μ_{ℓ^∞}) and (AV_{ℓ^∞}) hold for $(L/K, g = \infty, \ell)$, then $G(M)[\ell^\infty]$ is finite for any finite extension M/L and any commutative algebraic group G over M .*
- (2) *If both (μ_∞) and (AV_∞) hold for $(L/K, g = \infty)$, then $G(M)_{\text{tor}}$ is finite for any finite extension M/L and any commutative algebraic group G over M .*

Proof. Let G be a commutative algebraic group over M . Let $G_0 := \text{Res}_{M/L}(G)$ be the Weil restriction. Then G_0 descends to a commutative algebraic group over a p -adic subfield K_0 in L/K , which we also denote by G_0 . Setting $H := \text{Res}_{K_0/K}(G_0)$, then H is a commutative algebraic group over K and we have isomorphisms $H(L) \simeq \prod_{\sigma} G_0(L) \simeq \prod_{\sigma} G(M)$ where σ runs through all K -algebra embeddings $K_0 \hookrightarrow L$. Now the results immediately follow from Proposition 2.2. \square

3 Locally algebraic representations and the invariant δ_χ

We recall standard properties of locally algebraic representations (cf. [Se], [Co, Appendix B]). We also introduce an invariant δ_χ for crystalline characters χ . The keys in this section are Lemmas 3.3 and 3.9, which will be often used later.

3.1 Locally algebraic representations

Let k and E be p -adic fields and $\chi: G_k \rightarrow E^\times$ a continuous character. We often regard χ as a character of G_k^{ab} . Let $\text{Art}_k: k^\times \rightarrow G_k^{\text{ab}}$ be the local Artin map with arithmetic normalization. We define \mathbb{Q}_p -tori \underline{k}^\times and \underline{E}^\times to be the Weil restrictions of scalars $\underline{k}^\times := \text{Res}_{k/\mathbb{Q}_p}(\mathbb{G}_m)$ and $\underline{E}^\times := \text{Res}_{E/\mathbb{Q}_p}(\mathbb{G}_m)$.

Definition 3.1. We say that χ is *locally algebraic* if there exists a (necessarily unique) \mathbb{Q}_p -homomorphism $\underline{k}^\times \rightarrow \underline{E}^\times$ whose restriction to \mathbb{Q}_p -points agrees with $\chi \circ \text{Art}_k$ near 1.

Proposition 3.2. *Let $E(\chi)$ be the \mathbb{Q}_p -representation of G_k underlying a 1-dimensional E -vector space endowed with an E -linear action by G_k via χ . Then, $E(\chi)$ is Hodge-Tate if and only if χ is locally algebraic.*

Proof. The result is a consequence of [Se, III, A.6, Corollary]. \square

Assume that $E(\chi)$ is Hodge-Tate. For any $\sigma \in \Gamma_E$, let $\chi_{\sigma E}: I_{\sigma E} \rightarrow E^\times$ be the restriction to the inertia $I_{\sigma E}$ of the Lubin-Tate character associated with any choice of uniformizer of σE (it depends on the choice of a uniformizer of σE , but its restriction to the inertia subgroup does not). Then, taking a finite extension k' of kE large enough, we have

$$\chi = \prod_{\sigma \in \Gamma_E} \sigma^{-1} \circ \chi_{\sigma E}^{h_\sigma}$$

on the inertia $I_{k'}$ for some integer h_σ . We may assume that k' contains the Galois closure \tilde{k} of kE/\mathbb{Q}_p . Note that $\{h_\sigma \mid \sigma \in \Gamma_E\}$ is the set of Hodge-Tate weights of $E(\chi)$, that is, $C \otimes_{\mathbb{Q}_p} E(\chi) \simeq \bigoplus_{\sigma \in \Gamma_E} C(h_\sigma)$ where C is the completion of $\overline{\mathbb{Q}_p}$. Thus $h = h_{E(\chi)} := \sum_{\sigma \in \Gamma_E} h_\sigma$ is the sum of all Hodge-Tate weights of $E(\chi)$. We also set $\tilde{h} := [\tilde{k} : E] \cdot h$, which is the sum of all Hodge-Tate weights of $\tilde{k}(\chi)$. We denote by k_χ the definition field of χ and put $K_\chi = Kk_\chi$ for any p -adic field K .

Lemma 3.3. *Assume that χ is locally algebraic and let the notation for χ be as above. Let K and F be p -adic fields and $\psi: G_K \rightarrow F^\times$ a locally algebraic character such that the restriction of ψ to an open subgroup of G_{K_χ} is trivial. We fix a lift $\hat{u}: \overline{\mathbb{Q}_p} \rightarrow \overline{\mathbb{Q}_p}$ of each $u \in \Gamma_{\tilde{k}}$. If k_χ has a finite residue field, then we have*

$$\left(\prod_{u \in \Gamma_{\tilde{k}}} \hat{u} \circ \psi \right)^{\tilde{h}} = \left(\prod_{u \in \Gamma_{\tilde{k}}} \hat{u} \circ \chi \right)^{\tilde{r}}$$

on an open subgroup of G_{Kk} . Here, $\tilde{r} = \sum_{\tau \in \Gamma_{\tilde{k}}} r_\tau$ for some Hodge-Tate weight r_τ of $F(\psi)$.

Proof. Take a Galois extension K'/\mathbb{Q}_p so that all the properties below hold.

- (i) K' contains K, k' and the Galois closure of F/\mathbb{Q}_p ,
- (ii) ψ is trivial on $G_{K'_\chi}$ and
- (iii) $\psi = \prod_{\sigma \in \Gamma_{K'}} \sigma^{-1} \circ \chi_{\sigma F}^{n_\sigma}$ on $I_{K'}$ where $\chi_{\sigma F}$ is the restriction to $I_{\sigma F} (\supset I_{K'})$ of the Lubin-Tate character associated with a uniformizer of σF .

On the other hand, we have a decomposition $\mathcal{O}_E^\times = \mu_\infty(E) \times V_E$, where $\mu_\infty(E)$ is the set of roots of unity in E and V_E is an open subgroup of \mathcal{O}_E^\times which is isomorphic to $\mathbb{Z}_p^{[E:\mathbb{Q}_p]}$. Replacing K' by a finite extension, we may assume that

- (iv) $\chi(I_{K'})$ has values in V_E .

Note that χ coincides with $\prod_{\sigma \in \Gamma_E} \sigma^{-1} \circ \chi_{\sigma E}^{h_\sigma}$ on $I_{K'}$ by (i) and the set $\{n_\sigma \mid \sigma \in \Gamma_F\}$ is the set of Hodge-Tate weights of $F(\psi)$. Put $I_{K'}^{\text{ab}} = \text{Gal}(K'^{\text{ab}}/K'^{\text{ur}})$, $I_{\tilde{k}}^{\text{ab}} = \text{Gal}(\tilde{k}^{\text{ab}}/\tilde{k}^{\text{ur}})$, $N' = \text{Gal}(K'^{\text{ur}}K'_\chi/K'^{\text{ur}})$ and $\tilde{N} = \text{Gal}(\tilde{k}^{\text{ur}}\tilde{k}_\chi/\tilde{k}^{\text{ur}})$. Since ψ restricted to $G_{K'_\chi}$ is trivial, $\psi|_{I_{K'}}$ factors through N' . We have the following commutative diagram.

$$\begin{array}{ccccccc} \mathcal{O}_{K'}^\times & \xrightarrow[\text{Art}_{K'}]{\simeq} & I_{K'}^{\text{ab}} & \xrightarrow{\text{res}} & N' & \xrightarrow{\psi} & K'^\times \\ \downarrow \text{Nr}_{K'/\tilde{k}} & & \downarrow \text{res} & & \downarrow \text{res} & & \downarrow \\ \mathcal{O}_{\tilde{k}}^\times & \xrightarrow[\text{Art}_{\tilde{k}}]{\simeq} & I_{\tilde{k}}^{\text{ab}} & \xrightarrow{\text{res}} & \tilde{N} & & \overline{\mathbb{Q}}_p^\times \end{array}$$

Here, “Nr”, “res” and “Art” stand for the norm, the restriction and the local Artin map (with arithmetic normalization), respectively. We claim that there exists a homomorphism $\hat{\psi}: \tilde{N} \rightarrow \overline{\mathbb{Q}}_p^\times$ which makes the above diagram commutative. It follows from the condition (iv) that we may regard N' as a closed submodule of V_E via χ . In particular, N' is a sub \mathbb{Z}_p -module of V_E . By an elementary divisor theory, we may identify V_E and N' with $\bigoplus_{i=1}^{[E:\mathbb{Q}_p]} \mathbb{Z}_p$ and $\bigoplus_{i=1}^{[E:\mathbb{Q}_p]} p^{n_i} \mathbb{Z}_p$ for some $0 \leq n_i \leq \infty$, respectively. Thus we see that there exists an extension $V_E \rightarrow \overline{\mathbb{Q}}_p^\times$ of $\psi: N' \rightarrow K'^\times$. Moreover, it extends to some character $\mathcal{O}_E^\times \rightarrow \overline{\mathbb{Q}}_p^\times$. Composing this with $\chi: \tilde{N} \rightarrow \mathcal{O}_E^\times$, we obtain the desired $\hat{\psi}$.

We regard ψ as a character of $\mathcal{O}_{K'}^\times$ via local class field theory. Then, we have

$$\psi(x) = \prod_{\sigma \in \Gamma_F} \sigma^{-1} \text{Nr}_{K'/\sigma F}(x^{-1})^{n_\sigma} = \prod_{\sigma' \in \Gamma_{K'}} \sigma'^{-1} (x^{-1})^{n_{\sigma'}}$$

for $x \in \mathcal{O}_{K'}^\times$ since K'/\mathbb{Q}_p is a Galois extension. Here, $n_{\sigma'} := n_{\sigma'|_F}$ for $\sigma' \in \Gamma_{K'}$. Then, it follows from the existence of $\hat{\psi}$ that we obtain $\prod_{\sigma' \in \Gamma_{K'}} \sigma'^{-1} (x^{-1})^{n_{\tau\sigma'}} = \prod_{\sigma' \in \Gamma_{K'}} \sigma'^{-1} (x^{-1})^{n_{\sigma'}}$ for $x \in \mathcal{O}_{K'}^\times$ and $\tau \in \text{Gal}(K'/\tilde{k})$. By [Oz, Lemma 2.4], we have $n_{\sigma'} = n_{\rho'}$ for $\sigma', \rho' \in \Gamma_{K'}$ with $\sigma'|_{\tilde{k}} = \rho'|_{\tilde{k}}$. For any $\sigma \in \Gamma_{\tilde{k}}$, we define $r_\sigma := n_{\sigma'}$ for a lift $\sigma' \in \Gamma_{K'}$ of σ . Then we have $\psi(x) = \prod_{\sigma \in \Gamma_{\tilde{k}}} \sigma^{-1} \text{Nr}_{K'/\tilde{k}}(x^{-1})^{r_\sigma}$ for $x \in \mathcal{O}_{K'}^\times$. This implies that we have

$$\psi = \prod_{\sigma \in \Gamma_{\tilde{k}}} \sigma^{-1} \circ \chi_{\tilde{k}}^{r_\sigma} \quad (3.1)$$

on $I_{K'}$ where $\chi_{\tilde{k}}$ is the restriction to $I_{\tilde{k}}(\supset I_{K'})$ of the Lubin-Tate character associated with a uniformizer of \tilde{k} . On the other hand, we have

$$\chi = \prod_{\sigma \in \Gamma_E} \sigma^{-1} \circ \chi_{\sigma E}^{h_\sigma} = \prod_{\sigma \in \Gamma_E} \sigma^{-1} \circ \left(\prod_{\tau \in \Gamma_{\tilde{k}}, \tau|_{\sigma E}=1} \tau \circ \chi_{\tilde{k}} \right)^{h_\sigma} = \prod_{\sigma \in \Gamma_{\tilde{k}}} \sigma^{-1} \circ \chi_{\tilde{k}}^{\tilde{h}_\sigma} \quad (3.2)$$

on $I_{K'}$ where $\tilde{h}_\sigma := h_{\sigma|_E}$ for $\sigma \in \Gamma_{\tilde{k}}$.

Recall that $\hat{u}: \overline{\mathbb{Q}}_p \rightarrow \overline{\mathbb{Q}}_p$ is a lift of $u \in \Gamma_{\tilde{k}}$ and $\tilde{h} = [\tilde{k}: E] \sum_{\sigma \in \Gamma_E} h_\sigma$. We set $\tilde{r} := \sum_{\sigma \in \Gamma_{\tilde{k}}} r_\sigma$. We remark that r_σ is a Hodge-Tate weight of $F(\psi)$ by definition. It follows from (3.1) and (3.2) that we have $\prod_{u \in \Gamma_{\tilde{k}}} \hat{u} \circ \psi = \left(\prod_{\sigma \in \Gamma_{\tilde{k}}} \sigma^{-1} \circ \chi_{\tilde{k}} \right)^{\tilde{r}}$ and $\prod_{u \in \Gamma_{\tilde{k}}} \hat{u} \circ \chi = \left(\prod_{\sigma \in \Gamma_{\tilde{k}}} \sigma^{-1} \circ \chi_{\tilde{k}} \right)^{\tilde{h}}$ on $I_{K'}$. Hence we obtain

$$\left(\prod_{u \in \Gamma_{\tilde{k}}} \hat{u} \circ \psi \right)^{\tilde{h}} = \left(\prod_{u \in \Gamma_{\tilde{k}}} \hat{u} \circ \chi \right)^{\tilde{r}} \quad (3.3)$$

on $I_{K'}$. Since the restriction of ψ and χ to $G_{K'_\chi}$ is trivial and the residue field of k_χ is finite, the equality (3.3) holds on an open subgroup of $G_{K'}$. \square

Remark 3.4. Suppose $k = E$ is a Galois extension of \mathbb{Q}_p and $\chi = \chi_\pi: G_k \rightarrow k^\times$ is the Lubin-Tate character associated with a uniformizer π of k . The argument above shows Lemma 2.5 of [Oz]; if ψ is as in Lemma 3.3, then we have

$$\psi = \prod_{\sigma \in \Gamma_k} \sigma^{-1} \circ \chi_\pi^{r_\sigma}$$

on an open subgroup of G_{Kk} with some Hodge-Tate weight r_σ of $F(\psi)$. In fact, this follows immediately from (3.1) and the assumption that the restriction of ψ to an open subgroup of G_{k_π} is trivial.

3.2 The invariant δ_χ

We introduce a technical invariant for crystalline characters. The following observation of Conrad plays an important role.

Proposition 3.5 ([Co, Proposition B.4]). *Let $E(\chi)$ be the \mathbb{Q}_p -representation of G_k underlying a 1-dimensional E -vector space endowed with a E -linear action by G_k via χ .*

(1) *$E(\chi)$ is crystalline if and only if there exists a \mathbb{Q}_p -homomorphism $\chi_{\text{alg}}: \underline{k}^\times \rightarrow \underline{E}^\times$ such that $\chi \circ \text{Art}_k$ and χ_{alg} (on \mathbb{Q}_p -points) coincides on \mathcal{O}_k^\times .*

(2) *Let k_0 be the maximal unramified subextension of k/\mathbb{Q}_p and put $f = [k_0 : \mathbb{Q}_p]$. Assume that $E(\chi)$ is crystalline and let χ_{alg} be as in (1). (Note that $E(\chi^{-1})$ is also crystalline.) Then, the filtered ϕ -module $D_{\text{cris}}^k(E(\chi^{-1})) = (B_{\text{cris}} \otimes_{\mathbb{Q}_p} E(\chi^{-1}))^{G_k}$ over k is free of rank 1 over $k_0 \otimes_{\mathbb{Q}_p} E$ and its k_0 -linear endomorphism ϕ^f is given by the action of the product $\chi(\text{Art}_k(\pi)) \cdot \chi_{\text{alg}}^{-1}(\pi) \in E^\times$. Here, π is any uniformizer of k .*

Definition 3.6. If $E(\chi)$ is crystalline and χ_{alg} is as in (1) of Proposition 3.5, then we set

$$\delta_\chi := \chi(\text{Art}_k(\pi)) \cdot \chi_{\text{alg}}^{-1}(\pi) \in E^\times.$$

Here, π is any uniformizer of k .

Note that δ_χ is independent of the choice of π by Proposition 3.5 (1). We also note that we have $\delta_{\chi^{-1}} = \delta_\chi^{-1}$ by definition.

Example 3.7. Suppose $k = E$ and χ is the Lubin-Tate character $\chi_\pi: G_k \rightarrow k^\times$ associated with a uniformizer π of k . Then, the \mathbb{Q}_p -homomorphism $\chi_{\text{alg}}: \underline{k}^\times \rightarrow \underline{k}^\times$ corresponding to χ_π is given by $x \mapsto x^{-1}$. Thus we have $\delta_{\chi_\pi} = \pi$.

Definition 3.8. Let K/\mathbb{Q}_p be a finite extension of residual extension degree f_K and K_0/\mathbb{Q}_p the maximal unramified subextension of K/\mathbb{Q}_p . We denote by $\varphi_{K_0}: K_0 \rightarrow K_0$ the arithmetic Frobenius of K_0 , that is, the (unique) lift of p -th power map on the residue field of K_0 .

(1) Let D be a φ -module over K_0 , that is, a finite dimensional K_0 -vector space with φ_{K_0} -semilinear map $\varphi: D \rightarrow D$. Then $\varphi^{f_K}: D \rightarrow D$ is a K_0 -linear map. We call $\det(T - \varphi^{f_K} | D)$ the *characteristic polynomial of D* .

(2) For a \mathbb{Q}_p -representation V of G_K , we set $D_{\text{cris}}^K(V) := (B_{\text{cris}} \otimes_{\mathbb{Q}_p} V)^{G_K}$, which is a filtered φ -module over K .

Lemma 3.9. *Assume that $\chi: G_k \rightarrow E^\times$ is crystalline. Let $\delta_\chi \in E^\times$ be as in Definition 3.6. Let k' and E' be finite extensions of k and E , respectively.*

(1) *$\alpha \in \overline{\mathbb{Q}_p}$ is a root of the characteristic polynomial of the filtered φ -module $D_{\text{cris}}^{k'}(E'(\chi^{-1}))$ over k' if and only if $\alpha = \tau(\delta_\chi)^{f_{k'}/k}$ for some $\tau \in \Gamma_{E'}$.*

(2) *Assume that E' is a Galois extension of \mathbb{Q}_p . Let Γ be a finite set of \mathbb{Q}_p -algebra homomorphisms $\overline{\mathbb{Q}_p} \rightarrow \overline{\mathbb{Q}_p}$. Put $\hat{\chi} = \prod_{\hat{u} \in \Gamma} \hat{u} \circ \chi^{n_{\hat{u}}}$ for some integers $n_{\hat{u}}$. We regard $\hat{\chi}$ as a (crystalline)*

character from G_k to E'^\times . Then, any root of the characteristic polynomial of the filtered φ -module $D_{\text{cris}}^{k'}(E'(\hat{\chi}^{-1}))$ over k' is of the form

$$\left(\prod_{\tau \in \Gamma_E} \tau(\delta_\chi)^{t_\tau} \right)^{f_{k'/k}}$$

for some integers t_τ such that $\sum_{\tau \in \Gamma_E} t_\tau = \sum_{\hat{u} \in \Gamma} n_{\hat{u}}$. Furthermore, we can take each t_τ as a non-negative integer if $n_{\hat{u}} \geq 0$ for any $\hat{u} \in \Gamma$.

Proof. For any crystalline character $\psi: G_k \rightarrow E'^\times$, the set of roots of the characteristic polynomial of the filtered φ -module $D_{\text{cris}}^{k'}(E'(\psi))$ over k' is the $f_{k'/k}$ -th power of that of the filtered φ -module $D_{\text{cris}}^k(E'(\psi))$ over k . Hence it suffices to consider the case where $k' = k$.

(1) By Proposition 3.5, it suffices to show that $\alpha \in \overline{\mathbb{Q}_p}$ is a root of the characteristic polynomial of the multiplication-by- $(1 \otimes \delta_\chi)$ map on the k_0 -vector space $k_0 \otimes_{\mathbb{Q}_p} E'$ if and only if α is of the form $\tau(\delta_\chi)$ for some $\tau \in \Gamma_E$. Since this characteristic polynomial coincides with that of the multiplication-by- δ_χ map on the \mathbb{Q}_p -vector space E' , the result immediately follows (cf. [Ne, Proposition 2.6]).

(2) For crystalline characters $\chi_1, \chi_2: G_k \rightarrow E'^\times$, roots of the characteristic polynomial of $D_{\text{cris}}^k(E'(\chi_1\chi_2))$ is a product of those of $D_{\text{cris}}^k(E'(\chi_1))$ and $D_{\text{cris}}^k(E'(\chi_2))$ since we have a surjection $D_{\text{cris}}^k(E'(\chi_1)) \otimes_{k_0} D_{\text{cris}}^k(E'(\chi_2)) \rightarrow D_{\text{cris}}^k(E'(\chi_1\chi_2))$ induced from the natural map $E'(\chi_1) \otimes_{\mathbb{Q}_p} E'(\chi_2) \rightarrow E'(\chi_1) \otimes_{E'} E'(\chi_2) = E'(\chi_1\chi_2)$. Therefore, it suffices to show that, for any \mathbb{Q}_p -algebra homomorphism $\hat{u}: \overline{\mathbb{Q}_p} \rightarrow \overline{\mathbb{Q}_p}$, any root of the characteristic polynomial of $D_{\text{cris}}^k(E'(\hat{u} \circ \chi^{-1}))$ is of the form $\tau(\delta_\chi)$ with some $\tau \in \Gamma_E$. Comparing traces of two \mathbb{Q}_p -representations $E'(\hat{u} \circ \chi^{-1})$ and $E'(\chi^{-1})$ of G_k , we see that the semi-simplifications of them are isomorphic to each others. Hence we may assume that $\hat{u} = \text{id}$. Therefore, the result follows by (1). \square

4 Finiteness theorems for abelian extensions obtained by crystalline characters

Let k and E be p -adic fields and $\chi: G_k \rightarrow E^\times$ a continuous character. We assume that χ is crystalline. We denote by k_χ the definition field of χ and set $K_\chi := Kk_\chi$ for any p -adic field K . By definition, we have $\ker(\chi|_{G_K}) = G_{K_\chi}$. The aim of this section is to give some finiteness results on torsion points $G(K_\chi)_{\text{tor}}$ for commutative algebraic groups G over K , which are generalizations of the main theorem of [Oz]. The invariant $\delta_\chi \in E^\times$ for χ defined in the previous section plays a crucial role for our results. Let \tilde{k} be the Galois closure of kE/\mathbb{Q}_p and set $\tilde{d} := [\tilde{k} : \mathbb{Q}_p]$.

Theorem 4.1. *Let $\chi: G_k \rightarrow E^\times$ be a crystalline character. Assume that the following two conditions hold.*

(H1) *The residue field of k_χ is finite.*

(H2) *The sum $h_{E(\chi)}$ of all Hodge-Tate weights (with multiplicity) of the \mathbb{Q}_p -representation $E(\chi)$ is not zero.*

Furthermore, we consider the following conditions.

(W)' *$\text{Nr}_{E/\mathbb{Q}_p}(\delta_\chi)$ is a q_k -Weil number of weight $h_{E(\chi)}\tilde{d}/c$ for some integer $1 \leq c \leq \tilde{d}$. If $h_{E(\chi)} > 0$, we furthermore have that $\text{Nr}_{E/\mathbb{Q}_p}(\delta_\chi)$ is an algebraic integer.*

(μ)' *$q_k^{-h_{E(\chi)}} \text{Nr}_{E/\mathbb{Q}_p}(\delta_\chi)$ is a root of unity.*

(1) *Assume that (W)' does not hold. Then, the torsion subgroup $A(K_\chi)_{\text{tor}}$ of $A(K_\chi)$ is finite for any p -adic field K and any abelian variety A over K with potential good reduction.*

(2) *Assume that neither (W)' nor (μ)' holds. Then, the torsion subgroup $G(K_\chi)_{\text{tor}}$ of $G(K_\chi)$ is finite for any p -adic field K and any commutative algebraic group G over K .*

Applying the above theorem to the case where $k = E$ and χ is the Lubin-Tate character associated with a uniformizer of k , we can recover the main theorem of [Oz] with a slight refinement for the weight of a Weil number. We remark that the condition $h_{E(\chi)} > 0$ appeared in (W) is harmless since $k_\chi = k_{\chi^{-1}}$ and $\delta_\chi^{-1} = \delta_{\chi^{-1}}$. If $h_{E(\chi)}$ is zero, we have

Theorem 4.2. *Let $\chi: G_k \rightarrow E^\times$ be a crystalline character. Assume that the following two conditions hold.*

(H1) *The residue field of k_χ is finite.*

(H2) *The sum of all Hodge-Tate weights (with multiplicity) of the \mathbb{Q}_p -representation $E(\chi)$ is zero.*

Then, the torsion subgroup $G(K_\chi)_{\text{tor}}$ of $G(K_\chi)$ is finite for any p -adic field K and any commutative algebraic group G over K .

4.1 Proof of Theorem 4.1

We show Theorem 4.1. Throughout this section, we assume the conditions (H1) and (H2) in the theorem. We have $\chi = \prod_{\sigma \in \Gamma_E} \sigma^{-1} \circ \chi_{\sigma E}^{h_\sigma}$ on an open subgroup of the inertia $I_{k_{\tilde{E}}}$ for some integer h_σ . Here, \tilde{E} is the Galois closure of E/\mathbb{Q}_p . Note that $\{h_\sigma \mid \sigma \in \Gamma_E\}$ is the set of Hodge-Tate weights of $E(\chi)$. Thus $h := h_{E(\chi)}$ in the condition (H2) is equal to $\sum_{\sigma \in \Gamma_E} h_\sigma$. We put $\tilde{h} := [\tilde{k} : E] \cdot h$. In the rest of this section, we fix the choice of a lift $\hat{u}: \overline{\mathbb{Q}_p} \rightarrow \overline{\mathbb{Q}_p}$ for each $u \in \Gamma_{\tilde{k}}$.

Proof of Theorem 4.1 (1). Assume that $A(K_\chi)_{\text{tor}}$ is infinite. We may assume that A has good reduction over K . Since K_χ has a finite residue field and the reduction map of A restricted to the prime to p -part is injective, we see that the prime to p -part of $A(K_\chi)_{\text{tor}}$ is finite. Thus our assumption implies that $A(K_\chi)[p^\infty]$ is infinite. This is equivalent to the condition that $V_p(A)^{G_{K_\chi}}$ is non-zero. Since the G_K -action on the dual $(V_p(A)^{G_{K_\chi}})^\vee$ of $V_p(A)^{G_{K_\chi}}$ factors through an abelian quotient, if we take a p -adic field F large enough, we know that any irreducible non-zero G_K -stable F -submodule V of $(V_p(A)^{G_{K_\chi}})^\vee \otimes_{\mathbb{Q}_p} F$ is 1-dimensional. We take such F so that it contains E and it is a Galois extension of \mathbb{Q}_p . Let $\psi: G_K \rightarrow GL_F(V) \simeq F^\times$ be the character obtained by the G_K -action on V . We note that V is crystalline and its Hodge-Tate weights are in $\{0, -1\}$. Replacing K by a finite extension of itself and k , by (H1) and Lemma 3.3, we have

$$\left(\prod_{u \in \Gamma_{\tilde{k}}} \hat{u} \circ \psi \right)^{\tilde{h}} = \left(\prod_{u \in \Gamma_{\tilde{k}}} \hat{u} \circ \chi \right)^{\tilde{r}}$$

on G_K for some $-\tilde{d} \leq \tilde{r} \leq 0$ (here, we recall that $\tilde{d} = [\tilde{k} : \mathbb{Q}_p]$). We set $\hat{\chi} := \left(\prod_{u \in \Gamma_{\tilde{k}}} \hat{u} \circ \psi \right)^{\tilde{h}} = \left(\prod_{u \in \Gamma_{\tilde{k}}} \hat{u} \circ \chi \right)^{\tilde{r}}$.

Let α be a root of the characteristic polynomial of the filtered φ -module $D_{\text{cris}}^K(F(\hat{\chi}^{-1}))$ over K . Since $\hat{\chi}$ has two decompositions $\left(\prod_{u \in \Gamma_{\tilde{k}}} \hat{u} \circ \psi \right)^{\tilde{h}}$ and $\left(\prod_{u \in \Gamma_{\tilde{k}}} \hat{u} \circ \chi \right)^{\tilde{r}}$, we can study α from two perspectives. First we focus on $\hat{\chi} = \left(\prod_{u \in \Gamma_{\tilde{k}}} \hat{u} \circ \psi \right)^{\tilde{h}}$. We consider the invariant $\delta_\psi \in F^\times$ for ψ . (Note that we have $\delta_{\psi^{-1}} = \delta_\psi^{-1}$ by definition.) It follows from Lemma 3.9 (2) (with “ $\chi := \psi$ ”, “ $E'/E := F/F$ ”, “ $k'/k := K/K$ ”) that α is of the form

$$\alpha = \prod_{\tau \in \Gamma_F} \tau(\delta_\psi)^{s_\tau}$$

for some integers s_τ such that $\sum_{\tau \in \Gamma_F} s_\tau = \tilde{h}\tilde{d}$. Furthermore, Lemma 3.9 (1) shows that $\tau(\delta_{\psi^{-1}})$ is a root of the characteristic polynomial of the filtered φ -module $D_{\text{cris}}^K(F(\psi))$ over K . Since $F(\psi) = V$

is a subquotient representation of $V_p(A)^\vee \otimes_{\mathbb{Q}_p} F$, the element $\tau(\delta_{\psi^{-1}})$ is also a root of that of the filtered φ -module $D_{\text{cris}}^K(V_p(A)^\vee)$ over K . The Weil conjecture implies that $\tau(\delta_{\psi^{-1}})$ is a q_K -Weil integer of weight 1. Hence $\alpha^{-1} = \prod_{\tau \in \Gamma_F} \tau(\delta_{\psi^{-1}})^{s_\tau}$ is a q_K -Weil number of weight $\tilde{h}\tilde{d}$. Note that α^{-1} is in fact an algebraic integer if $\tilde{h} > 0$ since we can take each s_τ as a non-negative integer in this case. On the other hand, since $\hat{\chi} = \left(\prod_{u \in \Gamma_{\tilde{k}}} \hat{u} \circ \chi \right)^{\tilde{r}}$, it follows from Lemma 3.9 (2) that α is of the form

$$\alpha = \left(\prod_{\tau \in \Gamma_E} \tau(\delta_\chi)^{t_\tau} \right)^{f_{K/k}}$$

for some integers t_τ such that $\sum_{\tau \in \Gamma_E} t_\tau = \tilde{r}\tilde{d}$. Hence we conclude that $\alpha^{-1} = \left(\prod_{\tau \in \Gamma_E} \tau(\delta_\chi)^{-t_\tau} \right)^{f_{K/k}}$ is a q_K -Weil number of weight $\tilde{h}\tilde{d}$, and thus $\alpha_0 := \prod_{\tau \in \Gamma_E} \tau(\delta_\chi)^{-t_\tau}$ is a q -Weil number of weight $\tilde{h}\tilde{d}$. If we denote by \tilde{E} the Galois closure of E/\mathbb{Q}_p , then we have

$$\text{Nr}_{\tilde{E}/\mathbb{Q}_p}(\alpha_0) = \text{Nr}_{\tilde{E}/\mathbb{Q}_p}(\delta_\chi)^{\sum_{\tau \in \Gamma_E} (-t_\tau)} = \text{Nr}_{E/\mathbb{Q}_p}(\delta_\chi)^{-\tilde{r}\tilde{d}[\tilde{E}:E]}.$$

On the other hand, $\text{Nr}_{\tilde{E}/\mathbb{Q}_p}(\alpha_0)$ is a q -Weil number of weight $\tilde{h}\tilde{d} \cdot [\tilde{E}:\mathbb{Q}_p]$. Since $\tilde{h} = [\tilde{k}:E] \cdot h$ is not zero by the assumption (H2), we obtain that \tilde{r} is not zero and $\text{Nr}_{E/\mathbb{Q}_p}(\delta_\chi)$ is a q -Weil number of weight $-\tilde{r}^{-1}\tilde{h} \cdot [\tilde{E}:E]^{-1}[\tilde{E}:\mathbb{Q}_p] = -\tilde{r}^{-1}h\tilde{d}$. Furthermore, $\text{Nr}_{E/\mathbb{Q}_p}(\delta_\chi)$ is an algebraic integer if $\tilde{h} > 0$ since so is α_0 . This contradicts the assumption (W). \square

Proof of Theorem 4.1 (2). By (1) and Corollary 2.4, it suffices to show that the set $\mu_\infty(K_\chi)$ is finite for any finite extension K of k . Assume that $\mu_\infty(K_\chi)$ is infinite for some finite extension K of k . By the assumption (H1), we know that the prime-to- p part of $\mu_\infty(K_\chi)$ is finite. Thus the p -part of $\mu_\infty(K_\chi)$ is infinite. This implies that K_χ contains all p -power roots of unity, that is, the p -adic cyclotomic character $\chi_p: G_K \rightarrow \mathbb{Q}_p^\times$ is trivial on G_{K_χ} . Applying Lemma 3.3 and replacing K by a finite extension, we have $\left(\prod_{u \in \Gamma_{\tilde{k}}} \hat{u} \circ \chi_p \right)^{\tilde{h}} = \left(\prod_{u \in \Gamma_{\tilde{k}}} \hat{u} \circ \chi \right)^{\tilde{d}}$ on G_K . This implies $\chi_p^{\tilde{d}\tilde{h}} = \left(\prod_{u \in \Gamma_{\tilde{k}}} \hat{u} \circ \chi \right)^{\tilde{d}}$ on G_K . Set $\hat{\chi} := \left(\prod_{u \in \Gamma_{\tilde{k}}} \hat{u} \circ \chi \right)^{\tilde{d}}$. The characteristic polynomial of the filtered φ -module $D_{\text{cris}}^K(F(\chi_p^{-\tilde{d}\tilde{h}}))$ over K has a unique root $p^{\tilde{d}\tilde{h}f_{K/\mathbb{Q}_p}} = q^{\tilde{d}\tilde{h}f_{K/k}}$. As we have seen in the proof of Theorem 4.1 (1), if α is a root of the characteristic polynomial of the filtered φ -module $D_{\text{cris}}^K(F(\hat{\chi}^{-1}))$ over K , we have $\alpha = \left(\prod_{\tau \in \Gamma_E} \tau(\delta_\chi)^{t_\tau} \right)^{f_{K/k}}$ for some integers t_τ such that $\sum_{\tau \in \Gamma_E} t_\tau = \tilde{d}^2$. Since $\chi_p^{\tilde{d}\tilde{h}} = \hat{\chi}$ on G_K , we obtain

$$\left(\prod_{\tau \in \Gamma_E} \tau(\delta_\chi)^{t_\tau} \right)^{f_{K/k}} = q^{\tilde{d}\tilde{h}f_{K/k}}.$$

Denote by \tilde{E} the Galois closure of E/\mathbb{Q}_p . Taking $\text{Nr}_{\tilde{E}/\mathbb{Q}_p}$ to both sides of the above equality, we have

$$\text{Nr}_{E/\mathbb{Q}_p}(\delta_\chi)^{[\tilde{E}:E]\tilde{d}^2f_{K/k}} = q^{[\tilde{E}:\mathbb{Q}_p]\tilde{d}\tilde{h}f_{K/k}}.$$

However, this contradicts the assumption that (μ) does not hold. \square

4.2 Proof of Theorem 4.2

We show Theorem 4.2. We assume the conditions (H1) and (H2) in the theorem. Replacing E by a finite extension, we may assume that E is a Galois extension of \mathbb{Q}_p . Also, replacing k by a finite extension, we may assume that k contains E , k is a Galois extension of \mathbb{Q}_p and $\chi = \prod_{\sigma \in \Gamma_E} \sigma^{-1} \chi_E^{h_\sigma}$ on I_k . Note that we have $\sum_{\sigma \in \Gamma_E} h_\sigma = 0$ by (H2). Let k' be the maximal unramified extension of k contained in k_χ . Since the residue field of k_χ is finite, we know that k' is a finite extension of k

and we have $\chi(G_{k'}) = \chi(I_{k'})$. Furthermore, we see that k' is a Galois extension of \mathbb{Q}_p since k'/k is unramified and k/\mathbb{Q}_p is a Galois extension. Hence, replacing k by a finite extension again, we may assume $\chi(G_k) = \chi(I_k)$. We regard χ as a character of G_k^{ab} . Take a uniformizer π of k . Since we have $\chi(G_k) = \chi(I_k)$ and $\chi = \prod_{\sigma \in \Gamma_E} \sigma^{-1} \circ \chi_E^{h_\sigma}$ on I_k , there exists an element $\gamma \in \mathcal{O}_k^\times$ such that

$$\chi \circ \text{Art}_k(\pi) = \prod_{\sigma \in \Gamma_E} \sigma^{-1} \text{Nr}_{k/E}(\gamma)^{h_\sigma}.$$

For any integer n prime to p , put $\pi_n = \pi\gamma^n$. Then π_n is a uniformizer of k . Let $\chi_{\pi_n} : G_k \rightarrow k^\times$ be the Lubin-Tate character associated with π_n and we set

$$\chi_n := \prod_{\sigma \in \Gamma_E} \left(\prod_{\tau \in \Gamma_k, \tau|_E = \sigma} \tau^{-1} \circ \chi_{\pi_n} \right)^{h_\sigma} : G_k \rightarrow k^\times.$$

We regard χ_{π_n} and χ_n as characters of G_k^{ab} . By definition, we have $\chi_{\pi_n} \circ \text{Art}_k(\pi) = \gamma^n$. Since $\sum_{\sigma \in \Gamma_E} h_\sigma = 0$, we have

$$\begin{aligned} \chi_n \circ \text{Art}_k(\pi) &= \prod_{\sigma \in \Gamma_E} \left(\prod_{\tau \in \Gamma_k, \tau|_E = \sigma} \tau^{-1}(\gamma^n) \right)^{h_\sigma} = \prod_{\sigma \in \Gamma_E} \sigma^{-1} \text{Nr}_{k/E}(\gamma^n)^{h_\sigma} \\ &= \prod_{\sigma \in \Gamma_E} \sigma^{-1} \text{Nr}_{k/E}(\gamma)^{h_\sigma} = \chi \circ \text{Art}_k(\pi). \end{aligned}$$

Furthermore, we see $\prod_{\tau \in \Gamma_k, \tau|_E = \sigma} \tau^{-1} \circ \chi_{\pi_n} = \sigma^{-1} \circ \chi_E$ on I_k and thus we obtain $\chi_n = \chi$ on I_k . We conclude that $\chi_n = \chi$ on G_k by local class field theory. In particular, k_χ is a subfield of k_{π_n} for every integer n prime to p . Since $\text{Nr}_{k/\mathbb{Q}_p}(\delta_{\chi_{\pi_n}}) = \text{Nr}_{k/\mathbb{Q}_p}(\pi_n) = n^{[k:\mathbb{Q}_p]} \text{Nr}_{k/\mathbb{Q}_p}(\pi\gamma)$, we can choose n so that neither (W)' nor (μ)' in the statement of Theorem 4.1 for $\delta_{\chi_{\pi_n}}$ holds. Therefore, Theorem 4.1 shows that k_χ satisfies the desired property. This completes the proof.

5 The field \tilde{K}

We use the same notation $k, \pi, \phi, \dots, \tilde{K}$ as in the Introduction. In this section, we study some basic properties of the field \tilde{K} . Furthermore, applying results in the previous section to Lubin-Tate characters, we show theorems given in the Introduction. The theory of Lubin-Tate formal groups plays a key role here. It may be helpful for the readers to refer [Iw], [La] and [Yo] for standard properties of Lubin-Tate formal groups.

5.1 Formal groups and \tilde{K}

Let $F_\phi = F_\phi(X, Y) \in \mathcal{O}_k[[X, Y]]$ be the formal \mathcal{O}_k -module corresponding to ϕ , and denote by $[\cdot]_\phi : \mathcal{O}_k \rightarrow \text{End}_{\mathcal{O}_k}(F_\phi)$ the ring homomorphism corresponding to the \mathcal{O}_k -action on F_ϕ . Note that we have $[\pi]_\phi = \phi$. We also note that, for any algebraic extension L of k , $F_\phi(\mathbf{m}_L) = \mathbf{m}_L$ is equipped with an \mathcal{O}_k -module structure via F_ϕ , that is, $x \oplus y := F_\phi(x, y)$ and $a.x := [a]_\phi(x)$ for $x, y \in F_\phi(\mathbf{m}_L)$ and $a \in \mathcal{O}_k$. By definition, k_π is the extension field of k obtained by adjoining all π -power torsion points of F_ϕ . The isomorphism class of the formal \mathcal{O}_k -module F_ϕ depends not on ϕ but on π , and thus the field k_π is independent of the choice of ϕ . It follows from local class field theory that k_π is a totally ramified abelian extension of k , and the composite field of k_π and the maximal unramified extension k^{ur} of k coincides with the maximal abelian extension k^{ab} of k . The set $F_\phi[\pi^n]_\phi$ of π^n -torsion points of F_ϕ is a free $\mathcal{O}_k/\pi^n \mathcal{O}_k$ -module of rank one and $T_\pi := \varprojlim F_\phi[\pi^n]_\phi$ is a free \mathcal{O}_k -module of rank one. The Galois group G_k acts on T_π by the Lubin-Tate character $\chi_\pi : G_k \rightarrow \mathcal{O}_k^\times$. If we regard χ_π as a continuous character $k^\times \rightarrow k^\times$ by the local

Artin map with arithmetic normalization, then χ_π is characterized by the property that $\chi_\pi(\pi) = 1$ and $\chi_\pi(u) = u^{-1}$ for any $u \in \mathcal{O}_k^\times$. For any $a \in \mathbf{m}_K$, we denote by $K_{\phi,a}$ the extension field of K obtained by adjoining to K all $x \in \mathbf{m}_{\overline{K}}$ such that $\phi^n(x) = a$ for some $n \geq 1$. We see that the field \tilde{K} given in the Introduction is equal to the composite field of all $K_{\phi,a}$ for all $a \in \mathbf{m}_K$.

Proposition 5.1. (1) $K_{\phi,0} = Kk_\pi$.

(2) \tilde{K} does not depend on the choice of ϕ . Thus the field \tilde{K} is determined by K, k and π .

Proof. (1) The result follows immediately from the equation $[\pi^n]_\phi(X) = \phi^n(X)$.

(2) Take any $\phi' = \phi'(X) \in \mathcal{O}_k[[X]]$ with the property that $\phi'(X) \equiv X^q \pmod{\pi}$ and $\phi'(X) \equiv \pi X \pmod{X^2}$. Let $F_{\phi'} = F_{\phi'}(X, Y) \in \mathcal{O}_k[[X, Y]]$ be the formal \mathcal{O}_k -module corresponding to ϕ' . By [La, Chapter 8, Theorem 3.1], there exists an isomorphism of formal \mathcal{O}_k -modules $\theta: F_\phi \xrightarrow{\sim} F_{\phi'}$. This θ is an element of $X\mathcal{O}_k[[X]]$ and satisfies $\theta(X) \equiv X \pmod{X^2}$. Note that there exists a unique $\theta^{-1} \in X\mathcal{O}_k[[X]]$ such that $\theta \circ \theta^{-1} = \theta^{-1} \circ \theta = X$ and θ^{-1} is an inverse of $\theta: F_\phi \xrightarrow{\sim} F_{\phi'}$. For the proof, it is enough to show $K_{\phi,a} = K_{\phi',\theta(a)}$ for any $a \in \mathbf{m}_K$. Take any $x \in \mathbf{m}_{\overline{K}}$ such that $\phi^n(x) = a$ for some $n > 0$. Put $y = \theta(x)$. Then, $y \in \mathbf{m}_{\overline{K}}$ and we have

$$\theta(a) = \theta \circ \phi^n(x) = \theta \circ [\pi^n]_\phi(x) = [\pi^n]_{\phi'} \circ \theta(x) = [\pi^n]_{\phi'}(y) = \phi'^n(y).$$

Hence we have $y \in K_{\phi',\theta(a)}$. Since θ^{-1} is an element of $\mathcal{O}_k[[X]]$, we have $x = \theta^{-1}(y) \in K_{\phi',\theta(a)}$. This shows $K_{\phi,a} \subset K_{\phi',\theta(a)}$. The converse inclusion $K_{\phi,a} \supset K_{\phi',\theta(a)}$ follows by a similar argument. \square

Example 5.2. Suppose $K = \mathbb{Q}_p$ and $\pi = p > 2$. We check that the field \tilde{K} is just $K((\mathcal{O}_K^\times)^{1/p^\infty})$. Choosing $\phi(X)$ to be $(1+X)^p - 1$, we see that $\tilde{K} = K((1 + \mathbf{m}_K)^{1/p^\infty})$, which is a subfield of $K((\mathcal{O}_K^\times)^{1/p^\infty})$. Take any integer $n > 0$ and any α_n such that $\alpha := \alpha_n^{p^n}$ is an element of \mathcal{O}_K^\times . Since $p > 2$, we have $\alpha = \zeta(1 + \alpha')$ for some $\zeta \in \mu_{q_K-1}$ and $\alpha' \in \mathbf{m}_K$. Since p^n -th roots of ζ and $1 + \alpha'$ are elements of μ_{q_K-1} and $K_{\phi,\alpha'}$, respectively, we see $\alpha_n \in \tilde{K}$. This shows $K((\mathcal{O}_K^\times)^{1/p^\infty}) \subset \tilde{K}$.

We set $G := \text{Gal}(\tilde{K}/K)$ and $H := \text{Gal}(\tilde{K}/Kk_\pi)$. We often regard the Lubin-Tate character χ_π as characters of G_K, G and $G/H \simeq \text{Gal}(Kk_\pi/K)$.

Lemma 5.3. Let $\sigma \in G$. Assume that $\chi_\pi(\sigma)$ is a rational integer. Then we have $\sigma\tau\sigma^{-1} = \tau^{\chi_\pi(\sigma)}$ for any $\tau \in H$.

Proof. For the proof, it suffices to show

$$\sigma\tau\sigma^{-1}x = \tau^{\chi_\pi(\sigma)}x$$

for any $\tau \in H$ and $x \in \mathbf{m}_{\overline{K}}$ with $\phi^n(x) \in \mathbf{m}_K$ for some $n > 0$. We set $x(\rho) := \rho x \ominus x$ for any $\rho \in G$. It is not difficult to check that $x(\rho) \in F_\phi[\pi^n]_\phi$, $x(\rho) \oplus \rho x(\rho^{-1}) = 0$ and $[m]_\phi x(\tau) \oplus x = \tau^m x$ for any $m \in \mathbb{Z}$. Furthermore, we note that G acts on $F_\phi[\pi^n]_\phi$ by χ_π , H acts trivially on $F_\phi[\pi^n]_\phi$ and H is a normal subgroup of G . Therefore, we have

$$\begin{aligned} \sigma\tau\sigma^{-1}x &= \sigma\tau(x \oplus x(\sigma^{-1})) = \sigma\tau(x \ominus \sigma^{-1}x(\sigma)) \\ &= \sigma\tau x \ominus \sigma\tau\sigma^{-1}x(\sigma) = \sigma(x \oplus x(\tau)) \ominus x(\sigma) \\ &= \sigma x(\tau) \oplus (\sigma x \ominus x(\sigma)) = [\chi_\pi(\sigma)]_\phi x(\tau) \oplus x \\ &= \tau^{\chi_\pi(\sigma)}x \end{aligned}$$

as desired. \square

In particular, we see that H is abelian since $\chi_\pi|_H$ is trivial. We study more precise information about H in the next section.

The following two propositions are essentially shown by Kubo and Taguchi (cf. [KT, Lemmas 2.2 and 2.3]) but we include a proof for the sake of completeness.

Proposition 5.4. *Let E be a topological field and $\rho: G \rightarrow GL_E(V)$ an continuous E -linear representation of G of dimension n .*

- (1) *There exists a integer $m > 0$ depending only on K/k , π and n such that H^m acts unipotently on V .*
(2) *There exists a finite index subgroup H' of H such that H' acts unipotently on V .*

Proof. (1) Take any $\tau \in H$. Let $\lambda_1, \dots, \lambda_n$ be the eigenvalues of $\rho(\tau)$. Since $\chi_\pi: G \rightarrow \mathcal{O}_k^\times$ has an open image, there exists an integer $c \geq 0$ such that $1 + p^c = \chi_\pi(\sigma)$ for some $\sigma \in G$. Note that the choice of c depends only on K/k and π . By Lemma 5.3, we have $\rho(\sigma\tau\sigma^{-1}) = \rho(\tau)^{1+p^c}$. This gives the equality $\{\lambda_1, \dots, \lambda_n\} = \{\lambda_1^{1+p^c}, \dots, \lambda_n^{1+p^c}\}$ as multisets of n -elements. In other words, the multiplication-by- $(1+p^c)$ gives a permutation on the multiset $\{\lambda_1, \dots, \lambda_n\}$. Hence, for any $1 \leq i \leq n$, there exists an integer $1 \leq r \leq n$ such that $\lambda_i^{(1+p^c)^r} = \lambda_i$. If we denote by m the least common multiple of integers $(1+p^c)^r - 1$ for $1 \leq r \leq n$, then we have $\lambda_i^m = 1$ for any i . This shows that τ^m acts unipotently on V . Since m depends only on K/k , π and n , we obtained the desired result.

(2) Since H is abelian, if we take a finite extension E' of E large enough, the semisimplification of the restriction of $V \otimes_E E'$ to H is a direct sum of characters $H \rightarrow E'^\times$. It follows from (1) that these characters have finite images. Thus the result follows. \square

We denote by $\mathbb{F}, \mathbb{F}_\pi$ and $\tilde{\mathbb{F}}$ the residue fields of K, Kk_π and \tilde{K} , respectively. Note that \mathbb{F}_π is a finite field since k_π/k is totally ramified. Let $c = c(K/k, \pi)$ be the minimum integer $t \geq 0$ so that $1 + p^t \in \chi_\pi(G_K)$ (such c exists since $\chi_\pi: G_K \rightarrow \mathcal{O}_k^\times$ has an open image).

Proposition 5.5. *The residue field $\tilde{\mathbb{F}}$ of \tilde{K} is finite. Moreover, the extension degree $[\tilde{\mathbb{F}} : \mathbb{F}]$ is a divisor of $p^c [\mathbb{F}_\pi : \mathbb{F}]$.*

Proof. Take $\sigma \in G$ such that $1 + p^c = \chi_\pi(\sigma)$. By Lemma 5.3, we have $\tau^{p^c} = \sigma\tau\sigma^{-1}\tau^{-1} \in (G, G)$ for any $\tau \in H$. On the other hand, the closure $\overline{(G, G)}$ of (G, G) in G is the Galois group $\text{Gal}(\tilde{K}/M)$ where M is the maximal abelian extension of K contained in \tilde{K} . Thus we have $H^{p^c} \subset \overline{(G, G)} = \text{Gal}(\tilde{K}/M) \subset H$. This gives natural surjections

$$H/H^{p^c} \twoheadrightarrow H/\overline{(G, G)} = \text{Gal}(M/Kk_\pi) \twoheadrightarrow \text{Gal}(\tilde{\mathbb{F}}/\mathbb{F}_\pi).$$

In particular, the Galois group $\text{Gal}(\tilde{\mathbb{F}}/\mathbb{F}_\pi)$ is killed by p^c and hence $\text{Gal}(\tilde{\mathbb{F}}/\mathbb{F})$ is killed by $p^c f$ where $f := [\mathbb{F}_\pi : \mathbb{F}]$. Thus the surjection $\widehat{\mathbb{Z}} \simeq \text{Gal}(\tilde{\mathbb{F}}/\mathbb{F}) \twoheadrightarrow \text{Gal}(\tilde{\mathbb{F}}/\mathbb{F})$ factors through $\widehat{\mathbb{Z}}/p^c f \widehat{\mathbb{Z}} \simeq \mathbb{Z}/p^c f \mathbb{Z}$. This finishes the proof. \square

Remark 5.6. (1) If $p \neq 2$ and $K = k$, then \tilde{K}/K is totally ramified. In fact, we have $c = 0$ and $\mathbb{F}_\pi = \mathbb{F}$ in this case.

(2) Let $e_{K/k}$ be the ramification index of K/k . Since k_π/k is totally ramified, we see the inequality $[\mathbb{F}_\pi : \mathbb{F}] \leq e_{K/k}$. Hence we obtain $[\tilde{\mathbb{F}} : \mathbb{F}] \leq p^c e_{K/k}$.

5.2 The Galois group of \tilde{K}/Kk_π

The goal of this section is to show the following.

Theorem 5.7. *\tilde{K} is a $\mathbb{Z}_p^{\oplus [K:\mathbb{Q}_p]}$ -extension of Kk_π .*

Since an extension of a p -adic Lie group by a p -adic Lie group is again a p -adic Lie group (cf. [GW, Lemma 9.1]), we have

Corollary 5.8. *\tilde{K}/K is a p -adic Lie extension.*

Let $c = c(K/k, \pi)$ be the integer defined in the previous section.

Corollary 5.9. *The maximal abelian extension M of K contained in \tilde{K} is a finite extension of Kk_π . Moreover, the extension degree $[M : Kk_\pi]$ is a divisor of $p^{c[K:\mathbb{Q}_p]}$.*

Proof. We use the same notation as the proof of Proposition 5.5. By Theorem 5.7, we know that H/H^{p^c} is of order $p^{c[K:\mathbb{Q}_p]}$. Thus the result follows from $H^{p^c} \subset \text{Gal}(\tilde{K}/M) \subset H$. \square

In the rest of this section, we give a proof of Theorem 5.7. Since \tilde{K} does not depend on the choice of ϕ by Proposition 5.1, for the proof of the theorem, we may suppose that ϕ is a polynomial of degree q . Let $a \in \mathfrak{m}_K$. For any integer $n > 0$, we denote by $K_{\phi,a,n}$ the extension field of K obtained by adjoining to K all $x \in \mathfrak{m}_{\tilde{K}}$ such that $\phi^n(x) = a$. In other words, $K_{\phi,a,n}$ is the extension field of K obtained by adjoining to K all π^n -th roots of a in F_ϕ . Note that $K_{\phi,a,n}$ is a Galois extension of K and we have $K_{\phi,a,n} = K(a_n, F_\phi[\pi^n]_\phi)$. Here, a_n is any π^n -th root of a in F_ϕ (note that the set of the roots of $\phi^n(X) = a$ is just $a_n \oplus F_\phi[\pi^n]_\phi$). By definition, $K_{\phi,a}$ is equal to the composite field of all $K_{\phi,a,n}$ for all n .

Lemma 5.10. *Let $a, b \in \mathfrak{m}_K$. We have $K_{\phi,a} = K_{\phi,b}$ if any one of the following hold.*

- (1) $a \oplus b$ is torsion in F_ϕ .
- (2) $a = [\lambda]_\phi(b)$ for some non-zero $\lambda \in \mathcal{O}_k$.

Proof. (1) Let $n > 0$ be an integer and take any $x \in \mathfrak{m}_{\tilde{K}}$ such that $[\pi^n]_\phi(x) = a$. It suffices to show that x is an element of $K_{\phi,b}$. Taking any $b_n \in \mathfrak{m}_{\tilde{K}}$ such that $[\pi^n]_\phi(b_n) = b$, we have $[\pi^n]_\phi(x \oplus b_n) = a \oplus b$. By the assumption, we have $x \oplus b_n \in F_\phi[\pi^m]_\phi$ for some m large enough. This shows that x is an element of $K_{\phi,b,m} \subset K_{\phi,b}$.

(2) It suffices to consider the cases where $\lambda \in \mathcal{O}_k^\times$ and $\lambda = \pi^m$.

Assume that $\lambda \in \mathcal{O}_k^\times$. Let $n > 0$ be an integer and take any $x \in \mathfrak{m}_{\tilde{K}}$ such that $[\pi^n]_\phi(x) = a$. We have $[\pi^n]_\phi([\lambda^{-1}]_\phi(x)) = b$ and thus $[\lambda^{-1}]_\phi(x)$ is an element of the maximal ideal of $K_{\phi,b,n}$. Since $[\lambda]_\phi(X) \in \mathcal{O}_k[[X]]$, we have $x = [\lambda]_\phi([\lambda^{-1}]_\phi(x)) \in K_{\phi,b,n} \subset K_{\phi,b}$. This shows $K_{\phi,a} \subset K_{\phi,b}$. The converse inclusion $K_{\phi,b} \subset K_{\phi,a}$ follows by the same way.

Next we assume $\lambda = \pi^m$. It is not difficult to check that $x \in \mathfrak{m}_{\tilde{K}}$ satisfies $[\pi^n]_\phi(x) = a$ for $n \leq m$ (resp. $n > m$) if and only if $x \oplus [\pi^{m-n}]_\phi(b) \in F_\phi[\pi^n]_\phi$ (resp. $x \oplus b_{n-m} \in F_\phi[\pi^n]_\phi$). Here, b_{n-m} is an element of $\mathfrak{m}_{\tilde{K}}$ such that $[\pi^{n-m}]_\phi(b_{n-m}) = b$. Thus $K_{\phi,a,n}$ is equal to $K(F_\phi[\pi^n]_\phi)$ (resp. $K(b_{n-m}, F_\phi[\pi^n]_\phi)$). Now the result follows. \square

Let a_1, \dots, a_r be elements of $F_\phi(\mathfrak{m}_K)$. We define a continuous homomorphism

$$\varphi_i: G_{Kk_\pi} \rightarrow T_\pi$$

as follows: Take a system $(a_i^{(n)})_{n \geq 0}$ in $\mathfrak{m}_{\tilde{K}}$ such that $a_i^{(0)} = a_i$ and $[\pi]_\phi(a_i^{(n+1)}) = a_i^{(n)}$ for any n , and define a homomorphism $\varphi_i^{(n)}: G_{Kk_\pi} \rightarrow F_\phi[\pi^n]_\phi$ by $\varphi_i^{(n)}(\sigma) := \sigma(a_i^{(n)}) \oplus a_i^{(n)}$. We define φ_i to be the inverse limit of $(\varphi_i^{(n)})_{n \geq 0}$. It is not difficult to check that each $\varphi_i^{(n)}$, and thus also φ_i , is independent of the choice of $(a_i^{(n)})_{n \geq 0}$. By definition, the extension field of Kk_π corresponding to the kernel of φ_i is K_{ϕ,a_i} . We define a continuous homomorphism

$$\Phi: G_{Kk_\pi} \rightarrow \bigoplus_{i=1}^r T_\pi$$

by $\Phi = \varphi_1 \oplus \dots \oplus \varphi_r$. Note that the extension field K_Φ of Kk_π corresponding to the kernel of Φ is $K_{\phi,a_1} \cdots K_{\phi,a_r}$, that is, the composite field of $K_{\phi,a_1,n} \cdots K_{\phi,a_r,n}$ for all n . Note that we have an isomorphism

$$F_\phi(\mathfrak{m}_K) \simeq \mathcal{O}_k^{\oplus[K:k]} \oplus (\text{a finite } \pi\text{-power torsion group})$$

of \mathcal{O}_k -modules.

Lemma 5.11. *Assume that the images of a_1, \dots, a_r in $F_\phi(\mathfrak{m}_K)/(\text{tor})$ generate the free \mathcal{O}_k -module $F_\phi(\mathfrak{m}_K)/(\text{tor})$ (thus $r \geq [K:k]$). Then, we have $\tilde{K} = K_\Phi$.*

Proof. Let $x \in \mathbf{m}_K$. It suffices to show $K_{\phi,x} \subset K_{\Phi}$. Take $\lambda_1, \dots, \lambda_r \in \mathcal{O}_k$ such that $x \ominus ([\lambda_1]_{\phi}(a_1) \oplus \dots \oplus [\lambda_r]_{\phi}(a_r))$ is torsion. By Lemma 5.10 (1), we have $K_{\phi,x} = K_{\phi,y}$ where $y = [\lambda_1]_{\phi}(a_1) \oplus \dots \oplus [\lambda_r]_{\phi}(a_r)$. Thus we may assume $x = y$. For any $n > 0$ and any $j \in \{1, 2, \dots, r\}$, take $a_j^{(n)} \in \mathbf{m}_{\overline{K}}$ such that $[\pi^n]_{\phi}(a_j^{(n)}) = a_j$. Set $x^{(n)} := [\lambda_1]_{\phi}(a_1^{(n)}) \oplus \dots \oplus [\lambda_r]_{\phi}(a_r^{(n)})$. Then $[\pi^n]_{\phi}(x^{(n)}) = x$ and the set of π^n -th roots of x in F_{ϕ} is $x^{(n)} \oplus F_{\phi}[\pi^n]_{\phi}$. Hence, we obtain

$$K_{\phi,x,n} = K(x^{(n)}, F_{\phi}[\pi^n]_{\phi}) \subset K(a_1^{(n)}, \dots, a_r^{(n)}, F_{\phi}[\pi^n]_{\phi}) \subset K_{\phi,a_1} \cdots K_{\phi,a_r} = K_{\Phi}$$

for any n . This shows $K_{\phi,x} \subset K_{\Phi}$ as desired. \square

We say that a_1, \dots, a_r are *linearly independent over \mathcal{O}_k* if no non-trivial linear combination $\sum_{i=1}^r [\lambda_i]_{\phi}(a_i)$ with $\lambda_i \in \mathcal{O}_k$ vanishes. We remark that, if a_1, \dots, a_r are linearly independent over \mathcal{O}_k , then it implies $r \leq [K : k]$.

Lemma 5.12. *Assume that a_1, \dots, a_r are linearly independent over \mathcal{O}_k .*

- (1) *If $\lambda_1 \varphi_1 + \dots + \lambda_r \varphi_r = 0$ for $\lambda_1, \dots, \lambda_r \in \mathcal{O}_k$, then we have $\lambda_1 = \dots = \lambda_r = 0$.*
- (2) *The map $\Phi: G_{Kk_{\pi}} \rightarrow \bigoplus_{i=1}^r T_{\pi}$ has an open image.*
- (3) *K_{Φ} is a $\mathbb{Z}_p^{\oplus r \cdot [k:\mathbb{Q}_p]}$ -extension of Kk_{π} .*

To show this lemma, we use the following.

Lemma 5.13. *The continuous cohomology group $H^1(Kk_{\pi}/K, T_{\pi})$ is finite.*

Proof. Take a positive integer m large enough. We may suppose that the image of $\chi_{\pi}: \text{Gal}(Kk_{\pi}/K) \rightarrow \mathcal{O}_k^{\times}$ contains $1 + \pi^m \mathcal{O}_k$. Let K' be the subfield of Kk_{π}/K such that $\chi_{\pi}(\text{Gal}(Kk_{\pi}/K')) = 1 + \pi^m \mathcal{O}_k$. In particular, Kk_{π}/K' is a \mathbb{Z}_p^d -extension where $d := [k : \mathbb{Q}_p]$. Take a subfield M in Kk_{π}/K' with the property that Kk_{π}/M is a \mathbb{Z}_p -extension. Let σ_0 be a topological generator of $\text{Gal}(Kk_{\pi}/M)$ and c the positive integer such that $\pi^{-c}(\chi_{\pi}(\sigma_0) - 1) \in \mathcal{O}_k^{\times}$. Now we consider the following exact sequence

$$0 \rightarrow H^1(M/K', T_n^{\text{Gal}(Kk_{\pi}/M)}) \rightarrow H^1(Kk_{\pi}/K', T_n) \rightarrow H^1(Kk_{\pi}/M, T_n)$$

where $T_n := T_{\pi}/\pi^n T_{\pi}$. For any $n > c$, we have

- $H^1(Kk_{\pi}/M, T_n) \simeq T_n/(\sigma_0 - 1)T_n = T_n/\pi^c T_n$ (cf. [Wa, §1]), and
- $T_n^{\text{Gal}(Kk_{\pi}/M)} = T_n^{\sigma_0=1} = \pi^{n-c} T_n$.

In particular, p^c vanishes $H^1(Kk_{\pi}/M, T_n)$ and $T_n^{\text{Gal}(Kk_{\pi}/M)}$ for any n . Thus we see that p^{2c} vanishes $p^{2c} H^1(Kk_{\pi}/K', T_n)$. Since we have an exact sequence

$$0 \rightarrow H^1(K'/K, T_n^{\text{Gal}(Kk_{\pi}/K')}) \rightarrow H^1(Kk_{\pi}/K, T_n) \rightarrow H^1(Kk_{\pi}/K', T_n),$$

we obtain the fact that p^{3c} vanishes $H^1(Kk_{\pi}/K, T_n)$. Since we have an isomorphism $H^1(Kk_{\pi}/K, T_{\pi}) \simeq \varprojlim_n H^1(Kk_{\pi}/K, T_n)$ (cf. [NSW, Chapter II, Corollary 2.7.6]), we see that $H^1(Kk_{\pi}/K, T_{\pi})$ is killed by p^{3c} . Hence the proof finishes if we show that $H^1(Kk_{\pi}/K, T_{\pi})$ is a finitely generated \mathbb{Z}_p -module. We have an injection $H^1(Kk_{\pi}/K, T_{\pi})/pH^1(Kk_{\pi}/K, T_{\pi}) \hookrightarrow H^1(Kk_{\pi}/K, T_e)$ where e is the ramification index of k/\mathbb{Q}_p . Since $\text{Gal}(Kk_{\pi}/K)$, isomorphic to an open subgroup of \mathcal{O}_k^{\times} , is topologically finitely generated, we see that the set of continuous 1-cocycles from $\text{Gal}(Kk_{\pi}/K)$ to T_e is finite. Hence $H^1(Kk_{\pi}/K, T_e)$ is finite, and thus so is $H^1(Kk_{\pi}/K, T_{\pi})/pH^1(Kk_{\pi}/K, T_{\pi})$. By [NSW, Chapter II, Corollary 2.7.9], we obtain the fact that $H^1(Kk_{\pi}/K, T_{\pi})$ is a finitely generated \mathbb{Z}_p -module as desired. \square

Proof of Lemma 5.12. We follow the proofs of Lemmas 2.12 and 2.13 of [BGK].

- (1) We define an \mathcal{O}_k -linear map $\xi_n: F_{\phi}(\mathbf{m}_K)/[\pi^n]_{\phi} F_{\phi}(\mathbf{m}_K) \rightarrow H^1(Kk_{\pi}, F_{\phi}[\pi^n]_{\phi})$ to be the composite of the Kummer map $F_{\phi}(\mathbf{m}_K)/[\pi^n]_{\phi} F_{\phi}(\mathbf{m}_K) \hookrightarrow H^1(K, F_{\phi}[\pi^n]_{\phi})$ and the restriction map

$H^1(K, F_\phi[\pi^n]_\phi) \rightarrow H^1(Kk_\pi, F_\phi[\pi^n]_\phi)$. We have $\xi_n(a_i \bmod [\pi^n]_\phi F_\phi(\mathbf{m}_K)) = \varphi_i^{(n)}$. Since $F_\phi(\mathbf{m}_K)$ is π -adically complete, by taking the inverse limit of $(\xi_n)_n$, we obtain a morphism

$$\xi: F_\phi(\mathbf{m}_K) \hookrightarrow H^1(K, T_\pi) \rightarrow H^1(Kk_\pi, T_\pi)$$

of \mathcal{O}_k -modules (here, we use [NSW, Chapter II, Corollary 2.7.6]). By definition, we have $\xi(a_i) = \varphi_i$ for any i . By the equation $\lambda_1\varphi_1 + \cdots + \lambda_r\varphi_r = 0$, we obtain $\xi([\lambda_1]_\phi(a_1) \oplus \cdots \oplus [\lambda_r]_\phi(a_r)) = 0$. Since the kernel of the restriction map $H^1(K, T_\pi) \rightarrow H^1(Kk_\pi, T_\pi)$ is isomorphic to $H^1(Kk_\pi/K, T_\pi)$ and this is finite by Lemma 5.13, we obtain that $[\lambda_1]_\phi(a_1) \oplus \cdots \oplus [\lambda_r]_\phi(a_r)$ is a torsion element of the \mathcal{O}_k -module $F_\phi(\mathbf{m}_K)$. Since a_1, \dots, a_r are linearly independent over \mathcal{O}_k , we obtain $\lambda_1 = \cdots = \lambda_r = 0$. (2) Put $V = T_\pi \otimes_{\mathbb{Z}_p} \mathbb{Q}_p = T_\pi \otimes_{\mathcal{O}_k} k$ and $W = \bigoplus_{i=1}^r V$. Then W is a semi-simple $k[G_K]$ -module and its G_K -action factors through $\text{Gal}(Kk_\pi/K)$. Set $M := \text{Im}(\Phi) \otimes_{\mathbb{Z}_p} \mathbb{Q}_p$. Since we have $\tau\Phi(\sigma) = \Phi(\tau\sigma\tau^{-1})$ for any $\tau \in G_K$ and $\sigma \in G_{Kk_\pi}$, $\text{Im}(\Phi)$ is a $\mathbb{Z}_p[G_K]$ -stable submodule of $\bigoplus_{i=1}^r T_\pi$. (The author does not know whether the \mathcal{O}_k -action on $\bigoplus_{i=1}^r T_\pi$ preserves $\text{Im}(\Phi)$ or not.) In particular, M is a $\mathbb{Q}_p[G_K]$ -stable submodule of W .

We claim that M is a k -stable submodule of W . Put $G_\pi := \chi_\pi(G_K)$. This is an open subgroup of $\text{GL}_{\mathcal{O}_k}(T_\pi) = \mathcal{O}_k^\times$ and $\mathbb{Z}_p[G_\pi]$ is a \mathbb{Z}_p -subalgebra of $\text{End}_{\mathcal{O}_k}(T_\pi) = \mathcal{O}_k$. We see that $\mathbb{Z}_p[G_\pi]$ is open in \mathcal{O}_k (in fact, if we take $m > 0$ large enough so that $1 + \pi^m \mathcal{O}_k \subset G_\pi$, then $\mathbb{Z}_p[G_\pi]$ contains $\pi^m \mathcal{O}_k$). Thus we have $\mathbb{Q}_p[G_\pi] = \text{End}_k(V) = k$. Since $\mathbb{Z}_p[G_\pi]$ -action on $\bigoplus_{i=1}^r T_\pi$ preserves $\text{Im}(\Phi)$, the claim follows.

We show $M = W$. Assume that M is strictly smaller than W . Since W is semi-simple as a $k[G_K]$ -module, there exists a $k[G_K]$ -stable submodule M_1 of W such that $W = M \oplus M_1$. By the assumption, we know that M_1 is not zero. Take an integer i such that the projection to the i -th component $p_i: W \rightarrow V$ does not vanish on M_1 . Let $\eta: W \rightarrow V$ be the composite of $0_M \oplus \text{id}_{M_1}: W = M \oplus M_1 \rightarrow M \oplus M_1 = W$ and p_i . By definition, η is a morphism of $k[G_K]$ -modules and we have $\eta|_M = 0$ and $\eta|_{M_1} \neq 0$. We denote by $\eta_j: V \rightarrow V$ the composite of the injection $V \hookrightarrow W$ to the j -th component and η . We see $\eta(v) = \sum_{j=1}^r \eta_j(v_j)$ for any $v = (v_1, \dots, v_r) \in W$. Since $\eta_j \in \text{End}_k(V)$, we may regard η_j as an element of k . Then, we have $\eta(v) = \sum_{j=1}^r \eta_j v_j$ for any $v = (v_1, \dots, v_r) \in W$. Since $\eta|_M = 0$, we obtain

$$\sum_{j=1}^r \eta_j(\varphi_j(\sigma) \otimes 1) = 0$$

for any $\sigma \in G_{Kk_\pi}$ (here, we consider $\varphi_j(\sigma) \otimes 1$ as an element of the tensor product $T_\pi \otimes_{\mathcal{O}_k} k$). Taking $N > 0$ large enough so that $\pi^N \eta_j \in \mathcal{O}_k$ for all j , we have

$$\left(\sum_{j=1}^r \pi^N \eta_j \varphi_j(\sigma) \right) \otimes 1 = 0.$$

Since the natural map $T_\pi \rightarrow V$ is injective, we obtain $\sum_{j=1}^r \pi^N \eta_j \varphi_j(\sigma) = 0$. By (1), we have $\pi^N \eta_1 = \cdots = \pi^N \eta_r = 0$, and thus $\eta_1 = \cdots = \eta_r = 0$. This shows $\eta = 0$. This contradicts the fact that M_1 is not zero and $\eta|_{M_1} \neq 0$. Therefore, we obtain $M = W$. Since both $\text{Im}(\Phi)$ and $\bigoplus_{i=1}^r T_\pi$ are \mathbb{Z}_p -lattices in W , $\text{Im}(\Phi)$ is open in $\bigoplus_{i=1}^r T_\pi$.

(3) Since we have $\text{Gal}(K_\Phi/Kk_\pi) \simeq \text{Im}(\Phi)$, the result follows from (2). \square

Proof of Theorem 5.7. The result is an immediate consequence of Lemmas 5.11 and 5.12. \square

Remark 5.14. The author believe that, in Lemma 5.12 (2), the image of the homomorphism $\Phi: G_{Kk_\pi} \rightarrow \bigoplus_{i=1}^r T_\pi$ should be stable under the \mathcal{O}_k -action of $\bigoplus_{i=1}^r T_\pi$. If this is true, the Galois group $\text{Gal}(\tilde{K}/K)$ has a structure of \mathcal{O}_k -modules, free of rank $[K:k]$. Moreover, Lemma 5.3 should hold also for any σ (without the assumption that $\chi_\pi(\sigma)$ is a rational integer).

5.3 Proofs of Theorems 1.1 and 1.2

We show Theorems 1.1 and 1.2 given in the Introduction.

Proof of Theorem 1.1. Assume that there exist a finite extension L/\tilde{K} and an abelian variety A over L with potential good reduction such that $A(L)_{\text{tor}}$ is infinite. The goal is to check that (k, π) satisfies (W) under this assumption. We remark that (W) in Theorem 1.1 coincides with (W)' in Theorem 4.1 for $k = E$ and $\chi = \chi_\pi$ (here, we recall that $\delta_{\chi_\pi} = \pi$; see Example 3.7). Hence, by Theorem 4.1, it suffices to show that there exists a finite extension K'/K so that A is defined over K' and $A(K'k_\pi)[p^\infty]$ is infinite. At first, we take a finite extension K_1/K so that $L \subset K_1\tilde{K}$, A is defined over K_1 and has good reduction over K_1 . By the same method as the construction of \tilde{K} from K, k, π (and ϕ), we define \tilde{K}_1 to be the field corresponding to K_1, k, π (and ϕ). Clearly we have $L \subset \tilde{K}_1$ and thus $A(\tilde{K}_1)_{\text{tor}}$ is infinite. Since the residue field of \tilde{K}_1 is finite by Proposition 5.5, it follows from [Oz, Proposition 2.9] that the prime-to- p part of $A(\tilde{K}_1)_{\text{tor}}$ is finite. Thus $A(\tilde{K}_1)[p^\infty]$ is infinite. If we denote by $V_p(A)$ the rational p -adic Tate module of A , then the infiniteness of $A(\tilde{K}_1)[p^\infty]$ implies that $\tilde{V} := V_p(A)^{G_{\tilde{K}_1}}$ is a non-zero G_{K_1} -stable submodule of $V_p(A)$. We regard \tilde{V} as a representation of $\text{Gal}(\tilde{K}_1/K_1)$. By Proposition 5.4 (with $G := \text{Gal}(\tilde{K}_1/K_1)$ and $H := \text{Gal}(\tilde{K}_1/K_1k_\pi)$), there exists a finite Galois extension K'/K_1 in \tilde{K}_1/K_1 such that $H' := \text{Gal}(\tilde{K}_1/K'k_\pi)$ acts unipotently on \tilde{V} . Hence $\tilde{V}^{H'} = V_p(A)^{G_{K'k_\pi}}$ is non-zero, that is, $A(K'k_\pi)[p^\infty]$ is infinite as desired. \square

Proof of Theorem 1.2. Assume that neither (μ) nor (W) in the Introduction holds. By Corollary 2.4, for the proof of the theorem, it suffices to check (μ_∞) and (AV_∞) for $(L = \tilde{K}/K, g = \infty)$. The condition (AV_∞) is a consequence of Theorem 1.1. For (μ_∞) , it suffices to show that the set $\mu_\infty(L')$ is finite for any finite extension L'/L . Since the residue field of L' is finite by Proposition 5.5, the finiteness of the set $\mu_{\ell^\infty}(L')$ for any prime number $\ell \neq p$ follows. Furthermore, we see that L' does not contain μ_ℓ if $\ell \geq q_{L'}$ where $q_{L'}$ is the order of the residue field $\mathbb{F}_{L'}$ of L' . In fact, if L' contains μ_ℓ , then $\mathbb{F}_{L'}$ contains the residue field of $\mathbb{Q}_p(\mu_\ell)$. Hence, taking $f_\ell > 0$ the minimum integer s such that $p^s \equiv 1 \pmod{\ell}$, we have $q_{L'} \geq p^{f_\ell} \geq \ell + 1$. Finally, we show the finiteness of the set $\mu_{p^\infty}(L')$. Assume that $\mu_{p^\infty}(L')$ is infinite. Then L' contains $k(\mu_{p^\infty})$. By [Oz, Lemma 2.7] and the assumption that (μ) does not hold, we know that $k_\pi \cap k(\mu_{p^\infty})$ is a finite extension of k . Thus the extension $k_\pi(\mu_{p^\infty})/k_\pi$ is of infinite degree. It follows from local class field theory that the residue field of $k_\pi(\mu_{p^\infty})$ is infinite. Since L' contains $k_\pi(\mu_{p^\infty})$, we obtain the fact that the residue field of L' is also infinite but this is a contradiction. Therefore, the set $\mu_{p^\infty}(L')$ must be finite as desired. \square

5.4 Proof of Theorem 1.3

We show Theorem 1.3. Assume that we have found a finite set $\mathcal{W}_{\text{ab}} = \mathcal{W}_{\text{ab}}(f, g; k)$ of q -Weil integers with the property described in the theorem under the additional condition that G is an abelian variety with potential good reduction. Assuming this, we show that the set

$$\mathcal{W} = \mathcal{W}(f, g; k) := \mathcal{W}_{\text{ab}} \cup q \cdot \mu_{p-1}$$

satisfies the desired property. Assume that we have $\text{Nr}_{k/\mathbb{Q}_p}(\pi) \notin \mathcal{W}$. Let K be a finite extension of k with $f_K \leq f$. Take a finite extension L/\tilde{K} . Replacing L by a finite extension, we may assume that L/K is Galois. We consider (μ_∞) and (AV_∞) for $(L/K, g)$. The condition (μ_∞) follows from the facts that $q^{-1}\text{Nr}_{k/\mathbb{Q}_p}(\pi)$ is now not a root of unity and any finite extension of \tilde{K} has a finite residue field (see the proof of Theorem 1.2). Furthermore, the condition $\text{Nr}_{k/\mathbb{Q}_p}(\pi) \notin \mathcal{W}_{\text{ab}}$ assures (AV_∞) . Now the theorem follows from Proposition 2.2 (2).

In the rest of the proof, we show the existence of $\mathcal{W}_{\text{ab}} = \mathcal{W}_{\text{ab}}(f, g; k)$. First we consider the case where k is a Galois extension of \mathbb{Q}_p . Let K be a finite extension of k with $f_K \leq f$ and A an abelian variety over K , of dimension at most g , with potential good reduction. Suppose that

$A(L)_{\text{tor}}$ is infinite for a finite extension L/\tilde{K} . Replacing K by a totally ramified extension, we may suppose that A has good reduction over K (cf. [ST, §2]). The argument given in the proof of Theorem 1.1 shows that there exists a finite extension K'/K with the property that $V_p(A)^{G_{K'k_\pi}}$ is not zero. Let M be the Galois closure of $K'k_\pi$ over K , which is a finite extension of Kk_π . Then $(V_p(A)^{G_M})^\vee$ is a non-zero crystalline representation of G_K with Hodge-Tate weights in $\{-1, 0\}$. Here, the notation “ \vee ” stands for the usual dual representation. By [Oz, Lemma 2.5] (or Remark 3.4), there exist finite extensions K'/K and E/\mathbb{Q}_p with $K', E \supset k$ such that any Jordan-Hölder factor W of the E -representation $((V_p(A)^{G_M})^\vee \otimes_{\mathbb{Q}_p} E)|_{G_{K'}}$ is of the form

$$W = E(\hat{\chi}^{-1}), \quad \hat{\chi} = \prod_{\sigma \in \Gamma_k} \sigma^{-1} \circ \chi_\pi^{-r_\sigma} \quad (5.1)$$

for some integer $r_\sigma \in \{-1, 0\}$. We fix a lift $\hat{\sigma}: \overline{\mathbb{Q}_p} \rightarrow \overline{\mathbb{Q}_p}$ of each $\sigma \in \Gamma_k$ and denote by Γ the set of homomorphisms $\hat{\sigma}$ such that $r_\sigma = -1$. We have $\hat{\chi} = \prod_{\hat{\sigma} \in \Gamma} \hat{\sigma}^{-1} \circ \chi_\pi$ and $|\Gamma| = \sum_{\sigma \in \Gamma_k} (-r_\sigma)$. Let α be a root of the characteristic polynomial of $D_{\text{cris}}^{K'}(W)$. It follows from Lemma 3.9 that α is of the form

$$\alpha = a^{f_{K'/k}}, \quad a = \prod_{\tau \in \Gamma_k} \tau(\pi)^{t_\tau} \quad (5.2)$$

for some integers $t_\tau \geq 0$ such that $\sum_{\tau \in \Gamma_k} t_\tau = \sum_{\hat{\sigma} \in \Gamma} 1 = \sum_{\sigma \in \Gamma_k} (-r_\sigma)$. Since W is a subquotient E -representation of $(V_p(A)^{G_M})^\vee \otimes_{\mathbb{Q}_p} E$ and $(V_p(A)^{G_M})^\vee$ is a quotient \mathbb{Q}_p -representation of $V_p(A)^\vee$, we know that α is a root of the characteristic polynomial of $D_{\text{cris}}^{K'}(V_p(A)^\vee)$. Since A has good reduction over K , α is a $f_{K'/K}$ -th power of some root β of the characteristic polynomial of $D_{\text{cris}}^K(V_p(A)^\vee)$;

$$\alpha = \beta^{f_{K'/K}}. \quad (5.3)$$

By the Weil conjecture, β is a q_K -Weil integer of weight 1. Set $t_0 := \sum_{\tau \in \Gamma_k} t_\tau = \sum_{\sigma \in \Gamma_k} (-r_\sigma)$. We have $0 \leq t_0 \leq [k : \mathbb{Q}_p]$ since $r_\sigma \in \{-1, 0\}$. Furthermore, we have $t_0 \neq 0$. In fact, if we assume $t_0 = 0$, then $t_\tau = 0$ for any τ and thus $\beta^{f_{K'/K}} = 1$. However, this contradicts the fact that β is a q_K -Weil integer of non-zero weight 1. By (5.2) and (5.3), we have $a^{f_K} = \zeta \beta^{f_K}$ where ζ is a root of unity. Let $T_1 = T_1(f, g)$ be the set of p -Weil integers x of weight at most f such that $[\mathbb{Q}(x) : \mathbb{Q}] \leq 2g$. The set T_1 is finite. Let $k_1 = k_1(f, g; k)$ be the extension field of k obtained by adjoining T_1 . Then k_1 depend only on f, g and k . By the Weil conjecture, we have $\beta \in T_1$. This in particular implies $\beta, \zeta \in k_1$. Taking $\text{Nr}_{k_1/\mathbb{Q}_p}$ to the equality $a^{f_K} = \zeta \beta^{f_K}$, we obtain that

$$\text{Nr}_{k/\mathbb{Q}_p}(\pi)^{t_0 f_K [k_1:k]} \text{Nr}_{k_1/\mathbb{Q}_p}(\beta)^{-f_K}$$

is a root of unity in \mathbb{Q}_p , that is, a $(p-1)$ -th root of unity. Since we have $0 < t_0 \leq [k : \mathbb{Q}_p]$, the existence of the desired set $\mathcal{W}_{\text{ab}} = \mathcal{W}_{\text{ab}}(f, g; k)$ now follows.

Next we consider the case where k is not necessarily a Galois extension of \mathbb{Q}_p . Set $f_{(k)} := f \cdot e_{k_G/k} \cdot [k_G : k]$. For any finite Galois extension F/\mathbb{Q}_p , we already knows the existence of $\mathcal{W}_{\text{ab}}(f_{(k)}, g; F)$. We fix the choice of $\mathcal{W}_{\text{ab}}(f_{(k)}, g; F)$ for each such F . Let Gal_k be the set of Galois extensions F/\mathbb{Q}_p such that $F \supset k_G$ and $[F : k_G] \leq e_{k_G/k}$. (If k/\mathbb{Q}_p is Galois, then we have $f_{(k)} = f$ and $\text{Gal}_k = \{k\}$.) We define

$$\mathcal{W}_{\text{ab}} = \mathcal{W}_{\text{ab}}(f, g; k) := \{x \in \overline{\mathbb{Q}} \mid x^{f_{F/k}} \in \mathcal{W}_{\text{ab}}(f_{(k)}, g; F) \text{ for some } F \in \text{Gal}_k\}.$$

Since Gal_k is finite, the set \mathcal{W}_{ab} is also finite. It suffices to show that \mathcal{W}_{ab} satisfies the desired property. Let K be a finite extension of k with $f_K \leq f$ and A an abelian variety over K , of dimension at most g , with potential good reduction. Suppose that $A(L)_{\text{tor}}$ is infinite for a finite extension L/\tilde{K} . As explained above, we may assume that A has good reduction over K , and there exists a finite extension of M/Kk_π such that M is a Galois extension of K and $V_p(A)^{G_M}$ is not zero. The torsion subgroup $A(M)_{\text{tor}}$ of $A(M)$ is now infinite. On the other hand, it follows from [Oz, Lemma 2.8] that there exist $k' \in \text{Gal}_k$ and a uniformizer π' of k' with the properties that

$\mathrm{Nr}_{k'/k}(\pi') = \pi^{f_{k'/k}}$ and $k_\pi \subset k'_{\pi'}$. Putting $K' = Kk'$, we have $f_{K'} \leq f_K \cdot [K' : K] \leq f_K \cdot [k' : k] \leq f_{(k)}$. We denote by \tilde{K}' the field corresponding to K', k' and π' (cf. Proposition 5.1 (2)). Putting $L' = M\tilde{K}'$, then L' is a finite extension of \tilde{K}' and we have $A(L')_{\mathrm{tor}}$ is infinite. Therefore, we have $\mathrm{Nr}_{k'/\mathbb{Q}_p}(\pi') \in \mathcal{W}_{\mathrm{ab}}(f_{(k)}, g; k')$. Since we have $k' \in \mathrm{Gal}_k$ and $\mathrm{Nr}_{k'/\mathbb{Q}_p}(\pi') = \mathrm{Nr}_{k/\mathbb{Q}_p}(\pi)^{f_{k'/k}}$, we obtain $\mathrm{Nr}_{k/\mathbb{Q}_p}(\pi) \in \mathcal{W}_{\mathrm{ab}}(f, g; k)$. This finishes the proof.
